I'm attorney Jack Collins. I'm the general counsel of the Oak Bluffs Water District. We're a small rural water district with about 4,000 year-round customers. We serve the town of Oak Bluffs. We're a disadvantaged community on the island of Martha's Vineyard. There are less than 20,000 year-round residents, but our summer population goes well over 100,000. We have six towns on the island, three of which have municipal water systems. These systems are all supplied by three to five wells each, and we all share a single sole-source aquifer. We found confusing the presence of certain PFAS chemicals in one test at two of our five wells, followed six months later with no such specific PFAS category only to find some subsequent test. Maybe the rain events are triggering the PFAS releases, we'll find that out. The source of PFAS on our island apparently comes from the former use by the military or firefighting foam at the local airport. Given time, these flows are very well likely to show up in our other three wells or one or both of the other towns on the island. Our engineers estimated it'll cost us about $18 million just to treat these two wells, which is about six times our annual budget. We can't shut down a well because it's not going to provide sufficient PFAS-free water in the summertime. Drilling new wells that are outside the area affected by the airport's polluted ground and thereafter installing infrastructure around the island will likely be the only feasible alternative to installing remediation systems at one well after another. So, while we're exploring eligibility for grants and loans, we ask you to take two common sense approaches. One, we may need to excuse the extension provisions you've talked about. Hopefully, your regulations will take into consideration the time required to devise a regional approach to solving this problem, and we envision needing one or more new wells outside the area impacted by the contamination. And secondly, please be sure that your regulations provide for an alternate construction-based proposal or an appeal mechanism for struggling municipal water systems like us as we explore

reasonable alternatives and suggest and submit the same to the EPA with concrete plans to reduce the PFAS to the proposed level, but over a reasonable period of time. Thank you for your time.

EPA Response: The EPA acknowledges commenter's concerns about treating drinking water for the communities he represents. The EPA notes that both treatment of existing wells or identifying new sources of drinking water (e.g., drilling new wells with uncontaminated groundwater) are both possible approaches to complying with this PFAS NPDWR. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). The EPA anticipates the extended compliance deadline may give smaller and rural water utilities more time to apply for funding under BIL (please see section II of the final rule preamble for a discussion on BIL). The EPA also notes that SDWA § 1416(a) and (b)(2)(C) describe how the EPA or states that have primacy for exemptions may also grant an exemption for systems meeting specified criteria that provides an additional period for compliance. In a primacy state that has adopted the requirements for extensions, PWSs that meet the minimum criteria outlined in the SDWA may be eligible for an exemption of up to three years. For smaller water systems (≤3,300 population), exemptions can provide up to six additional years to achieve compliance.

Wagner Engineering (Doc. #3072-9, SBC-047359)

Thank you, Rob. My name is Dan Hilyer. I am the Utility Discipline Manager for Wagner Engineering. I want to first off thank EPA, applaud EPA, for their swift action to address the PFAS issues that are facing our country. I've got several comments here that I've phrased in the form of questions that address more the practicality of implementation for utilities. Is EPA prepared and willing to issue extension requests by utilities, due to limitations that would inevitably occur, due to the increased demand on testing labs, contractors, and materials that will be required to facilitate the necessary changes to water systems due to the proposed rule? Many of the systems that will be impacted by this rule will be groundwater systems that currently have minimal treatment requirements, and therefore are not required to have certified treatment operators, only certified distribution operators in most cases. The proposed rule will require treatment technologies that must be operated by certified treatment operators. This has the potential to significantly increase the demand for these operators and demand already outweighs the supply. Has EPA taken this into consideration, and what steps are being taken to address this learning issue?

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For concerns regarding operator certification, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Arizona Water Company (Doc. #3072-11, SBC-047364)

The water utility industry is facing unprecedented supply challenges, including materials, contractors, and engineers to design and construct these specialized treatment facilities. We used to take 18-24 months to construct, now it takes 36 months or longer. So, we anticipate there to be a shortage in the specialized treatment technology manufacturers, contractors, and design engineers, which may delay a water utility's ability to construct treatment and comply with EPA's requirements. We request EPA consider this and provide more than three years for water utilities to comply with the rules. I want to thank the EPA for the opportunity to speak here today.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

American Water (Doc. #3072-51, SBC-047383)

My name is Lynda DiMenna and I am the Chief Environmental and Safety Officer for American Water. As the largest publicly traded drinking water and wastewater provider in the United States, we support the EPA's efforts to protect public health by proposing national drinking water standards for PFAS. American Water's initial analysis was based on federal PFAS standards, more in line with the limit set by several states. We are now carefully reviewing the proposed regulation to assess the 4 parts per trillion requirements for PFAS and the application of the hazard index. Our review includes projected costs associated with PFAS treatment at the proposed limits and the impact it would have on our customers' bills and will inform the written comment we submit to the EPA on May 30th. In a recent study conducted by Black & Veatch on behalf of the American Water Works Association, the estimated national costs to install treatment facilities to process to remove PFAS to the EPA's proposed level exceeds $47 billion, approximately $35 billion above what would be required to meet the current state's established PFAS limits. On a national basis, more than $700 million annually will be required for operations and maintenance costs to test and monitor for compliance. Approximately $500 million more than what would be required to meet current state established PFAS limits, significantly higher than the EPA's cost estimates. Based upon initial estimates, American Water will likely have more than 100 of our current existing water treatment facilities that will need upgrades for PFAS removal capabilities. A three- to four-fold increase in the number of treatment plants which had the most stringent previously established state standards. We estimate an investment in excess of $1 billion of capital to install additional treatment facilities over a three- to five-year period. We estimate annual operating expenses related to testing and treatment could be nearly $50 million. These are preliminary estimates dependent on final rule and effective date, as well as our system-by-system engineering analyses.

EPA Response: The EPA has evaluated the costs and benefits associated with the final NPDWR, including the information submitted by the American Water Works Association (AWWA) that is referenced in the comment. A detailed discussion of the agency's response to the cost analysis is found in section 13 of the EPA's *Response to Comments* document. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Orange County Water District (Doc. #3072-54, SBC-047388)

Second, EPA has proposed the Safe Drinking Water Act's default three-year implementation timeline for water system compliance. Our existing state driven PFAS treatment program is already struggling to complete its projects within three years due to local permitting challenges and construction delays related to increasing demand for services and materials, labor shortages, and supply chain disruptions. Projects will only increase once EPA's rule is finalized. To avoid unnecessarily and burdensome consent agreements and orders for systems unable to come into compliance within three years, we reckon EPA itself allow for the two additional years for compliance time permitted under the Safe Drinking Water Act when capital projects are required instead of leaving that determination to the state primacy agencies.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Student, Vanderbilt University (Doc. #3072-72, SBC-047399)

Second, present technologists have different problems in reducing all the PFAS species and they're very low value, such as activated carbon, its performance works for short term PFAS, and ion exchange resins are hard to be regenerated while the RO membranes requires high energy costs. So instead of waiting for three years to achieve a very low MCL, a slightly higher but more feasible transition limitations is recommended to be achieved within a shorter time like one year or so. I believe any progress in PFAS removal can relieve and encourage the public. At the same time during the three years of implementation of this proposal, our destination can be an updated MCL taking account more PFAS species with improvement of scientific research. Besides, I think chemical factories that are discharging PFAS waste should be punished and pay for part of the waste, the water plant technology improvements. Finally, I really appreciate any efforts that EPA has done for protecting public health from PFAS contamination. Thank you.

EPA Response: The agency agrees with the commenter on the health concerns posed by PFAS and that establishing a national PFAS NPDWR as expeditiously as possible needed to

protect public health and the environment. While individual state primacy agencies could require action sooner, the agency cannot do so for all PWSs regulated through this NPDWR. SDWA § 1412(b)(10) requires that a "NPDWR shall take effect "3 years after the date on which the regulation is promulgated unless the administrator determines that an earlier date is practicable." For all the reasons discussed in section 12.1 of the EPA response in this *Response to Comments* document, EPA does not believe that it is "practicable" for water systems to comply earlier than three years. In fact, Section 1412(b)(2) also authorizes "the Administrator, or a State (in the case of an individual system), may allow up 2 additional years to comply with a maximum contaminant level…if the Administrator or the State…determines that additional time is necessary for capital improvements" and consistent with that provision, EPA is promulgating. a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Lastly, actions related to PFAS discharges and assigning liability is beyond the scope of this current rulemaking; please see the EPA response in section 15.1 for additional details.

New Mexico Rural Water Association (Doc. #3072-98, SBC-047411)

Thank you very much for putting this on. I'm John Jones. I'm a member of the board of the New Mexico Rural Water Association and I'm affiliated with a 75-meter system in the Central Highlands of New Mexico. Very few doubt that there's a need to treat for PFAS even in small communities, but we're concerned about processing costs for construction, treatment, disposal, and increased labor skills, the lack of engineers and a flawed supply chain.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). The EPA anticipates the extended compliance deadline may give smaller and rural water utilities more time to apply for funding under BIL (please see section II of the final rule preamble for a discussion on BIL). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-047701)

If EPA moves forward with a phased MCL level, this would also alleviate some of the supply chain, labor shortage, and data gap issues many PWSs are currently facing. EPA has looked at exposure of concentrations of certain PFAS over a lifetime, therefore, allowing time for water systems with low levels of PFAS to address contamination properly and cost-effectively will not pose additional health risks.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments*

document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

Loudoun Water (Doc. #1717, SBC-047689)

The underestimation of utilities impacted by the proposed rule and the unrealistic compliance deadline will place significant demand on limited resources for consulting engineers, contractors, suppliers, and primacy agency support to achieve compliance. If thousands of additional systems are competing for supplies of granular activated carbon that many other water and wastewater systems rely upon for their existing treatment processes; this will likely result in related cost increases.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach. For additional discussion on treatment technology availability and capacity, please see section 10.6 of the EPA response in this *Response to Comments* document.

Metropolitan Washington Council of Governments (COG) (Doc. #1791, SBC-043772)

Our second recommendation concerns the timeline for compliance with the proposed NPDWR, which provides only three years from the date of final rulemaking with a possible two-year extension that is not guaranteed. Experience at the local level indicates that a more realistic time frame needed to add infrastructure improvements such as a new water treatment train to an existing water treatment plant is seven to ten years. This considers things such as compliance with procurement laws, piloting, land use approvals, permit approvals, design and specifications, equipment acquisition, construction, commissioning, and more. Providing local governments and water utilities with maximum flexibility and longer compliance timeframes will be important to the successful implementation of the proposed NPDWR.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The EPA also notes that SDWA § 1416(a) and (b)(2)(C) describe how the EPA or states may also grant an exemption for systems meeting specified criteria that provides an additional period for compliance. PWSs that meet the minimum criteria outlined in the SDWA may be eligible for an exemption of up to three years. For smaller water systems (≤3,300 population), exemptions can provide up to six additional years to achieve compliance.

Teena Halbig (Doc. #2667, SBC-047348)

In Louisville, KY, we have CHEMOURS and adjacent is DOWDuPont plus many other mega industrial companies subjecting our population to humongous PFAS and other industrial pollutants which are polluting with impunity. The Air Pollution Control District (APCD) let DuPont Chemours get away with recent huge pollution for the measley sum of $7,500 – and intended to have their APCD Chair Carl Hilton sign this agreement when Carl worked for DuPont for 33 years, probably can be collecting a pension and possibly holds stock. It was not only unhealthy for citizens but unhealthy way for government to operate. I let the board and staff know of this conflict of interest and wanted to know their policies and bylaws. I wonder how many times Carl sat in his Chairman seat and participated in prior violations by DuPont Chemours? Please have ATSDR help the west end of Louisville where residents die 10 to 12 years earlier than east end residents. The APCD Director said in the past when a board member asked (after I spoke about PFAS) that "PFAS is mostly in the water". And I am very concerned about Louisville Water Co (LWC) where testing for about 17 PFAS (includes GenX) shows many ppt (includes GenX where Louisville is 2nd highest GenX in our DRINKING WATER out of 40 cities per EWG (Environmental Working Group, ewg.org). LWC should not be given 3 more years to meet new standards set by EPA since LWC already has data for years. Please do get the new standards/regs in place asap. LWC uses a lot of PR to brain wash customers that their water is the BEST!

EPA Response: The EPA acknowledges the commenter's concerns about drinking water and air in Louisville, KY. While outside the scope of the promulgation of the final PFAS drinking water standard, the EPA is initiating actions under multiple environmental authorities—the Resource Conservation and Recovery Act (RCRA), Toxic Substances Control Act (TSCA), Clean Water Act (CWA), SDWA and Comprehensive Environmental Response Compensation and Liability Act (CERCLA)—to identify past and ongoing releases of PFAS into the environment at facilities where PFAS has been used, manufactured, discharged, disposed of, released, and/or spilled. The EPA is conducting inspections, issuing information requests, and collecting data to understand the level of contamination and current risks posed by PFAS to surrounding communities and will seek to address threats to human health with all its available tools. The EPA works with its federal, state and Tribal regulatory partners through a comprehensive Safe Drinking Water Act compliance monitoring program to protect human health and the environment by ensuring that the regulated community obeys environmental laws/regulations through on-site visits by qualified inspectors, and a review of the information the EPA or a state/Tribe requires to be submitted. Requests for the Agency for Toxic Substances and Disease Registry (ATSDR) are beyond the scope of this rulemaking. (For information about ATSDR's process for citizens to request it assess public health concerns in a particular location, see https://www.atsdr.cdc.gov/petition-process.html.) Regarding commenter concerns on the compliance timeframe, please see section 12.1 of the EPA response in this *Response to Comments* document.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045488)

B. Advocacy recommends that EPA provide burden-reducing compliance flexibilities for small water systems.

To address the concerns raised above, the agency must consider and provide alternatives to reduce burden on small water systems. First, the agency should consider finalizing one of the regulatory alternatives to reduce the scope of the rule. Alternatively, the agency can phase in compliance by gradually lowering the MCLs to its target level (i.e., proposed MCLs). Finally, and most importantly, the agency must allow additional time for compliance for small water systems. If applied, these burden reducing flexibilities will allow the agency to achieve its statutory objective and reduce the significant economic burden on small water systems.

EPA Response: The EPA notes that the agency included multiple burden reduction flexibilities for small systems that resulted from its RFA pre-proposal Small Business Advocacy Review (SBAR) Panel process. For more information regarding the EPA's evaluation of the NPDWR under the RFA and about flexibilities the EPA included as a result of the SBAR Panel process, please see section XIII.C. of the final rule preamble and the final regulatory flexibility analysis in section 9.3 of the final rule economic analysis. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach and exemptions that may be available under SDWA Section 1416.

Sammamish Plateau Water and Sewer District (Doc. #1573, SBC-042462)

[The proposed rule is particularly unclear in the following areas, and should be revised to provide clarity to water utilities by addressing the following:]

• The compliance date for reducing PFAS levels in the event of an MCL exceedance is unclear. Clarity is important both for responding with treatment and mitigation plans, but also to assure USEPA recognizes the practical aspects of designing and constructing treatment.

EPA Response: The date by which systems must comply with the MCLs is five years following rule promulgation and that date is clearly provided in the final rule and preamble.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043334)

Comment 4

Section XI. Treatment Systems (pg. 18684)

In the first paragraph of this section, EPA states that "Water systems with PFAS levels that exceed the MCLs proposed would need to take action to provide drinking water which meets the

NPDWR by the compliance dates established in the rule when final." While it is clear in the proposed rule when monitoring for PFAS will be required (within 3 years of the rule becoming final), it is not clear when EPA expects water systems to actually meet the MCL's proposed in the rule. Similar language on page 18369 (Executive Summary), "Water systems with PFAS levels that exceed the proposed MCLs would need to take action to provide safe and reliable drinking water" does not provide any clear timeframe for which compliance with MCL's is required. Additional clarity is needed on this so that water systems can begin to prepare capital plans and budgets for installing the required Best Available Technology (BAT).

EPA Response: The date by which systems must comply with the MCLs is five years following rule promulgation as provided in the final rule and preamble.

Massachusetts Water Resources Authority (Doc. #3072-49, SBC-047382)

Finally, I'd like to add that EPA needs to evaluate how to create sufficient flexibility in the compliance framework to allow systems to come into compliance. The timeline simply doesn't work. Thank you.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044920)

EPA could also take a similar approach that it used with the arsenic rule (see table below), where systems were eligible for an exemption based on concentrations [FN14: https://www.epa.gov/sites/default/files/2015-09/documents/2005_11_10_arsenic_ars_final_app_g.pdf]. Water systems would still have five years for compliance but would be eligible for the three-year exemption based on the concentrations of PFAS in their system. A potential option would be using over or under 10.0 ppt as a determination threshold, as EPA already explored the option of a 10.0 ppt MCL and approximates 1,300 systems would be impacted. These 1,300 systems would need to be in compliance in the 5 years, but those under 10.0 ppt would have a little more time to explore other options or to spread out the demand for materials and labor. [Table 1: See Docket ID EPA-HQ-OW-2022-0114-1672]

This would allow for systems with the highest concentrations of PFAS, and therefore the highest risk to public health, to address the issue first and have first access to the materials and labor needed for treatment, like a "worst-first" approach. Water systems that are closer to the MCL would have a little longer to comply to alleviate strains in supply chain and labor and would not provide an unreasonable risk.

A feasible compliance timeline is paramount to the success of this rulemaking. Rampant noncompliance places an unnecessary burden on primacy agencies and EPA and undermines the confidence of the public in its drinking water. The public would be better served by knowing the path to compliance is achievable than by being routinely notified that their drinking water fails to meet newly implemented standards. Repeated notices of noncompliance will only drive more people to drink bottled water – which, ironically, does not have to comply with the same PFAS monitoring and treatment standards, and which therefore may actually contain higher levels of the contaminants than water from a PWS found to be in violation of EPA's new rule. EPA and water systems must work together to build and maintain trust in drinking water. Unfortunately, distrust of drinking water leads to individuals, including those in low-income and underserved communities, spending money needlessly on less-regulated water bottled in plastic.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach and exemptions. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring timing, please see section 8.1.1 of the EPA response in this *Response to Comments* document. With respect to public notice requirements related to violations of the PFAS NPDWR, please see section 9.2 of the EPA response in this *Response to Comments* document. All PN must include the elements identified in § 141.205(a), including what actions the consumers should take and whether alternative water supplies should be used. Consistent with the existing PN rule in § 141.203(b)(2), primacy agencies may allow less frequent repeat notices for Tier 2 PNs in certain circumstances; these notices must be in writing. The EPA believes repeat notices are beneficial in increasing the likelihood of reaching all affected parties and allow systems to provide updates for consumers on the situation. The Food and Drug Administration (FDA) has authority for bottled water which is outside of the scope of this NPDWR.

American Water Works Association (AWWA) (Doc. #1759, SBC-047705)

The EPA's proposed approach (4 ppt PFOA, 4 ppt PFOS, and hazard index of 1.0 for PFHxS, PFNA, HFPODA, and PFBS) will not be feasible, as they will create significant challenges for water systems to implement, is not clearly EPA's legal authority under SDWA, and rely on a series of critically flawed analyses that mischaracterize the impacts of the proposed rule. As discussed earlier, the large number of systems that will need to install drinking water treatment will create challenges in implementing the MCLs on the timeline provided by the EPA and, ultimately, systems will not be able to meet these timelines while also applying best engineering practices to plan, design, and construct these facilities.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The agency also disagrees with the commenter that the EPA does not have clear legal authority to regulate mixtures of PFHxS, PFNA, HFPO-DA and PFBS through a Hazard Index MCL; for additional discussion on this topic, please see section 3.2 of the EPA response in this *Response to Comments* document. With respect to commenter concerns on "impacts of the proposed rule," please section 13 of the EPA response in this *Response to Comments* document.

Aquarion Water Company (Doc. #1617, SBC-043377)

3. To address the issues with the 3-year compliance timeframe, and to ensure that water supplies with the most significant PFAS pollution are prioritized by stakeholders (e.g., utilities, regulators, funding agencies, local officials), we suggest that EPA consider a progressive approach to the new MCLs, by reducing the MCLs in stages over multiple years. This would allow stakeholders to focus first on water supplies with relatively high levels of PFAS that are the greatest risk to consumers. This approach would also allow utilities and regulators to learn more about treatment solutions and costs over time, and thus allow for more informed decision-making as the MCLs progressively decrease.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as a phased-in MCL. For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Beaufort-Jasper Water & Sewer Authority (BJWSA) (Doc. #1618, SBC-042935)

To address these concerns, we request that EPA modify the proposal to take a phased approach to PFAS regulation. Implementing a higher maximum contaminant level for PFAS initially will allow focus on source waters where more significant PFAS concentrations exists. This will also provide for a more reasonable approach and a better use of resources to address PFAS contamination in public waterways. An implementation schedule starting out with higher limits (e.g., 10 parts per trillion) followed by several multi-year periods of gradual contaminant limit reduction would allow utilities the time to plan and identify opportunities for source water reduction (which is the most cost-effective remedy available). We remind EPA that the health advisory level for PFAS contaminants PFOA and PFOS was 70 parts per trillion less than one year ago. With EPA's current proposal, the maximum allowable levels in drinking water will be substantially lower while giving utilities very little time to react, investigate, or plan.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as a discussion of phased-in MCLs. For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044909)

The greatest health risks from PFAS in drinking water will come from systems with the highest concentrations, not those at the margins of compliance with EPA's proposal. EPA should work to address these systems first to protect individuals in those service areas. EPA's proposal estimates approximately 4,300 PWSs will be impacted by this rule [FN7: EPA Economic Analysis, (USEPA, 2023j)]. Cleveland Water emphasizes that the upcoming implementation of UCMR 5 will provide more accurate estimations of the impacted systems' PFAS levels. Any system with levels above the proposed MCLs must promptly initiate planning and execute interventions to address PFAS contamination once this rule is finalized. It is important to anticipate that this substantial demand will exert significant pressure on supply chains and the labor market. Meanwhile, EPA estimates around 3,300 PWSs would be impacted if MCLs were implemented at 5.0 ppt, and about 1,300 PWSs with MCLs set to 10.0 ppt. These 1,300 PWSs with PFOA and/or PFOS above 10.0 ppt should be prioritized, as greater demands in GAC, materials, and labor could prevent these systems from quickly remediating the issue, potentially exposing the public in these service areas to higher concentrations of PFAS for a longer period.

If EPA chooses to rush through finalizing this rulemaking before the September 2024 statutory deadline, it would be advantageous to finalize an MCL at a level feasible by PWSs and still meaningfully protecting public health. EPA should initially require PWSs with levels of PFAS >10 ppt to implement actions to reduce the public's exposure to these levels first. Then, EPA can use UCMR 5 and other up-to-date research to further explore lowering that threshold. The agency would still be protecting the health of the public and would simultaneously be alleviating the strains, demands, and increased costs for labor, materials, and construction. This would also allow PWSs with lower concentrations to explore other, less costly, measures to reduce exposures to PFAS, yielding both fiscal and health-related advantages for the public.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that this rulemaking is rushed or that the agency needs to wait for additional information (such as UCMR 5 information) in order

to finalize the NPDWR at this time. The EPA currently has determined that these PFAS meet the criteria for regulation under SDWA, that such regulation is a priority, and that there is sufficient data and information to promulgate standards for the PFAS regulated through this NPDWR: please see section 6 of the EPA response in this *Response to Comments* document for the agency's discussion on occurrence.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-047704)

In addition, given the challenges with timelines and lab capacity as explained in Sections 5.5 and 5.6, if EPA were to finalize the rule with a 10 ppt MCL for PFOA and PFOS, with an extended compliance timeline, the agency would be protecting public health while simultaneously reducing burdens on PWSs. At the same time that EPA promulgates the final rule, the agency could recognize the possibility of moving forward to lower the MCL for PFOA and PFOS after receiving and analyzing additional information that would better inform a more complete and accurate RIA. This would include:

● Nationwide occurrence data received from UCMR 5;

● A more robust and accurate cost estimation; and

● A better reflection of up-to-date research and analyses on health benefits of further reducing PFAS concentration at the ppt level.

A phased MCL level would also alleviate some of the supply chain, labor shortage, and data gap issues many PWSs are currently facing. EPA has looked at exposure of concentrations of certain PFAS over a lifetime; therefore, allowing time for water systems with low levels of PFAS to address contamination properly and cost-effectively will not pose additional health risks.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline, as well as a discussion of phased MCLs. For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that the agency needs to wait for additional information (such as UCMR 5 information or additional health effects data) in order to finalize the NPDWR at this time. The EPA currently has sufficient data and information to promulgate standards for the PFAS regulated through this NPDWR: please see section 4 of the EPA response in this *Response to Comments* document for the agency's discussion on MCLGs, section 13 for the agency's discussion on the economic analysis, and section 6 of the EPA response in this *Response to Comments* document for the agency's discussion on occurrence.

Prince William County Service Authority (Doc. #1609, SBC-042838)

Additionally, the short schedule proposed by EPA effectively cuts off the ability of a water utility to benefit from upstream source reduction activities by others, such as product substitutions and/or treatment installation at upstream PFAS-discharging industries, which may eliminate the need for ratepayers to bear the cost of water treatment plant upgrades. For water systems experiencing PFAS concentrations slightly above the proposed MCLs, this is an especially problematic aspect of the proposed regulation that should be revised. For example, for water systems with concentrations of 5 or 6 ppt, targeted reductions by one or more upstream industries could potentially achieve a 4 ppt MCL far more cost-effectively than adding treatment to the water system.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045284)

If levels exceed health-based thresholds, the next step should be to evaluate options and employ a holistic long-term approach to help drinking water systems comply with PFAS MCLs. A first step should allow time for industrial sources to be identified and mitigated. Key efforts should include the elimination of environmental loading and drinking water supply protection. Finding and mitigating sources of PFAS contamination would serve the long-term goals for protecting drinking water supplies from PFAS and possibly other contamination, and we appreciate EPA actions of this kind.

The California-Nevada Section of AWWA sincerely appreciates the opportunity to share the preceding comments for your consideration. We remain committed to the SDWA framework and to its goal that every person should have access to the safest water possible, considering technical and economic feasibility.

Sincerely,

Sue Mosburg

Executive Director

EPA Response: The EPA notes that eliminating sources of PFAS contamination is beyond the scope of this rulemaking; however, the agency notes that it is taking an all-of-agency approach toward addressing PFAS (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion). Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension

pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Ohio Water Utility Council (OWUC), Ohio American Water Works Association (OAWWA) (Doc. #1782, SBC-044725)

OWUC appreciates EPA's goal of protecting public health and the drinking water sources for the citizens of the United States. Ohio's water utilities are committed to the same goal and are diligently working daily to provide that to our customers. While we agree with this goal, OWUC believes shifting the focus to eliminating PFAS substances at the source is a more effective use of resources by EPA. The regulatory requirements on industrial sources of PFAS substances are not on the same pace as those for public drinking water systems, where the exposure totals much less than industrial sources. Identifying these sources, eliminating contamination at those sites and lengthening the compliance schedule for this proposed rule will benefit drinking water systems by reducing or eliminating the needed treatment for PFAS and the associated costs.

Thank you again for the opportunity to comment on these proposed rules. Should the USEPA have additional questions or in need of clarification, the OWUC is available for discussion. Contact information is provided below.

Sincerely,

Sarah C. Van Frank-Affrunti

Ohio Water Utility Council, Chair

Ohio American Water Works Association Affruntis@swwater.org

EPA Response: The EPA notes that eliminating sources of PFAS contamination is beyond the scope of this rulemaking, however the agency notes that it is taking an all-of-agency approach toward addressing PFAS (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion). Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Fairfax Water (Doc. #1789, SBC-045294)

EPA Should Prioritize its PFAS Efforts on Eliminating Sources of Contamination

Fairfax Water supports EPA's efforts to reduce PFAS in the environment. However, instead of prioritizing regulation of sources of PFAS, EPA proposes to regulate PFAS through drinking water, a significant divergence from the "polluter pays" principle. PFAS compounds continue to be manufactured and used in a wide variety of industrial and consumer products. Water utilities

are passive receivers of PFAS compounds that make their way to our sources of supply. Through the proposed regulation, the rate-paying public will be responsible for bearing the entire cost of PFAS removal, not the polluters.

Further, the proposed compliance period provides no meaningful opportunity to identify and eliminate potential sources of PFAS that may contribute to exceedances of the proposed PFAS Maximum Contaminant Levels (MCLs) or Hazard Index (HI). Eliminating sources is the ultimate solution to removing PFAS from the environment. Fairfax Water's Occoquan Reservoir is an indirect potable reuse system with some industrial discharges to the publicly owned treatment works (POTW). The state has conducted some sampling for PFAS in the watershed and Fairfax Water is planning to do more. There are potential opportunities to remove PFAS sources from the water supply but no regulatory mechanism to do so. Providing adequate time for state regulatory agencies to identify PFAS sources and a national regulatory framework that supports the elimination of those sources would place the cost for remediation where it belongs - on the polluter instead of the public.

The PFAS treatment alternatives identified in the proposed rule do not destroy PFAS; they simply move PFAS from one medium to another, creating a further environmental risk to be borne by the public. Failure to address the fundamental issue of continued introduction of PFAS into the environment as part of a rational, comprehensive regulatory framework, while requiring water utilities to remove them from drinking water at great public expense, merely kicks the PFAS "can" down the road. We ask EPA to prioritize a comprehensive regulatory scheme at the national level to remove PFAS from the environment that focuses on controlling sources, not passive recipients like water utilities.

EPA Response: The EPA notes that eliminating sources of PFAS contamination is beyond the scope of this rulemaking; however, the agency notes that it is taking an all-of-agency approach toward addressing PFAS (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion). The EPA also notes that from a mass balance perspective, PFAS removal from drinking water is generally anticipated to result in lower concentrations of PFAS in the environment. With appropriate controls, landfills and thermal treatment of PFAS contaminated media can minimize PFAS releases to the environment (USEPA, 2020). Please see section 10.4.1 of the EPA response in this *Response to Comments* document for more discussion on media shifting. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Neuse Regional Water and Sewer Authority (Doc. #1822, SBC-044570)

2. EPA should shift compliance costs to those responsible for the PFAS pollution.

The costs to NRWASA to implement the Proposed Rulemaking will be unprecedented and unbudgeted. If it is determined that the concentration of any PFAS in a public water system has exceeded a permissible concentration level, the PFAS manufacturer or discharger should be responsible for paying the actual and necessary costs incurred by the public water system to remove. The manufacturer should correct or abate the adverse effects of PFAS in the water supply system resulting from the contamination for which the PFAS manufacturer is responsible.

The Proposed Rulemaking further notes that "[c]onventional and most advanced water treatment methods are ineffective at removing PFAS." [FN3: Id. at 18684.] Not only will NRWASA need to invest in one of the technologies contemplated by the Proposed Rulemaking, it also must provide for testing, personnel, and potentially hazardous waste disposal [FN4: See id. at 18686.]. This, combined with NRWASA's expected up-front compliance costs and additional annual costs will pose a significant strain on NRWASA's ability to provide water for the people of Lenoir and Pitt Counties.

Shifting costs or instituting a program requiring PFAS manufacturers to pay for these costs is consistent with EPA's guidance for addressing PFAS discharges in EPA and state issued NPDES permits. A similar regime should be part of the Proposed Rulemaking, or the effective date delayed until the cost issue can be addressed. NRWASA should not have to bear the full cost of treatment upgrades for contamination caused by those responsible for creating the PFAS problem. The Proposed Rulemaking should be revised to address this cost factor and to shift the cost to those responsible for creating PFAS pollution.

EPA Response: The EPA notes that eliminating sources of PFAS contamination is beyond the scope of this rulemaking; however, the agency notes that it is taking an all-of-agency approach toward addressing PFAS (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion). Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

American Water (Doc. #3072-51, SBC-047384)

Implementation timing should also consider the available capacity of engineers, contractors, and suppliers to build a required treatment and available capacity of vendors to supply ion exchange resin, granular activated carbon and media reactivation, waste disposal services on an ongoing basis. American Water calls for sound policies that will ensure compliance by all water utilities, whether privately or municipally owned. This includes advocating for policies that would hold polluters accountable for the ultimate responsibility for cleanup of these contaminants, falling to those who created the problem. This effort comes at a cost and states should treat these expenditures for regulated utilities as federally mandated requirements that are recoverable in customers' rates through expedited means. American Water joins other organizations urging U.S.

EPA, Congress, and other decision makers to implement policies that keep harmful PFAS out of drinking water supplies for our communities, exempt all water and wastewater systems from financial liability for PFAS under CERCLA.

EPA Response: The EPA notes that topics related to eliminating sources of PFAS contamination or assigning PFAS liability are beyond the scope of this rulemaking, however the agency notes that it is taking an all-of-agency approach toward addressing PFAS (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion). Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Kerri Spayd (Doc. #1790, SBC-045318)

Subject: EPA-HQ-OW-2022-0114

Follow Up Flag: Follow up

Flag Status: Flagged

As a resident of a small community that has a centralized facility with a hazardous waste violation, HSI 10141, and a Voluntary Remediation Plan that includes documentation of the presence of PFAS in the soil, I would like to know if the PFAS/PFOA rule will propagate new investigations and/or indicate the community ground water system be required to adhere immediately to the proposed rulings verses the three year mandatory compliance?

Thanks for your time,

Kerri Spayd

EPA Response: The NPDWR regulates PFAS levels in finished drinking water only; SDWA imposes no requirements to monitor or regulate the water quality levels of PFAS in drinking water sources. Additionally, the PFAS NPDWR does not require a PWS to determine the sources of PFAS in its source water. Regarding commenter concerns on the compliance timeframe, EPA has not found that it is practicable for water systems to comply with the rule earlier than the 3 year timeframe set out in SDWA for the reasons discussed in section 12.1 of the EPA response in this *Response to Comments* document

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043162)

A phased approach that prioritizes addressing a smaller set of water systems with higher PFAS concentrations first, and phases-in overtime whatever further reduced levels may be appropriate over the long-term for systems with lower PFAS concentrations, could be a better way to protect public health, avoid implementation and construction delays, and avoid wasted resources, especially when also considering the current construction market cost problems and price premiums and the schedule infeasibility problem discussed below.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on phased-in MCLs. Please see section 5.1.3 of the EPA response in this *Response to Comments* document for a summary of major comments. (cost considerations and alternative MCLs).

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043172)

Sixth, the short schedule under the proposal effectively cuts off the ability of water treatment plants and their ratepayers (the public) to benefit from source reduction activities by others, such as a product substitutions and treatment installation at upstream PFAS-discharging industries, which would eliminate the need for ratepayers to bear the cost of water treatment plant upgrades. For water systems experiencing PFAS concentrations slightly above the proposed MCLs, this is an especially problematic aspect of the proposed regulation that should be revised. For example, for water systems with concentrations of 5 or 6 ppt for PFOA or PFOS, targeted reductions by one or more upstream industries could potentially achieve a 4 ppt MCL far more cost-effectively than adding treatment to the water system. In this sense, the proposed regulation also runs contrary to the generally-accepted public policy concept of "polluter pays" and transfers the burden to families and other innocent ratepayers, because there is no time allowed in this regulation for source water reductions to be accomplished. The proposal's tight schedule forces all affected water systems to jump immediately into design and construction on a compressed timeline.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). While beyond the scope of this rulemaking, the EPA is making progress implementing many of the commitments in the Strategic Roadmap, including those that may significantly reduce PFAS source water concentrations. Please also see section 15.1 of the EPA response in this *Response to Comments* document.

13 Health Risk Reduction and Cost Analysis

13.1 Affected Entities and Major Data Sources Used to Develop the Baseline Water System Characterization

Summary of Major Public Comments and EPA Responses

One commenter was supportive of the EPA's baseline water system characterization and pointed out multiple areas where important considerations were accounted for and that reasonable assumptions were made.

One commenter cited preliminary research suggesting that the concentrations of PFOA and PFOS in rainwater are frequently higher than the 4.0 ppt Maximum Contaminant Level (MCL), and that this environmental contamination will lead to a dramatically higher number of public water systems (PWSs) affected by this rule than estimated by the EPA. The EPA disagrees with the commenter that additional unaccounted for sources of PFAS pollution will dramatically change the affected number of PWSs under the rule. As discussed in section VI of the preamble for the final rule and in USEPA (2024a), the EPA used PFAS occurrence data collected from PWSs to characterize baseline conditions in the PFAS National Primary Drinking Water Regulations (NPDWR). The drinking water PFAS occurrence estimates used in the baseline characterization reflect the finished water PFAS concentrations in PWSs. While the Safe Drinking Water Act (SDWA) does not require the EPA to assess contamination directly from rainfall, upstream sources of PFAS contamination into PWS source waters, including contamination from rainfall, may reasonably be captured in the baseline characterization due to fate and transport of PFAS into drinking water supplies. However, the PFAS occurrence information available from PWSs, which was used to support the agency's occurrence and baseline analyses in this rulemaking, is the most appropriate information to use to characterize PFAS occurrence in drinking water supplies because rainwater concentrations may not translate directly to PFAS occurrence levels in drinking water supplies. See discussion in sections 3.1.2, 3.2.2, and 6 of the EPA response in this *Response to Comments* document for further discussion and responses regarding occurrence information.

One commenter disagreed with the EPA's assumption that drinking water PFAS concentrations will remain constant in the absence of its proposed rule. This commenter stated that baseline PFAS concentrations are likely to decrease as states impose their own PFAS drinking water regulations and there are more voluntary actions to install PFAS treatment. The commenter also cited other rulemakings such as a hazardous substance designation under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), as a driver for utilities to take voluntary action to reduce PFAS concentrations in drinking water in order to reduce their CERCLA liability. While what *might* happen as a result of rulemaking currently under development under CERCLA authorities is beyond the scope of this rulemaking, the EPA disagrees that the CERCLA rulemaking once finalized would spur voluntary action to remove PFAS from drinking water in the interest of reduced liability for water systems. The commenter

provides no evidence to support this argument and given the input provided by water utilities in the CERCLA rulemaking process that handling drinking water treatment residuals increases, not decreases, concerns about perceived liability, it seems highly unlikely that CERCLA would drive water systems to remove PFOA and PFOS to below 4 ppt each, absent the NPDWR. The EPA notes that as discussed in the CERCLA rulemaking, among the possible indirect benefits of the CERCLA designation is a reduced amount of PFAS entering drinking water sources, but the timing and magnitude of those impacts are uncertain. While the EPA agrees that environmental concentrations of regulated PFAS may reasonably reduce over time as a result of federal, state, and local actions to reduce PFAS, the EPA is unable to accurately forecast the extent to which PFAS concentrations will be reduced in drinking water supplies as a result of other regulatory or voluntary actions. Therefore, the EPA maintains that the Unregulated Contaminant Monitoring Rule (UCMR) and state datasets, as used to characterize baseline occurrence conditions for the NPDWR, represent the most accurate and comprehensive information available on PFAS occurrence in PWSs. Additionally, actions taken by state regulators or utilities utilizing emerging contaminant grants may lead to localized decreases in PFAS drinking water concentrations, which have been accounted for as part of the baseline analysis as the EPA adjusted the baseline to reflect the assumption that PWS in states with existing regulations have baseline occurrence at the state MCLs. However, the baseline characterizes the nation as a whole, which will not see significant decreases in finished drinking water concentrations, in the absence of a NPDWR. The EPA further notes that, to the extent that the emerging contaminant grants effectively reduced PFAS concentrations in states without PFAS regulations that were reported to the EPA or state agencies in the years of occurrence data that we assessed for the baseline, the potential impact has been captured.

One commenter stated that the data used to inform baseline and compliance characteristics are incomplete and insufficient, and that characteristics for which data are missing in federal reporting systems are estimated using inappropriate assumptions. The EPA disagrees with these claims. The EPA periodically reviews inventory information in the Safe Drinking Water Information System / Federal Version (SDWIS/Fed); the inventory data in the national Error Code Tracking Tool (ECTT) indicate a high degree of completeness and accuracy in SDWIS/Fed, and that the information is largely representative of the regulated PWS. For more information on the ECTT, see (USEPA, 2007a) incorporated in the administrative record for this action.

Individual Public Comments

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045934)

The levels of PFOA and PFOS in rainwater have been shown to exceed the levels permitted under the proposed MCL.

Preliminary research has compared the levels of PFAS in rainwater to the levels of PFAS permitted under various worldwide drinking water standards. [FN15: Cousins, Ian T., et. al, Outside the Safe operating Space of a New Planteary Bounder for Per- and Polyfluoroalkyl

Substances (PFAS) Environ. Sci. Technol. 2022, 56, 11172, Figure 1.] This study shows that the concentrations of both PFOA and PFOS in rainwater frequently exceed the 4 ppt proposed MCL in both rural and urban areas. Because we are finding that concentrations in rainwater are often higher than the MCLs proposed, it is highly foreseeable that a 4 ppt MCL will impact a dramatically higher number of water and wastewater agencies than was estimated in the proposed rule.

EPA Response: Please see section 13.1 of the EPA response in this *Response to Comments* document. As discussed in that response, the EPA disagrees with the commenter that additional sources of PFAS pollution will dramatically change the affected number of PWSs under the rule because upstream sources of PFAS contamination into PWS source waters, including contamination from rainfall, may reasonably be captured in the baseline characterization due to fate and transport of PFAS into drinking water supplies.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046010)

Additional Assumptions in EPA's EA

Changes to Baseline Due to Voluntary Actions

EPA assumes that drinking water concentrations will remain constant in the absence of its proposed rule. As a result, EPA's assumption overstates the net benefits of the rule because other PFAS actions and regulations will likely decrease occurrence in drinking water.

In the absence of EPA's proposed rule, the baseline PFAS occurrence will likely decline due to increasing regulatory action at the state level and additional voluntary actions. Additionally, in September 2022, EPA published a NPRM designating PFOA and PFOS as CERCLA hazardous substances [FN45: "Designation of Perfluorooctanoic Acid (PFOA) and Perfluorooctanesulfonic Acid (PFOS) as CERCLA Hazardous Substances," Federal Register 87, no. 171 (September 2022): 54415–42.]. The designation, if finalized, will have far-reaching impacts as industries and utilities shift activity to prevent PFAS releases and litigation. Utilities may try to reduce PFOA and PFOS concentrations to reduce their CERCLA liability with or without a federal drinking water standard.

Finally, there will be more voluntary PFAS treatment installations as a result of increased federal funding initiatives dedicated to reducing PFAS contamination levels. Of the $48 billion appropriated for drinking water and wastewater in the IIJA, $4 billion is set aside to address emerging contaminants in drinking water with a focus on PFAS and an additional $5 billion will be appropriated to help small and disadvantaged communities address emerging drinking water contaminants [FN46: 46 U.S. Environmental Protection Agency, "Emerging Contaminants (EC) in Small or Disadvantaged Communities Grant (SDC)," n.d.]. This funding can only be used to address capital costs.

EPA Response: Please see section 13.1 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046024)

Affected Entry Points to System (EPTDSs) and Average Flow

EPA provides an estimate of total entry points to distribution systems (EPTDS) that will be affected by the proposed NPDWR (see Table 19). The analysis extends EPA's estimate further to distribute these EPTDSs by system size categories.

Table 19: Total EPTDSs Impacted

[Table 19: see docket ID EPA-HQ-OW-2022-0114-1738]

[FN128: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," tbls. 4–22.]

The analysis distributes the EPTDS by CWS size and source water type by applying ratios derived from the CWS inventory (see discussion preceding Table 10). The estimated number of affected EPTDSs by CWS size is summarized in the following table.

Table 20: Total Estimated EPTDSs that Exceed One or More MCL by CWS Size

[Table 20: see docket ID EPA-HQ-OW-2022-0114-1738]

Next, the average flow is calculated by dividing the average flow per CWS by the design flow per CWS. Flow increases with system size, with the largest CWSs having an average flow of 22 MGD for each entry point. Average daily production flow and design flow per system are based on regression equations from EPA's Geometries and Characteristics of Public Water Supplies report [FN129: U.S. Environmental Protection Agency, 4–14. Science Applications International Corporation and The Cadmus Group, "Geometries and Characteristics of Public Water Systems" (U.S. Environmental Protection Agency, December 2000).]. The average daily flow and design flow are functions of the population served, with different equations for source water type Table 21: Average Flow (MGD per EPTDS)

[Table 21: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: The excerpts above discuss the interim steps taken to characterize affected entities for purposes of the commenter's analysis of greenhouse gas emissions as a result of the PFAS NPDWR. Please see section 13.11 of the EPA response in this *Response to Comments* document for a summary of public comments on greenhouse gas emissions, Chapter 9 of the final economic analysis (EA) for the EPA's analysis of greenhouse gas emissions, and Chapter 4 of the final EA for the EPA's characterization of entry points and flow characteristics for affected entities.

American Water Works Association (AWWA) (Doc. #1759, SBC-046161)

5.1 Determining Design Parameters

5.1.1 Treatment Design Flow Determination

PWS data available in SDWIS do not include water usage data for each PWS and EPTDS. Instead, service population data from SDWIS was used and the average flow for each PWS was assumed based on a per capita per day usage of 150 gallons. While not reflective of each state's dynamics with respect to water usage, this was considered a reasonable number from a national perspective. Peaking factors for different size systems from the EPA's "Cost and Technology Document for Final Groundwater Rule" were used and are shown in Table 5-2. The trend of this dataset was best fit to a power equation to calculate peaking factor as a function of average daily flow as shown on Figure 5-1.

Table 5-2- EPA Peaking Factor for Various Average System Flows

[Table 5-2: Docket ID: EPA-HQ-OW-2022-0114-1759]

[Figure 5-1: Docket ID: EPA-HQ-OW-2022-0114-1759]

Figure 5-1 Peaking Factor as a Function of Average System Flow

The treatment design flow per EPTDS was determined by Equation 1:

[Equation 1: Docket ID: EPA-HQ-OW-2022-0114-1759]

The estimated number of EPTDS per system size is based on an evaluation by EPA published with the proposed national primary drinking water regulation for PFAS from March 2023. The number of EPTDS per system broken out by groundwater and surface water systems within each system size bin is summarized in Table 5-3.

Table 5-3 Number of EPTDS as a Function of System Size

[Table 5-3: Docket ID: EPA-HQ-OW-2022-0114-1759]

EPA Response: The excerpts above discuss the interim steps taken to characterize affected entities for purposes of the commenter's analysis of greenhouse gas emissions as a result of the PFAS NPDWR. Please see section 13.11 of the EPA response in this *Response to Comments* document for a summary of public comments on greenhouse gas emissions, Chapter 9 of the final EA for the EPA's analysis of greenhouse gas emissions, and Chapter 4 of the final EA for the EPA's characterization of entry points and flow characteristics for affected entities.

3M Company (Doc. #1774, SBC-045697)

d. Significant Data are Missing and Insufficient Detail is Provided Regarding Imputation

EPA lacks complete PWS-specific data across the 49,193 community water systems (CWSs) and 17,337 non-transient non-community water systems (NTNCWSs) in the Safe Drinking Water Information System (SDWIS/Fed) for many of the baseline and compliance characteristics necessary to estimate costs and benefits. Data are incomplete for design, average daily flow rates, water quality characteristics, treatment in-place, and labor rates, among other factors. EPA

does not explain 1) the number of CWSs for which data are missing, 2) the number of each baseline and compliance characteristic for CWSs that are missing by CWS category, 3) the number of NTNCWSs for which data are missing, or 4) the number of each baseline and compliance characteristic for NTNCWSs that are missing by NTNCWS category. EPA states that "[i]n some cases, the categorical data are simple point estimates. In this case, every model PWS in a category is assigned the same value" (USEPA 2023f, p. 18691). Consequently, many characteristics necessary to estimate costs and benefits—such as design, daily flow rates, water quality characteristics, among others—may be simple category-wide or nationwide averages. It appears that, in estimating the costs and benefits of the proposed NPDWR, EPA makes assumptions that are themselves based on assumptions.

The baseline and compliance characteristics are critically important to the cost analysis. For example, the SafeWater Multi-Contaminant Benefit-Cost Model (MCBC) uses the baseline and compliance characteristics as input values for a decision tree model. The decision tree model then selects the treatment technology or non-treatment alternative in response to estimated occurrence/co-occurrence estimates. These treatment technologies or non-treatment alternatives form the foundation of all costs and benefits estimated in response to the proposed rule. As EPA notes, "there are nearly 3,500 individual cost equations across the categories of capital and operation and maintenance (O&M) cost, water source, component level, flow, bed life (for GAC and ion exchange), residuals management scenarios (for GAC and ion exchange), and design type (for GAC)" (USEPA 2023f, p. 18692). These assumptions and imputation processes have a significant impact on the overall cost estimates, and EPA fails to transparently adequately describe them in detail or justify their use.

EPA Response: The EPA disagrees with the commenter's assertion that the agency used incomplete data in characterizing the baseline and compliance characteristics necessary to estimate costs and benefits. As discussed in this response, the EPA used the best available information and the data sources used are the most comprehensive available, which includes thorough data obtained from the EPA's SDWIS, the third Unregulated Contaminant Monitoring Rule, independent state sampling program datasets, the Geometries and Characteristics of Public Water Systems report, and the 2006 Community Water System Survey (CWSS). (See Chapter 4 of USEPA (2024b) for complete discussion on data sources used to characterize baseline conditions). The approach used by the EPA, which uses point estimates to characterize some baseline and compliance components for model systems, is the most suitable for estimating national benefits and costs. Moreover, the EPA has characterized baseline and compliance characteristics appropriately using information available at the PWS level from the Safe Drinking Water Information System which has a high degree of completeness and is largely representative of regulated PWSs. Model systems in SafeWater MCBC combine the PWS-specific data available in SDWIS/Fed with data on baseline and compliance characteristics available at the PWS category level. Point estimates are used in cases where there is no available information to inform the variability of the parameter, and in other cases where more robust data representing system variability are available, the category-level data include a distribution of potential values that SafeWater MCBC uses to sample from. In the Economic Analysis (EA), the

agency has transparently provided the parameter values used to characterize baseline and compliance characteristics for model systems. Additionally, the EPA disagrees with the commenter's claim that the EPA failed to transparently describe assumptions and impacts associated with the characterization of baseline and compliance characteristics. In the over 700-page EA and appendices, which include thorough explanations (or direct references to where to find explanations) of every component of the EA, the EPA summarized analytical assumptions and described how the quantitative analysis incorporates sources of uncertainty (see table 4-34 of the EA for a summary of sources that have quantifiable uncertainty and data limitations). The EPA notes that in most cases it is not possible to determine the extent to which a particular limitation or uncertainty can affect the magnitude of baseline conditions, however, the EPA described the potential direction of the impact on baseline inputs to the costs and/or benefits analysis when inference was possible. The result of this analysis, using best available information, using readily accepted analytical approaches, and thoroughly explaining the information and methodology used, reflects best available science.

In conclusion, the model systems are representative of PWSs, the EPA maintains that the information on baseline and compliance parameters provided in the rule is sufficiently comprehensive, and no further information is required.

Earthjustice et al. (Doc. #1808, SBC-046127)

4. EPA correctly accounts for existing state-level drinking water standards for PFAS in the baseline.

EPA undertook a detailed and thorough approach to account for existing state-level standards that limit the allowable levels of certain PFAS in drinking water. These states include NJ, VT, NH, MA, MI and NY. When baseline PFAS concentration levels for system points-of-entry in these states are estimated to exceed existing state-specific MCLs, then the estimated concentrations are instead assumed to equal the state-level MCLs – i.e., it is assumed that PWSs are in full compliance with any existing state standards for PFAS in drinking water. In making this adjustment, any incremental improvements already achieved by the state programs would be correctly accounted for in the baseline, and not falsely contribute to the estimated benefits and costs of the proposed federal PFAS NPDWS. This accounting of existing state-level standards in the baseline correctly results in a reduction in both benefits and costs compared to a baseline that would incorrectly disregard existing state regulations.

EPA Response: The EPA agrees with the commenter that the agency correctly accounted for existing state-level drinking water standards for PFAS in the baseline. Existing state-level drinking water PFAS standards were accounted for in the baseline water system characterization.

Groundwater Resources Association of California (Doc. #1831, SBC-045350)

[Based on our review of this document, GRA offers the following general comments and recommendations for consideration by the EPA as they finalize these regulations:]

3. Groundwater Considerations in Cost-Benefit-Risk Evaluation: Groundwater forms an essential source of water for drinking water and irrigation purposes across the nation. In California more than 500 groundwater basins and subbasins contribute an average of 40% (and more during droughts) to the State's total water supply. PFAS have been detected in California's Groundwater at levels above the proposed maximum contaminant levels (MCLs) (see Figure below).

The cost, benefit, and risk evaluations that form the basis for the proposed MCLs focus on treated water from Public Water Systems (PWS), which rely on both surface and groundwater sources.

EPA Response: The EPA has included both groundwater and surface water systems in the baseline analysis for the EA. Please see section 13.1 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046018)

2. Market Costs Approach

Affected Systems and Service Population

To estimate the number of affected groundwater (GW) and surface water (SW) systems by system size, the total inventory of community water systems (CWSs) by size of service population is multiplied by the average population per system [FN104: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," 4–7; U.S. Environmental Protection Agency, "SDWIS Federal Reporting Services Fourth Quarter 2021 Dataset," 2021, https://www.epa.gov/ground-water-and-drinking-water/safe-drinking-water-information-system-sdwis-federal-reporting.]. The CWS are broken out by size and by water source. Then, for both small and large systems, the analysis estimates the percentage of the population by system size [FN105: "Small systems" serve less than or equal to 10,000 people, while "large systems" serve populations greater than 10,000.]. For example, of the 53 million (M) in total population served by small systems, 29 M (or 55 percent) are served by systems within the 3,301-10,000 person service population size category. CWSs serving between 100,000-1 M people represent 41 percent of the total population served by large systems.

Table 8: Total CWSs and Service Population by System Size and Source

[Table 8: see docket ID EPA-HQ-OW-2022-0114-1738]

The analysis then applies these percentages to total populations affected by the proposed rule for small and large systems, which EPA estimates at 3.7 M and 60.6 M, respectively [FN106: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," tbls. 4–26.]. This assumption gives total affected population by system size, which then is divided by the average

population by system size to arrive at an estimated number of systems that will be required to treat.

Table 9: Total and Impacted Population at Small and Large PWSs

[Table 9: see docket ID EPA-HQ-OW-2022-0114-1738]

To estimate how these totals are distributed by water source type, the estimated number of systems per CWS size is multiplied by ratios from the CWS inventory. For example, as shown in Table 8, 650 of the 690 CWSs serving populations under 100 persons rely on ground water (GW). Thus, 94 percent of the approximately 800 number of affected systems in Table 9 for this system size are assumed to use ground water sources.

Table 10: Total Systems by Water Source

[Table 10: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: The commenter summarizes the EPA's methods for estimating population served and affected at PWSs in the Health Risk Reduction and Cost Analysis (HRRCA). Please see Chapter 4 of the EPA's EA (USEPA, 2024b) for full description of the EPA's methodology for characterizing baseline conditions in PWSs.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046012)

3. Data and Assumed Values Occurrence in Drinking Water

The analysis uses EPA's projection of PFOA and PFOS occurrence data and population estimates for the benefit estimates. As done in the EA, the distribution of occurrence of the selected PFAS in PWS is estimated and then modified to account for existing state regulatory standards.

The analysis adopts the results of the modeling in Cadwallader et al that the EA uses [FN61: Adam Cadwallader et al., "A Bayesian Hierarchical Model for Estimating National PFAS Drinking Water Occurrence" (AWWA Water Science, May 25, 2022).]. The authors' approach efficiently uses available data and established Markov methods to project which systems are likely to have PFAS occurrence in the absence of sampling data. The analysis replicated the paper's results with mechanical and mathematical methods [FN62: IBID]. Data points were extracted from the Figure 4 of Cadwallader et al. through a digital tool that uses reverse engineering to plot underlying numerical data from data visualizations [FN63: Ankit Rohatgi, "WebPlotDigitizer" (Pacifica, California, September 16, 2022),

https://automeris.io/WebPlotDigitizer/.]. The chart was uploaded onto a canvas and the y- and x-axes were calibrated as linear and logarithmic information, respectively, to extract the data points. We then fit a curve to the points to allow assignment of simulated concentration levels to segments of the population. Figure 4 below gives the baseline simulated drinking water concentration distribution.

Figure 4: Cumulative Distribution of Estimated Population Exposed to PFOA and PFOS

[Figure 4: see docket ID EPA-HQ-OW-2022-0114-1738]

The fitted curve overpredicts the total public drinking water population percentage by 12.5 percent at the high end of the distribution. As with any statistical estimation, there is more uncertainty at points further away from the central estimate. Since it is the high end of the distribution where the majority of the benefits will occur, the analysis trims the shape of the simulated curve by reducing the population amounts predicted by the curve by 12.5 percent so that the population in the analysis equals EPA's estimate of 277 million consumers of public drinking water.

Figure 2, the population distribution, was converted to the probability distribution and simulated drinking water concentration data were generated by randomly drawing drinking water concentration (DWC) from the probability distribution. The simulated DWC data are displayed in the boxplot in Figure 3:

Figure 5: Simulated Drinking Water Concentration of PFOA and PFOS Before the Proposed Rule

[Figure 5: see docket ID EPA-HQ-OW-2022-0114-1738]

Baseline Population

Some states have promulgated drinking water MCLs for PFAS [FN64: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," 4–22 & 4–23.]. In its EA, EPA reviewed state websites and identified states with standards promulgated as of July 2022 for the PFAS compounds considered under the proposed rule (see Table 2).

Table 2: State PFAS MCLs included in EPA's EA (ppt)

[Table 2: see docket ID EPA-HQ-OW-2022-0114-1738]

[FN65: Asterisks indicate PFAS regulations at an overall threshold value indicated in the Sum column.]

EPA assumed in its occurrence model that estimates exceeding state limits are equivalent to the state-enacted limit to estimate the benefits and costs of the proposed rule. EPA also assumed that the state MCL is the maximum baseline PFAS occurrence value for all entry points in the state [FN66: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," 4–23.]. This adjustment was made to the EPA's occurrence model PFAS estimates for PFOA, PFOS, and PFHxS. Systems in states with PFAS regulations are still expected to incur incremental costs to comply with the proposed rule since EPA's proposed standards are more stringent than current state drinking water standards. Similarly, EPA notes that "populations served by PWSs in the states with PFAS regulations are expected to benefit from further reductions in PFAS exposures." [FN67: U.S. Environmental Protection Agency, 4–23.].

While EPA adjusts the occurrence data to account for promulgated MCLs, it assumes its baseline will remain constant in the future, excluding proposed regulations as well as changes in drinking water PFAS occurrence due to issued and future guidance and other regulatory actions. Several states have passed non-MCL regulations or will promulgate either new MCLs or other actions in the future that all impact PFAS occurrence levels in drinking water. To allow comparisons with EPA's estimates, the analysis does not reduce the assumed population by assuming other states will promulgate state standards before the federal MCL. However, pending state standards and voluntary actions are likely to reduce baseline exposure and thus the incremental benefits of this action.

EPA Response: For the final rule, the EPA has updated the occurrence data used in the baseline analysis to account for all state promulgated MCLs. Between proposal and final, three additional states promulgated MCLs which are now reflected in the baseline characterization for the final rule.

Regarding the commenter's application of the results from Cadwallader et al. (2022), the EPA notes that the total population included in the agency's analysis was the summation of all "population served" for systems in SDWIS. The model generates estimates for systems and then the EPA used those systems' populations served to convert that to the total population associated with those systems. It appears that this commenter took a different approach to quantifying the total population, but the EPA cannot determine whether the commenter's scaling approach was appropriate, as the comment lacks documentation of this, and specifically of the handling of systems that have redundant populations.

Finally, please see section 13.1 of the EPA response in this *Response to Comments* document regarding the commenter's opinion that baseline levels of PFAS are likely to reduce. section 13.4 of the EPA response in this *Response to Comments* document for more information on the EPA's benefits assessment.

13.2 Cost-Benefit Model and Discount Rates

Summary of Major Public Comments and EPA Responses

The EPA received comments on discount rates used in the analysis. One commenter claimed that the 7 percent discount rate is more reflective of actual costs and benefits and that once the EPA adjusts the cost models to reflect actual costs to water systems, the incremental costs of complying with the Hazard Index MCL exceed the incremental benefits. The EPA disagrees with these claims. The discount rate is not meant to be reflective of the cost of capital to individual PWSs, but rather reflects the real time value of money. In compliance with Office of Management and Budget (OMB) guidance in effect at the time of rule proposal, the EPA estimated the costs of the proposed rule and other options at both a 3 percent and 7 percent discount rate to bracket the uncertainty in the actual time value of money. Another commenter described that "if the rate that the average saver uses to discount future consumption is taken as a measure of the social rate of time preference, then the real rate of return on long-term

government debt may provide a fair approximation" and that "this rate has averaged around three percent in real terms on a pre-tax basis." A couple of commenters strongly supported a lower discount rate due to the NPDWR's effects that carry over to future generations. One of these commenters agreed with the EPA's finding described in the proposed rule EA (USEPA, 2023a) that the lower, consumption-based discount rate of 3 percent was most appropriate relative to the 7 percent discount rate also presented in the rulemaking. This commenter also noted that use of lower discount rates is supported by economics literature. The commenter referenced draft revisions to OMB Circular A-4 guidance, which was announced during the comment period for the proposed regulation, that favored a substantially lower discount rate of 1.7 percent and the commenter stated that the 3 percent discount rate may be significantly higher than appropriate. Given the literature findings and also the OMB guidance revisions, the commenter asked that the EPA consider focusing the central analysis primarily on an assumed 3 percent (or even lower) discount rate, rather than treating the 3 and 7 percent assumptions as being equally valid in the main analysis. The EPA notes that the U.S. White House and Office of Management Budget recently finalized and re-issued the A-4 and A-94 benefit-cost analysis guidance (see OMB Circular A-4, 2023), and the update includes new guidance to use a social discount rate of 2 percent. The updated OMB Circular A-4 states that the discount rate should equal the real (inflation-adjusted) rate of return on long-term U.S. government debt which provides an approximation of the social rate of time preference. This rate for the past 30 years has averaged around 2.0 percent per year in real terms on a pre-tax basis. OMB arrived at the 2 percent discount rate figure by considering the 30-year average of the yield on 10-year Treasury marketable securities, and the approach taken by OMB produces a real rate of 1.7 percent per year, to which OMB added a 0.3 percent per-year rate to reflect inflation as measured by the personal consumption expenditure (PCE) inflation index. The OMB guidance states that Agencies must begin using the 2 percent discount rate for draft final rules that are formally submitted to the Office of Information and Regulatory Affairs (OIRA) after December 31, 2024. The updated OMB Circular A-4 guidance further states that "to the extent feasible and appropriate, as determined in consultation with OMB, agencies should follow this Circular's guidance earlier than these effective dates." Given the updated default social discount rate prescribed in the OMB Circular A-4 and also public input received on the discount rates considered by the EPA in the proposed NPDWR, for this final rule, the EPA estimated national benefits and costs at the 2 percent discount rate for the final rule and incorporated those results into the final EA. Since the EPA proposed this NPDWR with the 3 and 7 percent discount rates based on guidance in the previous version of OMB Circular A-4, the EPA has kept the presentation of results using these discount rates in Appendix P of USEPA (2024c). The Administrator reaffirms his determination that the benefits of the rule justify the costs. The EPA's determination is based on its analysis under in SDWA section 1412(b)(3)(C) of the quantifiable benefits and costs at the 2 percent discount rate, in addition to at the 3 and 7 percent discount rate, as well as the nonquantifiable benefits and costs. The EPA found that significant nonquantifiable benefits are likely to occur from the final PFAS NPDWR.

Some commenters provided comments about the SafeWater Mutli-Contaminant Benefit Cost (MCBC) model. One commenter urged the EPA to generate results at a PWS level in addition to

the 36 individual PWS categories. The EPA believes that the commenter's approach is neither feasible or appropriate. The SafeWater Cost Benefit Model (CBX) is a peer-reviewed stochastic model that the EPA used to estimate the compliance costs and benefits of the rule. The EPA enhanced the SafeWater CBX model to estimate costs and benefits of multiple contaminants concurrently (henceforth called SafeWater Multi-Contaminant Benefit Cost (MCBC)). Because of the hundreds of input parameters and thousands of individual data points that would be required to take the commenter's suggested approach, SafeWater MCBC cannot generate results at that resolution due to data and computational limitations. The EPA is unaware of any other stochastic model used to estimate national-level drinking water costs and benefits at this time which could take an approach as advocated by the commenter. Additionally, complete PWS-specific data across the 49,193 community water systems (CWSs) and 17,337 non-transient non-community water systems (NTNCWS) are not available in SDWIS/Fed for many of the baseline and compliance characteristics necessary to estimate treatment plant specific costs and benefits, such as design and average daily flow rates, water quality characteristics, treatment in-place, and labor rates. The EPA's estimates of benefits and costs using model systems is reasonable, consistent with best scientific practice (e.g., see *Guidelines for Preparing Economic Analyses* Chapter 5 and 8 discussions on use of models in economic analyses (USEPA, 2016a), and provides information that is sufficient for purposes of understanding and accounting for the costs of this rule in the rule decision making process. For more information about the development of the SafeWater models, including information about its peer review, please see Chapter 5, Section 5.2.3 of the *Economic Analysis for the Final Lead and Copper Rule Revisions* (USEPA, 2020a). In fact, in the peer review of the SafeWater model, reviewers were generally pleased with the modeling advances provided by the SafeWater framework. One reviewer indicated that "the model offers several advantages over existing methods of benefit and cost estimation. Benefits and costs calculations are fully integrated in the model, so that each uses the same samples of PWSs [model PWSs], the set of random vectors, and the same set of parameters (e.g. discount rates). Thus, each net benefit calculation is internally consistent because costs and benefits are fully comparable" (IntelliTech Systems, Inc., 2010). One commenter expressed concerns about the updates to the SafeWater MCBC model from the previous SafeWater CBX model, claiming that because the SafeWater MCBC model did not undergo yet another peer review, the resulting cost estimates are not reliable. The EPA disagrees with the commenter's claims which attempt to diminish the validity and application of the SafeWater MCBC model. For this rulemaking the model was updated to allow for multiple contaminant modeling, but all changes are still consistent with the original peer reviewed single contaminant methodology. Critical inputs to the SafeWater MCBC model have been peer-reviewed, including the Markov-Chain Monte Carlo occurrence model (as peer reviewed in Cadwallader et al., 2022) and work breakdown structure models for granular activated carbon (GAC), ion exchange (IX), and reverse osmosis (RO). The SafeWater MCBC model is based on the best available, peer-reviewed science and the model is appropriate for estimating national benefits and costs associated with the PFAS NPDWR. Furthermore, The EPA has performed a quantitative uncertainty analysis (made possible through the use of the SafeWater stochastic model) and thoroughly described the impacts that uncertain modeling components have on the estimated benefits and costs, which is consistent with OMB

Circular A-4 guidance (please see section 13.9 in this *Response to Comments* document for comments and responses on quantified uncertainties).

Individual Public Comments

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046014)

Discount Rates

Circular A-4 recommends providing estimates of net benefits using both 3 percent and 7 percent discount rates. OMB also outlines the rationale for discounting [FN87: U.S. Office of Management and Budget, 32.]:

• Resources that are invested will normally earn a positive return, so current consumption is more expensive than future consumption, since you are giving up that expected return on investment when you consume today.

• Postponed benefits also have a cost because people generally prefer present to future consumption. They are said to have positive time preference.

• Also, if consumption continues to increase over time, as it has for most of U.S. history, an increment of consumption will be less valuable in the future than it would be today, because the principle of diminishing marginal utility implies that as total consumption increases, the value of a marginal unit of consumption tends to decline.

OMB's basic guidance on discount rates is provided in Circular A-94, which explains that a real discount rate of 7 percent should be used as a base-case [FN88: U.S. Office of Management and Budget, 33; U.S. Office of Management and Budget, "Circular A-94,"n.d.]. This rate is an estimate of the average before-tax rate of return to private capital in the economy. "It is a broad measure that reflects the returns to real estate and small business capital as well as corporate capital. It approximates the opportunity cost of capital, and it is the appropriate discount rate whenever the main effect of a regulation is to displace or alter the use of capital in the private sector."

However, when regulation primarily and directly affects private consumption (e.g., through higher consumer prices for goods and services), a lower discount rate is appropriate. The alternative most often used is sometimes called the "social rate of time preference," meaning the rate at which society discounts future consumption flows to their present value. If the rate that the average saver uses to discount future consumption is taken as a measure of the social rate of time preference, then the real rate of return on long-term government debt may provide a fair approximation. OMB explains that this rate has averaged around three percent in real terms on a pre-tax basis.

EPA Response: As discussed in the section 13.2 of the EPA response in this *Response to Comments* document, the EPA has incorporated the 2 percent discount rate into the final EA. The

EPA now presents both the 3 and 7 percent discount rates for both costs and benefits in Appendix P of USEPA (2024cc).

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045049)

The NJDEP reviewed EPA's Cost Analysis for the proposed NPDWR, including the Cost-Benefit Model utilized. The NJDEP urges the EPA to generate the results of the Safe Water Multi-Contaminant Benefit Cost (MCBC) Model at the PWS level in addition to the utilized cost and benefit estimates for the 36 PWS categories. In addition, NJDEP urges EPA to collaborate with State drinking water regulators to obtain the most up-to-date cost data for the central database of component unit costs used for the Work Breakdown Structure (WBS) models to enable states to fully comment and evaluate these models. This would enable future retrospection on the validity of the Safe Water MCBC and WBS models as actual treatment or non-treatment costs of compliance with the proposed NPDWR become available. Discrepancies between the actual compliance costs and the PWS level estimates from the Safe Water MCBC and WBS models can then be used to improve these models for future analysis and proposals.

EPA requested comment on Table 26, which provides the initial treatment technology compliance forecast, presented in percentages, of systems adopting GAC, PFAS-selective IX, centralized RO, system interconnection, and using new wells across system design flows and TOC levels. This information is used in EPA's cost and benefit modeling. The NJDEP reviewed its records to provide the following breakdown of treatment technologies chosen by public water systems in New Jersey. As of May 17, 2023, 54% of the permits submitted to NJDEP are for strong base anion exchange, versus 46% of permits submitted for GAC. For smaller systems where the flow through the treatment plant is less than one MGD, systems favor strong base anion exchange as it is proposed in 71% of permits, while GAC was proposed in only 29% of permits. Currently, the NJDEP has not approved any systems to use reverse osmosis to remove PFAS. However, a pilot study application has recently been submitted to the NJDEP that includes reverse osmosis and an aqueous electrostatic concentrator, which is expected to be approved.

Additionally, NJDEP is interested in how the EPA incorporated construction lead times in its models to estimate the costs and benefits of the proposed NPDWR. Increasingly, public water systems are experiencing extended lead times in recent years due to supply chain issues for some of the key components used for PFAS treatment (such as GAC filter media). Extended construction lead times can result in (1) an opportunity cost for capital set aside for treatment that could otherwise be used for other purposes in the PWS, such as lead service line replacement and (2) exposure of systems to different costs of capital, as there has been significant fluctuation in interest rates over the last few years.

EPA Response: With respect to the commenter's recommendation to generate results at the PWS-level, please see section 13.2 of the EPA response in this *Response to Comments* document.

The EPA acknowledges the commenter's offer to collaborate with state drinking water regulators to maintain up to date cost data for the work breakdown structure (WBS) models. The EPA used the most up to date publicly available cost information to support the national costs estimates for the proposed and final rulemakings. The EPA's cost estimates for the final rule have been updated based on public comments received. These updates are discussed in section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA considered all cost estimates provided by commenters prior to finalizing this regulation.

The EPA acknowledges the commenter's submission of information on the breakdown of treatment technologies chosen by PWSs in New Jersey. This information is confirmatory of the observation on treatment technology selection trends that the EPA included in the EA for the rule. The EPA specifically notes that data examined in the *Technologies and Costs* document (USEPA, 2024d) show an increasing share of PWSs have selected IX in response to PFAS. The EPA expects this trend to continue, and New Jersey's information supports that expectation. The percentages for IX reported by New Jersey are higher than the EPA's decision tree for the final rule, especially for small water systems. The EPA chose to maintain the relative distribution between IX and GAC from the proposal because it reflects the distribution observed in the EPA's review of recent case study installations nationwide. A larger percentage of systems choosing GAC also tends to err on the side of higher capital costs for small systems.

With respect to RO/NF, the commenter notes there are no existing approvals in that state and there is one potential future approval of RO/NF installation. Many commenters raised significant challenges associated with this BAT, including but not limited to costs, operations and managing the treatment residuals from this process. Therefore, based on this and other comments, the EPA assumed zero percent of water systems would select this technology in the EA for the final rule. For more information on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document

In regard to the commenter's points associated with potential financial issues related to extended construction lead times:

(1) The EPA acknowledges that for systems that might experience unforeseen treatment construction delays the fact the cash reserves must be held could result in opportunity costs. The size of these opportunity costs are dependent on a number of factors for which there is insufficient data at the nation level to assess. In large part these potential opportunity costs can be mitigated through good project management and planning, and forecasting of construction payments. Understanding the schedule of payments may allow system financial managers the opportunity to make near money investments to help offset the costs of construction. The delays systems, in general, have experienced in recent years are widely known to both system managers and state regulators and therefore can be accounted for in project planning, therefore the agency finds that opportunity costs associated with this issue are likely to be small at the national level. The commenter used lead service line replacement as an example of potential opportunity costs. The EPA is aware that implementation timing associated with the PFAS rule and the proposed

LCRI has the potential to overlap; for more information, please see section 13.3 of the EPA response in this *Response to Comments* document.

(2) As expressed by the commenter, the EPA acknowledges that in the short-term interest rates can fluctuate. Given the fact that short-term rates fluctuate and are difficult to forecast (recent interest rate increases already seem to be tempering and currently capital markets are pricing in the Federal Reserve lowering interest rates in 2024 (Reuters, 2023), systems have the ability to shift their debt structure over time as interest rates change, and the EPA's period of analysis covers 81 years, the EPA utilizes estimated long-term estimated rates which are more stable. As an input to the Safewater MCBC model the EPA has estimated average long-term cost of capital (interest rate) paid by public and private PWSs of different size categories. The EPA uses the estimated PWS cost of capital as this best represents the actual financing costs of compliance that systems will incur over time. The EPA's estimated cost of capital range from 3.7- 8.6 percent. See Chapter 4.3.5 of the EA for the complete list of rates and a more detailed explanation of their derivation. Also note that the EPA's total estimated cost of capital may be greater than actual costs water systems bear when complying with the future PFAS regulatory revisions because financing support for PFAS treatment technology may be available from state and local governments, and the EPA programs (e.g., the Bipartisan Infrastructure Act and other federal funding administered through the Drinking Water State Revolving Fund (DWSRF)). The DWSRF provides below-market rate loans to fund infrastructure improvements to water systems to protect public health and ensure compliance with the Safe Drinking Water Act, and grants may be available through BIL funding (USEPA, 2023b).

The EPA notes that, as discussed section 12.1 of the EPA response in this *Response to Comments* document, the agency is authorizing a two-year capital improvement extension pursuant to SDWA 1412(b)(10). In the EA for the final rule, to reflect this nationwide two-year capital improvement extension to comply with MCL, the EPA assumes all water systems that exceed the MCLs take action to comply with the rule by the end of year 5 of the analysis instead of at the end of year 3 as proposed.

3M Company (Doc. #1774, SBC-045696)

c. The Benefit-Cost Model is New and Unvalidated

EPA previously developed a generalized tool known as the SafeWater Cost-Benefit Model (CBX) analysis tool to automatically estimate costs and benefits of drinking water standards. EPA indicates that CBX was designed to evaluate the impacts of a single proposed MCL and incorporates uncertainty in both input and output values to generate best-guess estimates of the impacts of proposed drinking water regulations. The single MCL CBX model was peer-reviewed.

For the proposed NPDWR, EPA developed a new model called the SafeWater Multi-Contaminant Benefit Cost Model (MCBC), which can track multiple substances and compare those to proposed MCLs developed for individual substances or mixtures of substances. EPA

states that MCBC modifies the "structure of the occurrence data input to the model…to not only handle multiple contaminants, but to incorporate all information from the PFAS occurrence model on the predicted co-occurrence of contaminants," allows the assignment of more than one compliance technology, and estimates the costs and benefits associated with estimated reductions in multiple contaminants (USEPA 2023i).

Unlike the CBX model, the MCBC model has not been validated, approved for use via a public review and comment process, or peer-reviewed by independent third-party experts. The absence of a peer review process casts doubts on the validity, reliability, and accuracy of the cost estimates derived from its use. Peer review is particularly necessary because the modifications of the MCBC model relative to CBX are significant. For example, the estimation of statistical uncertainty is calculated differently when two or more uncertain variables are considered simultaneously relative to just one uncertain variable. The resulting uncertainty propagates and compounds throughout the analysis. The impact of the modifications of the MCBC model relative to its CBX counterpart is unknown and is not explained in sufficient detail. This issue is further complicated by the opacity of the analysis, which does not allow stakeholders and members of the public to evaluate whether the uncertainty is being appropriately addressed. Without peer review, expert validation, and a public comment process allowing for input from stakeholders of the PWS community, the MCBC model and its resulting cost estimates cannot be considered validated, reliable, or accurate.

EPA Response: In regard to the commenter's assertion that the SafeWater MCBC model has not been validated and peer reviewed, and that the model and its resulting cost estimates cannot be considered validated, reliable, or accurate please see section 13.2 of the EPA response in this *Response to Comments* document above.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045772)

EPA's Cost Benefit Analysis Does Not Justify the Proposal

The Proposal includes four regulatory alternatives that were considered by EPA to support this rulemaking.

Proposed Option: PFOA and PFOS MCLs of 4.0 ppt and a HI of 1.0.

Option 1a: PFOA and PFOS MCLs of 4.0 ppt.

Option 1b: PFOA and PFOS MCLs of 5.0 ppt

Option 1c: PFOA and PFOS MCLs of 10.0 ppt

Tables 1 and 2 compare the "expected value" for annualized costs, benefits and net benefits for each of the options considered at a 3 percent and 7 percent discount rate, respectively.

Table 1. Annualized Quantified National Costs and Benefits (Million 2021$), 3 Percent Discount Rate

[Table 1: see docket ID EPA-HQ-OQ-2022-0114-1829]

Table 2. Annualized Quantified National Costs and Benefits (Million 2021$), 7 Percent Discount Rate

[Table 2: see docket ID EPA-HQ-OQ-2022-0114-1829]

The following observations ar made regarding the various proposals:

1. Given current inflation, rising interest rates, and future labor and supply chain issues, the 7 percent discount rate is likely more representative of actual costs and benefits.

2. With a 7 percent discount rate, only Option 1c results in a net benefit.

3. Regardless of the discount rate, when comparing the Proposed Option and Option 1a, there are minimal incremental benefits associated with the HI. This suggests that very few systems would be required to install treatment for to comply with the HI. When EPA adjusts the cost models to be more reflective of actual costs to water systems, the incremental cost of the HI MCL is likely to exceed the incremental benefit.

Based on these observations, it is suggested that, if EPA moves forward with a final PFAS rule, only Option 1c (10 ppt MCL for both PFOA and PFOS) is likely to meet the Agency's criteria that the rule must provide a net benefit.

EPA Response: As noted in section 13.2 of the EPA response in this *Response to Comments* document, the EPA disagrees with the commenter's generalization that the 7 percent discount rate is likely more representative of actual costs and benefits. There are a variety of considerations that may impact capital displacement resulting from the PFAS NPDWR. The EPA expects that a meaningful number of PWSs may not be managed as profit-maximizing private sector investments, which could impact the degree to which the rate of return on the use of capital in the private sector applies to PWS costs. As described in the preamble and EA, the Bipartisan Infrastructure Law (BIL) invests over $11.7 billion in the DWSRF), $4 billion to the Drinking Water SRF (State Revolving Fund) for Emerging Contaminants, and $5 billion in grants to Small or Disadvantaged Communities (EC-SDC), which is expected to defray many such PWS costs, and where that occurs, such costs are transferred to the government (please see section 2.4 of the EPA response in this *Response to Comments* document). Regardless, the impacts in this rulemaking are such that costs are expected to occur in the nearer term, and in particular that larger one-time capital investments are expected to occur in the near term; and public health benefits are expected to occur over the much longer term. Lastly (and as described in section 13.2 of the EPA response in this *Response to Comments* document), the EPA received several comments requesting that the agency consider a lower discount rate to better account for the rule's effects on future generations. These commenters pointed to the updated OMB Circular A-4 guidance (OMB, 2023) prescribing a new default discount rate of 2 percent. The EPA follows these recommendations to use the 2 percent default discount rate in the final rule EA. See the section 13.2 of the EPA response in this *Response to Comments* document for further information justification of the EPA's decision to use a 2 percent discount rate.

The EPA disagrees with the commenter's assertion that there are minimal incremental benefits associated with the Hazard Index. The EPA did not perform a quantitative benefits analysis for Hazard Index chemicals due to data limitations, however, inclusion of the Hazard Index and individual MCLs for PFHxS, PFNA, and HFPO-DA will trigger more systems to treat (as shown in Section 4.4.4 and Appendix N of the EA) and provides enhanced public health protection by ensuring reductions of these additional compounds when present above the Hazard Index of 1 or in exceedance of individual MCLs. Specifically, as exposures to PFHxS, PFNA, PFBS and HFPO-DA are reduced, the EPA anticipates additional public health benefits from avoided cardiovascular, developmental, and immune effects. Taking all quantified and nonquantified benefits into account, the incremental benefits of the final rule justify the incremental costs. For further discussion of the quantitative and qualitative benefits associated with the final rule, see Section 6.2 of the EA.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045834)

Finally, the quantifiable portion of the analysis overestimates the costs of compliance. For instance, the 7 percent7% discount rate, as EPA rightly points out, is tied to the expected return on capital in the domestic economy. Because the proposed regulation affects future consumption, a 7 percent discount rate is not appropriate for this rulemaking. Further, the quantifiable costs at 7 percent do not account for the existing stream of federal funding that would supply capital to minimize compliance costs. Thus, the usefulness of forecasting costs with such a discount rate in this context is specially limited.

EPA Response: Please see section 13.2 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046170)

The analysis that follows shows that the $3.1 billion dollar difference in annualized cost can be explained by the following primary factors:

1. Discount rate used. EPA presented cost estimates using both a 3% and 7% discount rate, which is consistent with current OMB guidance. AWWA presented costs for only the 7% rate. In the Economic Analysis, EPA notes that the lower, consumption-based discount rate is more appropriate for this rulemaking (Economic Analysis at 2-3), a conclusion that is supported by the economics literature (Howard and Schwartz, 2002). This factor alone explains $1 billion of the cost difference (Appendix A). The AWWA approach in this case is an overestimate. Factoring other cost considerations described below, in addition to the excess discount rate, would increase the magnitude of impact of the different discount rates. Further, OMB recently published draft revisions to its guidance (White House Office of Management and Budget, 2023) that favor a substantially lower consumption-based discount rate of 1.7%, consistent with Howard and Schwartz (2002). EPA's assertion that the lower, consumption-based discount rate is more appropriate for this rulemaking is supported by the literature and OMB's proposed update to its

guidance. Both indicate that even the 3% consumption-based discount rate EPA used here may be significantly higher than appropriate.

EPA Response: For a discussion of differences in underlying assumptions between the EPA's and the American Water Works Association's (AWWA's) cost estimates, please see section 13.3.3 of the EPA response in this *Response to Comments* document. In response to the commenter's suggestion that economic estimates be evaluated using a lower discount rate, based on this and other comments, the EPA has included analyses using a 2 percent discount rate. Please see sections 13.2 and 13.8 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046135)

15. EPA should further consider whether the central EA results should focus more on the lower 3% discount rate.

Although equal consideration of alternative 3% and 7% discount rates is currently the standard practice for Eas of federal regulations (OMB 2003), EPA should consider whether the lower 3% discount rate is more appropriate in the current context. This could be the case for several reasons, including the long 80-year time period for the analysis, the fact that future generations are impacted, and the considerable uncertainties in the magnitude of the future health benefits. [FN2: See the "Discount Rates" section in the proposed revisions to Circular A-4 (OMB 2023), for example, for further details.] Additionally, EPA states on page 2-3 of the EA that "OMB's Circular A-4 indicates that a 3 percent discount rate represents the rate that an average saver uses to discount future consumption and is therefore more appropriate for this rulemaking." [Emphasis added.] Given this rationale, discussions in the literature (e.g., Howard and Schwartz 2022), and the recently proposed revised guidance from OMB (2023) regarding discount rates, EPA should consider focusing the central analysis primarily on an assumed 3% (or even lower) discount rate, rather than treating the 3% and 7% assumptions as being equally valid in the main analysis.

EPA Response: In response to the commenter's suggestion that economic estimates be evaluated using a lower discount rate, based on this and other comments, the EPA has included analyses using a 2 percent discount rate. Please see sections 13.2 and 13.8 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046112)

Third, EPA should apply no (or at most a very low) discount rate to account for the intergenerational harms associated with PFAS and the nature of the rule's economic impacts. [FN132: See, e.g., Frank Ackerman and Lisa Heinzerling, Pricing the Priceless: Cost-Benefit Analysis of Environmental Protection, 150 U. Pa. L. Rev. 1553, 1571 (2002), https://scholarship.law.upenn.edu/penn_law_review/vol150/iss5/6 (questioning the use of discounting to address long-term, intergenerational harms, including those associated with "persistent toxins"); see also Institute for Policy Integrity, Comments on National Primary

Drinking Water Regulations: Lead and Copper Rule Revisions (Feb. 12, 2020), https://policyintegrity.org/documents/EPA_Lead_Copper_Rule_Comments_2020.02.11.pdf (arguing for a "3% or lower discount rate" for benefits of EPA drinking water rule).] In the event a discount rate for future benefits is applied, we agree with EPA's conclusion in the Draft EA that a lower, consumption-based discount rate is "more appropriate for this rulemaking" than a higher, capital-based discount rate [FN133: Draft EA at 2-3.] given the 80-year timeframe for analysis, the impacts on future generations, and the extent of uncertainties in the magnitude of future health benefits. [FN134: Guignet 2023 at 11; Peter Howard & Jason A. Schwartz, Valuing the Future: Legal and Economic Considerations for Updating Discount Rates, 39 Yale J. Regul. 595, 599, 603 (2022) (explaining why a consumption-based discount rate is appropriate for estimating benefits of rules designed to affect public health over a long time horizon).] Thus, if a discount rate is used, EPA should ensure that both the final EA and the final rule reflect and explain EPA's determination that a lower, consumption-based discount rate is more appropriate. [FN135: Draft EA at 2-3.] EPA's draft preamble does not include or explain this determination and instead presents benefit estimates based on a 3% consumption-based discount rate and a 7% capital-based discount rate as equally relevant to assessing the net benefits of the rule. [FN136: E.g., Proposed Rule, 88 Fed. Reg. at 18,724, table 66.] Further, if EPA continues to apply a discount rate in the final EA, it should consider utilizing a reduced consumption-based discount rate—below 2%—as the 3% rate used in the Draft EA does not reflect the best available economic data and literature. [FN137: Howard & Schwartz (2022) at 595–96, 599, 610–11, 617–19; see also White House Off. Of Mgmt. and Budget, Circular A-4 (Public Review Draft), at 76 (Apr. 6, 2023) (proposing consumption-based discount rate of 1.7%), www.whitehouse.gov/wp-content/uploads/2023/04/DraftCircularA-4.pdf.]

EPA Response: In response to the commenter's suggestion that economic estimates be evaluated using a lower discount rate, based on this and other comments, the EPA has included analyses using a 2 percent discount rate. Please see section 13.2 of the EPA response in this *Response to Comments* document.

13.3 Method for Estimating Costs (excluding disposal costs)

Summary of Major Public Comments and EPA Responses

The EPA received many public comments on the EPA's assessment of the costs of the proposed PFAS NPDWR. Comments specific to one aspect of the EPA's cost analysis and the EPA's responses to those comments can be found in the following subsections:

13.3.1 Primacy Agency Costs

13.3.2 HFPO-DA, PFNA, and PFBS National Costs

13.3.3 Water System Costs- Treatment

13.3.4 Water System Costs -Monitoring

13.3.5 Water System Costs- Administrative

13.3.6 Water System Costs- Non-Treatment

General comments on the EPA's cost analysis that are either not strictly related to one of the areas above or cover multiple cost topics are included below in section 13.3 of the EPA response in this *Response to Comments* document.

Some public commenters submitted their own estimates of national level costs, with a primary focus on the treatment costs associated with the proposed rule. The EPA's detailed responses to these commenter's approaches and conclusions of those comments can be found in section 13.3.3 in this *Response to Comments* document. Many commenters specifically cited AWWA's B&V cost estimates from an older version of the B&V report from March 2023. The EPA also notes that in their public comments on the proposed rule submitted in June 2023, AWWA submitted lower revised estimates in that report, of $2.5 to $3.2 billion dollars annually at the 3 and 7 percent discount rates respectively for NPDWR compliance costs. Some commenters cite the cost figures that AWWA describes as "national burden treatment costs." However, these cost estimates, as described in that report, include costs beyond those associated with the NPDWR, specifically costs associated with complying with existing state standards, and are therefore outside of the scope of this rulemaking. Additionally, these "national burden estimates" are flawed, as they appear to double count costs for water systems that are subject to an existing state regulation and the final rule once promulgated. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for the EPA's detailed response to the AWWA B&V (Black & Veatch) report. Some commenters cite the AWWA B&V reports estimation of the present value of the costs of the rule, $36 billion at the 3 percent discount rate in the June 2023 version.[1] In the EA for the proposed and final rule, the EPA presented discounted annualized, not present values, of benefits and costs in accordance with Circular A-4 guidance (see Section 12 "Discount Rates" of Circular A-4; OMB, 2023). As detailed in Circular A-4, "Benefits and costs often take place in different time periods. When this occurs, simply adding all of the expected benefits or costs without regard for when they actually occur fails to account for differences in those values that result from the differences in timing. If benefits or costs are delayed or otherwise separated in time from each other, the difference in timing should be reflected in your analysis through appropriate discounting." The EPA further notes that in the final rule, the EPA's inclusion of undiscounted benefits and costs, consistent with Circular A-4 clearly shows undiscounted costs and the years they are expected to occur. As detailed in Appendix P of the EA, the EPA estimates undiscounted costs of $15.5 billion for water systems nationally in the year that PWS are assumed to install treatment, followed by approximately $1.1 billion in operation and maintenance (O&M) costs in each of the years following plus additional capital costs in the following years as the useful life of the technologies expire and water systems replace capital infrastructure.

[1] Note there appears to have been a labelling error on Figures 7-1 and 7-2 of the AWWA B&V report. Those figures show the "national burden treatment costs" bars to be lower than the "NPDWR treatment cost" bars. The EPA presumes this is a mis label, as the text indicates the report's national burden include estimated costs beyond the NPDWR.

The EPA has carefully considered all public comments regarding the cost analysis and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to the EPA's cost analysis for the file rule are detailed in sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. Collectively, these changes resulted in an increase in the EPA's estimated annualized costs of the rule. The proposed rule estimated total national annualized costs were $771.77 million at the 3 percent discount rate and $1,204.61 million at the 7 percent discount rate (88 FR 18638; USEPA, 2023c). For the final rule, after considering public comments and incorporating numerous recommended changes, the EPA estimates the national costs to be $1,548.64 at the 2 percent discount rate, $1,545.61 at the 3 percent discount rate and $1,553.98 at the 7 percent discount rate.[2] Please see section 13.2 of the EPA response in this *Response to Comments* document for discussion of why the EPA incorporated costs at the 2 percent discount rate.

As discussed in detail in section XII.J of the Federal Register Notice (FRN), the quantified benefit-cost results above are not representative of all benefits and costs anticipated under the final rule. To fully weigh the costs and benefits of the action, the agency considered the totality of the monetized values, the potential impacts of the quantifiable and nonquantifiable uncertainties described in the FRN and EA, the nonquantifiable costs and benefits, and public comments received by the agency related to the quantified and qualitative assessment of the costs and benefits. Nonquantified costs are discussed in Chapter 5 and 7 of the EA. The EPA notes that the agency anticipates that nonquantified benefits are significantly greater than nonquantified costs. For more discussion, please see section XII of the FRN for the final rule. For the final rule, the EPA is reaffirming the Administrator's determination made at proposal that the quantified and nonquantifiable benefits of the rule justify its quantified and nonquantifiable costs.

Some commenters recommended that the EPA withdraw its cost estimate, give strong consideration to the AWWA B&V report, and "…produce a corrected cost analysis for public comment after considering public comments on the cost analysis." The EPA disagrees with the recommendation to produce a second version of the cost analysis for public comment. The EPA has met all statutory requirements under SDWA in development of the rule and the HRRCA and has considered and addressed all significant comments prior to finalization. Additionally, the agency has benefited from the public comments submitted on this rule and improved the cost analysis after considering and incorporating numerous suggestions from commenters. The EPA notes that all changes to the cost estimates flow from the proposed rule's cost analysis as informed by public comments. The EPA also notes that while the annualized costs have increased relative to the proposed rule, the changes are not of sufficient magnitude to impact the Agencies underlying conclusions at proposal. Therefore, the agency is neither required to re-propose the rule or produce revised public comment versions of analyses prior to finalization of the rule; nor

[2] Treatment technologies have both upfront capital costs and annual operations and maintenance costs. When the annual operation and maintenance costs are large relative to the up-front capital costs, the total annualized compliance cost is much less sensitive to the choice of discount rate. This is the case with GAC. Therefore, the annualized cost of the rule is similar at all the discount rates modeled.

does it think it appropriate to do so because the public was provided with sufficient information at proposal to provide informed input.

Some commenters state that while BIL funding is available, it is not enough to cover the compliance costs of the rule. For example, one commenter noted that, "[t]his amount of funding support, while crucial, will come nowhere near the cost to ratepayers that must be borne to implement necessary compliance actions for these MCLs." The EPA disagrees with the commenter that BIL funding will be nowhere near the cost" necessary to implement compliance actions. The EPA estimates that the initial capital costs of the rule in undiscounted dollars is approximately $14.4 billion. Given the BIL appropriations of $11.7 billion in DWSRF and an additional $5 billion for emerging contaminants, the EPA reasonably anticipates BIL funding is likely to be able support a substantial portion of the initial capital costs of the final rule.

Some commenters raised concerns about the potential overlap between the Lead and Copper Rule Revisions (LCRR) and the PFAS NPDWR. One commenter noted the two rules "will compound water rate affordability concerns." Another noted that water utilities "…faced with investment challenges, as many utilities are already investing large amounts of funding into complying with other proposed regulations, such as the Lead and Copper Rule Revisions…" The EPA acknowledges that implementation timing associated with the PFAS rule and the proposed Lead and Copper Rule Improvements (LCRI) has the potential to overlap. To the extent implementation overlaps, some rule start-up, administrative, and sampling/SL inventory costs associated with both rules could affect a large number of PWSs and States. The more significant costs of installing and operating PFAS treatment technology in a similar time frame with installing and operating corrosion control treatment (CCT) and/or conducting service line replacement are expected to fall on some systems. The EPA does not have sufficiently detailed PFAS occurrence, and lead service line/galvanized requiring replacement (LSL/GRR) service line and 90th percentile lead tap sample data to explore the potential treatment cost interactions of the two rules. The EPA further notes that SDWA Section 1412(b)(3.(C)(i)(III) requires that the EPA include quantifiable and non-quantifiable costs that are likely to occur solely as a result of compliance with the rule including monitoring, treatment and other costs and excluding costs resulting from compliance with other proposed or promulgated regulations. Finally, as noted, the EPA has proposed to replace the LCRR with the LCRI; the new proposed lead rule (LCRI) accounts for costs associated with that rule.

Individual Public Comments

Water Environment Federation (WEF) (Doc. #1529, SBC-043312)

Monitoring: States will be looking to EPA to determine how monitoring requirements will align with their existing program demands. EPA's proposed cost model includes treatment equipment; however, it is absent of the added costs of compliance, site developments, engineering, etc. Costs will be incurred by utilities and the residents relying on these essential services. Additionally, there are still concerns with laboratory capacity in some areas of the country. This could cause delays in analysis and increase costs to obtain compliance data.

EPA Response: The commenter is incorrect as the WBS models do include land, permits and pilot testing, equipment installation, process engineering and contractor's overhead and profit; see Chapter 5 of the EA for more information. For the EPA's response to comments on laboratory capacity, please see section 8 in this *Response to Comments* document on monitoring and compliance requirements. For the EPA's response to comments on monitoring costs, please see section 13.3.4 in this *Response to Comments* document.

Michigan Farm Bureau (MFB) (Doc. #1562, SBC-043358)

The American Water Works Association (AWWA) commissioned a study calculating the national cost estimate for water utilities to comply with MCL regulations, based on the UCMR-3. [FN13: Black & Veatch. 2023. WITAF 56 Technical Memorandum: PFAS National Cost Model Report. B&V Project No. 409850. Retrieved from: https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14-102450-257.] Based on the range of sizes and treatment systems of water utilities around the U.S., along with installation and operations and maintenance costs for currently available PFAS testing and treatment systems including granular activated carbon (GAC), ion exchange, and reverse osmosis and nanofiltration, AWWA estimates a national cost of more than $47 billion, or $5.2 billion annually – far beyond EPA's economic estimation of the annualized cost of compliance of $771 million to $1.2 billion annually [FN14: Environmental Protection Agency. 2023. Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation. EPA Document No. EPA-822-P-23-001. Retrieved from: https://www.epa.gov/system/files/documents/2023-03/Proposed%20PFAS%20NPDWR%20EA_final_03_09_2023_0.pdf.] – to sample and treat drinking water to 4 ppt each of PFOS and PFOA. And while EPA has worked hard to include support for water utilities such as:

• $11.7 billion to the Drinking Water State Revolving Fund (SRF)

• $4 billion in SRF for emerging contaminants

• $5 billion to Water Infrastructure Improvements for the Nation (WIIN) Grants to address emerging contaminants [FN15: Environmental Protection Agency. 2023. Drinking Water Grants and Other Financial Resources. Retrieved from: https://www.epa.gov/ground-water-and-drinking-water/drinking-water-grants.]

This amount of funding support, while crucial, will come nowhere near the cost to ratepayers that must be borne to implement necessary compliance actions for these MCLs.

More concerning in AWWA's report is the disproportionate impact these costs will have on small and rural communities. [FN16: Black & Veatch. 2023. WITAF 56 Technical Memorandum: PFAS National Cost Model Report. B&V Project No. 409850. Retrieved from: https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14-102450-257.] While there is a factor of scaling costs according to the

size of the system based on the number of ratepayers it serves, the cost does not reduce to zero: there is a base cost for capital investments, staff, training, sampling, laboratory fees, filter and treatment equipment, and ongoing operation and maintenance of that equipment to consider for every drinking water supplier regardless of size or number of users. AWWA's report concludes that the annual cost per household for large systems (>1,000,000 people) is between $80-$105, but the annual cost per household for small systems (<100 people) is $10,090-$11,150.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. Furthermore, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on annual costs per household served by small systems, please see section 13.10 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the availability of funding in comparison to the compliance costs of the rule, please see section 13.3 of the EPA response in this *Response to Comments* document.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042483)

• We believe that the cost estimates EPA has proposed are severely underestimated and request that further economic analysis be done to reflect costs more accurately.

O SAWS believes the current costs associated with compliance both now and in the future were underestimated in this evaluation due to escalating costs, supply chain issues, workforce shortages, etc. This is underscored by the range in estimated costs produced by the EPA ($1.2 billion) and other organizations, including engineering consultant Black and Veatch who provided an estimate to the America Water Works Association of $38 billion to comply with the proposed rule.

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Further, this commenter compares the EPA's estimate of annualized costs associated with the NPDWR over the period of analysis to a one-time cost estimate of the "national burden" associated with PFAS produced by AWWA; these numbers are not directly comparable, as discussed in section 13.3 of the EPA response in this *Response to Comments* document.

Missouri River Public Water Supplies Association (MRPWSA) (Doc. #1581, SBC-042408)

May 24, 2023

Mr. Michael S. Regan, Administrator

Office of Ground Water and Drinking Water, Standards and

Risk Management Division, U.S. Environmental Protection Agency 1200

Pennsylvania Avenue Northwest, Mail Code: 4670M, Washington, D.C. 20460

RE: Docket ID No. EPA-HQ-OW-2022-0114

Dear Administrator Regan:

The Missouri River Public Water Supplies Association (MRPSWA) appreciates the opportunity to submit comments regarding "Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation (NPDWR). MRPWSA was established in 1961 and represents 19 drinking water utilities on the lower Missouri River that collectively serve over 4.3 million people safe clean drinking water. We support responsible management of Missouri River resources and maintenance of congressionally authorized purposes of the river, including water supply, water quality, flood control, and navigation. MRPSWA would like to highlight several concerns for the EPA to consider including implications to water utility operations, logistical and cost consequences, supply chain difficulties, and premature regulation without the supporting part per trillion data that will be collected with UCMR5.

Regulation of PFOA and PFOS — MRPWSA supports the development of Maximum Contaminant Levels (MCLs) for PFOA and PFOS, but believes that U.S. EPA is underestimating the overall cost of complying with the proposed MCLs of 4.0 parts per trillion (ppt) for PFOA and PFOS and urges the Agency to use the information included in the comments submitted by the American Water Works Association (AWWA) and the Association of Metropolitan Water Agencies (AMWA) and others to re-evaluate EPA's cost estimates, review the cost-benefit analysis, and determine appropriate regulatory levels for PFOA and PFOS. U.S. EPA must also consider the time necessary for water systems to assess their levels, design treatment and receive approvals, and construct when developing the compliance deadlines in the final rule.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. The agency has considered all public comments submitted on the proposed PFAS NPDWR, including those referenced by this commenter. See the EPA responses to individual comments, including those referenced here, for specifics about how the EPA considered those comments. The EPA notes that AMWA relies on AWWA's cost model, and the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. For a more detailed discussion of the EPA's response to these and other comments on treatment costs associated with the rule, please see section 13.3.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1738, SBC-046019 in section 13.3.3 in this *Response to Comments* document. For the EPA's response to comments on the final MCLs and compliance timeline for the rule, please see sections 5 and 12, respectively, of the EPA response in this *Response to Comments* document.

Water & Health Advisory Council (Doc. #1590, SBC-042787)

There are also inconsistencies and disagreements regarding the economic impact of these proposed regulations. The U.S. EPA estimated an expected total annual cost of between $755,000,000 and $1.2 billion annually in the Economic Analysis. However, the American Water Works Association [Link: .awwa.org/AWWA-Articles/awwa-statement-on-proposed-pfas-drinking-water-standards] previously estimated that the national cost to comply with these regulations will be at least $3.8 billion annually. As stated by the U.S. EPA, the Bipartisan Infrastructure Law will provide some of the necessary funding to municipalities (a total of $9 billion). However, these funds are meant to cover not only PFAS, but drinking water systems impacted by other emerging contaminants, regulated contaminants that are not being adequately addressed (e.g., lead or arsenic), and critical infrastructure and maintenance upgrades. Federal funds devoted to PFAS will crowd out support for needs that may be more pressing in many parts of the U.S. Moreover, these economic impact analyses do not take into account costs associated with other programs that will be impacted by the U.S. EPA's stringent position on PFAS, such as environmental remediation programs, redevelopment, and wastewater treatment.

EPA Response: In response to the total national costs of the rule, please see section 13.3 of the EPA response in this *Response to Comments* document. In response to the recommendation to consider costs associated with other programs, please see section 15 of the EPA response in this *Response to Comments* document. Additionally, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Greater North Dakota Chamber et al. (Doc. #1593, SBC-042804)

The Safe Drinking Water Act requires consideration of the costs and benefits. The U.S. Chamber submitted a report to the Office of Management and Budget (OMB) modelling the potential costs attributable to various drinking water treatment levels. The estimated annualized costs for a proposed MCL of 4 ppt for PFOA and PFOS are approximately $1.8 billion annually and are more than twice as much as the EPA estimated costs in their economic analysis. The Chamber cover letter to OMB and the report are here [Link: https://www.globalenergyinstitute.org/sites/default/files/2023-03/221216Coverletter_DrinkingWaterMCLCosts_OMB.pdf] and here [Link: https://www.globalenergyinstitute.org/sites/default/files/2023-03/Potential%20Costs%20of%20Meeting%20Safe%20Drinking%20Water%20Act%20%28SDWA%29%20Standards%20for%20PFOA%20and%20PFOS.pdf]. The significant costs and impacts and their connection to other elements of the PFAS Strategic Roadmap, such as the proposed hazardous substance designation under CERCLA demand a full vetting by the stakeholder community.

EPA Response: For the EPA's response to the U.S. Chamber of Commerce comments, please see the EPA response to comment Doc. #1537, SBC-042649 in section 13.3.3 in this *Response to Comments* document. For the EPA's response to comments regarding management of treatment residuals, please see section 10.4 of the EPA response in this *Response to Comments* document.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042993)

The economic analysis indicates that, "costs presented include those expenses incurred by PWSs to (1) monitor for PFAS, (2) inform consumers, (3) install and operate treatment technologies, and (4) perform record-keeping and reporting to comply with the PFAS NPDWR; and the costs incurred by states (or primacy agencies, i.e., states with authority to implement and enforce SDWA regulations) to implement the rule". Michigan notes implementation of new drinking water standards carry beyond the Safe Drinking Water Act and may result in changes being made to related programs. For example, EGLE believes that revised MCLs might eventually result in changes being made to Water Quality Values (WQVs) to protect surface waters and requirements to protect groundwater. Michigan already has three WQVs for PFOS, PFOA, and PFBS and lists seven analytes to protect groundwater for drinking water. Anticipated revisions to WQVs and other conditions, due to the draft MCLs, will change treatment costs to protect surface waters, revise treatment limits to protect groundwater, and may also result in revised conditions to allow for beneficial reuse of biosolids. EGLE believes that all costs should be reflected in the analysis to determine appropriate MCLs.

EPA Response: For the EPA's response to comments recommending the agency include costs not solely due to compliance with the MCLs, please see section 15 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043628)

1. The costs in the USEPA Economic Analysis are significantly underestimated; when considered alongside AWWA's and BWWB's analyses, it is clear that the proposed rule is not financially justifiable. The USEPA performed an Economic Analysis to calculate the costs effectiveness of the proposed rule. The USEPA expects the annualized benefit of the rule to be $908 million with an associated cost of $1.2 billion dollars. However, independent analysis performed by AWWA demonstrates the USEPA has severely underestimated the annualized cost. The AWWA analysis estimates a cost to comply with the rule in excess of $54 billion which equates to an annualized cost of over $2.7 billion (approximately 230% of the number estimated by USEPA). Furthermore, BWWB has developed potential capital cost estimates for compliance with the proposed rule, based on specific and more realistic design assumptions, that are four (4) times higher than those generated by USEPA's cost model.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1602, SBC-043656 in section 13.3.3 in this *Response to Comments* document. As explained in section 13.3 of the EPA response in this *Response to Comments* document, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. The commenter did not provide sufficient detail to compare their cost estimates to the results of the EPA's WBS models. Furthermore, extrapolating from a single utility's experience is not an appropriate method to estimate national costs. See also section 13.3.3 of the EPA response in this *Response to Comments* document. While the EPA has considered the input from the AWWA report and other public comments about the EPA's estimated rule costs, because AWWA represents water systems, the EPA does not think it accurate to describe the AWWA report as "independent." Please see the EPA response to comment Doc. #1841, SBC-044850 in section 5.1.3 of this *Response to Comments* document for further discussion.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043638)

D. The USEPA expects the annualized national compliance cost of $1.2 billion, at 7% discount rate (Table 1). However, the independent analysis performed by AWWA (Figure 1) estimates a cost to comply with the PFAS Rule in excess of $54 billion, which equates to an annualized cost of over $2.7 billion (approximately 230% of the number estimated by USEPA). Although the independent analysis conducted by AWWA demonstrated substantially higher national costs than USEPA's cost analysis, it still underestimated costs. Removal of short- chain PFAS (such as PFBS and GenX (HFPO-DA)) were not included in the three different scenarios presented in Figure 1 (adapted from AWWA's independent analysis). Moreover, Zeng et al (2020), Tow et al (2021), and a case study conducted by CDM Smith concluded that GAC (one of EPA's Best Available Technologies (BATs)) is notably less effective for "short chain" PFAS, commonly necessitating a higher frequency of media replacements, which could drive up the O&M cost.

[Figure 1: See Docket ID EPA-HQ-OW-2022-0114-1602]

Figure 1. Summary of Present Value of Life-Cycle Costs for National Burdens and NPDWR Compliance Costs for Each Scenario, adapted from AWWA.

The second scenario is based on target concentrations for PFOA, PFOS, PFHxS, PFHpA, and PFNA (collectively referred to as "long-chain PFAS") of 4 ppt each. Note: PFHpA is not included as a species to be regulated by the proposed PFAS Rule.

BWWB has conducted a cost analysis for installing GAC as post-treatment for the finished water at their four (4) filter plants. Appendix-A presents a comparison of capital and O&M cost estimates generated by USEPA's model versus an extrapolation based on costs from a recent (and similarly sized) GAC installation project. BWWB estimated that the 80MGD Shades Mountain Filter Plant (SMFP) could cost more than four (4) times what USEPA's estimated as total capital cost. The magnitude of underestimation in USEPA's cost analysis is concerning.

2. Based on the current interest rate, which is closer to 7%, USEPA's net benefits of the proposed rule are estimated to be negative $296.5 million per year. It is questionable whether the proposed rule is financially justifiable.

USEPA's costs and benefits also seem to largely depend on the discount rate. BWWB proposed that USEPA conduct a sensitivity analysis which is necessary to indicate the net benefits at different interest rates and better understand how sensitive costs and benefits are to each interest rate.

[Table: See Docket ID EPA-HQ-OW-2022-0114-1602]

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1602, SBC-043656 in section 13.3.3 in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs; please see section 13.3.3 of the EPA response in this *Response to Comments* document. Therefore, the EPA disagrees with the commenter's characterization of the results from that report as an underestimate. The EPA acknowledges that that report does not consider costs associated with the Hazard Index; however, the EPA has specifically analyzed these costs; please see section 13.3.2 of the EPA response in this *Response to Comments* document for more information.

The EPA disagrees with the commenters suggestion to conduct a sensitivity analysis to examine the "…net benefits and different interest rates…" The EPA's analysis utilizes follows OMB A4 guidance by using a constant dollar baseline over the period of analysis therefore projected nominal interest rates are not used to adjust benefit values over time. A4 states, "To avoid the misleading effects of inflation in your estimates, it is important to measure the stream of effects in constant dollars." Please note that constant dollars analysis is separate from discounting future effects to present value/annualization and the discount rates, sometimes confused with nominal interest rates, used as part of that analysis. Per A-4 guidance, the EPA uses a discount rate which is adjusted to remove the effects of inflation to adjust the estimated benefits and costs of the regulation for differences in timing. Regarding the discount rate used in the EA for the final rule, please see section 13.1 of the EPA response in this *Response to Comments* document.

Finally, the EPA disagrees that the rule is not "financially justifiable." The Administrator has determined that the total quantifiable and nonquantifiable benefits justify the quantifiable and nonquantifiable costs, please see section 13.8 of the EPA response in this *Response to Comments* document. While the EPA has considered the input from the AWWA report and other public comments about the EPA's estimated rule costs, because AWWA represents water systems, the EPA does not think it accurate to describe the AWWA report as "independent." Please see the EPA response to comment Doc. #1841, SBC-044850 in section 5.1.3 of this *Response to Comments* document for further discussion.

American Water Works Company Inc. (Doc. #1608, SBC-043981)

Key Issues

American Water highlights the following overarching comments on the proposed rule.

• Regulation of PFOA and PFOS – American Water supports the development of Maximum Contaminant Levels (MCLs) for PFOA and PFOS but believes that the U.S. EPA is underestimating the overall cost of complying with the proposed MCLs of 4.0 parts per trillion (ppt) for PFOA and PFOS and urges the U.S. EPA to use the information provided in American Water's comments as well as comments submitted by the American Water Works Association (AWWA) and others to re-evaluate EPA's cost estimates, review the cost-benefit analysis, and determine appropriate regulatory levels for PFOA and PFOS. We believe that the U.S. EPA must also consider the time necessary for water systems to assess their levels, design treatment and receive approvals, and construct when developing the compliance deadlines in the final rule.

EPA Response: For the EPA's response to comments stating that the EPA has underestimated the costs of the rule, please see section 13.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Please see section 12 of the EPA response in this *Response to Comments* document for the EPA's response to comments on the compliance timeframe for the final rule.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044027)

10. EPA requests comment on implementation challenges and considerations for setting the MCL at the PQLs for PFOA and PFOS, including on the costs and benefits related to this approach.

a. EPAs cost estimates for PFAS removals are grossly underestimated.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043081)

Importance of an Accurate Cost Analysis

The EPA is encouraged to review and revise the cost analysis, and the EPA's WBS Model, to ensure that the monitoring and treatment costs are accurate. This cost analysis is critical given that it underpins the health risk reduction as well as the household affordability analysis. Inaccurate estimate of costs will mischaracterize the rules merits and the affordability for households in smaller communities. These analyses are critical for the Agency, and water systems, to understand public health priorities. Water systems are currently working to address various public health priorities, including lead service lines, cybersecurity, microbials and

disinfection byproducts, water supply challenges (e.g., drought, increasingly impaired water sources, etc.), and aging infrastructure. It is imperative that the overall analysis of the rule's impacts be accurate so that water systems and communities are assured that the investments in infrastructure represent the investments with the greatest societal benefit.

EPA Response: Please see sections 13.3.2, 13.3.3 and 13.10 of the EPA response in this *Response to Comments* document for the EPA's responses related to monitoring costs, treatment costs, and the affordability analysis respectively. The agency has conducted an accurate analysis of the rules impacts of the final rule and considered all public comments in doing so, please see section 13.3 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043060)

5. The Proposal's underlying cost analysis is inaccurate and underestimates the costs to implement the rule and the impacts on consumers. The Agency should work with utilities to develop a cost-estimating approach that better reflects best-engineering practices, refine the cost estimate for the Proposal and re-evaluate the results as part of the final rule.

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document.

Illinois Farm Bureau (IFB) (Doc. #1630, SBC-043135)

EPA has Underestimated the Challenges in Reaching These Levels

Agricultural producers support a national drinking water standard for PFOA and PFOS and other PFAS chemicals based on the best science available and an evaluation of risk— as opposed to the current patchwork of state requirements. However, there are substantial questions and concerns related to EPA's current proposal. As the costs that the proposed rule will impose are likely underestimated, it is critical that EPA obtain accurate and proven data. The proposed MCLs must be changed to properly balance costs and benefits, as the statute requires.

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document. In regard to "properly balancing costs and benefits," please see section 13.8 of the EPA response in this *Response to Comments* document.

Association of Environmental Authorities (AEA) (Doc. #1635, SBC-042963)

Cost estimates for addressing PFAS must be realistic so that infrastructure and affordability programs match the needs. AWWA and NACWA agree that EPA estimates of $772 million to $1.2 billion nationally for implementation of the NPDWR are likely to be too low. AWWA and NACWA believe the costs could be at least three times higher-- $3.8 billion. Costs in New Jersey, the most densely populated state, are likely to be at the high end of any estimates. Costs reported here so far appear to support the AWWA/NACWA estimate. An investor-owned utility has been

quoted as saying it is spending $34 million on PFAS remediation at New Jersey 15 sites. Last year, Willingboro, N.J. broke ground on a treatment plant for a single well that is costing more than $5 million. Earlier this year, the Ridgewood, N.J. town council approved funding ordinances totaling $60.5 million to provide PFAS treatment for 33 wells.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document. Furthermore, extrapolating from individual utilities or states' experience is not an appropriate method to estimate national costs. As the commenter pointed out, costs will vary by state, depending on standards, PFAS occurrence, number of water systems treating, among many other factors. The EPA does not dispute the commenter's reported costs for the New Jersey systems, but the comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models.

GFL Environmental (Doc. #1648, SBC-043223)

Cost Implications

• Overall costs are significantly underestimated: EPA should consider incremental overall costs and benefits associated with the proposed MCLs and MCLGs. The US Chamber of Commerce estimates annualized costs for a proposed MCL of 4 ppt for PFOA and PFOS are approximately $1.8 billion annually which is more than twice as much as the EPA's economic analysis of estimated costs at $772 million to $1.2 billion. The costs associated with meeting the MCLG (0 ppt), or non-detect, are orders of magnitude higher at almost $60 billion (EPA, 2023). Another report published by American Water Works Association (AWWA, 2023), is also estimating costs much higher than EPA's estimated annual cost. AWWA estimates the national cost for water systems to install treatment to remove PFOA and PFOS to levels required by EPA's proposal exceeds $3.8 billion annually (AWWA, 2023). Pre- treatment costs for wastewater generators, which will undoubtedly be required prior to disposal at publicly owned treatment works have not been considered.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. Furthermore, the EPA disagrees with the many of the assumptions and approaches in the cost estimate referenced by the commenter. For the EPA's response to the US Chamber of Commerce national cost comments, please see the EPA response to comment Doc. #1537, SBC-042649 in section 13.3.3 in this *Response to Comments* document. Additionally, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. In response to the commenter's statement about costs for wastewater generators, the treatment technologies the EPA anticipates PWS to use to comply with the rule in the EPA's analysis (GAC and ion exchange) do not result in PFAS-laden liquid

residuals that would be disposed at publicly owned treatment works. Therefore, inclusion of pre-treatment costs would not be appropriate.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043214)

• The Health Risk Reduction and Cost Analysis (HRRCA) does not accurately address PWSs in rural parts of the United States. The Department suggests EPA consider the following factors in its final rulemaking.

O A low-end capacity of 1 million gallons per day greatly exceeds that of a small Village class entity thus the cost to small communities is a one-size fits all and does not accurately account for the very small systems.

O The treatment alternative does not include the costs of manifolding a small system's supply wells. In order to treat the water supply for these types of systems, the source water will need to be piped together to be treated.

O The cost estimate of water treatment plant operator salaries is not based in reality of what a small system can afford, or the willingness of a certified operator to relocate to rural parts of the United States.

The Department supports EPA's efforts to protect the public from PFAS exposure and appreciates the EPA considering stakeholder comments on the proposed PFAS rule.

Sincerely,

Jim Macy

Director

Nebraska Department of Environment and Energy

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. Additionally, the EPA disagrees with the comment that the cost analysis did not properly estimate the cost for small rural PWSs. The cost analysis for all PWSs is based on the estimated design and average daily flows at each entry point to distribution systems (EPTDS) which is estimated based on the population served. The commenter is incorrect; the EPA did not apply a low-end capacity limit of 1 million gallons per day in estimating these costs. The EPA's cost curves are based on model estimates that explicitly include capacities less than this limit, to as low as 0.03 million gallons per day. In addition, if small PWSs manifold wells together prior to treatment they will achieve economies of scale not accounted for in the cost analysis. In this situation, the EPA may have overestimated the cost of treatment. In regard to the EPA's estimates of the labor rate at water systems, the agency notes that the analysis utilizes a range of labor rates, that decrease as system size decreases. To the extent the labor rates for small water systems exceed actual water system labor rates, this would overestimate national costs of the rule. In response to the commenter's concern regarding certified operators at small systems

and funding available to help support operator training, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document and section 12 of the EPA response in this *Response to Comments* document.

National Association of Manufacturers (NAM) (Doc. #1655, SBC-043195)

EPA's proposed regulations are not economically feasible

EPA's regulations under the SDWA must be feasible considering costs for compliance when setting an MCL. [FN1: 42 U.S.C. 300g-1(b)(B)(4)(D).] EPA appears to be severely underestimating potential compliance for the water systems that will be required to monitor, sample and treat at near zero levels. The American Water Works Association published a report in March, 2023 that found that potential compliance on the PFOA and PFOS regulations would exceed $3.8 billion annually. [FN2: https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14-102450-257] That is only for two of the six substances being regulated, once costs are factored in for the other substances, that could raise the annual cost substantially. EPA should set the MCLs at a level that balances the benefits and costs of cleanup to ensure that the regulations can be successfully implemented.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. Additionally, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA also disagrees with the commenter's assertion that "once costs are factored in for the other substances, that could raise the annual cost substantially." For the final rule, the EPA examined the incremental costs associated with the Hazard Index and individual MCLs for PFHxS, PFNA and HFPO-DA and found that national costs increase by approximately 5 percent. For more information, please see section 13.3.2 of the EPA response in this *Response to Comments* document. In regard to the recommendation that the EPA should "set the MCLs at a level that balances the benefits and costs of cleanup," please see section 13.8 of the EPA response in this *Response to Comments* document on the Administrator's benefit cost determination.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043167)

In light of the above data and information, VMDWA urges EPA to withdraw its cost estimate, give strong consideration to the AWWA report, and produce a corrected cost analysis for public comment. In so doing, VMDWA also recommends that EPA obtain data from the state primacy agencies and review their experience in reviewing applications under WIFIA, ARPA, Safe Drinking Water State Revolving Fund Program, and the Bipartisan Infrastructure Legislation as to high bid prices.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. Additionally, the EPA disagrees with many of the assumptions in AWWA's

B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA requested comment on treatment costs and received many comments from primacy agencies; the EPA has considered these comments and made appropriate adjustments to the cost estimates in the final rule.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043402)

In light of the above data and information, MAMWA urges EPA to withdraw its cost estimate, give strong consideration to the AWWA report, and produce a corrected cost analysis for public comment. In so doing, MAMWA also recommends that EPA obtain data from the state primacy agencies and review their experience in reviewing applications under WIFIA, ARPA, Safe Drinking Water State Revolving Fund Program, and the Bipartisan Infrastructure Legislation as to high bid prices.

EPA Response: Please see the EPA response to comment Doc. #1657, SBC-043167 in section 13.3 in this *Response to Comments* document.

National Association of Clean Water Agencies (NACWA) (Doc. #1659, SBC-043152)

EPA Grossly Underestimates the Cost Impacts to Public Water Systems

EPA estimates that regulating these PFAS chemicals will cost PWSs at least $772 million per year. EPA's more conservative cost estimate, the 7% discount rate, quantifies costs to PWSs upwards of $1.2 billion per year. EPA also acknowledged PWSs would incur between $30 and $60 million annually for disposing of spent PFAS-contaminated treatment residuals if PFAS were designated as a hazardous waste and regulated under hazardous waste disposal requirements.

Our sister drinking water association, the American Water Works Association (AWWA), has comprehensively assessed what it would cost nationally for water systems to install treatment systems to remove PFOA and PFOS, and by their calculation it would exceed $3.2 billion annually.

NACWA's understanding of the costs associated with implementation of EPA's proposed rule is consistent with AWWA's cost estimation. Many communities will have to find new water sources or install expensive advanced treatment and will require substantial rate increases to pay for increased ongoing operation and maintenance costs.

This gross underestimation by EPA of the true costs of compliance does a major disservice to the public by ignoring the rightful concerns about water affordability.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report

and the report's overall conclusions about the estimated national costs, for more information, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043676)

The City has significant concerns regarding EPA's methods to evaluate costs and benefits of this proposed rule, including calculations of household affordability and other concerns discussed in more detail in comments to be provided by the American Water Works Association (AWWA).

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. Additionally, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the affordability analysis and determination, please see section 13.10 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043718)

Cost Estimates

Section XII.C.1.A

As proposed, EPA's current cost estimate for water systems' compliance is significantly underestimated. EPA estimates the costs of this proposed rule are $772 million per year nationally. Based on Colorado's publicly available voluntary PFAS sampling data reported from about half of community water systems, 30 public water utilities have PFOA and PFOS levels above the 4 ppt proposed MCL. Considering only half of the water systems in Colorado participated in this sampling effort, it would be safe to assume there are 60 systems (double the amount) that will be affected by an MCL of 4 ppt. If every state in the U.S. is in a similar situation to Colorado, the EPA's estimated cost for each utility over the PFOA and PFOS adjustments to meet MCLs would be at least $257,000 annually. This estimate only considers systems above PFOA and PFOS MCLs, and HI exceedances are not included. It is not feasible for water systems to be able to make the necessary changes for that estimated amount. EPA's estimate does not include funds needed for addressing HI exceedances, nor increases in material costs due to demand of GAC or other treatment technologies, treatment below the MCLs or inflation.

According to a study done by Black and Veatch on behalf of AWWA, the costs of installing drinking water treatment for removing only PFOA and PFOS will exceed $3.8 billion per year nationally. This cost estimate uses data provided by water systems that have done their own cost studies. Compared to EPA's estimate, they estimate more impacted systems and higher costs than what EPA estimated. Aurora Water estimates yearly costs to increase from $250,000 to $550,000 for removing PFOA and PFOS to the proposed level of 4 ppt for one of the three treatment

facilities. The other two facilities will need to construct treatment at a cost of approximately $15 million with ongoing O&M cost of about $550,000 per year, each. Aurora expects additional increases in treatment material costs, inflation and supply chain limitations.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document for the EPA's response to comments stating that the agency has significantly underestimated the costs of the proposed rule. Furthermore, extrapolating from individual utilities or states' experience is not an appropriate method to estimate national costs. The EPA therefore disagrees with the commenter's assumption that the number of systems exceeding 4ppt in Colorado could be extrapolated nationally. For the EPA's response to comments on the number of water systems expected to be triggered into action under the final rule, please see section 6.5 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's statements about Hazard Index feasibility and costs. The EPA estimated the costs associated with the Hazard Index and individual MCLs for PFHxS, PFNA and HFPO-DA for the final rule; please see section 13.3.2 of the EPA response in this *Response to Comments* document for the EPA's response to comments on the subject and Appendix N of the EA for the final rule for the EPA's results.

For the EPA's response to comments about the demand created by the rule, and the potential impact on prices of materials including GAC, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Association of California Water Agencies (ACWA) (Doc. #1675, SBC-044930)

A. Costs

COMMENT 1 – COST ASSESSMENT – EPA's cost assessment does not capture the full costs that will be borne by water agencies and ratepayers.

ACWA believes that this proposal is not feasible because the anticipated costs of this regulation are not adequately captured under EPA's cost assessment.

The SDWA was amended in 1996 to specifically require cost-benefit analysis as part of the regulatory process. The updated statutory language requires EPA to set maximum contaminant levels (MCLs) as close to the maximum contaminant level goal as is "feasible." "Feasible" is defined as "the use of the best technology and treatment approaches examined for effectiveness under field conditions, taking cost into consideration." [FN3: EPA, SDWA Economic Analysis (last updated Feb. 14, 2023), click here. [Link:]]

EPA estimates the costs of this proposed rule for water utilities to be between $772 million and $1.2 billion annually [FN4: Fed. Reg. 18,638, 18,700 (Mar. 29, 2023), click here. [Link:

https://www.federalregister.gov/documents/2023/03/29/2023-05471/pfas-national-primary-drinking-water-regulation-rulemaking]]. ACWA, along with other national water groups, believes that EPA's economic analysis does not accurately reflect the anticipated costs of the proposed rule on our members [FN5: Bloomberg, US Plan to Limit PFAS in Water Draws Concern Over Cost, Science (Mar. 15, 2023), click here. [Link: https://www.bgov.com/next/news/RRK2FCDWLU6B]]. Moreover, EPA's economic assessment was calculated in 2021 dollars, [FN6: Fed. Reg. at 18,700]and does not account for inflation increasing the capital and operation and maintenance (O&M) costs for water agencies [FN7: Circle of Blue, Inflation Weighs on U.S. Water Utilities (April 7, 2022), click here. [Link:]].

When PFAS are detected in a water system, they can have severe and far-reaching impacts. For instance, in California, water supply agencies, pumpers, and purveyors have had to take groundwater wells out of service due to PFAS detections and are taking steps to find and pay for alternative short-term water supplies, all while also developing PFAS remediation programs. As one example, it is anticipated PFAS remediation programs will cost hundreds of millions of dollars in Los Angeles and Orange Counties alone [FN8: See American Society of Civil Engineers, California water district moves ahead with PFAS treatment systems (Oct. 25, 2021), click here [Link: https://www.asce.org/publications-and-news/civil-engineering-source/civil-engineering-magazine/article/2021/10/california-water-district-moves-ahead-with-pfas-treatment-systems#:~:text=Of%20the%2019%20retail%20water,of%20engineering%20for%20the%20OCWD.]; see also Reuters, California agency sues 3M, others over groundwater contamination (Nov. 9, 2021), click here. [Link:]].

More specifically, to meet the requirements of this proposed rule, a southern California member estimates PFAS project costs to be $170 million in its service area alone. Moreover, in anticipation of EPA's proposal, the American Water Works Association commissioned a study to estimate the national cost for water systems to install treatment to remove PFOA and PFOS to required levels. According to the study, estimated costs will exceed $3.2 billion annually, and the majority of treatment costs will be passed on to communities and ratepayers [FN9: See Black & Veatch, WITAF 56 TECHNICAL MEMORANDUM PFAS National Cost Model Report (Mar. 7, 2023), click here. [Link: https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14-102450-257]].

EPA Response: For the EPA's response to comments stating that the agency has underestimated the costs of the proposed rule, please see section 13.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on feasibility of the final MCLs, please see section 5 of the EPA response in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. For the EPA's response to this report, as well as response to recommendations to update the dollar year used in the analysis, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

The EPA does not dispute the commenter's estimate of southern California PFAS project costs, but the comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044949)

11. Rapidly evolving PFAS research complicates cost-forecasting for water testing, treatment technologies and healthcare. Shifting state and federal regulations generate unanticipated expenses in drinking water sampling and filtration, product testing, and treatment of wastewater and landfill leachate. There are uncertainties in how long filters will perform and what their disposal costs may be, treatment methods are rapidly evolving and demand for filtration systems is skyrocketing, driving up costs and causing delays on top of existing supply-chain challenges. Water treatment operators that find PFAS during sampling must test water more frequently, an ongoing expense that drives up operating costs. Treatment add-ons to existing plants will likely require the acquisition of additional land, operators and ancillary equipment.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. The EPA used the best information available at this time to estimate the costs; for more information section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter's assertion that there are significant "uncertainties in how long filters will perform;" see the EPA's *Best Available Technologies and Small System Compliance Technologies Support Document* for more information (USEPA, 2024e), including the EPA's evaluation of the performance of each technology. Please see section 13.3.3 in this *Response to Comments* document for the EPA's response to comments on performance monitoring that may occur as a result of the rule. Finally, the EPA includes the costs associated with "treatment add-ons" referenced by the commenter including land, operator labor, and a variety of indirect capital costs in the costs analysis, see Chapter 5 of the EA for more information.

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044306)

The EPA has likely estimated the number of utilities that will be impacted at the proposed MCLs and the cost impacts to be far too low.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045047)

Cost Analysis

Cost-Benefit Model

Based on an initial analysis of New Jersey's records, NJDEP believes EPA has underestimated the costs of implementing the proposed standards. In a preliminary statewide assessment, NJDEP estimated that it may cost New Jersey over $1 billion to implement the proposed standards. This estimate includes costs for drinking water sampling, capital expenditures for affected systems to install treatment, sampling through the State's ambient monitoring networks, and New Jersey Pollution Discharge Elimination System (NJPDES) monitoring. Importantly, this estimate does not include the sustained operational and maintenance costs that will be necessary for affected systems to maintain treatment.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. The EPA does not dispute the commenter's estimate of implementation costs in New Jersey, but the comment lacks sufficient detail to compare these costs to the results of the EPA's WBS and SafeWater models. The cost quote provided by the commenter appears to include costs not associated with compliance with a state or federal drinking water standard (i.e., Sampling through the state's ambient monitoring networks, and New Jersey Pollution Discharge Elimination System (NJPDES) monitoring) and is therefore not directly comparable to the EPA's NPDWR cost estimates. Further, this commenter cites a one-time cost estimate of capital investments in the state, which is not directly comparable to the EPA's annualized values. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

<u>New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045050)</u>

National Cost Estimate

The NJDEP is concerned that the National Cost Estimate, calculated using the MCBC model that EPA used for this PFAS National Primary Drinking Water Regulation Rulemaking, significantly understates the annualized costs associated with the proposed standards. Using the lifetime and higher discount rate provided in EPA's analysis (80 years and 7%), the NJDEP annualized the capital construction costs for PFAS treatment as reported by systems which have already installed PFAS treatment to meet the NJDEP's own drinking water standards for PFOA, PFOS, and/or PFNA.

The NJDEP subsequently compared the annualized capital construction cost New Jersey public water systems have experienced with EPA's forecasted annualized costs in their corresponding category, as outlined in Table C-1 in Appendix C of EPA's Economic Analysis for this proposal. The average difference between the actual annualized construction cost and forecasted EPA number was $840 per year. Note that the annualized cost for New Jersey used in this comparison does not include operating and maintenance costs due to a lack of data available (unlike the EPA's annual cost estimate which does include O&M costs), meaning that the real difference in annualized costs between the EPA economic analysis and the reality facing public water systems may be greater.

As such, the NJDEP urges the EPA to review the economic analysis methodology and underlying data used to come to the forecasted conclusions to arrive at a more accurate estimate of the annualized costs for public water systems.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. Additionally, the EPA does not dispute the commenter's estimate of costs in New Jersey, but the comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. As it relates to the commenter's stated average difference between the EPA's system level cost ranges in Appendix C-1 and the information included in the commenter's letter, the EPA notes that the stated average difference of $840 dollars per year is at most an approximately 6 percent difference from the lowest median cost estimates in the EPA's Table C-9 in the EA for proposal (the EPA's median cost estimate for groundwater systems serving less than 100 customers was $15,360; ($840/$15,360*100=5.46 percent)). When compared to many of the EPA's estimates in Table C-9, $840 dollars is less than 1 percent of the EPA's median annualized cost estimate. While the EPA recognizes there are likely site-specific instances where costs exceed the EPA's cost ranges, there are also likely site-specific instances where costs are less than the EPA's cost ranges, and the level of accuracy in the EPA's cost assessment is appropriate for a national level analysis. Further, the EPA notes that the agency made a number of changes to the treatment cost estimates for the final rule, detailed in section 13.3.3 of the EPA response in this *Response to Comments* document, that are very likely to narrow the gap between New Jersey's cost information and the EPA's unit cost information.

Association of California Water Agencies et al. (Doc. #1701, SBC-043836)

Accurately Reflecting Costs and Household Affordability

A major concern our groups have is the enormous cost of this rulemaking, which will be imposed on water systems, communities, and their ratepayers. With this rule, communities will be financially responsible for expensive treatment technologies to remove PFAS from water down to the lowest level that can be reliably detected. While EPA's costs and benefit analysis estimates that the costs of this proposal amount to $770 million to $1.2 billion annually, other available data from existing facilities and industry work estimate that the cost could exceed $3.2 billion annually1. [FN1: Black & Veatch, 2023. WITAF 056 Technical Memorandum Update: PFAS National Post Model Report. Prepared for American Water Works Association. May 26, 2023.]

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Please see section 13.10 in this *Response to Comments* document for the EPA's response to comments on the affordability analysis.

Association of California Water Agencies et al. (Doc. #1701, SBC-043840)

A robust and accurate cost and benefit analysis is crucial for making sound decisions that are protective of public health and appropriately prioritize investments. EPA should improve its cost analysis, and subsequently the household affordability analysis, to be more reflective of available information on PFAS treatment costs. This is imperative to ensure that the proposed rule is not only accurately reflecting the financial impacts on communities as a whole but also examines affordability for low-income households specifically.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Please see section 13.10 in this *Response to Comments* document for the EPA's response to comments on the affordability analysis.

California Farm Bureau Federation (Doc. #1704, SBC-045069)

[For example, the U.S. Chamber analysis highlights the following:]

• The Safe Drinking Water Act requires consideration of the costs and benefits. The estimated annualized costs for a proposed MCL of 4 ppt for PFOA and PFOS are exorbitant. The significant costs and impacts, and their connection to other elements of the PFAS Strategic Roadmap such as the proposed hazardous substance designation under CERCLA, require further analysis and consideration.

EPA Response: Please see the EPA's response to the US Chamber of Commerce's cost estimates in the EPA response to comment Doc. #1537, SBC-042649 in section 13.3.3 in this *Response to Comments* document. Further, for the EPA's response to comments on disposal of spent drinking water materials under possible future regulatory actions under other statutes, see section 10.4.1 of the EPA response in this *Response to Comments* document.

California Farm Bureau Federation (Doc. #1704, SBC-045065)

The Challenges in Reaching These Levels Have Been Underestimated

While farmers, ranchers, and other agricultural producers support a national drinking water standard for PFOA and PFOS and other PFAS chemicals based on the best science available and an evaluation of risk, there are substantial questions and concerns related to EPA's current proposal. The extensive review of the proposed cost-benefit analysis, completed by the U.S. Chamber of Commerce, highlights costs associated with this rule have not been accurately calculated for a variety of reasons.

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document and the EPA's response to the US Chamber of Commerce's cost estimates in the EPA response to comment Doc. #1537, SBC-042649 in section 13.3.3 in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1711, SBC-044462)

[The Agency's proposal suffers from the following significant shortcomings –]

• EPA's estimate of the costs of its proposal relies on occurrence data for PFOA and PFOS that do not provide an appropriate baseline and is much lower than the costs predicted by an independent analysis,

EPA Response: While not explicitly stated in Doc #1711, the EPA assumes this commenter is referring to AWWA's cost estimates. For the EPA's response to the AWWA B&V report, please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the national occurrence model used in the EA, please see section 6.5 of the EPA response in this *Response to Comments* document. While the EPA has considered the input from the AWWA report and other public comments about the EPA's estimated rule costs, the EPA does not think it accurate to describe the AWWA report as "independent." Please see the EPA response to comment Doc. #1841, SBC-044850 in section 5.1.3 of this *Response to Comments* document for further discussion.

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045931)

COMMENT 2 — EPA HAS FAILED TO ADEQUATELY CONSIDER COSTS IN THE PROPOSED RULE.

EPA has failed to capture or consider the full range of costs of its MCL for water and wastewater agencies or their customers.

The proposed NPDWR fails to adequately consider the costs associated with its proposal as required by the Safe Drinking Water Act ("SDWA") and recognized as an obligation by in EPA's SDWA Economic Analysis. [FN6: EPA, SDWA Economic Analysis (last updated Feb. 14, 2023) (https://www.epa.gov/sdwa/sdwa-economic-analysis).] EPA's SDWA Economic Analysis states that when there is no reliable method, a treatment technique is set rather than an MCL. [FN7: EPA, SDWA Economic Analysis (last updated Feb. 14, 2023) (https://www.epa.gov/sdwa/sdwa-economic-analysis).] The SDWA requires the EPA to review costs that occur solely as a result of compliance with the MCL such as monitoring and treatment. [FN8: 42 CFR 300g (b)(3)(C)(i)(III).]

EPA's NPDWR estimates that the cost to water utilities will be between $772 million and $1.2 billion annually. [FN9: EPA, PFAS National Primary Drinking Water Regulation Rulemaking, 88 Fed. Reg. 18638, 18700 (proposed Mar. 29, 2023) (hereinafter "Proposed Rule").] This estimate fails to take into account a number of factors including inflation and rising capital and operational costs. Further this estimate fails to consider the cost of action upon detection of one of the PFAS chains. These costs include, but are not limited to: identifying and paying for alternative water sources for PFAS contaminated sources, particularly in locations or periods where water is scarce; developing, piloting, and implementing new treatment systems (in lieu of EPA final treatment direction); and the incremental impacts and costs of the proposed Hazard

Index for PFNA, PFHxS, PFBS, and GenX. In anticipation of EPA's proposed NPDWR, the American Water Works Association commissioned a study to estimate the national cost for water systems to install treatment to remove PFOA and PFOS to required levels. According to the study, estimated costs will exceed $3.2 billion annually and the majority of treatment costs will be passed on to communities and ratepayers. [FN10: Black & Veatch, WITAF 56 TECHNICAL MEMORANDUM PFAS National Cost Model Report (Mar. 7, 2023) (https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14-102450-257).]

Many members of POWER! Project that their costs of constructing PFAS treatment and residual disposal will reach tens of millions, and in some cases exceed $100 million, for each water agency, and result in significantly increased annual operation and maintenance costs. EPA has failed to adequately capture or consider the full impacts of its proposed 4 ppt MCL for PFOA and PFOS, or its novel Hazard Index regulating four new PFAS at similar levels, for the thousands of water and wastewater agencies across the country or their ratepayers.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter's statement that the agency "…has failed to capture or consider the full range of costs of its MCL for water and wastewater agencies or their customers," as the agency has met all statutory and Executive Order requirements to consider such impacts using the best available data. In the EA for both the proposed and final PFAS NPDWR, the EPA evaluated the costs of each of the activities or "costs of action" mentioned by the commenter, including pursuing non-treatment options (i.e., New water sources) where viable, developing, piloting, and implementing new treatment systems, and the cost impacts of the Hazard Index MCL specifically (please see section 13.3.2 of the EPA response in this *Response to Comments* document for more information). Finally, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Monterey One Water (Doc. #1715, SBC-043828)

Economic Impact

Monterey One Water urges EPA to reassess the economic impact of the rule on water utilities to ensure that policymakers have accurate information when providing financial support for PFAS remediation. Our Agency remains concerned about the cost of meeting the proposed MCLs within the aggressive compliance window and the financial impact that the treatment and removal of PFAS may have on our ratepayers. EPA has estimated that the total cost of compliance for public water systems will range from $769 million to $1.2 billion. While the estimate incorporates monitoring, equipment, capital costs, operations and maintenance, regulatory reporting, and public communications, it falls well below the $3.2 billion that the water treatment sector has estimated the rule will cost water utilities annually. We urge EPA to

review the economic analysis prepared earlier this year for the American Water Works Association and consider whether any revisions are needed to its own economic analysis.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. Additionally, the EPA has considered all public comments, including those regarding the economic impacts of the rule, in finalizing the rule. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Loudoun Water (Doc. #1717, SBC-043521)

Loudoun Water is a member of the American Water Works Association (AWWA) and is aware of the findings from the national cost assessment, March 2023, conducted by Black & Veatch on behalf of the AWWA. The study found that MCLs set at 4 ppt for PFOA and for PFOS would trigger $5.2 billion in annualized national costs (capital, O&M, monitoring, etc.) for impacted facilities assuming a seven percent discount rate, as compared to EPA's estimate of $1.211 billion, using the same discount rate. Loudoun Water believes that EPA's estimate of the cost of compliance is greatly understated without considering the many factors likely to push the cost higher.

EPA should re-evaluate the costs of rule implementation to ensure the current realities of utility input costs and supply chain limitations are accurately reflected in its analysis. Utilities need a comprehensive understanding of EPA's proposed regulatory framework for PFAS from drinking water sources of supply to water treatment plant residuals to make cost effective decisions and reduce rate impacts to our customers.

EPA Response: This commenter cites AWWA's cost estimates of $5.2 billion annually included in an older version of the B&V report from March 2023. According to the March 2023 version of the report, that figure represents AWWA's understanding of the "national burden" of removing PFOA and PFOS to 4ppt each, not just the NPDWR costs, which AWWA presents separately. The EPA notes that in their public comments on the proposed rule submitted in June 2023, AWWA submitted lower revised estimates in that report, of $2.5 to $3.2 billion dollars annually at the 3 and 7 percent discount rates respectively. Furthermore, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For more information on the EPA's whole-of-agency approach to addressing PFAS, see the EPA's PFAS Strategic Roadmap.

Environmental Working Group (EWG) (Doc. #1721, SBC-045416)

For an independent review of the EPA's cost analysis, please see the memorandum dated May 30, 2023, prepared by Elin Warn Betanzo of Safe Water Engineering, LLC, referenced in and appended to comments submitted by Earthjustice et al. The analysis confirms that EPA's analysis

of costs of the proposal were grounded in sound, and in some cases, conservative assumptions. For instance, the lowest discount rate EPA considered was 3 percent, while OMB's recently revised draft guidance for economic analyses favors a substantially lower, consumption-based discount rate of 1.7 percent. [FN62: Elin Warn Betanzo, Safe Water Engineering, LLC, Analysis of the USEPA Proposed PFAS National Primary Drinking Water Regulation Treatment Costs and Comparison to the AWWA National PFAS Cost Model Report (May 30, 2023) (citing Circular A-4: Memorandum from the Off. Of Mgmt. & Budget to Heads of Exec. Agencies & Establishments; re: Regul. Analysis (Apr. 06, 2023) at 4). See also Earthjustice et al., supra note 7.] The analysis also highlights some unmodeled considerations that "would have the impact of decreasing overall costs…" including, among other things, the extent to which water systems would consolidate with other systems to meet the MCLs instead of installing treatment, use point-of-use (POU) devices for compliance, and innovation in the marketplace. [FN63: Id. At 21]

EPA Response: This comment generally supports the EPA's analysis. For the EPA's response to comments on discount rates used in the analysis, please see section 13.2 of the EPA response in this *Response to Comments* document.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043586)

5. Costs to public water systems including funding treatment design and installation, operation and maintenance, availability of certified operators for implementing treatment options, potential treatment supply chain product availability, and disposal of PFAS waste represent challenges especially to our many small water systems.

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043577)

I want to urge the EPA to conduct a more robust analysis that more accurately captures the costs of compliance, and if necessary, collects more data to inform and address the gaps that currently exist before adopting a rule. This should be a reasonable request given that the agency caveated its own work in the posting by listing a host of data limitations and uncertainties from a lack of modeling national costs for treatment associated with potential Hazard Index exceedances.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Further, the EPA notes that it is best practice to identify known data limitations and uncertainties in any scientific or economic analysis, including this one (see e.g., US EPA Guidelines for Economic Analysis for more information). Identification of uncertainties is also required by the statute, see SDWA Section 1412(b)(3)(C)(i)(VII). For the EPA's response to comments on the costs associated with the Hazard Index specifically, please see section 13.3.2 in this *Response to Comments* document.

U.S Conference of Mayors, National League of Cities and National Association of Counties (Doc. #1733, SBC-043890)

Overarching Concerns and Recommendations

As EPA continues to develop this regulation, we offer several of our priority concerns and recommendations relating to local governments' ability to effectively and cost-efficiently implement the proposed changes while also protecting public health.

1. Financial Impacts

The Agency's proposed regulation will have a significant impact on public water systems, and the financial burden will ultimately be passed on to local governments and community ratepayers. In proposing this new regulation, the Agency has conducted a cost-benefit analysis and concluded annual costs of $770 million and benefits of approximately $1.2 billion. However, the American Water Works Association (AWWA) has estimated annual costs between $2.5-$3.2 billion. [FN1: WITAF 56 Technical Memorandum Update, "PFAS National Cost Model Report," May 26, 2023]

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Arizona Corporation Commission (ACC) (Doc. #1735, SBC-045181)

Based on the construction costs provided above, the ACC believes that the EPA's estimated costs for nationwide compliance are underestimated. Specifically, Table 22 of the EPA's PFAS NPDWR paper, which estimates the annual cost per household for systems with 25-500 customers, indicates costs ranging from $376 to $645. Considering a service life of 10 years for treatment equipment, [FN3:10-Year service life figure obtained from the EPA handbook titled "Asset Management: A Handbook for Small Water Systems," published in 2018.] the ACC estimates that the annual bill impact for smaller systems requiring FCRT for one well with a flow rate of 0.2 MGD exceeds $1,000 per household. The ACC believes that the EPA's estimate did not account for inflation in the construction sector, potential increases in demand for specialized treatment equipment, additional infrastructure requirements to operate remediation technologies effectively, and the financial strain resulting from a narrow compliance window.

EPA Response: This comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Regarding the impacts of inflation on the cost estimates, the EPA does not disagree that inflation could increase the cost of the rule in nominal terms. However, as prices rise, so would the benefits of the rule (e.g., increased cost of health care treatment avoided). Therefore, following common practice, the EPA estimated the cost and benefits of the rule in real terms (constant 2022 dollars). The EPA disagrees with the commenter's assumption of a service

life of 10 years. Although some individual treatment system components may have a useful life of 10 years or less, the EPA estimates that overall treatment system useful life can be 20 to 30 years or more, depending on system size and materials of construction. This estimate is based on the composite useful life of treatment systems derived from the useful lives of individual treatment system components and industry information (including the Asset Management Handbook cited by the commenter).

Florida Section American Water Works Association – Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044485)

XIII. Health Risk Reduction and Cost Analysis

The Florida Water Sector supports health risk reduction and understands its importance to EPA's Cost Analysis. Providing safe and reliable drinking water is our number one priority. However, we recommend EPA perform additional cost analyses based on some additional considerations. In addition, we do not believe all utilities will be able to comply with the new regulations in the three years allotted.

EPA Response: Please see section 13.3 in this *Response to Comments* document for the EPA's response to comments on the overall cost analysis. For the EPA's response to comments on the compliance timeline for the final rule, please see section 12 of the EPA response in this *Response to Comments* document.

Arizona Water Company (Doc. #1758, SBC-044533)

Capital and operation and maintenance (O&M) costs for PFAS removal facilities will be expensive. The Company expects to spend approximately $200 Million in capital costs and $25 Million in annual O&M costs to remove PFAS from its water supplies to comply with the proposed MCLs. These costs will be extraordinary and result in massive cost increases that must be passed directly on to the Company's customers. To avoid rate shock, the Company is requesting assistance with the capital and O&M costs for PFAS removal facilities via federal funding. The Company recommends the EPA provide resources on the specific amounts of government funding available to private utilities to construct PFAS removal facilities. Based on the Company's estimates, over approximately eight years, the O&M costs for PFAS removal facilities will surpass the capital costs for their construction. Without any government funding assistance, these O&M costs will be passed directly on to customers and increase their rates. The Company recommends the EPA provide resources to private utilities to help fund the O&M costs associated with operating and maintaining PFAS removal facilities in addition to capital costs to construct them.

EPA Response: The EPA has used best available science and information to estimate costs imposed by the rule, including operation and maintenance costs, in its EA. Please see section 13.3 in this *Response to Comments* document for the EPA's response to comments on the overall cost analysis. Regarding funding, the passage of the Infrastructure Investment and Jobs

Act (IIJA), often referred to as the Bipartisan Infrastructure Law or BIL, invests over $50 billion to improve drinking water, wastewater, and stormwater infrastructure – the single largest investment in water by the federal government. This historic investment specific to safe drinking water includes $11.7 billion in the Drinking Water SRF; $4 billion to the Drinking Water SRF for Emerging Contaminants; and $5 billion in grants for Emerging Contaminants to Small or Disadvantaged Communities from federal fiscal years 2022 through 2026 (USEPA, 2023d). For more information on the EPA's response to comments about the availability federal funding available to support the rule, including O&M costs, please see section 2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045561)

Additional recommendations are detailed in this letter, including:

1. The proposal's underlying cost analysis is inaccurate and substantially underestimates costs to compliance costs and the financial impacts on consumers. The agency should work with AWWA and other stakeholders to develop a cost-estimating approach that is more reflective of best-engineering practices and should refine the cost estimate for the proposal. Any final rule should re-evaluate the determinations that benefits justify the costs and the rule is affordable for small systems, considering the updated cost analysis to support any rule.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the Administrator's determination that the benefits justify the costs, please see section 13.8 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the affordability determination, please see section 13.10 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045556)

A recent analysis by Black & Veatch estimated that the costs of the proposed standards could exceed $2.5 to $3.2 billion annually (Black & Veatch, 2023 – See Appendix B). The Administrator will need to determine if these costs are justified by the benefits, estimated to be $0.8 to $1.2 billion annually, and whether it is a meaningful opportunity to protect public health when this investment will divert water systems investments from other needs to assuring compliance with any final PFAS rule requirements.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the Administrator's determination that the benefits of the rule justify its costs, please see section 13.8 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045609)

7. Compliance Cost Analysis

According to the proposal, EPA anticipates that nearly 67,000 water systems will need to comply with the proposed rule. These water systems will need to review and understand how to implement the rule, conduct initial monitoring of the regulated PFAS at each entry point to the distribution system, and potentially work to install drinking water treatment systems or take another mitigation strategy. The proposal does not fully capture these costs. Because the SDWA requires EPA to take costs into consideration, including when setting the appropriate MCL, and to issue a determination as to whether the benefits of the maximum contaminant level justify, or do not justify, the costs, EPA can only comply with its statutory requirements by conducting an analysis that fully captures these costs and making them available for public comment. [FN24: See 42 U.S.C. §§§ 300g–1 (b)(3)-(4).] The following sections provide recommendations to improve the cost analysis.

EPA Response: The EPA disagrees with the commenter that the proposal did not fully capture the costs associated with the rule. Please see section 13.3 of the EPA response in this *Response to Comments* document for the EPA's response to comments on the overall cost analysis. For the EPA's response to comments on the Administrator's determination that the benefits of the rule justify its costs, please see section 13.8 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the feasibility determination, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045619)

Importance of an Accurate Cost Analysis

The EPA is encouraged to review the cost analysis, and the EPA's WBS Model, to ensure that the monitoring and treatment costs are accurate. As noted above, EPA cannot fulfill its obligations under the SDWA unless the cost assessment is accurate. In addition, this cost analysis is critical given that it underpins the HRRCA as well as the household affordability analysis. An inaccurate estimation of costs will mischaracterize the proposal's regulatory impact, merits, and the affordability for households in smaller communities. These analyses are critical for the agency, and water systems, to understand public health priories. Water systems are currently working to address various public health priories, including lead service lines, cybersecurity, microbials and DBPs, water supply challenges (such as drought, increasingly impaired water sources), and aging infrastructure.

Black & Veatch estimates that the cost of rule will range from more than $2.5 to $3.2 billion annually (Black & Veatch, 2023 – See Appendix B). As proposed, this rule will be one of the most costly rules under SDWA ever proposed and will be a burden carried by less than 10% of water systems. It is imperative that the overall analysis of the proposal's impacts be accurate so

that water systems and communities are assured that the investments in infrastructure being made represent the investments with the greatest societal benefit.

EPA Response: Please see section 13.3 in this *Response to Comments* document for the EPA's response to comments on the overall cost analysis. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Please see section 13.10 in this *Response to Comments* document for the EPA's response to comments on the affordability analysis.

Connecticut Section of the AWWA (CTAWWA) and Connecticut Water Works Association (CWWA) (Doc. #1763, SBC-044236)

Costs and Funding Sources

We encourage EPA to review its cost model for the proposed PFAS Rule. It is our understanding that many more systems will exceed the proposed MCLs than have been projected by EPA. In addition, our membership continues to experience cost increases related to equipment, materials, and workforce. These current costs should be reflected in the benefit cost analysis to ensure the appropriateness of the PFAS Rule.

According to American Water Works Association (AWWA) data, EPA has underestimated the cost of compliance with the proposed perfluorooctanoic acid (PFOA) and perfluorooctyl sulfonate (PFOS) standards. Cost models prepared for AWWA by the consulting engineering firm Black & Veatch (WITAF 56 Technical Memorandum – PFAS National Cost Model Report), as well as our members' experience in Connecticut, differ significantly from EPA's model. EPA's benefit cost analysis must accurately evaluate the cost impact of the rule to make a sound decision on the appropriateness of the rule requirements.

EPA Response: The EPA has used the best available information to inform the estimates of the number of water systems exceeding the MCLs as well as cost information in the final rule. Based on public comment, the EPA has updated its occurrence analyses, For more information please see section 6.2 of the EPA response in this *Response to Comments* document on state drinking water data and section 6.5 of the EPA response in this *Response to Comments* document on the PFAS national occurrence model. Additionally, please see section 13.3.3 of the EPA response in this *Response to Comments* document regarding the EPA's treatment cost estimates and consideration of recent price increases. Additionally, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

U.S. Poultry & Egg Association et al. (Doc. #1765, SBC-044549)

5. Flaws in the Economic Analysis

In accordance with the SDWA, if the agency establishes an MCL for any contaminant, the combination of technology, treatment techniques, or other means required to meet the level must not be more stringent than feasible. This rule wildly underestimates the burden of cost that will be placed on thousands of public water supply systems, including poultry and egg facilities that fall into the category of a non-transient, non-community water systems (NTNCWSs). The costs associated with establishing the proposed MCLs to levels that are essentially zero levels, will subject rural municipalities and poultry companies to bear unnecessary financial burdens associated with engineering, purchasing and installing multiple additional treatment technologies.

The American Water Works Association (AWWA) published a report in March of 2023 titled, "PFAS National Cost Model Report" that provides national cost estimates for setting an MCL of 4 ppt for PFOA and PFOS. It found the national cost for water systems to install treatment to remove PFOA and PFOS to levels required by this proposal exceed $3.8 billion annually. The report further estimated that annual costs to households in small communities, often where poultry and egg industry facilities are located, can amount to $10,000. Flaws in EPA's economic analysis are further aggravated by the fact that the agency's analysis fails to account for expenses associated with annual operating and maintenance – expenses likely to be overly burdensome given these treatment technologies are unique to wastewater treatment plant personnel.

The undersigned organizations have a strong interest in a responsible rulemaking process that protects the environment and the health of the public. However, the proposal to establish the incredibly low MCL's and MCLG's for the six PFAS listed in the regulation will subject the regulated community to a high level of uncertainty. A regulation as highly technical and far reaching as this demands far more time and consideration. The organizations listed below appreciate the opportunity to submit these comments and the agency's thoughtful deliberation.

If you have any questions related to these comments or would like additional information, please contact Paul Bredwell at pbredwell@uspoultry.org.

EPA Response: The EPA disagrees with the commenter that the MCLs are not feasible and the characterization that they are "essentially zero." For the EPA's response to comments on the agency's feasibility determination, including analytical feasibility, please see section 5 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter's conclusion that the rule "will subject rural municipalities and poultry companies to bear unnecessary financial burdens associated with engineering, purchasing and installing multiple additional treatment technologies." The EPA has determined that the benefits of the rule justify its costs; therefore, compliance with the final NPDWR is not an unnecessary financial burden. For more information, please see section 13.8 of the EPA response in this *Response to Comments* document. In response to the commenter's reference to AWWA's comment letter, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs as well as household level costs; for more information, please see section 13.3.3 of the EPA response in this *Response to Comments* document. The commenter's assertion that the agency fails to account for expenses associated with annual operation and maintenance is incorrect, as these costs are included in the EPA's cost analysis. The EPA notes that the agency does not consider costs when setting a maximum contaminant level goal (MCLG): the MCLG is the maximum level of a contaminant in drinking water at which no known or anticipated adverse effect on the health of persons would occur, allowing an adequate margin of safety. See section 4 of the EPA response in this *Response to Comments* document for further discussion. MCLGs are non-enforceable public health goals and, as a result, do not impact regulatory certainty. The EPA further disagrees that the MCLs in the rule will subject the regulated community to uncertainty: the rule requirements are clear, feasible technologies are available to meet the MCLs and analytical methods are available to monitor for the regulated PFAS, among other things. Finally, the EPA disagrees that the treatment technologies available for PFAS removal are unique to wastewater treatment plants; all of the best available technologies (BATs) identified in the final rule have demonstrated use at full scale drinking water treatment plants. For more information see the *EPA's Best Available Technologies and Small Systems Compliance Technologies* support document (USEPA, 2024e).

3M Company (Doc. #1774, SBC-045692)

In the cost analysis EPA did conduct, documented in the Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (USEPA 2023i), EPA uses opaque methodological approaches, fails to document the assumptions it applies, and fails to provide an adequate and transparent description of the analytical approaches, models, and tools that it uses to estimate costs. These omissions impose substantial uncertainty on many steps of this convoluted cost analysis. That uncertainty propagates and compounds throughout the analysis and imposes biases on various intermediate calculations. These biases subsequently yield potentially highly uncertain cost estimates of questionable accuracy.

EPA is missing critical data and is forced to use category-wide and/or nationwide estimates for baseline and compliance characteristics in the selection of treatment technology or non-treatment alternative. The absence of this data negates EPA's ability to present cost analysis results at the PWS-level. Instead, EPA collapses the more than 66,000 PWSs and summarizes nationwide cost and benefit estimates for 36 general PWS categories. [FN95: The Bayesian model EPA used to establish a national distribution of PFAS concentrations as part of the benefit-cost analysis did not include important covariates including distance from the PFAS source, topography, number of private drinking water wells in the area or state, climatology, distance to nearest large water and river systems, and other environmental factors. EPA's Bayesian model outputs are clearly not representative of the PFAS exposure distribution on a national level. Therefore, any benefit-cost conclusions drawn based on these data and model outputs do not represent the expected PWS concentrations across the US and cannot be used to support a MCLG. EPA does not provide details of the Bayesian model that are commonly included in the description by practicing statisticians. Therefore, evaluation of adequacy and believability of the model outputs cannot be understood, as required by EPA's QC practices] This generalization and reporting opacity prevent an evaluation of the potential distributional impacts of the proposed NPDWR.

EPA Response: The EPA disagrees with the comment that the cost analysis is not transparent. The EPA has documented its approach fully in Chapter 5 and the appendices of the EA. In addition, the EPA has made all of the input data and model source code available in the docket. Please see section 13.1 in this *Response to Comments* document for the EPA's response to comments on the EPA's SafeWater model, including comments related to the EPA's use of PWS strata to estimate national benefit and cost results.

In response to comments on the Bayesian occurrence model including its validity, national representativeness, and documentation, please see section 6.5 of the EPA response in this *Response to Comments* document. Further, the peer-reviewed paper, Cadwallader et al. (2022) includes documentation on logic behind the model development, and the supplemental information for that paper also includes model inputs, model code, and the seed (the starting point for random number generation). This information is sufficient to replicate the model run, and the EPA therefore disagrees with the commenter's assertions about lack of transparency.

The EPA disagrees with the commenter's assertion that the "benefit-cost conclusions drawn based on these data and model outputs" cannot be used to support an MCLG. The MCLG is a health-based value and does not account for limits of detection and treatment technology effectiveness. Further, the EPA disagrees with this statement to the extent it applies to the EPA's analysis ability to support an MCL. The EPA used the best available peer reviewed data, as required by SDWA, including a peer-reviewed nationally representative occurrence model, to inform the HRRCA for the rule. The occurrence model was created to estimate national occurrence. The data came from a census of large systems and a nationally representative subset of small systems. From these, it is appropriate to make nation-scale estimates. System to system variability is inherently captured in the fact that the EPA used a nationally representative set of systems to inform a distribution of system-level means.

Finally, for the EPA's response to comments on the Administrator's benefit cost determination, please see section 13.8 of the EPA response in this *Response to Comments* document.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045275)

Economic feasibility of the regulations is not sufficiently considered and addressed.

6. EPA should reevaluate the high cost of the regulation with stakeholder input, and address affordability issues in a new economic feasibility assessment.

The EPA's environmental justice public meetings identified affordability of water requiring PFAS treatment as a prominent concern. [FN5: Environmental Justice Considerations for the Development of the Proposed PFAS Drinking Water Regulation, Public Meeting Summary – March 2, 2022. EPA Document EPA-HQ-OW-2022-0114-0009] A national cost estimate conducted for AWWA [FN6: Black & Veatch, WITAF 56 Technical Memorandum, PFAS National Cost Model Report (Mar. 7, 2023)] placed the cost of new MCLs for PFOA and PFOS set at 4 ppt to amount to over $3.8 billion annually for community water systems. Extrapolating to estimate annual household costs for removing PFAS from drinking water, the per-household cost ranged from $80 - $105 in the largest category of water systems, to more than $10,000 for water systems serving less than 100 consumers. Household costs even at the high end of population served will make rate increases due to the proposed regulation of PFOA and PFOS very difficult for low-income households to pay. The Hazard Index MCL for the group of four contaminants will presumably increase the number of water systems incurring costs for construction and operation of water treatment, exacerbating the very high cost and adding to an affordability crisis for drinking water.

CA-NV AWWA also comments that EPA has not met its obligation to fully evaluate the economic feasibility of this proposed regulation. First, the regulation lacks sufficient data on occurrence of PFAS in water sources of small systems for its economic analysis, relying instead on assumptions and statistics to cover acknowledged gaps. EPA further failed to conduct meaningful consultation with small business advocates. The U.S. Small Business Administration

Office of Advocacy pointed out in its letter on this docket (April 18, 2023) that "The rule is expected to impose a costly regulatory burden on small entities such as small public water systems."[FN7: Letter from U.S. Small Business Administration Office of Advocacy, accessed at https://www.regulations.gov/comment/EPA-HQ-OW-2022-0114-1505.] Moreover, the letter describes the inadequacy of EPA's consultation:

"In advance of the proposed rule, EPA convened a SBREFA panel to consult with small entity representatives (SERs). EPA presented to the small entities some PFAS background (with only PFOA and PFOS specifically identified) and potential monitoring and reporting rule compliance considerations and treatment and feasibility considerations. EPA, however, did not provide the SERs with the identity of the other four PFAS, any MCL values, any MCLG values and the technical details and analyses supporting these additional elements."[FN8: SBA Office of Advocacy, p. 3.]

EPA Response: Please see section 13.10 in this *Response to Comments* document for the EPA's response to comments on affordability and household level costs. In response to the commenters reference to AWWA's initial cost estimates from March 2023, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the costs of the Hazard Index, please see section 13.3.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter's claim that the EPA failed to conduct consultation with small business entities. For more information, please see section XIII.C of the final rule preamble and section 14.3 of the EPA response in this *Response to Comments* document.

City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043788)

EPA's annualized costs for monitoring and treatment are significantly less than water sector agencies' assessments. In an AWWA study [FN1:Black & Veatch, prepared for American Water Works Association. (2023). WITAF 56 Technical Memorandum, PFAS National Cost Model Report (B&V Project No. 409850). https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemorandum.pdf?ver=202303-14-102450-257], the total National Cost Burden for systems of all sizes for regulatory limit of 4 ppt for PFOA and PFOS (the HI PFAS were not included) was $5.2 billion annually (pg. A-1, while EPA's expected value for the proposed option (4 ppt for PFOA & PFOS, 1.0 HI, 88 FR 18724) was $1.2 billion.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Further, the EPA notes that AWWA has since lowered their cost estimates from the figure quoted in this comment ($5.2 billion annually); that figure appears in an earlier March 2023 version of the B&V report and represents AWWA's understanding of the "national burden" of removing PFOA and PFOS to

4ppt each, not just the NPDWR costs, which AWWA presents separately. Please see section 13.3 of the EPA response in this *Response to Comments* document for more information.

Vermont Rural Water Association (Doc. #1798, SBC-045333)

Pownal Fire District #2, serving 400 people, is a Vermont community water system impacted by PFAS. Treatment costs are still adding up, but so far, over $3 million has been spent on engineering, treatment, and remediation. Pownal has been lucky in that all of the costs have been covered by the industrial site that was responsible for contamination. That is not the case for most of the public water systems that have found PFAS levels exceeding the state's MCL. Site investigations have failed to determine an external potentially responsible party. The public water systems are being held responsible for the investigation and clean-up costs. That, in turn, leads to expensive and time-consuming battles with insurance companies.

Another Vermont community water system impacted by PFAS is Craftsbury Fire District #2, serving 420 people through 64 connections. Since being required to issue a "Do Not Drink" order in December 2021 due to an MCL exceedance, the system has spent over $250,000 on their search for a new water source, but have not located a well with a high enough yield. That cost is seven times their typical annual budget. In addition, Sterling College, a small university with a focus on the environment and sustainability, has experienced declining enrollments as a result of the "Do Not Drink" order impacting the school. Public trust has been lost which has negatively affected the economic health of this community.

The chemical manufacturers that created PFAS compounds should be responsible for their remediation in the environment, including our drinking water. Establishing MCLs places the burden on the public water systems. They are not the source of this contamination, but have been blamed for aquifers contaminated by firefighting training exercises and decades of build-up in septic tanks and leachfields from cleaning products.

For these reasons, on behalf of Vermont's small drinking water systems, we urge you again to carefully consider the economic and social impacts of the proposed federal PFAS regulation. Thank you for considering these comments. Please contact me if you have any questions or need clarification.

Thank you,

Liz Royer

Executive Director

EPA Response: The EPA acknowledges the information provided by the commenter on experiences of water systems in Vermont with PFAS contamination. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for the EPA's response to comments on treatment costs associated with the rule. In response to the commenter's statements regarding the responsibility of chemical manufacturers for remediation costs, please see section 15 of the

EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1624, SBC-043467 in section 14.10 in this *Response to Comments* document.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044665)

II. EPA's cost of compliance estimate significantly understates the cost of compliance and must be corrected and republished.

We believe that EPA's estimate of the cost of compliance with its proposed MCLs for PFAS is upwards of an order of magnitude too low. In fact, EPA's annualized cost figure is so far off the mark that republishing the proposed rule – after considering proposing higher MCLs based upon more accurate cost estimation – is warranted. We fail to understand why EPA did not solicit project cost information from its State partners for affected water utilities across the country. The Agency must consult with its WIFIA and Safe Drinking Water State Revolving Fund Program managers about their experience with PFAS barrier costs. EPA should identify with specificity the projects (including both capital and anticipated operation and maintenance) that (1) have been funded to date, (2) which have been approved for funding through ARPA, Bipartisan Infrastructure Funding, or the SRF Program, and (3) which have been proposed but not yet funded.

EPA must consult the State drinking water primacy agencies about their cost experience and cost projections for PFAS barrier technology installations. The state agencies are the best source for PFAS barrier technology cost information. We believe this essential outreach will cause EPA to significantly increase its cost estimate. EPA's failure to adequately consult its state water agency partners about the cost implications of the proposed MCLs is a fatal error that must be corrected.

EPA presents a total annualized cost estimate of $750M-$1B:

In Table 37, EPA summarizes the total annualized quantified cost of the proposed option at both a 3 percent and 7 percent discount rate expressed in millions of 2021 dollars. The first three rows show the annualized PWS sampling costs, the annualized PWS implementation and administrative costs, and the annualized PWS treatment costs. The fourth row shows the sum of the annualized PWS costs. At a 3 percent discount rate, the expected annualized PWS costs are $769 million. The uncertainty range for annualized PWS costs are $699 million to $862 million. Finally, annualized primacy agency implementation and administrative costs are added to the annualized PWS costs to calculate the total annualized cost of the proposed option. At a 3 percent discount rate, the expected total annualized cost of the proposed rule is $777 million. The uncertainty range for the total annualized costs of the proposed rule is $706 million to $872 million. At a 7 percent discount rate, the expected total annualized cost of the proposed option is $1.211 billion, while the uncertainty range for the total annualized costs of the proposed option is $1.103 billion to $1.353 billion.

88 Fed. Reg. at 18700 (emphasis added).

There are numerous instances of cost estimations by associations, states, consultants, and municipalities that demonstrate that the costs for PFAS barrier technologies far exceed EPA's estimate of $750M to $1B annually.

EPA Response: The commenter claims that the EPA may have underestimated costs by an order of magnitude (i.e., that the rule could cost more than 7.5-12 billion dollars per year to implement) but provides no supporting information or data as to why they think the rule would cost this much per year. Please see section 13.3 of the EPA response in this *Response to Comments* document for the EPA's discussion in response to the commenter's regarding the total national rule costs. In response to the commenter's statements that the EPA must consult and primacy agencies on costs, the EPA received public comment from a commenter representing primacy agencies, as well as numerous individual primacy agencies, and made adjustments to the cost analysis based on their input. The EPA used the most up to date publicly available cost information to support the national costs estimates for the proposed and final rulemakings. The EPA's cost estimates for the final rule have been updated based on public comments received on the proposed rule. These reflect the updates to the cost estimates recommended by many commenters; please see section 13.3.3 of the EPA response in this *Response to Comments* document for the EPA's response to comments on treatment costs and estimates provided in public comments from associations, states, consultants, and municipalities.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044667)

In March of this year, Black & Veatch conducted a national cost assessment on behalf of the American Water Works Association (AWWA) that found that MCLs set at 4 ppt for PFOA and PFOS would trigger $5.2 billion in annualized national costs (capital, O&M, monitoring, etc.) for impacted facilities. [FN1: AWWA, WITAF 56 Technical Memorandum: PFAS National Cost Model Report A-1 (March 2023); Link: https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14-102450-257.] AWWA also found that just the costs to install PFAS barrier technology for PFOA/PFOS removal is above $3.8 billion annually.

The Commonwealth of Pennsylvania formally estimated earlier this year as part of its MCL development that it would cost affected water systems in Pennsylvania more than $121 million annually to comply with Pennsylvania's less stringent MCLs for PFOA (14 ppt) and PFOS (18 ppt). EPA's much lower proposed MCLs will likely result in doubling or tripling the Pennsylvania cost estimate. Extrapolating from Pennsylvania's estimate alone shows how wildly understated EPA's annual cost estimate is and highlights the need for EPA to perform a much more accurate and robust cost assessment.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. This commenter cites AWWA's cost estimates of $5.2 billion annually included in an older version of the B&V report from March 2023. The EPA notes that in their public comments on the proposed rule submitted in June 2023, AWWA submitted lower revised

estimates in that report, of $2.5 to $3.2 billion dollars annually at the 3 and 7 percent discount rates respectively. Furthermore, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. The EPA does not dispute the estimate of costs in Pennsylvania referenced by the commenter; however this figure may not be directly comparable to the EPA's national cost estimates due to difference in discount rates applied and period of analyses for each estimate. The commenter provides no supporting information that the "EPA's much lower proposed MCLs will likely result in doubling or tripling the Pennsylvania cost estimate." Further, PFAS occurrence varies across the country, and the commenter provides no data to support the assumption that costs in Pennsylvania are representative of costs nationally. Please see the EPA response to comment Doc. #1713, SBC-045902 in section 6.8 in this *Response to Comments* document for discussion about how extrapolating from only states with high PFAS occurrence can result in elevated national estimates.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044672)

In light of the above data and information, we urge EPA to withdraw its cost estimate, give strong consideration to the AWWA report, and produce a corrected cost analysis for public comment. In so doing, EPA must obtain data from the state primacy agencies and review their experience in reviewing applications for funding under WIFIA, ARPA, Safe Drinking Water State Revolving Fund Program, and the Bilateral Infrastructure Legislation as to bid prices in general and PFAS barrier technology in particular.

EPA must reconsider its proposal and republish higher MCLs for PFOA and PFOS based upon the significantly – potentially an order of magnitude – higher costs than those identified in its proposed rule. EPA must also consider the complete impracticability of adding 3-6,000 PFAS barrier technology projects over the next 3-5 years on top of the historic number of water plant projects that are currently in process.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. The EPA has thoroughly considered all public comments submitted on the proposed PFAS rule, including comments submitted by AWWA. The EPA incorporated a number of recommendations from public commenters into the agency's cost models that are reflected in the cost analysis for the final rule. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 in this *Response to Comments* document for the EPA's response to AWWA B&V report and a discussion of updates to the cost models. The EPA disagrees with the commenter's recommendation to promulgate less stringent MCLs based on their cost estimates; for more on the EPA's response to comments on the MCLs, please see section 5 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the compliance dates, please see section 12 of the EPA response in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044643)

II. EPA's cost of compliance estimate significantly understates the cost of compliance and must be corrected and republished.

We believe that EPA's estimate of the cost of compliance with its proposed MCLs for PFAS is upwards of an order of magnitude too low. In fact, EPA's annualized cost figure is so far off the mark that republishing the proposed rule – after considering proposing higher MCLs based upon more accurate cost estimation – is warranted. We fail to understand why EPA did not solicit project cost information from its State partners for affected water utilities across the country. The Agency must consult with its WIFIA and Safe Drinking Water State Revolving Fund Program managers about their experience with PFAS barrier costs. EPA should identify with specificity the projects (including both capital and anticipated operation and maintenance) that (1) have been funded to date, (2) which have been approved for funding through ARPA, Bipartisan Infrastructure Funding, or the SRF Program, and (3) which have been proposed but not yet funded.

EPA must consult the State drinking water primacy agencies about their cost experience and cost projections for PFAS barrier technology installations. The state agencies are the best source for PFAS barrier technology cost information. We believe this essential outreach will cause EPA to significantly increase its cost estimate. EPA's failure to adequately consult its state water agency partners about the cost implications of the proposed MCLs is a fatal error that must be corrected.

EPA presents a total annualized cost estimate of $750M-$1B:

In Table 37, EPA summarizes the total annualized quantified cost of the proposed option at both a 3 percent and 7 percent discount rate expressed in millions of 2021 dollars. The first three rows show the annualized PWS sampling costs, the annualized PWS implementation and administrative costs, and the annualized PWS treatment costs. The fourth row shows the sum of the annualized PWS costs. At a 3 percent discount rate, the expected annualized PWS costs are $769 million. The uncertainty range for annualized PWS costs are $699 million to $862 million. Finally, annualized primacy agency implementation and administrative costs are added to the annualized PWS costs to calculate the total annualized cost of the proposed option. At a 3 percent discount rate, the expected total annualized cost of the proposed rule is $777 million. The uncertainty range for the total annualized costs of the proposed rule is $706 million to $872 million. At a 7 percent discount rate, the expected total annualized cost of the proposed option is $1.211 billion, while the uncertainty range for the total annualized costs of the proposed option is $1.103 billion to $1.353 billion.

88 Fed. Reg. at 18700 (emphasis added).

There are numerous instances of cost estimations by associations, states, consultants, and municipalities that demonstrate that the costs for PFAS barrier technologies far exceed EPA's estimate of $750M to $1B annually.

EPA Response: Please see the EPA response to comment Doc #1816, SBC- 044665 in section 13.3 in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044645)

In March of this year, Black & Veatch conducted a national cost assessment on behalf of the American Water Works Association (AWWA) that found that MCLs set at 4 ppt for PFOA and PFOS would trigger $5.2 billion in annualized national costs (capital, O&M, monitoring, etc.) for impacted facilities [FN1: AWWA, WITAF 56 Technical Memorandum: PFAS National Cost Model Report A-1 (March 2023).]. AWWA also found that just the costs to install PFAS barrier technology for PFOA/PFOS removal is above $3.8 billion annually.

The Commonwealth of Pennsylvania formally estimated earlier this year as part of its MCL development that it would cost affected water systems in Pennsylvania more than $121 million annually to comply with Pennsylvania's less stringent MCLs for PFOA (14 ppt) and PFOS (18 ppt). EPA's much lower proposed MCLs will likely result in doubling or tripling the Pennsylvania cost estimate. Extrapolating from Pennsylvania's estimate alone shows how wildly understated EPA's annual cost estimate is and highlights the need for EPA to perform a much more accurate and robust cost assessment.

EPA Response: Please see the EPA response to comment Doc. #1816, SBC-044667 in section 13.3 in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044650)

In light of the above data and information, we urge EPA to withdraw its cost estimate, give strong consideration to the AWWA report, and produce a corrected cost analysis for public comment. In so doing, EPA must obtain data from the state primacy agencies and review their experience in reviewing applications for funding under WIFIA, ARPA, Safe Drinking Water State Revolving Fund Program, and the Bilateral Infrastructure Legislation as to bid prices in general and PFAS barrier technology in particular.

EPA must reconsider its proposal and republish higher MCLs for PFOA and PFOS based upon the significantly – potentially an order of magnitude – higher costs than those identified in its proposed rule. EPA must also consider the complete impracticability of adding 3-6,000 PFAS barrier technology projects over the next 3-5 years on top of the historic number of water plant projects that are currently in process.

EPA Response: Please see the EPA response to comment Doc. #1816, SBC-044672 in section 13.3 in this *Response to Comments* document.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044628)

In light of the above data and information, we urge EPA to withdraw its cost estimate, give strong consideration to the AWWA report, and produce a corrected cost analysis for public comment. In so doing, EPA must obtain data from the state primacy agencies and review their experience in reviewing applications for funding under WIFIA, ARPA, Safe Drinking Water State Revolving Fund Program, and the Bilateral Infrastructure Legislation as to bid prices in general and PFAS barrier technology in particular.

EPA must reconsider its proposal and republish higher MCLs for PFOA and PFOS based upon the significantly – potentially an order of magnitude – higher costs than those identified in its proposed rule. 88 Fed. Reg. at 18700 (emphasis added).

There are numerous instances of cost estimations by associations, states, consultants, and municipalities that demonstrate that the costs for PFAS barrier technologies far exceed EPA's estimate of $750M to $1B annually.

EPA Response: Please see the EPA response to comment Doc. #1816, SBC-044665 in section 13.3 in this *Response to Comments* document.

Plymouth Village Water & Sewer District (Doc. #1827, SBC-044560)

[Please carefully consider the following points to help inform the pending rulemaking on this class of pervasive and persistent PFAS chemicals:]

• EPA has not accurately estimated costs associated with treating PFAS to the proposed MCL. EPA's annualized costs for treatment are $772 million per year, which contrasts with an AWWA estimate of $3.8 billion per year. A growing body of actual cost data indicates EPA's O&M estimates may be even further off, by up to an order of magnitude. It is important that projected and actual costs be accurate to develop an MCL that balances health risk reduction, technical

feasibility, and cost. Reasonable, defensible, and cost-effective MCLs are also required to maintain public trust in both EPA and public water providers.

EPA Response: The commenter claims that the EPA may have underestimated costs by an order of magnitude (i.e., that the rule could cost more than 7.5-12 billion dollars per year to implement) but provides no supporting information or data as to why they think the rule would cost this much per year. Please see section 13.3 of the EPA response in this *Response to Comments* document for the EPA's discussion about response to comments about the costs of the rule. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the MCLs, and consideration of benefits and costs in developing the MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Plymouth Village Water & Sewer District (Doc. #1827, SBC-044555)

The EPA has also pointed out that quantifying the potential benefits is challenging, currently estimated at $908 million to $1.2 billion annually. A study released by the American Water Works Association (AWWA) on March 7, 2023 found that the estimated national cost for water systems to install treatment systems to remove PFOA and PFOS at EPA required levels would exceed $3.8 billion annually. (AWWA PFAS National Cost Model Report)

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the benefits of the rule, please see section 13.4 of the EPA response in this *Response to Comments* document.

Corix Infrastructure Inc. (Doc. #1834, SBC-045362)

Comments

1. The proposal's economic analysis does not seem to adequately recognize or address the costs that the rule will impose on water systems, particularly in light of impending and required capital and regulatory projects, for example, the revised Lead and Copper Revisions and lead service line replacements.

A recent study by Black & Veatch on behalf of the American Water Works Association concluded that the projected costs associated with PFAS treatment at the proposed limits would exceed $47 billion dollars, which is orders of magnitude more than EPA's estimate.

The cost of the technologies to remove PFAS contaminates from drinking water supplies is substantial and far exceeds all the estimates EPA makes in the proposed rule. We recommend and request that EPA consider and rely on the reports prepared by water industry experts that are based on case studies and then re-evaluate how it balances the levels of reductions set with the

cost to achieve those levels. As discussed below, how the technological changes necessary to achieve the levels set by EPA will be financed is a key component of this rulemaking.

EPA should explain its approach to affordability to ensure that funding will be available to achieve the aims of the regulation. Corix urges EPA to recognize with respect to affordability issues and funding that is provided, it is important that these rules and policies apply equally to all community water systems and wastewater treatment systems regardless of whether the systems are publicly or privately owned or operated.

Access to safe, clean drinking water is a necessity and this action by EPA must ensure that this access is affordable and equitable.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document for discussion about the overall costs of the rule and response to comments on the potential impacts of the Lead and Copper Revisions (LCR). The EPA notes that the commenter incorrectly compares AWWA's one-time estimate of costs to the EPA's annualized values, please see section 13.3 of the EPA response in this *Response to Comments* document for more information. Further, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments about federal funding and how it is distributed, please see section 2.4 of the EPA response in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1841, SBC-044838)

EPA Has Significantly Underestimated the Costs of Complying with the Proposed Standards

EPA estimates that the annual cost to public water systems (PWS) of complying with the proposed MCLs would total $764 million to $1.2 billion over 20 years. Although a significant number, comparable to the estimated benefits of the rule, EPA's estimate is well below those developed by the American Water Works Association (AWWA) which totals $5.2 billion annually for just the PFOA and PFOS standards. [FN159: AWWA. WITAF 56 Technical Memorandum: PFAS National Cost Model Report. Black & Veitch (2023). https://www.awwa.org/Portals/0/WITAF56FinalTechnicalMemorandum31423.pdf?ver=2023-03-14-104547- 133 (AWWA WITAF 56)] The disparity is based on EPA's assumptions regarding the number of systems impacted and the costs for those systems to comply.

Regarding the number of systems impacted, EPA estimates that 6.5 percent (4,300) of the nearly 66,000 community water systems (CWSs) and non-transient non-community water systems (NTNCWSs) in the country [FN160: According to EPA's Safe Drinking Water Information System there are just over 49,000 community water systems and about 17,000 non-transient non community water systems active in the US.] will exceed the proposed MCL for PFOA or PFOA, based on a Bayesian hierarchical model using the results of EPA's third Unregulated Contaminant Monitoring Rule (UCMR 3) as the primary data set supplemented with more recent

state data. [FN161: EPA estimates that an additional 10 systems would be impacted by the proposed Hazard Index of 1.0 (USEPA Economic Analysis, at 4-25 Tables 4-18 and 4-19).] Extrapolating from data collected from UCMR 3 and state surveys, on the other hand, AWWA estimates that 12 percent of community water systems (CWS) will be impacted by the proposed MCL for PFOA and PFOS. [FN162: The report notes that the analysis likely underestimates the number of systems impacted since the detection limits for UCMR 3 were above the proposed MCLs. The AWWA analysis does not include NTNCWSs; as a result, comparisons to the EPA analysis are limited to CWSs.]

There also is a significant disparity between the EPA and AWWA estimates of the compliance costs per CWS. EPA's estimate for the annualized per CWS costs are generally an order of magnitude lower than those developed by AWWA. While some of the difference likely results from the assumptions made by the two organizations, the disparity in the estimates, particularly for the smaller systems, raises significant concerns about accuracy of EPA's cost analysis. [FN163: It was not clear whether EPA's economic analysis includes the engineering costs for treatment systems. These costs can be significant for larger systems.]

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. This commenter cites AWWA's cost estimates of $5.2 billion annually included in an older version of the B&V report from March 2023. According to the March 2023 version of the report, that figure represents AWWA's understanding of the "national burden" of removing PFOA and PFOS to 4ppt each, not just the costs associated with compliance with the NPDWR, which AWWA presents separately. The EPA notes that in their public comments on the proposed rule submitted in June 2023, AWWA submitted lower revised estimates in that report, of $2.5 to $3.2 billion dollars annually at the 3 and 7 percent discount rates respectively. Furthermore, the EPA disagrees with many of the assumptions in AWWA's B&V report, including the representation of occurrence and capital costs, as well as the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the national occurrence model, please see section 6.5 of the EPA response in this *Response to Comments* document.

Paul Eldredge (Doc. #2770, SBC-047457)

A Government Accountability Office (GAO) study of drinking water data collected from six states showed at least 18% of 5,300 water systems studied had PFOA and/or PFOS exceeding the proposed MCLs of 4 ppt alone. Levels of initial noncompliance may be even higher than anticipated due to sampling bias since the proposed limits are the lowest level many laboratories can reliably detect, and some systems have not already pursued such sensitive testing for all six chemicals listed.

USD urges EPA to conduct a fuller analysis that more accurately captures the costs of compliance and if necessary, collect more data to inform and address the gaps that currently

exist. This should be a reasonable request given that the agency caveated its own work in the posting by listing a host of data limitations and uncertainties from a lack of modeling national costs for treatment associated with potential Hazard Index exceedances.

These levels are significantly lower than any state has proposed for PFAS chemicals, which would seem to indicate that even states highly concerned with PFAS contamination have arrived at different conclusions than EPA with regard to the cost and benefit analysis. Analysis fundamental to the 1996 amendments to the SDWA, require a detailed risk and cost assessment, and best available peer-reviewed science, when developing standards. These requirements may imperil the financial sustainability and affordability of some water systems, which will warrant greater assistance in terms of funding. To not clarify the extent of these costs now would be a grievous mistake as water systems and governments across all levels budget for the future and may be forced into competing for limited federal dollars.

EPA Response: Please see section 13.3 in this *Response to Comments* document for the EPA's response to comments on the total national costs of the rule and section 13.3.3 in this *Response to Comments* document for the EPA's response to comments on the treatment costs associated with the rule. For the EPA's response to comments citing the Government Accountability Office (GAO) report mentioned by the commenter, please see the EPA response to comment Doc. #1729, SBC-043576 in section 6.5 in this *Response to Comments* document. In response to the comment regarding the proposed and final MCLs, please see section 5 of the EPA response in this *Response to Comments* document. In response to the commenter's mention of the EPA's data limitation documentation in the EA, in the interest of transparency, it is best practice to identify known data limitations and uncertainties in the analyses. Identification of uncertainties is also required by SDWA Section 1412(b)(3)(C)(i)(VII). For the EPA's response to comments on the costs associated with the Hazard Index specifically, please see section 13.3.2 of the EPA response in this *Response to Comments* document. In regard to the commenter's assertion that "…even states highly concerned with PFAS contamination have arrived at different conclusions than EPA with regard to the benefit/cost analysis," the commenter provides no detail or references to support this statement. While no specific references were given, potential differences in conclusions could arise from differences in number entities included in the analysis, baseline levels of PFAS contamination, estimation of health risk reduction benefits, and the estimation of costs.

<u>The ELAM Group (Doc. #3072-61, SBC-046377)</u>

Thank you, Rob. My name is James Hogan. I'm the president and CEO of the Environmental Liability and Asset Management Group. Our environmental consulting firm specializes in provisioning environmental liability. We participate in the ASTM standards for developing lifecycle costs associated with environmental liability. We find critical elements of any lifecycle includes asset, retirement obligations, site characterization, treatment remediation, waste disposal, and closure. We understand this is a very important juncture given that MCLs are enforceable and represent the highest level of a contaminant that is allowed in drinking water

based on a cost-benefit analysis. I urge the U.S. EPA to critically evaluate its own cost-benefit analysis with a particular focus on its variables that are most sensitive to significant cost variation. These variables must be singled out and thoroughly vetted prior to finalization of this rule or the U.S. EPA will have failed the public in upholding the very definition of an MCL. Thank you.

EPA Response: This comment lacks sufficient detail to incorporate this suggestion into the analysis. The EPA has considered the quantifiable and non-quantifiable uncertainties in the cost analysis, for more information see Chapter 5 of the EA. See also section 13.3.3 of the EPA response in this *Response to Comments* document.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043481)

EPA Has Underestimated the Challenges in Reaching These Levels

Farmers, ranchers and other agricultural producers support a national drinking water standard for PFOA and PFOS and other PFAS chemicals based on science and an evaluation of risk— to replace the current patchwork of state requirements. However, it is critical that EPA gets this right. The costs that the proposed rule will impose are significant, and likely underestimated. The proposed MCLs must be changed to ensure firm scientific backing and consideration of the potentially enormous financial burdens imposed, as the statute requires.

The U.S. Chamber of Commerce has done an extensive review of the proposed cost-benefit analysis that highlights many of our shared concerns. The costs associated with this rule have not been accurately calculated for a variety of reasons, which the U.S. Chamber of Commerce has expounded upon in more detail in their comments.

EPA Response: The EPA disagrees with the U.S Chamber of Commerce's estimate of costs, please see the EPA response to comment Doc. #1537, SBC-042649 in section 13.3.3 in this *Response to Comments* document. Further, the comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. See also section 13.3.3 of the EPA response in this *Response to Comments* document.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044769)

Separately, WDEQ is concerned with EPA's use of the relatively limited UCMR 3 data and limited state-provided data to estimate PFAS occurrence and concentrations within PWSs and apply those estimates to the cost-benefit modeling and timeframes anticipated for PWSs to reach compliance under the proposed PFAS NPDW rule. The proposed rule provides some exemptions for PWSs serving a population under 3,300 and for PWSs that need financial assistance for necessary improvements. However, WDEQ is concerned that even with these exemptions, it is not financially feasible for the 379 PWSs in Wyoming that serve a population under 3,300 people to implement any necessary modifications to their infrastructure. Due to the ubiquitous nature of PFAS in the environment, the necessary supplementation of source water from lakes, reservoirs,

rivers, and groundwater, and the proposed MCL concentrations, Wyoming is concerned that a majority of PWSs in Wyoming may need to make costly updates to their infrastructure to maintain compliance under the SDWA.

EPA Response: For the EPA's response to comments on the use of UCMR 3 data, state data, and the national occurrence model, please see sections 6.1, 6.2, and 6.5, respectively, of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the feasibility determination for the final rule, please see section 5 of the EPA response in this *Response to Comments* document. With respect to timeframes provided for compliance, please see section 12 of the EPA response in this *Response to Comments* document.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-052833)

Another concerning reference comes from estimates made by the Commonwealth of Pennsylvania, which estimated it would cost affected water systems in Pennsylvania over $121 million annually to comply with significantly higher MCLs for PFOA (14 ppt) and PFOS (18 ppt) under that state's requirements. The fact that this one state accounts for 10 percent of EPA's estimated total annual cost to the Nation, and that this one state prepared its estimate using significantly less stringent MCL values (high concentrations), tends to confirm the AWWA estimate and cast significant additional doubt on the accuracy of the EPA's earlier estimate.

EPA Response: The estimated costs from the Commonwealth of Pennsylvania may not be directly comparable to the EPA's national cost estimates due to difference in discount rates applied and period of analyses for each estimate. Further, PFAS occurrence varies across the country, and the commenter provides no data to support the assumption that costs in Pennsylvania are representative of costs nationally. Please see sections 13.3.3 and 13.3 of the EPA response in this *Response to Comments* document.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-052843)

Another concerning reference comes from estimates made by the Commonwealth of Pennsylvania, which estimated it would cost affected water systems in Pennsylvania over $121 million annually to comply with significantly higher MCLs for PFOA (14 ppt) and PFOS (18 ppt) under that state's requirements. The fact that this one state accounts for 10 percent of EPA's estimated total annual cost to the Nation, and that this one state prepared its estimate using significantly less stringent MCL values (high concentrations), tends to confirm the AWWA estimate and cast significant additional doubt on the accuracy of the EPA's earlier estimate.

EPA Response: Please see the EPA response to comment Doc. #1657, SBC-052833 in section 13.3 in this *Response to Comments* document.

13.3.1 Primacy Agency costs

Summary of Major Public Comments and EPA Responses

Many commenters state that the EPA has underestimated the costs to primacy agencies required to comply with the rule. One commenter stated, "EPA's analysis of primacy agency costs does not accurately capture all the activities that primacy agencies will undergo for PFAS implementation and underestimates the number of hours for the primacy tasks." Commenters recommend that the EPA use findings from the Association of State Drinking Water Administrators (ASDWA)'s PFAS Cost of State Transactions Study (PCoSTS) to reevaluate the primacy agency costs estimated in the EA (ASDWA, 2023). The EPA's response to specific recommendations is discussed below.

The EPA agrees with commenters on the burdens associated with regulatory start up; primacy package adoption; technical, managerial and financial (TMF) assistance to water systems; and reviewing and approving treatment. Commenters pointed out activities not explicitly accounted for in the regulatory start up estimate in the EA for proposal including accreditation of laboratories for PFAS testing; SDWIS updates; monitoring schedule updates; time spent responding to questions from members of the public; inquiries from public officials; and media requests immediately following the final publication of the NPDWR. Commenters also pointed out that adopting primacy packages is a significant undertaking with "specific and very detailed administrative procedures that must be adhered to in order to adopt water quality regulations" and that "some primacy agencies have requirements for robust public comment periods as a component of new rule adoption." As recommended by commenters, the EPA created a new cost item for primacy package adoption. Commenters stated the EPA's assumption in the proposal that the amount of time a primacy agency will need to review treatment plans directly correlates with the size of the water system was inaccurate. Commenters noted that "…small systems often take the most time as they need significant assistance to navigate the process for the design and construction of new treatment and get into compliance." After considering these comments, the EPA agrees that reviewing and approving treatment for small systems is likely to take more time given the assistance needed for these systems. Because small systems often lack the technical, managerial, and financial capacity, it is likely that primacy agencies will spend more time assisting these systems in navigating compliance with the PFAS NPDWR. As such, the EPA adjusted burden estimates in the final rule to reflect the largest primacy agency burden per EPTDS at the smallest systems and decreased burden hours with increasing system size, as commenters suggested.

Several commenters disagreed with the EPA's exclusion of additional costs to primacy agencies associated with reporting regarding violations, variances and exemptions, enforcement actions, and other compliance related primacy agency activities in the national cost analysis. One commenter estimated the PFAS NPDWR will likely result in hundreds of violations once in effect. The EPA recognizes that these activities do have an associated burden for primacy agencies but disagrees that these costs should be included in the EA. The EPA assumed 100 percent compliance for its national level analysis in the EA for the final rulemaking because the

EPA has determined that the final rule is feasible given known occurrence concentrations and efficacy of the technologies available. Further, this is consistent with the approach taken in EAs for other NPDWRs (USEPA, 2005a; USEPA, 2019; USEPA, 2020a). Commenters recommended that the EPA include hours for additional annual reporting. The EPA disagrees and expects that adding PFAS results to already-required reports will have no discernable incremental burden for quarterly or annual reports to SDWIS Fed.

Commenters recommended that the EPA include the costs associated with various compliance activities. Given the EPA's assumption discussed above, the EPA disagrees and did not take commenters' recommendations to include the costs associated with assisting out of compliance systems and assisting systems to remain in compliance, pursuing enforcement actions, staff time checking in with system violations and reviewing system variances and exemptions. The EPA did include the costs associated with compliance activities for systems in compliance, including updating inspection standard operating procedures (SOPs) and additional sanitary survey burden at water systems that have installed treatment to comply with the PFAS NPDWR.

Several commenters suggested that the EPA underestimated the level-of effort for primacy agencies to provide training to PWSs. They pointed out that one full-time staff could not provide in-person training at each PWS. The EPA disagrees with this as training does not need to be provided in person at each PWS. Virtual sessions, or regional training sessions, where training is provided to many PWS at once, are feasible. After considering all public comments, the EPA used the estimate in the PCoSTs model related to average hours per primacy agency to provide initial training and technical assistance to systems.

Some commenters stated that the EPA's estimate of 4 hours for a primacy agency to review and consult with systems on the installation of treatment technology or alternative methods, including source water change was too low. Most of these commenters did not provide a recommended number of hours for the EPA to consider instead. One commenter provided an estimated range from 8 to 40 hours, depending on source water type. Another recommended the EPA increase the estimate to 8 hours per water system. The EPA appreciates the estimates provided by these commenters; however, the EPA decided to retain the estimates used in the proposal, consistent with the estimate included in the EPA's EA for LCRR. The EPA retained the original estimate because the EPA determined that the four hours represents a reasonable estimate of the national average. The EPA recognizes that some states may take longer, and others may take less than 4 hours on average. The EPA does not have enough data submitted by commenters or otherwise available to update the national average estimate.

After considering public comment, the EPA's estimated burden hours for many primacy agency activities increased significantly and had an upward effect on the cost estimates. However, after considering public comment, the EPA also made changes to the monitoring requirements and introduction of annual monitoring, (please see section VIII of the preamble for this rulemaking and section 8 of the EPA response in this *Response to Comments* document for more information). These changes, which will reduce monitoring burden overall, also had a downward effect on estimated amount of time primacy agencies would spend reviewing monitoring results.

The introduction of annual monitoring significantly reduced the amount of water systems estimated to taking quarterly samples continuously, and therefore reduced the amount of time primacy agencies would spend reviewing sample results. The net effect is that the agency's estimates of the final rule annualized primacy agency costs decreased compared to the proposed rule estimates.

Individual Public Comments

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044953)

15. Although private wells are excluded from SDWA, they still present challenges for primacy agencies. Private well owners will place an increased demand for analytical services that will further strain analytical capacity. In addition, private well owners will also place demand for carbon media, resins and membranes. To meet the public health concerns raised by PFAS in community groundwater coming from waste sites, landfills, industries and various sources (including septic systems), NYS has already expended more than $30 million on assistance to private well owners for testing and mitigation of PFOA and/or PFOS based upon mitigation when private wells in an investigation area have results above the NYS MCL of 10 ppt separately for each. This number does not include $80M+ that NYS has spent to address both private and public water supplies in the City of Newburgh and Town of New Windsor. Should this public health protective target be reduced further there will be a substantial increase in costs to mitigate the widespread occurrence of PFOA/PFOS below 10 ppt in community groundwater. While EPA may have infrastructure funding targeted for this need, it is not clear that the Agency is aware of the magnitude of the anticipated need in this area.

While many homes with private well contamination may be able to connect to a public water supply, many homes will not, and will instead seek mitigation of their private water supplies. DEC has been providing Point of Entry Treatment (POET) in many areas of the State affected by PFAS contamination. Installation of each POET is approximately $4,000 inclusive of design services and labor and an operation and maintenance cost of $1 ,500 per POET annually. These costs are reflective of bulk purchase and installation scenarios,

EPA Response: As the commenter correctly notes, the EPA does not regulate drinking water wells that serve fewer than 25 persons, often referred to as "private wells;" nor does it provide recommended criteria or standards for such wells. The EPA offers information regarding the importance of testing these wells and guidance on technologies that may be used to treat or remove any contaminants. While the EPA does not dispute that primacy agencies may incur costs associated with PFAS in unregulated drinking water wells, those costs should not be included in the EA as they are not a direct result of this regulation, but rather, an activity undertaken by primacy agencies at their discretion or to meet their individual state requirements. The EPA notes that SDWA Section 1412(b)(3)(C)(i)(III) requires that the EPA include quantifiable and non-quantifiable costs that are likely to occur s*olely as a result of compliance with the rule* including monitoring, treatment and other costs and excluding costs resulting from compliance with other proposed or promulgated regulations (emphasis added). Therefore, it would be inappropriate for

the EPA to estimate costs for activities that are not directly mandated by the PFAS NPDWR itself. For the EPA's response to comments on laboratory and treatment technology demand and capacity, please see sections 8.7.2 and 10.6, respectively, of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044434)

EPA requests comment on whether factors such as anticipated Federal funding, the structure of PWSs relative to private enterprises, or the nature of the public health benefits should be further explored in the final rule analysis, including as it relates to the estimated range of impacts under the applied discount rates.

• Increased tracking for HI MCL calculations, increased compliance, and increased planning and project reviews for potentially 20% of PWSs will require significant resources to successfully implement. It is unclear if these costs were considered in the cost estimates of the PFAS rule.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document and Chapter 5 of the EA for discussion about costs anticipated to be incurred by primacy agencies.

Missouri Department of Natural Resources (Doc. #1563, SBC-042524)

EPA seeks comment on its PFOA and PFOS evaluation of feasibility for the proposal, including analytical measurement and treatment capability, as well as reasonable costs, as defined by SDWA.

The Department agrees with comments from the Association of State Drinking Water Administrators (ASDWA) that EPA has grossly underestimated the costs for the proposed PFAS Rule. The Department recommends EPA re-evaluate the cost estimates borne by state agencies using ASDWA's PFAS Cost of State Transactions Study (PCoSTS) Model.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document for discussion about costs to primacy agencies. Based on public comments, including the information provided in the PCoSTS model, the EPA has increased estimated burden hours for many primacy agency activities significantly which had an upward effect on the cost estimates.

Lakewood Water District (LWD) (Doc. #1574, SBC-042751)

Implementation Costs

We were struck by the dramatic underestimation of the level of effort needed to stand up the systems and organizations needed to implement these proposed PFAS regulations. Table 36 is a standout example of this underestimation.

Table 36 suggests that a Primacy Agency (such as we have here in Washington State) could "…read and understand the rule, as well as adopt regulatory requirements" (emphasis added) with 416 hours of staff time. This estimate is so low that it must be a clerical error.

In order to adopt regulatory requirements, most states (like Washington state) have specific and very detailed administrative procedures that must be adhered to in order to adopt water quality regulations. The required administrative procedures at the state level are not unlike the procedures that the EPA is following for the development of its PFAS rules. Rulemaking at the state level takes months and requires massive amounts of specialized staff time, many times the 416 hours shown in Table 36.

Table 36 also suggests that a Primary Agency could "…provide initial training and technical assistance to systems" with 2080 hours of staff time. 2080 hours is one Full Time Equivalent employee. Washington State (which is not unique in this regard) has over 2,400 water systems that will be covered by this proposed rule. 2080 hours means less than 1 hour of "training and technical assistance" would be provided per system. This is totally unrealistic.

These are but two examples of gross underestimation of implementation costs. EPA must revisit these cost estimates to update them to more realistic numbers.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document about costs to primacy agencies and the EPA's revisions to the cost analysis for the final rule. Based on public comments, the EPA has increased estimated burden hours for many primacy agency activities increased significantly and had an upward effect on the cost estimates. The resulting cost estimates for primacy agencies reflect the best available information.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043047)

EPA Analysis of Primacy Agency Costs

DEQ recommends that EPA reevaluate the primacy agency costs portion of the preamble.

EPA's analysis of primacy agency costs does not accurately capture all the activities that primacy agencies will undergo for PFAS implementation and underestimates the number of hours for the primacy tasks.

Timelines for reviewing and approving treatment technologies have been underestimated in the proposal. In addition to reviewing and approving engineering reports and construction design plans for treatment, states will also need to review and approve pilot tests needed to ensure treatment efficacy of the selected treatment technology.

Mandatory reporting, enforcement actions, and general operations of State PWS programs will incur additional state staff time.

DEQ recommends EPA consider technical assistance in its multiple components.

EPA's estimates and assumptions regarding the amount of technical assistance that will be needed for systems to come into compliance is underestimated. Multiple components of technical assistance include those listed below.

• In-person training that will involve time to develop workshop materials, as well as significant travel time depending on the location of the systems.

• Extensive outreach activities related to achieving compliance by small and disadvantaged communities

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document about costs to primacy agencies. Based on this and other public comments, the EPA has increased estimated burden hours for many primacy agency activities, including reviewing and approving treatment plans including pilot study results, which has had an upward effect on the cost estimates. Regarding initial training and technical assistance, for the cost analysis for the final rule, the EPA used an estimate 1,500 hours per primacy agency, as recommended by another commenter and included in the PCoSTS model. In response to the commenter's reference to outreach activities specifically for small and disadvantaged communities, the EPA notes that while this is encouraged, it is not required by the rule. The EPA also notes that the EPA's free Water Technical Assistance (WaterTA) services support communities to identify water challenges, develop plans, build capacity, and develop application materials to access water infrastructure funding. The EPA collaborates with states, Tribes, territories, community partners, and other key stakeholders to implement WaterTA efforts, for more information see https://www.epa.gov/water-infrastructure/water-technical-assistance-waterta#:~:text=What%20is%20WaterTA%3F,to%20access%20water%20infrastructure%20funding. For more information regarding this program and other available funding, particularly for small and disadvantaged communities, please see section 2.4 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044069)

Implementing this rule will require considerable staff resources from primacy agencies already burdened by new priorities in addition to the typical Safe Drinking Water Act (SDWA) implementation programs. ASDWA's PCoSTS estimates that the primacy agency staff time required for the first year of rule implementation, which includes one-time activities such as regulatory start-up and review and approval of water system treatment plans, will be 1,039,750 hours. At the state and local hourly government employee rate of $57.60 based on the U.S. Bureau of Labor Statistics, the first year of implementation will cost primacy agencies $59,889,624.

ASDWA's model also estimates the primacy agency staff time in subsequent years for annual implementation activities, such as reporting, compliance, and technical assistance. Following the first year of implementation, ASDWA estimates the proposed rule will require 325,850 hours of staff time at a cost of $18,768,960 annually. Combining the cost of the first year of

implementation with four subsequent years of annual rule requirements (for a total of 2,343,150 staff hours), ASDWA's model estimates that the proposed NPDWR will increase primacy agency staff hours by roughly 469,000 hours annually in its first five years of implementation, translating to an annual cost of approximately $27 million.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document. For the EPA's revised national primacy agency cost estimates see Chapter 5 of the EA. Further, as detailed in section XIII of the FRN for the final rule, during the initial three-year period, primacy agencies will incur burdens associated with one-time startup activities. The burden associated with reading and understanding the rule, adopting the regulatory requirements, and training internal staff is estimated to be an average of 4,320 hours per primacy agency. The burden associated with primacy agency review of initial monitoring data is 73,000 hours. The total burden for these activities, for the three-year period, for all 56 primacy agencies is estimated to be 399,000 hours. The estimate provided by the commenter is not directly comparable to the EPA's because the EPA's Information Collection Request (ICR) estimates focuses solely on burdens incurred in the first three years of after rule promulgation. Therefore, the primacy agency burden hours associated with reviewing and approving treatment, a significant component of both the EPA's and this commenter's estimate of the overall burden associated with the rule, is not included in the EPA's ICR burden hours estimate.

Regarding the total primacy agency monetized burden estimates, for modeling purposes, the EPA assumes all primacy agency activities associated with reviewing and approving treatment occur in year 5 of the analysis. As seen in the EPA's undiscounted costs estimates over the period of analysis, the EPA estimates approximately $6.5 million in each of the first three years of the analysis associated with implementation and start up totals approximately $19.5 million.The EPA's estimate is lower to this commenter's estimate that the first year of implementation will cost primacy agencies $59,889,624. The commenter's estimate is likely higher because it appears to include burdens associated with activities that the EPA has determined are not appropriate for inclusion in the EPA's cost analysis, such as compliance activities (please see section 13.3.1 of the EPA response in this *Response to Comments* document for the EPA's response to comments on consideration of compliance and violations related burden for primacy agencies in the EA).

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044120)

APPENDIX A:

PFAS Cost of State Transactions Study (PCoSTS)

ASDWA developed a PFAS Cost of State Transactions Study (PCoSTS) [Link: https://www.asdwa.org/wp-content/uploads/2023/05/PCoSTS-Final.pdf] as an independent analysis of the primacy agencies' burden for EPA's economic analysis developed for the proposed PFAS National Primary Drinking Water Regulation. The goal of this study was to provide a national annualized estimate of primacy agency staff time for PFAS rule implementation, with the exception of information on regulatory start-up activities for the first

year. The individual agency workload will differ with each primacy agency, and the study serves as a national average of primacy agency workload.

ASDWA staff worked with its PFAS State Resources subgroup and PFAS Economic Analysis subgroup to divide the proposed rule into five tabs that categorize workload by the following activities:

• Regulatory Start-Up,

• Annual Reporting,

• Water System/Operator Technical, Managerial, and Financial Assistance and Training,

• Reviewing and Approving Treatment, and

• Compliance.

Within each tab are assumptions of activities that are included in the correlated tab estimations, specifically the hours each (Hours Ea.) columns.

Regulatory Start-Up

As previously stated, this is the only tab that estimates hours for the first year of

implementation. The remaining tabs estimate the annual time for the transactions that primacy agencies will undertake under the current proposal. Within this tab, the estimates focus on the activities associated with the preparation of the proposed new rule. For example, these start-up actions include the development of training materials and the training of primacy agency staff, creating and modifying existing reports, lab accreditation, and hosting meetings for the general public.

This tab estimates the time associated with annual reporting. Some of the estimates within this tab include enforcement actions and reporting violations to EPA and responding to EPA's requests on system-specific issues.

Water System/Operator TMF Assistance and Training

The estimates in this tab are for the time primacy agencies will spend answering operator questions and assisting systems with funding applications.

Reviewing and Approving Treatment

This tab is broken down by system size based on an estimation of the percentage of systems needing additional treatment for compliance. This tab focuses on the workload associated with reviewing and approving treatment and includes items such as consulting utilities on source water changes, assisting with building infrastructure, and review of pilot projects.

Compliance

This tab focuses on the workload that includes assisting out-of-compliance systems and helping systems remain in compliance, as well as pursuing enforcement actions and reviewing system specific variances and exemptions.

[Figure: See Docket ID EPA-HQ-OW-2022-0114-1628]

The $57.60 hourly rate comes from the U.S. Bureau of Labor Statistics and includes both salaries/wages and benefits [FN2: U.S. Bureau of Labor Statistics. (2023, March 27). Compensation costs for civilian workers averaged $42.48 per hour worked in December 2022. TED: The Economics Daily. Accessed May 22, 2023 from Compensation costs for civilian workers averaged $42.48 per hour worked in December 2022 : The Economics Daily: U.S. Bureau of Labor Statistics (bls.gov); Link: https://www.bls.gov/opub/ted/2023/compensation-costs-for-civilian-workers-averaged-42-48-per-hour-worked-in-december-2022.htm]. Combining the cost of the first year of implementation with four subsequent years of annual rule requirements (for a total of 2,343,150 staff hours), ASDWA's model estimates that the proposed NPDWR will increase primacy agency staff hours by roughly 469,000 hours annually in its first five years of implementation. This translates to an annual cost of almost $27 million.

[see docket ID EPA-HW-OW-2022-0114-1628]

Appendix B. Comments by ASDWA For the Proposed PFAS NPDWR

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document for how the agency has increased about costs to primacy agencies. Based on this and other public comments, the EPA has increased estimated burden hours for many primacy agency activities, including regulatory start-up and primacy package adoption, water system operator training, and reviewing and approving treatment, and as recommended by the commenter, which had an upward effect on the cost estimates. Please see section 13.3.1 of the EPA response in this *Response to Comments* document for the EPA's response to commenter recommendations to include costs associated with compliance in the EA.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044062)

2. ASDWA recommends that EPA utilize findings from ASDWA's PFAS Cost of State Transactions Study (PCoSTS) [Link: https://www.asdwa.org/wp-content/uploads/2023/05/PCoSTS-Final.pdf] to reevaluate the primacy agency costs portion of the preamble and economic analysis to better reflect the true state burden. EPA's estimate for state staff time for rule adoption, treatment review and approval, mandatory reporting, and review of source water changes is inaccurate and underestimated. In particular, the Agency has unrealistic expectations for the considerable time that primacy agencies will spend providing technical assistance to water systems. Gaining an improved understanding of primacy agency costs will assist EPA to identify revisions to improve rule feasibility and reduce these costs.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document for how the agency has increased about costs to primacy agencies. Based

on this and other public comments, the EPA has increased estimated burden hours for many primacy agency activities increased significantly and had an upward effect on the cost estimates. As discussed in section 13.3.1 of the EPA response in this *Response to Comments* document, after considering public comment, the EPA has also finalized an annual compliance monitoring option for lower risk systems which will reduce system and primacy agency long-term burden. Please see section 8 of the EPA response in this *Response to Comments* document for further discussion of monitoring requirements.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044116)

ASDWA recommends that EPA update the proposal's economic analysis to better capture the burden on the state workforce with respect to the review and approval of PFAS treatment technologies.

Timelines for reviewing and approving treatment technologies have been underestimated in the proposal. In addition to reviewing and approving preliminary engineering reports (PER) and construction design plans for treatment technologies installed to maintain compliance with this rule, primacy agencies will also need to review and approve the pilot tests needed to ensure treatment efficacy of the selected BAT. Some primacy agencies may have limited experience with some of the BAT or may not have approved the technology for PFAS; as such, timelines for review and approval of these technologies are not as straightforward as what was presented in the proposal. EPA should continue research on small scale treatment technology and provide guidance for primacy agencies to alleviate this feasibility concern.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document about costs to primacy agencies. Based on this and other public comments, the EPA has increased estimated burden hours for many primacy agency activities increased significantly and had an upward effect on the cost estimates. Additionally, for the EPA's response to comments about guidance associated with the PFAS rule, please see section 1.2 of the EPA response in this *Response to Comments* document. For the EPA's response to comments about continuing agency efforts to address PFAS, including additional research, please see section 2.5 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044076)

Primacy Agency Staff and Resource Burden

EPA Analysis of Primacy Agency Costs

ASDWA has developed a PFAS Cost of State Transactions Study (PCoSTS) [Link: https://www.asdwa.org/wp-content/uploads/2023/05/PCoSTS-Final.pdf] as an independent analysis of the primacy agencies' burden to help inform EPA's economic analysis developed for the proposed PFAS drinking water regulation (Appendix A). ASDWA recommends that EPA

utilize findings from ASDWA's analysis to reevaluate the primacy agency costs portion of the preamble and economic analysis to reflect the primacy agency burden accurately.

EPA's analysis of primacy agency costs does not accurately capture all the activities primacy agencies will undergo for PFAS implementation. Additionally, the Agency's analysis underestimates the number of hours for the primacy agency tasks. ASDWA recommends that EPA utilize ASDWA's PCoSTS model to reevaluate the primacy agency costs portion of the preamble to better reflect the true burden as detailed below.

ASDWA's PCoSTS model estimates the primacy agency staff time required for the first year of rule implementation, which includes one-time activities such as regulatory start-up and review and approval of water system treatment plans. ASDWA estimates that the first year of implementation for the proposed PFAS drinking water regulation will require 1,039,750 hours of primacy agency staff time. At the state and local hourly government employee rate of $57.60 based on the U.S. Bureau of Labor Statistics, this will cost primacy agencies $59,889,624. ASDWA's model also estimates the primacy agency staff time that will be required for subsequent years for annual regulatory activities, such as reporting, compliance, and technical assistance. Subsequent years following the first year of implementation will require 325,850 hours of staff time at a cost of $18,768,960 annually.

Combining the cost of the first year of implementation with four subsequent years of annual rule requirements (for a total of 2,343,150 staff hours), ASDWA's model estimates that the proposed NPDWR will increase primacy agency staff hours by roughly 469,000 hours annually in its first five years of implementation. This translates to an annual cost of approximately $27 million.

EPA underestimates the time for each primacy agency to read and understand the rule and adopt regulatory requirements. The time needed to adopt regulatory requirements will vary greatly across the country. Some primacy agencies have requirements for robust public comment periods as a component of new rule adoption. Additionally, primacy agencies may need to accredit laboratories for PFAS testing, which will increase the amount of staff resources needed for implementation. Primacy agency staff will also need to create or modify existing reports, such as the Consumer Confidence Report (CCR), Safe Drinking Water Information System updates, and monitoring schedule updates. Finally, this estimate does not consider the amount of time primacy agency staff will spend responding to questions from members of the public, inquiries from public officials, and media requests immediately following the final publication of the NPDWR. ASDWA estimates 210,700 hours for primacy agency staff working on the regulatory start-up of this proposal, with an associated cost of $12,136,320.

EPA's analysis assumes that the amount of time a primacy agency will need to review treatment plans directly correlates with the size of the water system, and this assumption is inaccurate. ASDWA's members have reported that small systems often take the most time as they need significant assistance to navigate the process for the design and construction of new treatment and get into compliance. Primacy agencies often work with these communities to locate consultants for preliminary engineering reports (PERs), develop construction plans and

specifications, help obtain funding, and manage construction. Additionally, this assistance often goes beyond just the construction of the treatment and start-up as systems work to remain compliant. Assistance with operation and maintenance (O&M) is often required. ASDWA's model estimates 503,200 hours costing $28,984,344 for treatment review and approval, with the vast majority of hours and dollars used addressing small systems.

EPA's assumption that the mandatory reporting regarding violations, variances and exemptions, enforcement actions, and general operations of primacy agency programs will not incur any additional primacy agency staff time is inaccurate. The proposal is a new regulation that will impact several thousand systems and likely result in hundreds of violations once the rule goes into effect. Each of those violations and the actions needed to return these systems to compliance will take additional time and effort. Additionally, primacy agencies anticipate that their staff will have to spend significant time working with water systems to develop and maintain monitoring schedules, particularly because the level needed for reduced monitoring is below the PQL. Although EPA plans to provide a public tool for systems to determine their Hazard Index, ASDWA's members anticipate many of these systems will still go to their primacy agencies for assistance. ASDWA estimates 245,000 staff hours will be dedicated to compliance at a cost of $14,112,000.

EPA's estimate for the primacy agencies to review source water changes, four hours, is inaccurate. Changing sources has treatment design considerations and typically have significant implications on finished water quality, such as corrosion control, disinfection by-products, disinfectant residual, etc., that must be carefully considered. This analysis of the potential for unintended consequences from source changes will take significantly longer than four hours.

EPA's estimates do not appropriately consider the primacy agency staff time needed to implement pilot testing for new treatment. Staff review time will be needed for both the design of the pilot as well as all the pilot testing data, ranging from a desktop analysis to bench-scale testing to a full pilot plant. This staff time should be appropriately captured in EPA's final estimates.

ASDWA's PCoSTS model details the increased staff resources for rule implementation. State drinking water programs are already hard-pressed financially. Ongoing regulatory oversight to ensure compliance is constant, and several proactive actions such as addressing cyanotoxins and providing oversight for the development of lead service line inventories, have increased states' workloads. States consistently step in to help solve problems and return systems to compliance as quickly as possible.

State-provided funding has historically compensated for inadequate federal funding, but state budgets have been variable for the past few years, given the COVID-19 pandemic and other economic issues. These increases in primacy agency responsibilities should be met with a corresponding increase in the Public Water System Supervision (PWSS) Grant Program, recognizing EPA's limited ability to influence Congressional PWSS appropriations. Without the additional PWSS funding, primacy agencies will have to make tough decisions on prioritizing

support to existing programs. Limitations on primacy agency resources result in fewer opportunities to work individually with water systems to improve compliance and protect public health. Insufficient federal support for the PWSS program increases the likelihood of scenarios that put the public's health at risk.

ASDWA recommends EPA split "technical assistance" into multiple components.

EPA's estimates and assumptions regarding the amount of technical assistance that will be needed for systems to come into compliance are underestimated. As previously discussed, small systems will need extensive assistance, but even medium and large systems will need support. Some primacy agencies have reported regularly getting in-person training requests from all sizes of water systems. These requests result in primacy agency staff driving across the state to conduct training for the system's employees. Primacy agencies have received feedback from operators that they prefer in-person training and find them more effective than online training for complex issues. The complexities of the PFAS regulation will drive the development and delivery of a significant amount of in-person training. This work involves time to develop the workshop materials and significant travel time depending on the system's location. With concerns over contaminating a sample during collection and using a new Hazard Index approach, primacy agencies anticipate receiving a significant number of in-person training requests.

To get a more accurate estimate of the primacy agency burden for technical assistance, ASDWA recommends that EPA split "technical assistance" into multiple components. Currently, the economic analysis is unclear on exactly what the Agency is considering under the category of "technical assistance." EPA's estimate is low by a significant amount if all technical assistance activities are considered. ASDWA recommends that EPA break down its analysis into the components below.

• Assistance to obtain valid water samples.

• Assistance to systems to locate consultants to develop Preliminary Engineering Reports (PERs).

• Assistance to systems to identify and evaluate options for potential new water sources.

• Assistance to systems to identify funding.

• Assistance to systems during the piloting process and determining the appropriate treatment.

• Assistance to systems in developing construction plans and specifications.

• Development and presentation of new training modules for systems.

ASDWA recommends that EPA include a separate category for compliance activities, as these activities will take up a substantial portion of staff time.

Some primacy agencies have reported that staff will need to devote additional time to sampling training, sanitary surveys, evaluating compliance data, updating inspections standard operating

procedures, and verifying treatment. PFAS sampling involves special care to avoid unintentional contamination and, therefore, will require more training.

Primacy agencies in states already regulating PFAS have noted that some systems, particularly small or disadvantaged ones, choose to be continually out of compliance due to laboratory testing and treatment costs. This decision requires primacy agencies to continually do outreach to these communities.

The reduced monitoring schedules and determinations will take significant time due to how often water systems will be triggered back into standard monitoring. Tracking compliance monitoring schedules for systems that go back and forth between standard and reducing monitoring will take significant staff time.

ASDWA recommends that EPA include the costs associated with primacy agencies that conduct compliance sampling for their water systems within the Agency's economic analysis.

EPA's economic analysis appears to exclude the costs that will be borne by primacy agencies that conduct compliance sampling for their water systems. This subset of ASDWA's members will be significantly impacted by this increase in required sampling, both financially and with their staffing needs. ASDWA's members have reported that the initial monitoring requirements within the proposed NPDWR will cost the affected primacy agencies between $900,000 and $2.33 million. These figures exclude any purchasing systems. One primacy agency estimated that routine monitoring would cost the agency roughly $450,000 per year. Finally, one primacy agency noted that due to the precautions necessary for PFAS sampling, the agency does not intend to take these samples alongside their standard sampling collection. Therefore, the primacy agency expects five additional FTEs will be required to meet the compliance sampling demand.

EPA Response: The EPA has considered information provided by commenter and agrees regarding increasing burdens associated with regulatory start up; primacy package adoption; technical, managerial and financial (TMF) assistance to water systems; and reviewing and approving treatment. The EPA agrees with the commenter and has made these changes because commenters pointed out activities not explicitly accounted for in the regulatory start up estimate in the EA and commenters also pointed out that adopting primacy packages is a significant undertaking, as discussed in section 13.3.1 of the EPA response in this *Response to Comments* document. Commenters also stated the EPA's assumption in the proposal that the amount of time a primacy agency will need to review treatment plans directly correlates with the size of the water system was inaccurate. Commenters noted that "…small systems often take the most time as they need significant assistance to navigate the process for the design and construction of new treatment and get into compliance." After considering these comments, the EPA agrees that reviewing and approving treatment for small systems is likely to take more time given the assistance needed for these systems. Because small systems often lack the technical, managerial, and financial capacity, it is likely that primacy agencies will spend more time assisting these systems in navigating compliance with the PFAS NPDWR. As such, the EPA adjusted burden estimates in the final rule to reflect the largest primacy agency burden per EPTDS at the smallest

systems and decreased burden hours with increasing system size, as commenters suggested. All adjustments made on primacy agency burden are discussed in section 13.3.1 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's recommendation to break down the technical assistance burden estimate into 7 sub-task level estimates, as that recommendation would add unnecessary complexity, and the commenter did not provide sub-task level estimates for the EPA's consideration. However, as discussed in detail in section 13.3.1 of the EPA response in this *Response to Comments* document, the agency did include many of the commenter's recommendations into the primacy agency burden estimates, including using the commenter's recommended estimate for total hours per primacy for technical assistance.

In addition, the EPA clarifies the agency included the sampling costs associated with primacy agencies that conduct compliance sampling for their water systems in the sampling component of the PWS cost estimate within the agency's EA. The EPA acknowledges that some primacies conduct sampling for their water systems, but does not have information to estimate how frequently this occurs, so as a simplifying assumption, modelled all samples being taken by PWS. This assumption has no effect on the total national costs of the rule. While these costs are not included in the primacy agency portion of the analysis, they are not excluded from the analysis as suggested by the commenter.

Finally, please see the EPA response to comment Doc. #1628, SBC-044069 in section 13.3.1 in this *Response to Comments* document regarding this commenter's estimates of the national level primacy agency costs of the rule.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044128)

Economic Analysis

Level of Effort for Primacy Agencies

The NPDWR includes an analysis of primary agency costs, but TCEQ believes EPA's economic analysis underestimates the level of effort and costs for primacy agencies to implement the rule. TCEQ does not agree with EPA's assumption the implementation of the PFAS NPDWR will not incur any additional staff time. The proposed regulation, in addition to existing workloads which are exacerbated by newly promulgated NPDWRs, will significantly increase staff time to implement the rule.

Due to the growing complexity of federal drinking water regulations, the knowledge required of water system operators has reached insurmountable proportions causing a strong reliance on technical and informational assistance from state regulators. At the same time, TCEQ finds it increasingly difficult to absorb and communicate all the regulatory requirements, both to the regulated community and to state personnel. Each new requirement adds to the collective impact of an already large and demanding body of regulations. Although this may be difficult to quantify, TCEQ urges EPA to reassess and lean toward more generous cost estimates. It is

imperative that the final rule accurately portrays the resources primacy agencies will need to implement the rule, since many primacy agencies need to use this information to justify staffing levels and costs. EPA should also reconsider the estimate of effort required by primacy agencies to support small systems and provide technical assistance as they navigate the process to add new treatment capabilities and achieve compliance with the rule.

While several treatment options exist, public water systems will need support and information to evaluate the challenges and benefits of different technology options. Primacy agencies will have to review additional pilot projects, which may range from a desktop analysis to a full-scale pilot study. PFAS compounds are difficult to remove. As with any treatment technology, the efficacy of the PFAS removal technology at a specific public water system is impacted by the type and concentrations of PFAS compounds in the source water, the targeted finished water concentration, and other parameters that may interfere with treatment (e.g., total organic carbon, nitrate, sulfate). Each public water system will have to find the technology that will work best for its specific circumstances and, depending on the factors noted above, conduct pilot studies to verify efficacy. Many states do not have specific design criteria for these best available technologies. PFAS projects will involve a pilot study protocol, pilot study report, and associated plans and specifications review, which require approximately 188 staff hours to complete.

EPA also underestimates the time needed to review source water changes. Changing water sources can have significant implications on finished water quality that need to be carefully considered and evaluated. For example, review times for new sources typically average 40 staff hours for a surface water intake, 24 staff hours for a groundwater well, and eight staff hours for an interconnect project.

EPA Response: The EPA agrees with commenters on the burdens associated with regulatory start up; TMF assistance to water systems; and reviewing and approving treatment. Based on input from this and other commenters, the EPA adjusted burden estimates for these categories of costs. All adjustments made on primacy agency burden are discussed in section 13.3.1 of the EPA response in this *Response to Comments* document. Please see the EPA response to comment Doc. #1628, SBC-044076 in section 13.3.1 in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044172)

C. State Agency Staff and Resource Needs

1. NCDEQ recommends that EPA reevaluate state agency costs portion of the preamble and economic analysis to reflect the agency burden accurately.

EPA's analysis of state costs does not capture all the activities associated with PFAS implementation. Additionally, the Agency's analysis underestimates the number of hours to carry out state agency tasks. NCDEQ recommends that EPA adjust the state agency costs portion of the preamble to better reflect the anticipated staff and resource needs as detailed below.

EPA's analysis should add staff time to include a public comment period as a component of new rule adoption, develop laboratory accreditation programs, and responding to questions from members of the public, inquiries from public officials, and media requests.

EPA's analysis assumes that the amount of time a state agency will need to review treatment plans directly correlates with the size of the water system. This assumption is inaccurate. Small systems often take the most time as they need significant assistance to navigate the process for the design and construction of new treatment and get into compliance. Additionally, this assistance often goes beyond just the construction of the treatment and start-up as systems work to remain compliant. Assistance with operation and maintenance (O&M) is often required.

NCDEQ urges EPA to adjust the assumption that the mandatory reporting regarding violations, variances and exemptions, enforcement actions, and general operations of state agency programs will not incur any additional agency staff me. The proposal is a new regulation that will impact approximately two thousand North Carolina systems and likely result in a large number of violations once the rule goes into effect. Each of those violations and the actions needed to return these systems to compliance will take additional time and effort such as working with water systems to develop and maintain monitoring schedules. Although EPA plans to provide a public tool for systems to use to determine their hazard index, many of these systems will go to their state agency officials for guidance and assistance. Small systems will need extensive assistance, but medium and large systems will also need staff support. We anticipate providing in person training that will require development of workshop materials and travel time depending on the training's location.

EPA's estimate for state agencies to review source water changes, four hours, should be adjusted upward to eight hours. Changing source water typically has significant implications on finished water quality, such as corrosion control, disinfection byproducts, disinfectant residual, etc., that must be carefully considered. This analysis of the potential for unintended consequences from source changes can take significantly longer.

EPA's estimates should increase state agency staff time needed to evaluate pilot testing for new treatment. Our staff will be needed for both evaluating the design of the pilot as well as reviewing all the pilot testing data. We recommend that this staff time should be increased in EPA's final estimates.

2. NCDEQ recommends that EPA include a separate cost category for state agency compliance assistance activities.

Staff will need to devote additional time to sampling training, sanitary surveys, evaluating compliance data, updating inspections standard operating procedures, and verifying treatment.

The reduced monitoring schedules and determinations will take additional time due to how often water systems will be triggered back into standard monitoring. Tracking compliance schedules for systems that transition between standard monitoring and reduced monitoring will take staff

time based on the number of systems affected and frequency of transition. NCDEQ is available to work with EPA in estimating this cost category.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1628, SBC-044076 in section 13.3.1 in this *Response to Comments* document. Regarding the commenter's statement about the burden associated with tracking compliance schedules, the EPA acknowledges that primacy agencies will spend time tracking compliance schedules. As the commenter points out, the costs associated with this specific activity will likely vary significantly based on the number of systems impacted and the frequency of transition. For modelling purposes, as described in Chapter 4.4.4 of the EA, the EPA assumes that EP PFAS concentrations are constant. Therefore, the agency does not model water systems switching between compliance schedules over the entire period of analysis, but rather models an initial monitoring frequency and a post-compliance monitoring frequency based on the modelled occurrence information for water systems (see Chapter 5.3.2 of the EA for more information). By extension, the EPA does not model the shifts in primacy agency tracking burden associated with reduced monitoring over the period of analysis. Finally, for reasons described in section 13.3.1 of the EPA response in this *Response to Comments* document, the EPA assumes 100 percent compliance with the rule and does not include costs associated with non-compliance in the EA.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044197)

7. NCDEQ recommends that EPA update the proposal's economic analysis to better capture the burden on the state workforce with respect to the review and approval of PFAS treatment technologies.

Timelines for reviewing and approving treatment technologies have been underestimated in the proposal. In addition to reviewing and approving engineering reports and construction design plans for treatment technologies installed to maintain compliance with this rule, state agencies will also need to review and approve the pilot tests needed to ensure treatment efficacy of the selected BAT. NCDEQ has limited experience with some of the BAT and has not approved the technology for PFAS regulation compliance; as such, timelines for review and approval of these technologies are not as straightforward as what was presented in the proposal.

EPA Response: Based on this and other comments, the EPA has updated burden estimates associated with reviewing and approving treatment technologies. Please see section 13.3.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1628, SBC-044076 in section 13.3.1 in this *Response to Comments* document.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044940)

May 30, 2023

U.S. Environmental Protection Agency

EPA Docket Center

Office of Groundwater and Drinking Water Mail Code 28221T

1200 Pennsylvania Ave.

Washington, DC 20460

Re: Docket #EPA-HQ-OW-2022-0114

To whom it may concern:

The New York State Department of Health (Department), in consultation with our partners at the New York State Department of Environmental Conservation (DEC), is pleased to provide comments on the National Primary Drinking Water Regulation (NPDWR) for per- and polyfluoroalkyl substances (PFAS). We appreciate and support the Biden Administration's decision to address PFAS chemicals through these regulations. New York State has been and continues to be a national leader in PFAS regulation, assessment and mitigation. We hope that our experience in regulating PFOA and PFOS can assist the United States Environmental Protection Agency (EPA) in realizing meaningful public health protections through implementation of its PFAS action plan and regulatory agenda.

The following comments first address regulatory implementation and enforcement consistent with the Department's primary enforcement authorities under the Safe Drinking Water Act. These comments also address consistency in the application of the underlying health science (reference doses, cancer slope factors) across EPA's programs, the health basis of the proposed Hazard Index (HI) approach, and additional implications of the proposed MCL rulemaking.

1. The Department has been implementing enforceable maximum contaminant levels (MCLs) of 10 parts per trillion (ppt) for PFOA and PFOS since 2020. Since January 1, 2021, the number of violations issued for PFOA and PFOS is approximately equal to the number of violations that the Department and its local health department (LHD) partners have issued for all remaining compounds for which there is a national primary drinking water regulation (NPDWR) or State Maximum Contaminant Level (MCL). Currently, out of the 2,576 public water systems (PWS) with results, approximately 250 PWS exceed the regulatory standard at 10 ppt. We anticipate nearly 550 PWS in New York State may exceed the regulatory standard at 4 ppt. If compliance with other MCLs remains constant, nearly 70% of all MCL violations issued in New York will be for PFOA and/or PFOS. The workload involved in determining monitoring frequency, modifying schedules in the Safe Drinking Water Information System (SDWIS), and notifying public water supplies of the schedules is significant and deserves consideration.

Table 1: PFOA and PFOS Occurrence in New York State

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1677]

2. While an increase in primacy agency workload is to be expected any time a new MCL standard is promulgated, the workload associated with promulgating these standards is expected

to be more significant. Workload for primacy agencies has been increasing to unsustainable levels at a time when the Drinking Water State Revolving Fund (DWSRF) base grant funds, and thus set asides used to fund primacy agency programs, have been reduced by upwards of 50%. These sources have historically been used to fund regulatory program staff and ensure the EPA's mission is fully executed in accordance with the Department's primacy enforcement authority. Although the Infrastructure Investment and Jobs Act (IIJA) has provided a much welcome boost to primacy agency programs in the form of set asides, the effective date of this proposed NPDWR is expected to be in late 2026 or early 2027, which is the last year IIJA funds will be awarded. If a regulation with such broad impact is promulgated, EPA must work with Congress to concurrently increase funding to the Public Water System Supervision (PWSS) state and tribal assistance grant to ensure that primacy agencies have a stable source of funding for staff to ensure the public health protection goals in the NPDWR proposal are realized well into the future.

EPA Response: The EPA acknowledges commenter's stated support for the agency's efforts to address PFAS through this NPDWR. For the EPA's response to comments on the primacy agency burden associated with the final rule and response to comments recommending the EPA include violations related costs in the EA, please see section 13.3.1 of the EPA response in this *Response to Comments* document.

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044355)

b. Agency Impact. This new Federal Drinking Water Regulation comes at an unprecedented time, when State Agencies have two other major rule revisions (LCRR and CCR) to implement. NH has reviewed the amount of time staff have spent managing the current State Administrative Rule for PFAS monitoring, and based on the new Federal MCLs and increased monitoring requirements we anticipate staff will be spending 35 more hours per week minimum managing the PFAS program alone. This is a very conservative estimate, and includes the review of sample results, schedule changes, enforcement actions, treatment approvals, and the inevitable influx of questions from public water system. NH did not consider time spent updating the rules or database applications and reports; those items will require a significant amount of time but are a one-time effort.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document.

Clean Water Action/Clean Water Fund (Doc. #1697, SBC-045006)

EPA should also ensure that state agency support reflects the true costs of implementing the new regulations. The PFAS CoSTS analysis developed by the Association of State Drinking Water Administrators (ASDWA) estimates first year implementation costs for state agencies to be $59, 889,624 and annual costs after that to be $18,768,960.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045109)

2) What is needed to effectively communicate information about PFAS to the public?

The monitoring burdens through the sampling framework identified will require additional staffing. The proposed regulation will require considerable additional staffing by the primacy agency from administrative support to receive and process data, to compliance analysts to review and respond to the data, to engineering resources to review and approve treatment designs. It is estimated that a minimum of 4 additional staff would be needed in a state like Vermont. There will also be considerable demands on the external partners such as consulting engineers to ensure treatment meets all necessary standards prior to being placed into service.

EPA Response: For the -EPA's response to comments on primacy agency burden associated with the rule, including technical assistance, review of compliance results and setting monitoring schedules, and reviewing treatment, please see section 13.3.1 of the EPA response in this *Response to Comments* document. All of these activities are included in the EPA's cost estimates, for more information see Chapter 5 of the EA.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045091)

Adequate Technical Managerial and Financial capacity is always a concern with new regulations, especially pertaining to small systems. Experience in Vermont has shown that small systems often lack the resources necessary to respond to and properly maintain any required treatment when PFAS contamination is in the community. The impact of treatment and O&M expense is often amplified in small water systems where costs are borne by a smaller user base and are unable to be spread across tens of thousands of users.

Providing support and oversight to small systems across the state is a very time-intensive endeavor and is extremely demanding on state resources for a small state such as Vermont.

EPA Response: The EPA increased the primacy agency burden estimate associated with reviewing and approving small system treatment plans; please see section 13.3.1 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045145)

3. EPA Analysis of Primacy Agency Staff and Resource Burden

EPA's analysis of primacy agency resource implications does not fully capture all the activities that primacy agencies will undertake to implement the PFAS NPDWR and underestimates the

number of hours for primacy agency tasks. MassDEP has been regulating PFAS in drinking water since October 2020 and has significant experience estimating the impacts of rule implementation on MassDEP's staff. EPA should substantially increase support to states to facilitate implementing the rule.

EPA underestimates the time for MassDEP to read and understand the rule, as well as adopt regulatory requirements. The amount of time needed to adopt regulatory requirements will vary greatly across the country. MassDEP has requirements for robust public comment periods as a component of new rule adoption. Additionally, MassDEP may need to modify its laboratory accreditation program which will increase the amount of staff resources needed for implementation.

EPA assumes that the amount of time a primacy agency will need to review treatment plans directly correlates with the size of the water system, but this assumption is inaccurate. Assisting small systems often takes the most time, as they need significant support navigating the process for the design and construction of new treatment to get into compliance. MassDEP often works with these systems to locate consultants for preliminary engineering reports (PERs), develop construction plans and specifications, help obtain funding, and manage construction. Additionally, this assistance often lasts beyond the construction and start-up of the treatment to include ongoing operation and maintenance (O&M) support.

EPA's assumption that the proposed regulation would not cause any additional primacy agency staff time to be needed to comply with the reporting requirements of 40 CFR § 142.15 is inaccurate. The proposal will be a new regulation that will impact several hundred systems in Massachusetts and is likely to result in many violations once finalized. Reporting such violations and other elements of § 142.15 (variances and exemptions, enforcement actions, and general operations of primacy agency programs) will take additional time and effort.

EPA's estimate of four hours for the primacy agencies to review source water changes is inaccurate. Changing sources typically has significant implications on finished water quality, such as implications for corrosion control, disinfection by-products and disinfectant residual, that need to be carefully considered. This analysis of the potential for unintended consequences from source water changes will take significantly longer than four hours.

EPA's estimates do not appropriately consider the amount of primacy agency staff time needed to implement pilot testing for new treatment. Staff review time will be needed for both designing the pilot and analyzing all the pilot testing data, ranging from a desktop analysis to bench-scale testing to a full pilot plant. EPA underestimates the amount of technical assistance that will be needed for systems to come into compliance. The complexities of the PFAS regulation will drive the development and delivery of a significant amount of in-person training. This is the case even in the Commonwealth, despite our prior experience implementing the Massachusetts PFAS MCL, because the federal standard, if adopted, would require additional training due to the differences between the state and federal rules and would cover many additional public water systems that have not previously had to treat or otherwise remediate PFAS.

EPA's trigger level for quarterly monitoring is very low - right at the detection limit of these compounds. Although a PWS may qualify for reduced monitoring, subsequent rounds of monitoring could identify trace amounts of PFAS that would return the PWS to quarterly monitoring. Primacy agencies will spend significant resources developing reduced monitoring schedules, and making determinations to change monitoring frequencies, and tracking compliance schedules for systems that go back and forth between quarterly monitoring and reduced monitoring.

EPA's proposal does not allow the state sufficient time to develop appropriate reporting mechanisms. Due to initial monitoring that may begin immediately after final rule promulgation, reporting of this data will likely have to be either via paper, which will introduce a burden on states that currently receive such results electronically, or via an electronic process that is not CROMERR compliant as there will be insufficient time to develop, test and launch a new system or to modify an existing system.

EPA Response: Based on this and other comments, the EPA increased the primacy agency burden estimate associated with reviewing and approving small system treatment plans, including reviewing pilot study results; please see section 13.3.1 of the EPA response in this *Response to Comments* document. Additionally, for the final rule, the EPA has increased the trigger levels from the proposed values to ½ of the MCLs. For more information about trigger levels and the EPA's response to comments related to trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. The EPA included the primacy agency burden associated with reviewing sample results during the initial monitoring period and the long-term monitoring period in the cost analysis, see Chapter 5 of the EA for more information. Regarding the concerns raised about record keeping and reporting of PFAS data, especially during the initial monitoring period, please see sections 11.2 and 11.3 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045240)

Economic Considerations & Costs

1. CT DPH agrees that a national drinking water regulation for PFAS is an important step to protect the public from the harmful effects from consuming PFAS in public drinking water. CT DPH believes EPA's estimates for primacy agency costs may not accurately account for all the activities that CT DPH will undertake for implementation of the NPDWR. For example, of the public water systems CT DPH regulates, a great proportion are small systems. These often take the most time as they need significant assistance to get their systems into compliance. CT DPH staff often work with small systems to locate consultants for engineering reports and construction plans and specifications, and then again to help these systems obtain funding. Additionally, the level of assistance required by small systems often goes significantly beyond just the establishment of the system and its infrastructure, as the help of CT DPH is often needed to

maintain compliance, assist in creating public messaging, attend public meetings, and address other issues as they arise.

Further, CT DPH believes that the mandatory reporting regarding violations, variances and exemptions, enforcement actions, and general operations will demand additional state staff time as all rules have such as the Revised Total Coliform Rule and the Groundwater Rule. As a new NPDWR for PFAS is implemented, CT DPH anticipates a significant number of public water systems in Connecticut will face compliance challenges. Many such cases will demand additional time and attention from CT DPH.

2. Increasing workloads for CT DPH will require additional staff. Like many primacy agencies, CT DPH has encountered challenges recruiting to fill vacant positions. There are significant workforce needs in the area of environmental engineering which presents a continuous challenge.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045205)

6. CT DPH recommends EPA reevaluate primary agency costs. As has been suggested by the Association of State Drinking Water Administrators, CT DPH anticipates costs associated with implementation of the Proposed PFAS NPDWR will significantly surpass that which have been estimated by EPA. Small systems account for a significant proportion of public water systems in Connecticut, and CT DPH has found that small systems often require more assistance than larger systems in complying with new regulations. Also, voluntary monitoring of PFAS thus far indicates that a proportion of public water systems in Connecticut will need to remediate PFAS to comply with the new NPDWR. Accordingly, CT DPH expects increased demand for technical and financial assistance as well as more compliance and possible enforcement actions. This will represent a significant addition to the current workload for CT DPH staff.

EPA Response: Based on this and other comments, the EPA has made adjustments to primacy agency cost burden estimates. Please see section 13.3.1 of the EPA response in this *Response to Comments* document.

Environmental Council of the States (ECOS) (Doc. #1752, SBC-044504)

The NPDWR includes an analysis of primary agency costs, but states have raised concerns that it does not capture all activities that primacy agencies will need to conduct to implement the rule. The Association of State Drinking Water Administrators (ASDWA) has developed a PFAS Cost of State Transactions Study [Link: https://www.asdwa.org/wp-content/uploads/2018/05/CoSTS-Report-Final-2018.pdf] to analyze primacy agencies' burden to help inform EPA's economic analysis developed for the proposed regulation. EPA should consider these findings as part of its evaluation of this portion of the proposed rule. Specifically, ECOS urges EPA to reconsider the

estimate of state effort required to support small systems and provide technical assistance as they navigate the new PFAS drinking water standard and add new treatment capabilities to achieve compliance.

EPA Response: Based on this and other comments, the EPA has made adjustments to primacy agency cost burden estimates. Please see section 13.3.1 of the EPA response in this *Response to Comments* document.

Fairfax Water (Doc. #1789, SBC-045300)

Additionally, there will be significant impacts on the limited resources of primacy agencies to support utilities in the compliance process. Our primacy agency, the Virginia Department of Health, historically received about $18 million per year since 2018 from EPA to implement the baseline Drinking Water State Revolving Loan Fund. In fiscal year 2024 they received less than $7 million as a result of Congressionally directed spending. This reduction prevented them from filling seven positions in FY23, and possibly more positions in FY24 might need to be held vacant - positions that would support utility implementation of PFAS treatment, particularly at small systems.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document. In addition, the EPA acknowledges that some primacy agencies, like many public agencies and organizations, face budgetary pressures and capacity issues. The EPA has estimated costs of the final NPDWR to primacy agencies using the best available information and considering all public comments. For more information see the EPA's primacy agency cost estimates in Chapter 5.4 of the EA and the EPA's analysis pursuant to the Unfunded Mandates Reform Act (UMRA) in Chapter 9.5.

Missouri Department of Natural Resources (Doc. #1563, SBC-042512)

The Department also agrees with ASDWA that EPA has significantly underestimated the cost of the proposed rule. The EPA economic analysis does not reflect costs borne by many states that provide analytical services for all required safe drinking water compliance sampling. We encourage EPA to consider the updated information provided by ASDWA in calculating the cost to state programs to implement the final rule.

EPA Response: Please see section 13.3.1 of the EPA response in this *Response to Comments* document.

13.3.2 HFPO-DA, PFNA, PFBS National Cost

Summary of Major Public Comments and EPA Responses

A few commenters recommended that the EPA further consider the costs associated with compliance with the Hazard Index MCL. Specifically, commenters stated that the EPA's analysis of system level costs associated with the Hazard Index does not adequately characterize the

overall costs that will be incurred due to the Hazard Index standard. One commenter stated that the EPA "should not move forward with the Hazard Index until it has satisfied its statutory and policy obligation to conduct a cost-benefit analysis" (Doc. #1634, SBC-043237). Some commenters voiced concern regarding the EPA's assumption that costs associated with compliance with the Hazard Index MCL are insignificant and asserted that these costs must be reexamined, stating that this assessment "requires more knowledge on the nationwide occurrence of these compounds" and that the EPA "cannot assume that addressing the costs of PFOA and PFOS is sufficient when the additional four PFAS will be driving treatment decisions at some PWSs" (Doc. #1738, SBC-046002). Conversely, one commenter asserted that available occurrence data demonstrate that few systems will be required to install treatment to comply with the Hazard Index MCL that would not already be treating to comply with the PFOA and PFOS MCLs.

The EPA disagrees with commenters who state that the agency did not meet its requirements under SDWA, which requires the agency to analyze "quantifiable and nonquantifiable costs…that are likely to occur solely as a result of compliance with the maximum contaminant level." In the proposal, the EPA analyzed the quantifiable costs of the Hazard Index at the system level, using the best available information at the time of publication, and analyzed the nonquantifiable costs of the Hazard Index by including a qualitative discussion of the national level impacts and therefore met the statutory requirements under SDWA 1412 (b)(3)(C). After considering recommendations from public commenters to further analyze the costs of the Hazard Index and the data available to support a quantitative analysis of the costs of the Hazard Index, the EPA decided to conduct a sensitivity analysis of the costs of the Hazard Index and individual MCLs for PFHxS, PFNA and HFPO-DA at the national level. The results of the sensitivity analysis supported the EPA's assumption in the proposal that quantified national costs are marginally underestimated as a result of this lack of sufficient nationally representative occurrence data.

To estimate quantified costs of the final rule presented in the national-level summary tables, the EPA first estimated baseline PFAS occurrence using a Bayesian hierarchical model fitted with sampling data collected from systems participating in UCMR 3. The model included three of the six PFAS compounds regulated through this NPDWR: PFOA, PFOS, and PFHxS (please see section VI of the final rule preamble). This permitted the agency to quantify costs at a national level with a higher degree of confidence and precision for these three PFAS than if simple extrapolations had been used. Since there are some limitations with nationally representative occurrence information for the other compounds that were either not included in UCMR 3 (HFPO-DA) or did not have a sufficient number of observed values above the UCMR 3 reporting limits (PFNA, PFBS), the EPA has a lesser degree of confidence and precision for its quantified estimates of these three PFAS, which are informed by a significant amount of available state-level data. Therefore, the EPA presented the cost estimates for PFNA, HFPO-DA, and PFBS in a sensitivity analysis in the EA (i.e., national-level sensitivity analysis, see

Appendix N.3 of USEPA, 2024c) instead of including these costs in the summary tables of quantified national level costs.[3]

In the EA for the proposed PFAS NPDWR, the EPA used a model system approach[4] to illustrate the potential incremental costs for removing PFAS not included in the national economic model (i.e., PFNA, HFPO-DA, and PFBS). After considering public comments on the incremental cost analysis, many of which encouraged the EPA to further evaluate and consider quantified costs of the Hazard Index MCL where feasible, the EPA updated and combined existing analyses contained in the rule proposal to evaluate the incremental costs associated with the Hazard Index MCL and individual MCLs for PFNA and HFPO-DA with a quantified national level sensitivity analysis in the final rule. The updated analysis for the final rule builds on the proposal analysis by combining information that was presented separately at proposal. The analysis in Appendix N of the final EA utilizes the system level treatment cost information presented at proposal (See Appendix N of USEPA, 2023f) with updates to the cost models for the final rule detailed in section XII.A.2 of the FRN. These treatment costs were applied to the number of systems expected to exceed the standards based on PFNA, PFBS, and HFPFO-DA occurrence using the approaches for estimating occurrence of these compounds presented at proposal (see section 10.3 of USEPA, 2023e). This modified analysis was primarily conducted to ensure that the EPA has not, as some commenters claim, substantially underestimated the potential magnitude of these costs. The EPA notes the approach presented in Appendix N for the final rule and summarized here, by connecting analyses for proposed rule, allows the agency to consider and compare the relative degree of the potential overall costs of these otherwise nonquantifiable costs of the Hazard Index and PFNA and HFPO-DA MCLs relative to overall national rule costs. This analysis confirms the EPA's findings at proposal that the Hazard Index costs (and those costs for regulating PFNA and HFPO-DA individually) make up a small portion of the overall rule costs. Likewise, the EPA notes that while these costs are presented in Appendix N because of the lesser degree of confidence and precision in the estimates, the EPA has considered these costs as part of this final regulation. It has done so by evaluating nonquantifiable costs and accounting for uncertainty, characterizing these otherwise nonquantifiable costs in Appendix N to generate cost estimates that, while useful, are not as statistically robust as the national cost estimates presented

[3]When available, nationally representative occurrence information is preferable for an economic analysis of national level costs and benefits. In the case of PFOA, PFOS, and PFHxS, the EPA has a sufficiently robust nationally representative dataset from UCMR 3. The EPA used additional state data that were available at systems that were part of this UCMR 3 set of systems to fit the national occurrence model that informed cost estimates for PFOA, PFOS, and PFHxS (see Cadwallader et al., 2022). In the case of PFNA, HFPO-DA, and PFBS, the EPA lacks the same level of precision as described above for PFOA, PFOS, and PFHxS. State-led data collection efforts provided valuable information about occurrence for PFNA, HFPO-DA, and PFBS, however they did not provide the nationally representative foundation provided by UCMR3 for PFOA, PFOS, and PFHxS to be incorporated into the MCMC national occurrence model.

[4] At proposal, the EPA used a model system approach for estimating potential incremental treatment costs associated with co-occurring PFAS at systems already required to treat in the national model framework and the potential per system costs for the set of systems triggered into treatment as a result of Hazard Index MCL exceedances not already captured in the national analysis. For further detail on the assumptions and findings of the EPA's analysis of incremental costs of other PFAS at rule proposal, please see Appendix N.3 in the Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (USEPA, 2023f).

in Chapter 5 of the EA. Using this analysis, the agency has confirmed the Hazard Index and PFNA and HFPO-DA MCLs drive a relatively low percentage of the overall rule costs. The EPA has also considered these costs in the context that the Hazard Index and PFHxS, PFNA, and HFPO-DA MCLs are expected to deliver important nonquantifiable health benefits, including PFNA birth weight benefits[5] and other nonquantifiable benefits associated with the reduction of the Hazard Index PFAS (PFNA, PFHxS, HFPO-DA, and PFBS)[6] described in Chapter 6.2 of the EA.

The proposed rule included a Hazard Index MCLG and MCL for any mixture of one or more of PFHxS, HFPO-DA, PFNA, and PFBS. The final rule includes a Hazard Index MCLG and MCL for any mixture of two or more of PFHxS, HFPO-DA, PFNA, and PFBS. The final rule also includes individual MCLGs and MCLs for PFHxS, PFNA, and HFPO-DA. The EPA's cost analysis at proposal considered the costs associated with the individual MCLs for PFHxS, PFNA, and HFPO-DA because the proposed Hazard Index MCL would function as individual MCLs when these contaminants occur in isolation. While the rule structure has changed in the final NPDWR, the costing framework used at proposal is still applicable in the final rule: what was considered a Hazard Index MCL exceedance at proposal would be an individual MCL exceedance under the final rule should those contaminants occur in isolation. Further, a Hazard Index exceedance in the final rule (defined as two or more of PFHxS, PFNA, HFPO-DA, and PFBS) is unchanged from a costing perspective to what the EPA proposed. Whether a system exceeds a Hazard Index MCL or individual MCL in the final rule, these costs are captured in the cost estimates the EPA considered and presented in Appendix N.3 of the EA and summarized in this section. Specifically, if a system exceeds only one of the individual MCLs for PFHxS, PFNA, or HFPO-DA that exceedance is costed by estimating the removal needed to achieve compliance with a given individual MCL. If a system exceeds the Hazard Index MCL, that exceedance is costed by estimating the removal of the combination of contaminants needed to achieve compliance with the Hazard Index MCL. Therefore, the national level cost estimate for PFHxS is reflective of both the total national cost of the PFHxS individual MCL and instances of Hazard Index MCL exceedances where PFHxS is present above its HBWC while other Hazard Index PFAS are present.

To understand the totality of national-level cost impacts for the Hazard Index MCL, the EPA considered both the contribution of PFHxS (estimated as part of the national level cost analysis), as well as the costs for PFNA, HFPO-DA, and PFBS (estimated in the Appendix N sensitivity analysis). Together, these provide information on the costs for the Hazard Index MCL and the

[5] As discussed in Appendix K.4, a 1 ppt reduction in both PFOA and PFOS for a system serving a population of 100,000 would result in $0.101 million in annualized birth weight benefits. If including a 1 ppt PFNA reduction, in addition to a 1 ppt reduction in both PFOA and PFOS, for a system serving a population of 100,000, the resulting annualized birth weight benefits would increase by $0.464 to $0.689 million, depending on the slope factor used for PFNA. The EPA estimates that 208 water systems may exceed the PFNA MCL.

[6] The EPA also anticipates additional substantial benefits to PWS customers associated with reduced exposure to Hazard Index compounds (PFHxS, HFPO-DA, PFNA, and PFBS) not included in the primary analysis. The nonquantifiable benefits impact categories include developmental, cardiovascular, immune, hepatic, endocrine, metabolic, reproductive, musculoskeletal, and carcinogenic effects. See Chapter 6.2 of the EA for more information.

individual MCLs for PFHxS, PFNA, and HFPO-DA, as a whole. Due to available data informing the Bayesian hierarchical occurrence model, the EPA was only able to quantify the portion of total costs for the Hazard Index MCL attributable to PFHxS[7] in the national level analysis. The EPA notes that this estimate also represents the national level quantified costs for the individual PFHxS MCL. The EPA acknowledges that this $11.6 million estimate is only a portion of the costs imposed by the Hazard Index MCL and also does not account for the costs imposed by the individual PFNA and HFPO-DA MCLs. The EPA accounted for those potential additional costs through the sensitivity analysis described in Appendix N, in which the EPA found that costs of treating for PFNA, HFPO-DA, and PFBS to meet the Hazard Index MCL and individual MCLs for PFNA and HFPO-DA increased national costs by approximately 5 percent, from $1,549 million to $1,631 million. These costs represent the total costs of the final rule; in other words this includes the costs associated with individual MCLs for PFOA, PFOS, PFHxS, HFPO-DA, and PFNA, as well as the Hazard Index MCL. Due to data limitations, the EPA has not separately estimated the costs of the Hazard Index in the absence of the individual MCLs. The sensitivity analysis demonstrates that the quantified national analysis cost estimate that includes only PFOA, PFOS, and PFHxS (where PFHxS represents only a portion of the Hazard Index costs) marginally underestimates total rule costs when also considering the potential cost impacts attributable to HFPO-DA, PFNA, and PFBS. The cost estimates stemming from both the quantified national estimate for PFOA, PFOS, and PFHxS, and from the sensitivity analysis conducted for PFNA, HFPO-DA, and PFBS together inform the impact of the Hazard Index MCL as required by the HRRCA under SDWA.

To fully weigh the costs and benefits of the action, the agency considered the totality of the monetized values, the potential impacts of the nonquantifiable uncertainties, the nonquantifiable costs and benefits, and public comments received by the agency related to the quantified and qualitative assessment of the costs and benefits. For the final rule, the EPA is reaffirming the Administrator's determination made at proposal that the quantified and nonquantifiable benefits of the rule justify its quantified and nonquantifiable costs.

In light of the individual MCLs, the EPA has separately presented national level marginal costs associated with the individual MCLs for PFHxS, PFNA and HFPO-DA in the absence of the Hazard Index MCL; see Chapter 5.1.3 and Appendix N.4 of the EA for details. Therefore, the costs for the individual PFHxS, PFNA, and HFPO-DA MCLs have been considered both in the proposed and final rule. For more information on the agency's methodology, findings, and

[7] The EPA notes that there are anticipated to be circumstances where PFHxS exceeds its individual MCL and HBWC where PFNA, PFBS, and HFPO-DA do not co-occur. While resulting in an exceedance of the PFHxS MCL, if PFHxS exceeds its HBWC without other Hazard Index PFAS present, this would not result in an exceedance of the Hazard Index MCL. At rule proposal, a single exceedance of any of the four Hazard Index PFAS would have resulted in an exceedance of the Hazard Index MCL. However, to improve rule implementation and to support effective risk communication, the EPA has structured the final rule such that a Hazard Index exceedance only occurs when there are two or more of the Hazard Index PFAS present. Therefore, while for purposes of informing its quantified cost analysis the EPA is assuming that every PFHxS exceedance of the MCL also causes an exceedance of the Hazard Index MCL, this approach results in the EPA overestimating PFHxS-attributable Hazard Index costs in its national cost analysis.

limitations of the EPA's updated analysis of costs associated with compliance with the Hazard Index , please see Appendix N.3 of the EA (USEPA, 2024cc).

Individual Public Comments

New York Section American Water Works Association (NYSAWWA) (Doc. #1591, SBC-042373)

We are concerned that the Hazard Index (HI) approach as a calculation will become increasingly complicated over time as additional PFAS compounds are considered for regulation. We also note that EPA's cost-benefit analysis does not extend into an evaluation of the HI for the selected additional PFAS, and that occurrence data for several of the selected additional PFAS is lacking.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document for discussion of costs estimated for Hazard Index PFAS. As discussed in that section, the EPA has assessed the quantified and nonquantified costs for the Hazard Index PFAS and individual MCLs for PFNA, PFHxS, HFPO-DA; however, the presentation of that information is different than for the national-level analysis for PFOA, PFOS, and PFHxS as compared to the HFPO-DA, PFNA, and PFBS. The EPA also notes that the national level cost estimates presented in Section 5.1.3 of the EA do include costs associated with PFHxS occurrence above the PFHxS MCL and PFHxS health-based water concentration (HBWC) when one or more other Hazard Index PFAS are present. With respect to the commenter's concern that the Hazard Index approach "will become increasingly complicated over time as additional PFAS compounds are considered for regulation", the agency disagrees as the EPA believes the Hazard Index approach can be an adaptive and flexible framework for considering additional PFAS. Additionally, to assist in the calculation of these values, the agency is developing a calculator tool to easily determine your Hazard Index result. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For additional, discussion, please see section 5.2.1 of the EPA response in this *Response to Comments* document.

Association of California Water Agencies (ACWA) (Doc. #1675, SBC-044933)

B. Regulatory Approach

In addition to our concerns with costs, ACWA has several issues with the current proposal including the novel Hazard Index approach, use of the trigger level, and the compliance deadline.

COMMENT 3 – HAZARD INDEX – ACWA is concerned with a Hazard Index approach for drinking water.

EPA plans to regulate PFOA and PFOS as individual contaminants, and four other PFAS – PFNA, PFHxS, PFBS, and HFPO-DA ("GenX Chemicals") – as a mixture known as a Hazard Index [FN21: 88 Fed. Reg. at 18,638.]. The Hazard Index is a tool that EPA uses to understand health risk from chemical mixtures [FN22: EPA, Understanding the PFAS National Primary

Drinking Water Proposal Hazard Index (Mar. 2023), click here. (Link: https://www.epa.gov/system/files/documents/2023-03/HowdoIcalculatetheHazardIndex._3.14.23.pdf)]. This proposal marks the first time EPA will use a Hazard Index under the SDWA [FN23: 88 Fed. Reg. at 18,669.]. Specifically, EPA is proposing a Hazard Index, which would be exceeded with individual concentrations of GenX Chemicals at 10 ppt, PFBS at 2000 ppt, PFNA at 10 ppt, and PFHxS at 9 ppt, [FN24: 88 Fed. Reg. at 18,669.] or would be exceeded at far lower levels if multiple of these PFAS substances are present.

ACWA is encouraged by EPA's efforts to regulate PFAS creatively as these substances are ubiquitous and regulating contaminant by contaminant is cumbersome and time consuming for the agency and the public. While ACWA appreciates EPA's efforts to provide an online tool that will calculate the Hazard Index automatically, we have issues with the feasibility and precedent in using the Hazard Index.

We are concerned that the Hazard Index approach essentially sets a de-facto MCL without conducting the full SDWA cost-benefit analysis for the covered PFAS. Before EPA moves forward with using the Hazard Index, the agency has a responsibility under SDWA to fully assess the cost-benefit implications of such a proposal on drinking water agencies.

ACWA suggests EPA allow for additional data, such as the completed fifth Unregulated Contaminant Monitoring Rule (UCMR 5) data, to better influence the unproven Hazard Index approach in drinking water.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document for discussion of costs estimated for Hazard Index PFAS. Because the EPA has evaluated both quantifiable and nonquantifiable costs and benefits associated with the Hazard Index MCL and individual MCLs for PFHxS, PFNA, and HFPO-DA, the EPA has conducted a "full SDWA cost-benefit analysis" for those MCLs. As discussed in sections 13.3.2 and 13.8 of the EPA response in this *Response to Comments* document, the agency quantified costs of the Hazard Index and individual MCLs for PFNA, HFPO-DA and PFHxS and listed anticipated nonquantifiable costs (see Tables 5-22 and 7-6 of the EA for an overview of nonquantifiable costs). The agency also quantified benefits for other PFAS in the regulation where there was sufficiently robust information to do so (see Appendix K of the EA which discusses the EPA's evaluation of the impacts of PFNA on birth weight in a quantitative sensitivity analysis) and has discussed the extensive nonquantifiable benefits associated with reducing these PFAS in drinking water. After considering this and other comments, the EPA conducted a sensitivity analysis of Hazard Index and individual MCLs for PFNA, HFPO-DA and PFHxS costs at the national level. Please see section 13.3.2 of the EPA response in this *Response to Comments* document for further discussion. For responses to comments on the Hazard Index standard itself, please see section 5.2 of the EPA response in this *Response to Comments* document. In response to the commenter's suggestion that the EPA "allow for additional data, such as the completed fifth Unregulated Contaminant Monitoring Rule (UCMR 5) data", please see section 6.8 of the EPA response in this *Response to Comments* document. Based on public

comments, the EPA is also regulating PFHxS, PFNA, and HFPO-DA individually in addition to under the Hazard Index approach; please see section 5.3 of the EPA response in this *Response to Comments* document.

Alabama Water and Wastewater Institute (AWWI) (Doc. #1700, SBC-043509)

AWWI is concerned with the USEPA's novel use of the hazard index for regulatory compliance. The quantified health effects noted in the proposed PFAS regulation present and cite references to the health effects of individual PFAS compounds, such as PFOS and PFOA, but does not cite references to peer reviewed research into the quantified health effects based on the proposed hazard index calculation for the combination of multiple PFAS compounds (PFHxS, HFPO-DA, PFNA, and PFBS). AWWI would recommend that the USEPA consider the removal of the hazard index calculation as a primary drinking water regulation given the lack of cited documentation regarding the health effects based upon the combination of PFAS compounds used in the calculation.

EPA Response: In response to the commenter's recommendation that the EPA "consider the removal of the Hazard Index calculation as a primary drinking water regulation given the lack of cited documentation regarding health effects", the EPA disagrees; please see section V.B of the preamble for this action and sections 4.3 and 5.2 of the EPA response in this *Response to Comments* document for more information on the Hazard Index, including health effects.

The commenter is incorrect about the EPA not referencing peer-reviewed papers and assessments which discuss the health effects of these four PFAS and/or dose additivity of these PFAS. For example, the peer-reviewed Agency for Toxic Substances and Disease Registry (ATSDR) Toxicological Profile for Perfluoroalkyls (ATSDR, 2021) referenced in section III of the preamble for this action discusses health effects of PFHxS and PFNA, and peer-reviewed the EPA human health toxicity assessments of PFBS (USEPA, 2021a) and HFPO-DA (USEPA, 2021b), also referenced throughout section III of the preamble, discuss health effects of PFBS and HFPO-DA, respectively. Additionally, the EPA's mixtures framework document (USEPA, 2024f) and Hazard Index MCLG document (USEPA, 2024g), both of which are supporting documents for this NPDWR, discuss dose additivity and/or health effects of these PFAS. Please see section 4.3 of the EPA response in this *Response to Comments* document for discussion about health effects for PFAS included in the Hazard Index (e.g., section 4.3.3 in this *Response to Comments* document). Please specifically see section 4.3.1 of the EPA response in this *Response to Comments* document, which discusses PFAS dose additivity, including the scientific basis informing the EPA's decision to regulate these PFAS under the Hazard Index approach. In terms of *quantified costs and benefits* of Hazard Index PFAS, please see the EPA response to comment Doc. #1675, SBC-044933 in section 13.3.2 of this *Response to Comments* document. Please also see section 13.6 of the EPA response in this *Response to Comments* document for the EPA's responses to comments on nonquantifiable benefits of the PFHxS, PFNA, PFBS, and HFPO-DA and additional co-removed PFAS not included in this regulatory action.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044054)

32. EPA requests comment on the assumption that exceedances of HI PFAS not included in the national cost analyses (HFPO-DA, PFBS, and PFNA) will not significantly impact overall compliance costs and national costs estimates are, therefore, unlikely to be substantially underestimated.

a. Since EPA's other cost analyses are grossly underestimated, it is assumed that the costs of treatment for the additional analytes are greatly higher than anticipated.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-053307)

Second, the occurrence data for PFAS in the HI raises questions that have a significant impact on the cost estimates. Under Section 5.3.1.1.1 of the EPA's "Economic Analysis", the EPA notes that a key parameter estimating the operating costs of GAC and IX is the expected bed life. PWD agrees with this assessment and understands that some uncertainty will always exist when estimating this parameter on a nationwide scale. However, EPA notes in Section 5.3.1.1.1.2 that removal of the PFAS compounds in the HI is estimated using only one PFAS compound, PFHxS, due to a lack of occurrence data. This lack of data for the other three compounds in the HI suggests that EPA may have over-estimated bed life in the "Economic Analysis." Given the competition of sorption sites in GAC and IX when there is co- occurrence of PFAS, results calculated based on only one PFAS compound would result in an overestimation for the life of the media.

EPA Response: The EPA included the potential additional costs of the Hazard Index and individual MCLs for PFNA, PFHxS, and HFPO-DA in both the proposed and final rule in a sensitivity analysis. As discussed in section 13.3.2 of the EPA response in this *Response to Comments* document, for the proposed rule, the EPA analyzed the quantifiable costs of the Hazard Index at the system level and, based on public comments received, for the final rule, the EPA conducted a sensitivity analysis of Hazard Index and individual MCLs for PFNA, PFHxS, and HFPO-DA costs at the national level, which can be found in Appendix N.3 of the EA.

The EPA disagrees with the commenter that the agency has overestimated the media bed life by calculating it based on "only one PFAS compound." SafeWater MCBC calculates bed life using a system of equations that considers the percent removal required for each PFAS that occurs at an entry point and has an MCL or other limit in the regulatory option, even if the contaminant occurs at a concentration below the regulatory limit. Including contaminants that are below their respective limits avoids exceedances resulting from chromatographic peaking, which is a potential consequence of competition that is discussed in greater detail in the *Technologies and Costs* document (USEPA, 2024d). Furthermore, for IX, the bed life equations incorporate total PFAS concentration along with percent removal of target contaminants and thus explicitly

account for competition. The equations for GAC do not incorporate total PFAS concentration. The analysis did not find total PFAS concentration to be statistically significant, likely because competition among PFAS was overwhelmed by competition/fouling from TOC (which typically occurs in the milligrams per liter range compared to the nanograms per liter range for PFAS). Nevertheless, multiple PFAS were present in all the underlying studies used to develop the bed life equations for both GAC and IX; none of the studies were single-solute studies. Therefore, the GAC equations implicitly include the effects of competition; the IX equations include competition both explicitly and implicitly.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046000)

In Table 41 (88 FR 18703), EPA states the UCMR 3 data for PFBS and PFNA are insufficient and that there are no UCMR 3 data for GenX available. If EPA does not have the data to support whether utilities will be out of compliance with the HI, then it cannot appropriately assume that these potential exceedances do not need to be part of the cost estimate. AMWA disagrees with EPA that excluding information on PFBS, PFNA, and Gen X occurrence in the national cost estimates is insignificant.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document. The EPA notes that the commenter mischaracterizes the agency's assessment of PFBS and PFNA occurrence data. The EPA had insufficient data above the UCMR 3 reporting limits for incorporation of those chemicals into the Bayesian statistical model. This does not mean that the EPA cannot produce national-level estimates of PFBS and PFNA occurrence; it is merely using a different methodology that has more statistical uncertainty. The results of non-targeted state monitoring for PFBS and PFNA were used for national extrapolation. Please see section VI.F of the preamble for this action and section 10 of the PFAS *Occurrence and Contaminant Background Support Document* (USEPA, 2024a) for more discussion.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046002)

Costs associated with treating HI PFAS must be considered. This requires more knowledge on the nationwide occurrence of these compounds. The agency cannot assume that addressing the costs of PFOA and PFOS is sufficient when the additional four PFAS will be driving treatment decisions at some PWSs. It is incorrect for EPA to assume that designation of PFAS compounds as hazardous substances will result in insignificant costs of affordability. EPA's own analysis (tables 22 and 23 in the preamble) estimates that the total annual household cost could increase as much as 9.4% to 14% for GAC treatment, up to $100 more a year, if PFAS are designated as hazardous substances under CERCLA and hazardous constituents under RCRA. To say this increase is insignificant disregards hardships the public faces and the difficult financial situations many households are in, particularly in rural and less advantaged communities that will see the highest of these increases.

EPA Response: The EPA notes that costs associated with treating Hazard Index PFAS and individual MCLs for PFNA, PFHxS, and HFPO-DA were considered for both the proposed and final regulation. For a discussion of costs associated with treating PFNA, PFHxS, PFBS and HFPO-DA, please see section 13.3.2 of the EPA response in this *Response to Comments* document.

In response to the commenter's assertion on affordability, please see section 13.10 of the EPA response in this *Response to Comments* document. Further, the EPA would like to clarify that the agency did not assume "the designation of PFAS compounds as hazardous substances will result in insignificant costs" as stated by the commenter. In the EA for the proposed rule, the EPA concluded that and, with respect to small system affordability, "[a]lthough costs increase in this scenario, the increases are not significant enough to change the conclusions about affordability." As stated in the FRN for the final rule, PFAS-contaminated wastes are not considered Resource Conservation and Recovery Act (RCRA) regulatory or characteristic hazardous wastes at this time and therefore total costs reported do not include costs associated with hazardous waste disposal of spent filtration materials. Further, if finalized, the designation of PFOA and PFOS as CERCLA hazardous substances would not require waste (e.g., biosolids, treatment residuals, etc.) to be treated in any particular fashion, nor disposed of at any specific particular type of landfill. The designation also would not restrict, change, or recommend any specific activity or type of waste at landfills.

American Public Works Association (APWA) (Doc. #1584, SBC-047709)

Data Limitations and Uncertainties in the Cost Analysis below, given the available occurrence data for the other compounds in the proposed rule (PFNA, HFPO-DA, and PFBS) and the regulatory thresholds under consideration, EPA did not model national costs associated with potential HI exceedances as a direct result of these compounds; therefore, the additional treatment cost, from co-occurrence of PFNA, HFPO-DA, PFBS or other PFAS, at systems already required to treat because of PFOA, PFOS, or PFHxS MCL and HI exceedances are not quantitatively assessed in the national cost estimates. Nor are treatment costs for systems that exceed the HI based on the combined occurrence of PFNA, HFPO-DA, PFBS, and PFHxS (where PFHxS itself does not exceed 9 ppt) included in the national monetized cost estimates.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1675, SBC-044933 in section 13.3.2 in this *Response to Comments* document.

Orange County Water District (OCWD), California (Doc. #1634, SBC-043237)

Hazard Index

EPA is proposing the first use of the Hazard Index concept to regulate four individual PFAS in drinking water beyond PFOA and PFOS. The Hazard Index chemicals were not included in the required cost-benefit analysis, in part because national occurrence data is unavailable. As such

neither EPA, water utilities, ratepayers, nor federal policymakers can accurately estimate the impacts of the Hazard Index. Cost-benefit analysis is one of the fundamental tenets of the SDWA, as its 1996 Amendments formally require a Health Risk Reduction and Cost Analysis in support of any national primary drinking water regulation. Furthermore, an economic analysis is required for all significant federal rules under Executive Order 12866. EPA should not move forward with the Hazard Index until it has satisfied its statutory and policy obligation to conduct a cost-benefit analysis.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1675, SBC-044933 in section 13.3.2 in this *Response to Comments* document.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044957)

19. The HI approach encompasses at least one chemical (PFBS) that is likely to have reduced retention and more rapid breakthrough than the long-chain PFAS. It is unclear if the operation and maintenance costs for PFBS changeout have been considered separately and if there is sufficient science to support such an analysis. Based on data available to New York State, it is unlikely, however, that PFBS will be the driver for media changeout at the 2,000 ppt health-based water concentration.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document. For GAC, the EPA agrees that PFBS can break through more rapidly than longer-chain PFAS. For IX, functional group (sulfonate versus carboxylate) appears to be more significant than chain length. Therefore, the EPA's bed life equations for IX estimate that PFBS would break through more rapidly than PFOS, but less rapidly than PFOA, all other conditions being equal. The EPA did not have data to include PFBS in the national analysis but considered it in a supplemental cost analysis (Appendix N.3 of the EA). Based on this supplemental analysis, the EPA agrees that PFBS is unlikely to be a driver for media changeout at the HBWC for the final rule.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045998)

Section 8.11: Cost of hazard index PFAS

As detailed in Section 3.2 above, there may be systems that have one or more of the four PFAS Health Index chemicals driving their treatment response, particularly if they do not have PFOA or PFOS. Therefore, there will be significant costs associated with treating for them.

EPA's assumption that costs associated with compliance with the HI PFAS must be reexamined. If EPA does not have the proper data to quantify the number of systems with HI PFAS and undetectable levels of PFOA and PFOS, then it is inappropriate for EPA to assume the cost is not significant. As mentioned in section 3.2, some AMWA members have indicated that HI PFAS are either the driver of treatment decisions when co-occurring with PFOA and/or PFOS or are the

only PFAS with detectable concentrations at their utility. This means the HI PFAS are responsible for some or all the costs of treatment at several large utilities. EPA cannot say the costs of treating the four HI PFAS are insignificant until they have a nationwide dataset that assesses the number of systems affected by each of the six PFAS included in this proposal.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1591, SBC-042373 and Doc. #1675, SBC-044933 in section 13.3.2 in this *Response to Comments* document.

Orange County Water District (Doc. #3072-54, SBC-047389)

Finally, EPA's proposing the first use of the hazard index to regulate four individual PFAS. Our concern is that the hazard index was not included in the required cost-benefit analysis and thus neither EPA nor water utilities and the rate payers understand the true impact of the proposed regulation. Cost-benefit analysis is one of the fundamental tenants of the Safe Drinking Water Act, as the 1996 Amendments formally require a health risk reduction and cost analysis in support of any National Primary Drinking Water Regulation. Furthermore, an economic analysis is required for all significant federal rules under Executive Order 12866. EPA shouldn't move forward with the hazard index until it has satisfied its statutory policy obligation to conduct the cost-benefit analysis. We appreciate the opportunity to participate in the public hearing. Thank you.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1591, SBC-042373 and Doc. #1675, SBC-044933 in section 13.3.2 in this *Response to Comments* document.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042484)

As stated in the proposed rule, there is insufficient data to quantify the costs associated with HFPO-DA, PFNA, and PFBS. Without a complete data set, these should be further evaluated prior to publishing this rule.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1675, SBC-044933 in section 13.3.2 in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1711, SBC-044465)

[The Agency's proposal suffers from the following significant shortcomings –]

• EPA has not provided data to support its analysis of benefits predicted from the implementation of the HI MCL,

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1675, SBC-044933 in section

13.3.2 in this *Response to Comments* document for responses to comments regarding costs associated with Hazard Index PFAS. Additionally, while the EPA's national benefits analysis solely quantifies health benefits for PFOA and PFOS, the EPA has qualitatively summarized the potential health benefits resulting from reduced exposure to PFAS other than PFOA and PFOS, including the PFNA, PFHxS, PFBS and HFPO-DA, among others. The EPA has used the best scientific information available to describe the nonquantified adverse health effects anticipated with reduced exposure to these PFAS and, in addition, performed a quantitative sensitivity analysis on PFNA birth weight effects using a model system approach. For further discussion of the nonquantifiable benefits anticipated to result from the final rule, please see Section 6.2.4 of the EA (USEPA, 2024b). For more information on the EPA's PFNA/birth weight sensitivity analysis methodology and results, please see Appendix H of the EA (USEPA, 2024c).

American Chemistry Council (ACC) (Doc. #1711, SBC-044463)

[The Agency's proposal suffers from the following significant shortcomings –]

• EPA does not have sufficient occurrence data for three of the substances to serve as a basis for estimating costs of compliance with its proposed HI MCL,

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1675, SBC-044933 in section 13.3.2 in this *Response to Comments* document.

The Chemours Company FC, LLC (Doc. #1845, SBC-046055)

III. EPA's cost-benefit analysis is fundamentally flawed

Section 1412(b)(4)(C) of the SDWA requires that any proposed MCL be justified by a cost-benefit analysis: "At the time the Administrator proposes a national primary drinking water regulation under this paragraph, the Administrator shall publish a determination as to whether the benefits of the maximum contaminant level justify, or do not justify, the costs based on the analysis conducted under paragraph (3)(C)."

In an attempt to meet that requirement, EPA has accompanied its proposed regulatory framework with a purported cost-benefit analysis covering six substances— PFOS, PFOA, and the four included in the proposed HI. But particularly for the latter four, and especially for HFPO-DA, the analysis is fundamentally flawed, because having proceeded with regulation before even the preliminary UCMR results are available for HFPO-DA, EPA has no basis as to what the costs of the proposed MCL would be. In the absence of data on the occurrence of HFPO-DA, EPA simply does not know what the costs of compliance will be.

Indeed, EPA acknowledges that it does not have the data to calculate the impact of its proposed HI approach. In its Economic Analysis,[FN33: U.S. EPA, EPA Document No. EPA-822-P-23-001, Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (March 2023) (emphasis added).] EPA states:

"EPA has estimated the national level costs of the proposed rule associated with PFOA, PFOS and PFHxS. There are limitations with nationally representative occurrence information for the other compounds in the proposed rule (PFNA, HFPO-DA and PFBS), therefore the additional treatment cost, from co-occurrence of PFNA, HFPO-DA, PFBS or other PFAS, at systems already required to treat because of PFOA, PFOS, or PFHxS MCL and HI exceedances are not quantitatively assessed in the national cost estimates. Nor are treatment costs for systems that exceed the HI based on the combined occurrence of PFNA, HFPO-DA, PFBS, and PFHxS (where PFHxS itself does not exceed its HBWC of 9.0 ppt) included in the national monetized cost estimates."

Because EPA assumed in its quantitative cost analysis that an HI-based MCL would not add to the nationwide estimated treatment costs, those costs are, as EPA acknowledges, underestimated: "In instances when concentrations of PFBS, PFNA, and/or HFPO-DA are high enough to cause a hazard index exceedance, the modeled costs may be underestimated. If these PFAS occur in isolation at levels that affect treatment decisions, or if they occur in sufficient concentration to result in an exceedance when the concentration of PFHxS alone would be below the HI, then costs would be underestimated."[FN34: Id. (emphasis added).]

EPA has included analysis of "system level" costs that could result from the HI proposal, but those costs are speculative at best, and do not address the overall costs that will be incurred as a result of the proposal. Nor does the analysis meet the cost-benefit requirements of Section 1412(b)(4)(C). This is particularly befuddling because, as discussed above, significant portions of the data that EPA is now missing will be available soon.

EPA Response: Please see section 13.3.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1675, SBC-044933 in section 13.3.2 in this *Response to Comments* document discussing how the EPA met its obligations to conduct the HHRCA under SDWA. Please see section 13.8 of the EPA response in this *Response to Comments* document for response to comments regarding the Administrator's determination that the benefits of the rule justify its costs.

13.3.3 Water System Costs – Treatment (excluding disposal)

Summary of Major Public Comments and EPA Responses

Many commenters state that the EPA has underestimated the treatment costs required to comply with the proposed PFAS NPDWR. One commenter suggested that the EPA has not complied "with its statutory requirements by conducting an analysis that fully captures these costs." The EPA disagrees with the few commenters that suggested the EPA has not met its requirements under SDWA, and the EPA emphasizes the agency has used the best available peer reviewed science to inform its cost estimates, including treatment costs, of the PFAS NPDWR. Specific aspects of comments related to treatment costs and the EPA's response are discussed below.

Many commenters cited rising costs in the drinking water sector and discussed the effects of inflation and the COVID-19 pandemic on the costs of labor, construction, and capital, among

other materials related to compliance with the PFAS NPDWR. These commenters emphasized the significant impacts felt from supply chain and workforce issues. The EPA recognizes these impacts, and as recommended by commenters, adjusted the cost estimates by escalating unit costs using indices including the Bureau of Labor Statistics producer price indices (USBLS, 2010). The EPA updated each unit cost using the change in the relevant price index from year 2020 to 2022. For example, the EPA applied the percent increase of the price of metal tanks and vessels (50 percent increase from 2020 to 2022) to the price of metal tanks and vessels in the WBS cost models. The EPA also collected new vendor price quotes for cost driver equipment components (e.g., pressure vessels, treatment media) and made several other adjustments to WBS model assumptions, described below. Taken together, these adjustments increased the system level capital cost estimates in the EPA's cost assessment by a percentage that varied depending on the system size and treatment technology. For small systems using GAC and IX, the increase ranged from approximately 40 percent to 110 percent. For medium systems, the increase was approximately 20 to 60 percent; for large systems, 10 to 40 percent. Additionally, while revising the SafeWater model to incorporate new information from public comments, the EPA identified and corrected a coding error related to the discounting of future operation and maintenance costs resulting in increased estimated annualized treatment costs. The result of these changes are increased cost estimates for the final rule.

Some commenters stated that the EPA "…should also take into consideration that this regulation will create significant demand for certain PFAS treatment and products, likely driving up the costs for the installation and maintenance of all PFAS treatment." These commenters specifically cited increased demand for specialized treatment design, construction work, activated carbon, disposal, engineering consultants, planners, contractors, among others, that would lead to an increase in costs associated with the rule. One commenter discussed "the adverse cost impacts of extremely high numbers of public utility and other infrastructure projects being attempted over the next five-to-ten years given high federal grant and loan appropriations activity in these areas." The EPA disagrees that treatment capital, operation and maintenance costs and other rule associated costs are likely to increase significantly as a result of heightened demand. As discussed in section XI.D of the FRN, the EPA is authorizing a two year nationwide capital improvement extension for all systems nationwide to comply with the MCLs. This means that water systems must demonstrate compliance with the MCLs by five years following rule promulgation, rather than three years as proposed, and the EPA expects this will allow additional time for supply, where lacking, to meet demand for treatment technologies and associated contracting and engineering services. Further, the EPA anticipates that the demand created by the rule will be spread over multiple technologies (BATs and small system compliance technologies, or SSCTs) as well as non-treatment options. These multiple routes to compliance will alleviate any price pressure that would otherwise be put on any single media or treatment action as demand will be spread out amongst them. Comments from a major BAT supplier indicated excess capacity as well as investment in production (see comment Doc. #1620, SBC-042939). Furthermore, the EPA expects that structural demand increase will lead to supply increases as well as innovation such as proposed technologies which were not designated as BATs. This has been historically demonstrated multiple times in prior drinking water rules; for further

discussion, please see section 10 of the EPA response in this *Response to Comments* document. Lastly, the EPA anticipates that there is currently more than enough existing disposal capacity to meet the needs of the final rule and therefore disagrees disposal prices are likely to increase; for more information and the EPA's response to comments on disposal capacity, please see section 10 of the EPA response in this *Response to Comments* document.

Many commenters shared some information about the costs that they have incurred or estimated they would incur at a system level to install, operate, and maintain treatment to remove PFAS. Some system level cost information provided by commenters fell within the ranges of costs presented in the EPA's supporting documentation for the proposal and other information provided by commenters exceeded the EPA's system level cost ranges. The EPA does not dispute the commenters' stated experience of costs to install, operate and maintain treatment to remove PFAS; however, many of these comments lacked supporting details. Many of the comments cited preliminary or conceptual estimates and did not specify the methods and assumptions used to develop the estimate. Furthermore, most comments did not include information to confirm that all of the reported or estimated costs were or would be directly associated with PFAS treatment, as opposed to other infrastructure improvements (e.g., capacity expansion, administrative facilities, distribution system improvements) completed as part of the same project. Most commenters also did not include information to confirm that key design and operating parameters (e.g., empty bed contact time, media replacement frequency) would be similar to the typical values assumed in the EPA's estimates. To fully evaluate the commenters' reported or estimated costs in comparison to WBS model results, the EPA would need itemized line-item cost details and engineering design parameters. To inform the cost estimates of the proposed and final PFAS NPDWR, the EPA conducted an extensive review of the literature. The EPA has further validated the unit costs in the PFAS rule with equipment cost information from 2023 from a major supplier of treatment media. While the EPA recognizes there are likely site-specific instances where costs exceed the EPA's cost ranges, there are also likely site-specific instances where costs are less than the EPA's cost ranges, and this level of accuracy is appropriate for a national level analysis.

Other commenters compared state-level costs to the EPA's national level cost estimates, noting that the EPA's estimates appeared too low. Utilizing this permit data and project cost data submitted by water systems in applications to the DWSRF, one state estimated that total capital costs for installation of PFAS treatment to meet the EPA's proposed standards across the state could be as high as $1.065 billion. The EPA's EA analysis, however, presents national level cost estimates that are annualized over the period of analysis and are therefore not directly comparable to a single year estimate of capital costs.

A few commenters stated that the EPA incorrectly omitted the costs associated with performance monitoring, which commenters believe will be necessary because a water system needs to know how often it needs to replace its media. The EPA disagrees that large amounts of additional samples in performance monitoring will be required, and the commenter provided no data to support their assertion that this would be necessary. The EPA anticipates that many water systems will conduct a pilot test before implementing a full-scale treatment installation and that

the operational results from the pilot test will be a sufficient indicator of performance; therefore, water systems should not have to collect large amounts of performance samples indefinitely during the full-scale operation of treatment technologies. The EPA includes the costs of pilot testing, and sampling during that time, in the treatment capital cost estimates. In response to public comments, the EPA increased the estimated length of the pilot study and the frequency of sampling during the pilot study. Additionally, the EPA added a full year of confirmation sampling after full-scale installation to the estimated pilot study costs. Taken together, these changes doubled to more than tripled the pilot study costs included in the EPA's estimates.

In response to public comments about residual management concerns for high pressure membrane technologies, the EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the EA for the final rule. Therefore, the EPA assumes that RO/NF will not generally be used solely for the purpose of complying with the final rule. For more information on public comments on residuals management and the EPA's response, please see section 10 of the EPA response in this *Response to Comments* document.

A few commenters stated that the EPA underestimated or insufficiently incorporated contingency in its cost estimates. For example, one commenter stated that the EPA's contingency assumptions in the proposal were "…inconsistent with recommended best practices for cost estimators and [are] expected to be a major contributor to the EPA WBS' failure to accurately capture costs for PFAS treatment facility implementation." In response to these comments, the EPA changed its approach and incorporated contingency for all systems, not just high-cost systems. The EPA also increased the complexity factor applied to estimate contingency for systems using GAC. Taken together, these changes result in a contingency factor of 5 to 10 percent depending on total project cost at all cost levels for systems installing treatment. Additionally, the EPA includes a miscellaneous allowance of 10 percent. This allowance can be viewed as either as a form of contingency or a method to increase the level of project definition (thus reducing the amount of contingency required).

Many commenters cited and expressed agreement with the conclusions of a study conducted by Black & Veatch on behalf of the American Water Works Association (AWWA) (hereafter referred to as AWWA's B&V report) (AWWA, 2023). The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs of the PFAS NPDWR. The tables below detail some of the key assumptions related to 1) PWSs that exceed the MCL, 2) capital costs and 3) operation and maintenance costs that overestimate national treatment costs in AWWA's B&V report and the EPA's response to those assumptions and resulting estimates. In combination, all these factors result in an overestimate of treatment costs. For example, AWWA's B&V report Table 6-1 reports an average capital cost per entry point EPTDS for the smallest size category of $900,000. Using AWWA's B&V report's (overestimated) design flow calculations, the treatment system design flow at each EPTDS would be approximately 0.062 million gallons per day (mgd). For comparison, Forrester (2019) reports capital equipment costs of approximately $300,000 for a 1 mgd GAC PFAS treatment system. Even after adding indirect capital and building costs, the $900,000 estimate appears substantially overestimated, given that it is for a treatment system designed for approximately

1/16th of the flow of the system in the Calgon estimate (Forrester, 2019). When AWWA's B&V report's EPTDS level results are aggregated nationally to an overestimated number of systems treating for PFAS, the overestimates are compounded at the national level.

The EPA Response to assumptions about PWSs exceeding the MCLs in AWWA's B&V Report

Analytical Component	AWWA's B&V report	EPA response
PFAS occurrence estimates	Used an occurrence dataset comprised of UCMR 3 and information from state regulatory agencies. Estimates the following number of water systems will exceed 4.0 ng/L PFOA and/or PFOS: Serving 10,000 or less: 7,056 PWS (8,808 EPTDS) Serving more than 10,000: 393 PWS (1,214 EPTDS) Total PWSs: 7,449 PWSs (10,022 EPTDS)	The dataset used is not appropriate for national extrapolation, for example, 90 percent of non-UCMR systems used in the report come from just 6 states. As a result, AWWA's B&V report likely overestimates the number of water systems exceeding the MCLs, particularly small water systems. After incorporating updated state monitoring data into its occurrence model, the EPA estimates the following number of water systems will exceed 4.0 ng/L of PFOA and/or PFOS (**mean** (5th-95th from Chapter 4.4 of the EA): Serving 10,000 or less: **3,870** (2,795-5,097) PWS **5,11**5(3,666-6,858) EPTDS Serving more than 10,000: **1,266** (1,203-1,328) PWS **3,878** (3,701-4,056) EPTDS Total PWSs: **5,136** (4,018-6,441) PWSs **8,993** (7,497-10,711)EPTDS AWWA's B&V report did not specify, what measures, if any were taken to ensure the data was nationally representative and this may be one cause of their overestimation of water systems exceeding the MCLs. The EPA used QC measures to ensure that the data represented finished drinking water and that the set of systems used to inform the model was nationally representative. Additional state data that were available at systems that were part of this nationally representative set of systems were used to fit the model. For more information, see section VI Occurrence of the preamble for the final rule.
Number of EPTDS installing treatment	Assumes every EPTDS a system will require treatment regardless of whether a given EPTDS exceeds the MCL.	This is an incorrect assumption and likely leads to a significant overestimate of national costs. A single water system often have EPTDS that use different water sources, and therefore have different PFAS concentrations. The EPA conducted an EPTDS-level cost analysis as compliance with the rule is determined at the EPTDS-level and treatment is installed at the EPTDS-level.

Analytical Component	AWWA's B&V report	EPA response
PWSs in states with existing PFAS regulations	Includes estimates of the costs to PWSs to comply with existing state PFAS regulations; and does not assume that PWSs are already in compliance with state standards.	This approach overestimates costs for water systems in states with existing state standards. The EPA adjusts the baseline by setting the maximum pre-regulation concentrations equal to the state MCL for systems in states with promulgated regulations. This allows the EPA to capture the incremental costs of the PFAS NPDWR more accurately.
Non-treatment options	Assumes all exceeding EPTDS will install a treatment technology to comply with the PFAS NPDWR.	This assumption overestimates costs, as the EPA is aware of a number of water systems that have elected to drill a new well to reduce PFAS concentrations in supplied water. Another commenter pointed out that Michigan expects up to 26 percent of water systems to interconnect with other systems to comply with their state standard. Other commenters pointed out the viability of interconnection and new wells as compliance options will vary regionally, and the EPA agrees. Nevertheless, the absence of these options entirely in AWWA's B&V report overestimates national costs.

The EPA Response to key capital cost assumptions in AWWA B&V Report

Analytical Component	AWWA B&V report	EPA response
Equipment lifespan	Assumes a fixed life cycle cost using a fixed 20-year lifespan for all capital equipment.	A 20-year lifespan may be reasonable for very small systems but based on the composite useful life of treatment systems derived from the useful lives of individual treatment system components and industry information, the EPA estimates that treatment system useful life can be 30 years or more for medium to larger systems using more durable materials of construction.
Contingency factors	Includes a contingency factor of 4 percent under contractor markup and an additional contingency factor of 30 percent under non-construction costs.	The inclusion of contingency twice is unusual and may not reflect actual realized contingency costs at project completion. A Construction Industry Institute (2001) study found that projects of $100 million or less incurred only 74 percent or less of the contingency initially budgeted. The EPA updated its approach to incorporate a contingency factor of 5 to 10 percent depending on total project cost at all cost levels for systems installing treatment. The EPA also included a miscellaneous allowance of 10 percent, which can be considered a form of contingency.
Building costs	Assumes a fixed unit cost of $200/square foot for buildings.	AWWA's fixed unit cost likely overestimates actual building costs, particularly for small systems that may not require complex or architecturally detailed buildings. The EPA estimates that building costs vary depending on building quality and square footage and range from $57/square foot to $204/square foot.
Pumping and backwash assumptions	Assumes that all GAC and IX treatment systems require a new influent pumping station, and all GAC and IX treatment systems require new backwash pumps.	AWWA's assumptions overestimate costs as many systems, including small groundwater systems, likely have sufficient existing influent pumping pressure to cover the additional head loss. Some systems using GAC (especially small systems) may not need a dedicated new backwash pump

Analytical Component	AWWA B&V report	EPA response
	Except for the two smallest size categories, assumes all GAC and IX treatment systems require backwash recovery basins providing 20 feet of water depth.	and may be able to accomplish backwash using existing influent or treated water pumps. In applications using PFAS-selective IX resins, periodic backwashing is not recommended (Berretta et al., 2021), so the need for these pumps is questionable and the assumption overestimates costs.
Capital equipment costs	The Association of Metropolitan Water Agencies (AMWA) and the AWWA surveyed its members to obtain recent cost data on installed PFAS treatment systems at drinking water treatment plants.	The EPA updated its equipment costs to 2022 dollars using current price indices. The EPA also collected new vendor price quotes for cost driver equipment components (e.g., pressure vessels, treatment media) and made several other adjustments to WBS model assumptions about pilot study costs and contingency costs that increased total capital costs. The B&V model, as presented in Figure 7-1 of AWWA's public comment letter, appears to overestimate costs for many of the case studies included in the B&V report. For example, it results in higher costs for 28 of the 32 case studies (88 percent) shown in Figure 7-1. The EPA assessed the WBS model results in comparison to the costs of GAC equipment packages from 2023 supplied by a nationally recognized vendor of GAC media and GAC treatment systems. Based on this assessment, the EPA concluded that the direct capital costs in the WBS model for comparable packages of equipment, excluding items the vendor does not supply, range from 23 percent lower to 19 percent higher than the vendor costs and with two exceptions, they are within 10 percent of the vendor costs.
Small system capital costs	Listed capital costs for small systems ranging from $900,000 to $5,300,000.	The EPA accounts for the use of package systems. AWWA Appendix B Table 3-1 indicates that their pressure GAC model accepts treatment capacity inputs from 1 to 12 mgd. It does not indicate how the model handles design flows less than 1 mgd. It is possible that the parametric estimates the model uses are not a good fit below this threshold and does not account for the use of package systems.
Average and design flow estimates	Service population data from SDWIS was used and the average flow for each PWS was assumed based on a per capita per day usage of 150 gallons. Peaking factors for different size systems from the EPA's "Cost and Technology Document for Final Groundwater Rule" were used.	Estimated design flow of a water system effects the size and cost of the capital equipment that will be installed on site. Average flow estimates are the driver for many operational costs. AWWA's approach to estimating design and average flow requirements overestimates the treatment system flow requirements, particularly for smaller systems. For the smallest systems, AWWA's approach overestimates flows by up to 30 percent. The EPA estimated the average daily flow and design flow for drinking water systems based on the empirical relationship between retail population served and flow. This relationship was derived using the data collected via the CWSS. It is reported in the EPA's Geometries and Characteristics of Public Water Systems report (USEPA, 2000). As detailed in Table 4-34 of the EA for the final rule, water use efficiency has increased substantially since these relationships were developed, and therefore the trend of lower residential water use could

Analytical Component	AWWA B&V report	EPA response
		result In lower flow per population and lower treatment costs as compared to predicted values in the EPA's analysis.

The EPA Response to key operation and maintenance cost assumptions in AWWA B&V Report

Analytical Component	AWWA B&V report	EPA response
bed life	The BV values utilized for GAC were derived from data collected during a Black & Veatch GAC pilot study for Cape Fear Public Utility Authority (CFPUA). The values utilized for IX were derived partially from data collected during a Black & Veatch IX pilot study for CFPUA and partially from data collected during an IX pilot study for La Habra Height County Water District.	AWWA estimates bed life for all systems using parameters derived from one or two pilot studies. These site-specific pilot studies may not be representative of the range of water quality conditions experienced by systems across the country. For GAC in particular, using the parameters in AWWA's Table 5-9 results in estimated bed lives of less than 7,000 and 9,000 BVs for 90 percent removal of PFOA and PFOS respectively. These short bed life estimates result in high annual operating costs and may be an artifact of the relatively high influent TOC in the CFPUA pilot study that is the basis of AWWA's estimates. Surface and groundwater systems with more moderate to low influent TOC would be expected to experience much longer GAC bed life and lower operating costs.
Disposal of treatment media	Assumed that spent GAC media would be incinerated "because of the unknown viability of GAC media reactivation under CERCLA." Replacement costs were therefore assumed to be virgin media.	The EPA has proposed PFOA and PFOS be designated as hazardous substances under CERCLA and is in the process of proposing some PFAS be listed as hazardous constituents under RCRA. If finalized, these actions would not require waste (e.g., biosolids, treatment residuals, etc.) to be treated in any particular fashion, nor disposed of at any specific particular type of landfill. The designation and listing also would not restrict, change, or recommend any specific activity or type of waste at landfills. However, waste management facilities may, at their own discretion, refuse to accept PFAS-containing materials or drinking water treatment operations may choose to send spent GAC and resin containing PFAS to facilities permitted to treat and/or dispose of hazardous wastes. Even where reactivation is not feasible, disposal in a RCRA permitted hazardous waste landfill is expected to be a more cost-effective option than incineration. Therefore, the assumption of incineration and replacement with virgin media overestimates the disposal costs in the B&V report.

A few commenters stated that the WBS model results were inaccurate because the models "…were developed from 2006 to 2012" and/or underwent peer review more than 10 years ago. WBS model development did not cease in 2012. The EPA has continued to maintain and update

the models throughout the intervening years. This maintenance includes updating unit costs on an annual basis and incorporating the latest results from the scientific literature on treatment design and effectiveness for emerging contaminants like PFAS. For example, for the final rule, the EPA updated unit costs and made changes to model design parameters as described in the paragraphs above. Also, although initial external peer review of the models used for this rule took place more than 10 years ago, the EPA has conducted internal quality assurance review on an ongoing basis as part of the regular update cycle. Versions of the model incorporating annual updates have been available for external review and public use on the EPA's website since approximately 2016. The versions used to support this proposed rulemaking were available for review in the docket for this proposed regulation; likewise, the versions updated after considering public comments are available in the docket for this final action. All design parameters, including specific adjustments to estimate the cost of PFAS treatment, are also described in detail in the supporting documentation, included in the docket. The EPA further notes that there is no indication that the B&V cost model has been peer reviewed and has relatively limited publicly available associated documentation.

Individual Public Comments

U.S. Chamber of Commerce (Doc. #1537, SBC-042649)

• The Safe Drinking Water Act requires consideration of the costs and benefits. The Chamber submitted a report to the Office of Management and Budget (OMB) modelling the potential costs attributable to various drinking water treatment levels. The estimated annualized costs for a proposed MCL of 4 ppt for PFOA and PFOS are approximately $1.8 billion annually and are more than twice as much as the EPA estimated costs in their economic analysis. Our cover letter to OMB and the report are here and here. The significant costs and impacts and their connection to other elements of the PFAS Strategic Roadmap, such as the proposed hazardous substance designation under CERCLA demand a full vetting by the stakeholder community.

This modelling effort developed the costs related to various drinking water treatment at 70 ppt, 20 ppt, 10 ppt, 4 ppt, and non-detect:

• The non-detect level costs are orders of magnitude higher than the other costs at almost $60 billion.

• At 4 ppt, which is at the lowest level of detection we found that the costs are approximately $32.5 billion over 20 year project implementation and operations and maintenance.

• AWWA's estimates were more significant – as high as $50 billion for 20 ppt.

EPA Response: The EPA disagrees with the many of the assumptions and approaches in the commenter's report "Potential Costs of Meeting Safe Drinking Water Act (SDWA) Standards for PFOA and PFOS" (US CC, 2022) referenced in their comment letter submitted on the proposed PFAS NPDWR. The report lacks the detailed documentation required to conduct a

complete review of the commenter's methodology, however the EPA notes the following key limitations with the approach that the commenter uses to estimate national costs.

1) The commenter utilized a dataset from which they state 95 percent of the dataset is limited to 8 states to estimate the number of water systems expected to exceed various PFAS thresholds. Use of non-nationally representative data is likely to bias the commenter's results. The EPA used QC (quality control) measures to ensure that the state data utilized in the agency's model was nationally representative. The commenter's report does not appear to present the estimated number of water systems exceeding each threshold. The number of water systems expected to install treatment is a key driver of national costs, without which is it difficult to compare to the EPA's national cost estimates.
2) The commenter assumes all PWSs that install treatment will use GAC. The EPA's cost analysis for the proposed and final rule more accurately includes the range of BATs and SSCTs available to PWS, as well as non-treatment options to comply with the rule.
3) The report relies on GAC capital costs provided in 2021 by California's State Water Resources Control Board (SWRCB). Very little information is provided about the design parameters used to develop these estimates or the scope of equipment included. However, the first three cost estimates shown in Table 2 assume the use of a single vessel. For treatment of PFAS, design engineers and GAC vendors commonly recommend two vessels in series. The assumption of a single vessel suggests that the GAC capital costs used in the report are generic estimates, not specific to treatment of PFAS.
4) The table below compares the equipment costs from Table 2 of the report to costs for GAC equipment packages supplied by a nationally recognized vendor of GAC media and GAC treatment systems. The vendor packages are identical to those in Table 2 in terms of diameter, number of vessels, and GAC mass per vessel. The costs used in the report are several times higher than the vendor costs. The costs used by the commenter are not likely to be representative of costs nationwide. Equipment prices in California are likely to differ from other parts of the country, and it is under what is included in "GAC equipment."

Vessel Diameter (ft x vessels)	GAC Mass (lb/vessel)	Equipment Cost from SWCRB (2021)	Equipment Cost from GAC Vendor (2023)	Difference
6 x 1	6,000	$ 437,000	$ 120,000	264%
8 x 1	10,000	$ 536,000	$ 130,000	312%
12 x 1	20,000	$ 745,000	$ 180,000	314%
12 x 2	20,000	$1,490,000	$ 370,000	303%

5) The report assumes GAC system operation and maintenance (O&M) costs are $280 per million gallons. The source of this assumption is cited as the EPA's WBS model. It is unclear how the report derived a single value from the WBS model. O&M costs from the EPA's WBS model for GAC can vary dramatically depending on input parameters,

primarily bed life and average flow. The report's estimate of $280 per million gallons is near the low end of the range of O&M costs generated by the WBS model for the final PFAS rule.

6) The report assumes GAC system operation and maintenance (O&M) costs are $280 per million gallons. The source of this assumption is cited as the EPA's Work Breakdown Structure (WBS) model. It is unclear how the report derived a single value from the WBS model. O&M costs from the EPA's WBS model for GAC can vary dramatically depending on input parameters, primarily bed life and average flow. The report's estimate of $280 per million gallons is near the low end of the range of O&M costs generated by the WBS model for the final PFAS rule.

Items #3 and #6 are likely to underestimate national treatment costs. Items #2, #4, and #6 are likely to lead to a significant overestimation of national treatment costs. Absent more information, the effect of item #1 is unknown. The commenter concludes that "the estimated annualized costs for a proposed MCL of 4 ppt for PFOA and PFOS are approximately $1.8 billion annually." Collectively, the EPA disagrees with many of the assumptions in the report and the report's overall conclusions about the estimated national costs. The EPA notes that in response to comments received on the agency's cost analysis for proposal, the agency has made a number of changes to the treatment cost analysis, detailed in section 13.3.3 of the EPA response in this *Response to Comments* document.

In response to the commenter's reference to AWWA B&V estimates of national costs, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for more details.

Bowling Green Municipal Utilities (Doc. #1767, SBC-043932)

EPA's Cost Model Underestimates the Cost of the Proposed Rule: EPA underestimates the cost of drinking water treatment to remove PFOA and PFOS. Cost models prepared for AWWA by Black & Veatch as well as examples of previously built PFAS treatment systems differ significantly from EPA's model. EPA's benefit cost analysis must accurately evaluate the cost impact of the rule to make a sound decision on the appropriateness of the rule requirements.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1841, SBC-047718)

The EPA analysis also does not include an estimate of the cost for the largest sized systems which AWWA estimates face annual costs of over $50 million per system. Using AWWA's projection that four systems within this largest category will be required to come into compliance with the proposed regulation, the annualized cost for this size category exceeds $200 million. It

is not clear whether EPA's total cost estimate includes an estimate for systems in the largest size category since no data are provided.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Additionally, AWWA's comment letter does not provide information on the four systems expected to exceed the MCLs or information on how that was determined. The EPA's EA for the final rule included costs for two systems within the largest size category that each would need to install treatment at multiple entry points. The EPA reviewed UCMR3 data and recent system consumer confidence reports to obtain entry point PFAS values rather than model treatment costs using the PFAS occurrence values simulated from the MCMC model. The EPA used these values to determine which entry points at these systems exceed the MCLs and/or Hazard Index for the proposed rule and alternative options (see Appendix N of the EA for more information).

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043942)

EPA also fails to consider and weigh the costs of additional sampling that will need to be conducted to evaluate selected treatment media for contaminant breakthrough.

EPA Response: The EPA included pilot testing costs in the treatment capital cost estimates for the proposed rule and further updated these costs for the final rule, including adding a full year of full-scale confirmation sampling. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045911)

Furthermore, EPA has likely underestimated the quantity of spent GAC that will require treatment. EPA identified proposed Bed Volumes for GAC that exceed the values that AWWA identified in their analysis. The generation rate of spent carbon is a function of bed volume and replacement frequency. EPA's cost estimate basis for bed volume was a range of 5,000 to 150,000 for GAC [FN154: 88 Fed. Reg. at 18695.]. AWWA's analysis limited the carbon life to a maximum of 40,000 bed volumes for GAC. Bed volumes directly impact operating costs of these systems; EPA's assumptions of longer bed volumes would result in incurring lower costs due to less frequent media exchange and disposal.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Horsham Water & Sewer Authority (HWSA) (Doc. #1686, SBC-043811)

Regarding operating costs, again EPA failed to use actual real data and the results are cost estimates that are low. For instance, EPA's model for the number of bed volumes (BVs) GAC can effectively treat for various PFAS compounds provided in EPA's Technologies and Costs for

Removing Per- and Polyfluorinated Substances (PFAS) from Drinking Water document to support this rule incredulously relies on a total of ten (10) waters, all of which were pilot data or benchtop data using Rapid Small Scale Column Testing (RSSCT), and for low Total Organic Carbon (TOC) waters such as most groundwaters, EPA only used data four (4) waters, all four being RSSCT data only. This despite EPA admitting on page 23 of this same document, that "there is no consensus in the literature regarding methods to scale up GAC from RSSCT to full-scale". Not surprisingly, when we use our real-world full-scale data to verify the accuracy of this model, we get drastically lower values for the number of BVs for all compounds we have breakthrough data for (PFOA, PFHxS, PHFpA, PFBS, and PFHxA). For instance, using the data for our Well 2 when the well was initially put in service with two (2) vessels in series using virgin GAC, once we received sampling data that showed breakthrough of PFHxA at the mid-point of the two vessels (weeks after the actual sampling data due to laboratory turnaround time), we began scheduling a change out of the first vessel, but it would take another five (5) months to get the GAC changeout completed. We continued to do monthly sampling and during the time from the PFHxA breakthrough to changeout we experienced the breakthrough of PFBS, PFHpA, PFOA and finally PFHxS such that we can conservatively calculate actual number of BVs using the sampling dates showing the first breakthrough (may have occurred earlier). The table below compares our actual BVs (the actual BVs may have been less than these numbers if the breakthrough occurred prior to the monthly sampling date) versus EPA's model equation.

[Table: see docket ID EPA-HQ-OW-2022-0114-1686]

The model results for the number of BVs needed are two (2) to three (3) times higher than our actual data for Well 2. The average for all 26 GAC changeouts we have performed to date at all our sites is 21,555 BVs which includes the average 4-5 months from breakthrough to changeout, so the Well 2 example above is on the long side for our typical filter run times. While it is recognized that the model was developed for national cost estimating purposes and not for use on individual waters, if the model does not even closely represent actual conditions the resultant cost estimates are flawed. We believe the EPA model greatly overestimates the efficiency of GAC for removing various PFAS compounds, particularly for low TOC waters such as ours, and therefore will greatly underestimate both overall national operating costs, and unfortunately small system operating costs in particular which use predominantly low TOC groundwaters. Not all data is equal in weight, and real-world full-scale data trumps pilot plant data, which in turn, trumps bench top/laboratory data. It is rather inconceivable that EPA chose to rely on such a limited data set from only four waters, all using RSSTs no less, which as EPA acknowledges, are questionable as to their relevance to full-scale applications, to develop their low TOC equation when we believe there is ample full-scale data such as ours available (EPA identifies 30 full-scale GAC systems in the report).

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Additionally, the commenter did not provide quantitative data on the percent removal or total organic carbon (TOC) concentration used to calculate the "EPA Model Calculated Bed Volumes" shown in the commenter's table, so the EPA cannot confirm that the

commenter's comparison is based on an accurate application of the bed life equations. Also, to compensate for potential overestimation when extrapolating from rapid small-scale column tests (RSSCTs) to full-scale, the EPA did not incorporate the increase in bed life that would be expected from operating multiple contactors in series when applying the results of the equations. In other words, the EPA converted the results of the equations in bed volume to bed life in units of time using a 10-minute empty bed contact time (EBCT), typical of a single vessel. The commenter did not indicate the EBCT of their treatment system, but if their bed volumes are calculated using a 20-minute total EBCT, typical of two vessels in series, they would be expected to be one half of the EPA's results for the same replacement frequency. The EPA used the best available, peer-review data in estimating bed life; see Chapter 5.3.1 of the EA for more information Finally, as the commenter points out, the equations were developed for national cost estimating purposes, not for use on individual waters, which may have water quality characteristics that result in longer or shorter bed life.

New England Water Works Association (Doc. #1836, SBC-045397)

Cost:

NEWWA believes that the technical memorandum [FN9: WITAF 56 TECHNICAL MEMORANDUM, PFAS National Cost Model Report, B&V PROJECT NO. 409850 https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14- 102450-257] prepared by Black & Veatch on behalf of American Water Works Association (AWWA WITAF 56) provides the most accurate depiction of the costs which will be incurred by utilities should EPA's proposal be finalized. We would urge EPA to revisit their cost assumptions as they significantly underestimate the true impact for communities. By comparison, the most recent estimate by Black & Veatch estimates that the annualized cost of the rule could exceed $3.2 billion based on a PFOA and PFOS MCL of 4 ppt each. NEWWA subsequently confirmed that the costs are underestimated in review of the EPA's cost analysis for different size systems with the results of a recent survey by Kleinfelder.

Kleinfelder's focused survey of New England utilities found that the median capital cost per million-gallons- per-day treated for PFAS removal (MGD) was $4.3 million. While it may be too soon to fully understand the impact of ongoing operations and maintenance (O&M) costs, the survey responses indicated yearly maintenance costs per vessel at $200,000, and yearly facility O&M costs from $250,000-$373,000.

GAC media costs have been increasing steadily as illustrated in the following chart. We are concerned that costs will continue to rise for all PWS who use GAC for treatment when there is a rush to provide it to systems for PFAS remediation:

[Figure 2: see docket ID EPA-HQ-OQ-2022-0114-1836]

Figure 2: Trend in Costs Over Time for Granular Activated Carbon Media.

EPA Response: This comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs; for more information, please see section 13.3.3 of the EPA response in this *Response to Comments* document. With regard to the impact of demand for GAC on costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046020)

Monitoring and Administrative Costs

In its EA, EPA estimates startup, sampling, and treatment administration cost elements that are applied to this estimate of systems per ETPSs for each CWS size [FN114: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation Appendices," tbl. C–9; Black & Veatch, "PFAS National Cost Model Report," tbl. A-1.]. The tables below display each of these cost breakdowns. Implementation startup costs account for labor and costs per system, along with average hours per system to read and adopt the rule and average hours per system to attend one-time trainings provided by primary agencies. Total costs range from $460,000 to $3,600,000. Laboratory analysis costs, labor rate, and the number of samples are used to estimate monitoring and sampling costs per location. Quarterly sampling costs per location are $5,200 for small systems and $5,300 for large systems, while triennial costs are between $710 and $1,500 per location (Table 15).

Table 15: Sampling Costs

[Table 15: see docket ID EPA-HQ-OW-2022-0114-1738]

[FN115: Lab analysis cost per sample for the field reagent blank under EPA Method 533.]

[FN116: Lab analysis cost per sample for the field reagent blank under EPA Method 537.1]

EPA Response: This comment reiterates information provided in the EPA's background materials and does not need a response.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045995)

Section 8.9: Lab capacity and sample costs

As mentioned earlier, significantly more samples need to be taken by PWSs to assess the extent of issues related to PFAS in the source and finished waters. EPA estimates the cost per sample of EPA methods 533 and 537.1 are $376 and $302, respectively. AMWA believes these costs are generally on par with current pricing for large commercial labs. Using the three estimations from individual water systems mentioned in Section 5.5, additional testing will significantly increase costs. Using method 537.1 costs, the increase in costs for those water systems that must do additional testing will be: $270,720 additional costs for 720 samples/year, $188,000 for 500

samples/year, and $60,160 for 160 samples a year. These cost estimates do not even factor in sampling and delivery costs. These costs are not unique to these three systems and will be required at any system implementing or even considering a treatment technique. Some utilities also use both methods as an additional assurance, which would almost double the costs.

Based on EPA's estimations of annual PWS sampling cost of $90.32 million, this results in EPA expecting a total of approximately 240,213 (90.32 million divided by $376, cost per sample) samples annually for all water systems. With approximately 52,000 water systems subject to this proposed rulemaking, that results in between 4-5 samples per water system (240,213 samples divided by 52,000 water systems). This is an unrealistic estimation. Not only do many water systems have multiple EPTDS which will increase this sample number, but compliance monitoring samples are not the only samples that will need to be analyzed. Additionally, since EPA has made it difficult to prove detections less than the proposed trigger level, which is below the PQL, many water systems will not be able to qualify for continued reduced monitoring, which would have made this number more reasonable.

AMWA asserts that it will not be simple for PWSs to acquire data below the PQL. AMWA members have indicated that a popular commercial lab has informed them that a water system on a UCMR 5 contract who would like to see results below 4 ppt would need to perform an entirely separate sampling event due to QAQC considerations. This would require water systems to pay twice for results below 4 ppt if they cannot amend the contract, and they would still only receive results above 2 ppt. Most PWSs will not be able to gain the data necessary to comply with the proposed reduced monitoring requirements, and could see significant increase in costs to get data between 2-4 ppt.

EPA Response: Regarding the need for ongoing performance monitoring in addition to compliance monitoring, the EPA anticipates that many water systems will conduct a pilot test before implementing a full-scale treatment installation and that the operational results from the pilot test will be a sufficient indicator of performance; therefore, water systems should not have to collect large amounts of performance samples indefinitely during the full-scale operation of treatment technologies. The EPA included pilot testing costs in the treatment capital cost estimates for the proposed rule and further updated these costs for the final rule. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Please see section 13.3.4 of the EPA response in this *Response to Comments* document regarding response to comments about PWSs acquiring data below the PQL.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046034)

Significant Cost Increases for Current Operations

The potential increase in operating expenses for PFAS treatment comes at a time when Fairfax Water has seen double- and triple-digit percentage increases in essential supplies such as chemicals and ductile iron pipe. While Fairfax Water's production has been essentially flat, since January 2020, its chemical budget has increased 52%. Costs for sodium hypochlorite

(disinfectant) in that time have increased 175% and costs for poly-aluminum chloride (coagulant) have increased 67%. Costs for ductile iron pipe, used in the distribution system to replace aging infrastructure, have on average increased 54% for 4-inch to 36-inch pipe and 128% for 42-inch and 48-inch pipe. Purchased power costs have increased 31% since July 2022. Costs for GAC have increased 17% in two years.

EPA Response: After considering this and other public comments, the EPA has updated the dollar year used in the WBS models to $2022; for more information, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043095)

The cost analysis for drinking water treatment is demonstrably underestimating the impacts of the rule based on case study data and a model by Black & Veatch, which was crafted leveraging long-standing national PFAS treatment design expertise.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

North Penn Water Authority (NPWA) (Doc. #1470, SBC-043293)

Impact on North Penn Water Authority

Specifically with regard to the North Penn Water Authority, we are fortunate to have one of the most reliable and advanced, state-of-the-art water treatment plants in the nation at Forest Park in Chalfont, which we jointly own and operate in partnership with the North Wales Water Authority. It serves a total population of about 200,000 people in a large geographic region in Montgomery and Bucks Counties, outside Philadelphia. The plant, which treats surface water from Lake Galena, supplemented by water drawn from the Delaware River, has been operating continuously since 1994, and has since been expanded twice and the treatment technology upgraded several times in order to keep up with changing water quality regulations over the past 25-plus years. The original sand filters have been replaced with membranes, which is one of the most effective methods of water treatment available anywhere in the world.

The good news is that NPWA will be able to meet these new stringent standards imposed by EPA. But the bad news is that in order to continue to maintain compliance in the future, Forest Park will most likely have to incur significant additional costs to change out the Granular Activated Carbon systems more frequently than the current practice. Also, the plant will most likely need to be expanded yet again to accommodate the added capacity that will be needed, as we anticipate that many surrounding communities may conclude that it would be better to buy water from Forest Park rather than to incur the added costs of installing expensive PFAS treatment systems on their groundwater wells.

EPA Response: The EPA agrees that some systems will incur additional costs to comply with the new standards and has included these costs in the cost analysis. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Greater Cincinnati Water Works (GCWW) (Doc. #1550, SBC-042689)

May 12, 2023

U.S Environmental Protection Agency

EPA Docket Center

Office of Ground Water and Drinking Water 1200 Pennsylvania Avenue NW

Washington, DC 20460

Re: Docket ID No. EPA-HQ-OW-2022-0114

PFAS National Primary Drinking Water Regulation Rulemaking

To Whom It May Concern:

Thank you for the opportunity to comment on the USEPA's proposed PFAS National Primary Drinking Water Regulation. Greater Cincinnati Water Works (GCWW) is a municipal water utility serving 1.1 million people in the Greater Cincinnati area. We treat water from two different sources, both of which are impacted by low levels of PFAS contamination. Eighty-eight percent of our water comes from the Ohio River. The treatment plant for this source already incorporates granular activated carbon which removes most of the PFAS compounds. However, we will likely incur additional operating costs of $150,000-$300,000/year to ensure compliance at this facility.

The remaining 12% of our water comes from a ground water source with levels of PFAS averaging within 1 ppt of the proposed MCL for PFOA and PFOS. This plant, like many across the United States, is not designed to remove PFAS compounds. Our current estimate is at least $60 million in capital costs to retrofit the 40 million gallon/day plant for PFAS removal. Our cost estimates are in line with the costs of plants such as Cape Fear, NC which are doing retrofits to add PFAS removal processes. Our construction estimates do not include the on-going operation and maintenance costs, nor does it account for disposal of any waste materials from the PFAS treatment. Based on our estimates, we believe EPA's estimated costs for nationwide compliance are significantly underestimated. We believe the estimates do not adequately take into account the recent period of inflation in the construction sector, nor the additional increases which will occur due to increased demand for specialized treatment design and construction within a very narrow time window to achieve compliance. As an example, with a recent construction project for a new clearwell the lowest bidder was 30% higher than our consulting engineer's estimate. We are also seeing significant increases in all our capital projects, many of which seem to be due to a shortage of qualified contractors. Other utilities are seeing similar situations.

EPA Response: The comment lacks sufficient detail to compare the estimate of $150,000-$300,000/year additional operating cost to the results of the EPA's WBS models. The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $25 million to $42 million for a 40 million gallon/day facility using GAC to treat groundwater. Although the commenter's estimate of $60 million exceeds the EPA's ranges, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for this facility would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

City of Wilmington, Ohio (Doc. #1572, SBC-042465)

Comments of the City of Wilmington, Ohio

Proposed National Primary Drinking Water Regulation (NPDWR) for Per- and Polyfluoroakyl Substances (PFAS)

Public Docket ID: EPA-HQ-OW-2022-0114

The City of Wilmington has just 12,000 residents with a median household income about $25,700 less than the national median and $19,900 less than the Ohio median. Now, this small city has to deal with a primary drinking water source being contaminated with PFAS because of activities at the former Clinton County Air Base, which has been converted into the Wilmington Air Park and remains an active airport.

Early estimates indicate it will cost between $5 and $10 million to upgrade the Water Treatment Plant to be able to reliably remove PFAS substances and meet the proposed MCLs. In addition, an annual increase of up to $500,000 in operations and maintenance costs is expected. The additional O&M cost alone would necessitate a 10 percent rate increase for our residents, who are already on the hook for significant sewer rate increases to pay for a new wastewater treatment plant. If loan financing must be used for the capital improvements to the water plant, rates will have to go even higher.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Lakewood Water District (LWD) (Doc. #1574, SBC-042747)

May 24, 2023

Michael Regan, Administrator Environmental Protection Agency 1200 Pennsylvania Avenue, N.W.

Mail Code: 1309

Washington, DC 20004

RE: Per- and polyfluoroalkyl substances (PFAS): Perfluorooctanoic acid (PFOA) and Perfluorooctanesulfonic acid (PFOS) National Primary Drinking Water Regulation Rulemaking, Docket No. EPA–HQ–OW-2022-0114

Dear Administrator Regan,

I am the General Manager for Lakewood Water District (LWD) submitting comments on EPA's proposed PFAS drinking water regulations. LWD is the largest water District in Pierce County, Washington. Located just south of Tacoma, Washington, and adjacent to Joint Base Lewis McChord (JBLM). LWD serves more than 65,000 customers directly and over 60,000 more via wholesale water supply contracts with five neighboring purveyors.

LWD has been dealing with PFAS contamination of its aquifer system since 2016 when PFAS migrating from JBLM was first detected in the District's wells. PFAS has now been detected in 13 of the District's wells resulting in four of those wells being shut down due to exceedance of Washington State PFAS State Action Levels (SAL).

To address this widespread PFAS contamination, LWD has developed a multi-year $28 million program to clean up and mitigate PFAS contamination at the 13 contaminated wellfields. So far, this program has cleaned up two wellfields (four wells) utilizing Granular Activated Carbon (GAC) systems at the cost of more than $8.86 million. Supplementing this treatment approach, LWD is also pursuing drilling replacement wells into much deeper (hopefully) uncontaminated aquifers. These new wells are expected to offset supplies lost due to PFAS contamination.

With this context in mind, LWD's comments on EPA's proposed PFAS rules are framed from actual real-world experience with addressing PFAS contamination of drinking water. Our comments fall into six broad categories:

1. Costs are systematically underestimated.

2. Federal funding support is exaggerated.

3. Proposed trigger levels are inappropriate.

4. Proposed Hazard Index approach is flawed.

5. Penalties for monitoring are counterproductive.

6. Timeline to implement is not feasible.

Costs are Systematically Underestimated

The cost presented in the proposed rules systematically underestimates:

* Capital costs

* Operational costs, and

* Implementation costs

The following paragraphs provide examples and highlights regarding this underestimation and are not intended to be an exhaustive treatise. Rather, these examples highlight the serious shortcomings in the EPA's assumptions regarding the cost of implementation and compliance with the proposed rules.

Capital Costs

As described above, LWD has completed two GAC systems to remove PFAS from groundwater. LWD's first GAC system was at the Ponders well site, which has two wells. Design started in April 2018; the GAC system came online in January 2020. The all-in costs, including engineering, permitting, bidding, and administrative costs, were $ 3.3 million for just over 2,000 gallons per minute (GPM), or $1.65 million per 1,000 GPM.

LWD's second site, Scott's well site, has two wells producing about 3,000 GPM, with all the same components mentioned above. LWD started design in May 2020, completed construction, and brought it online in May 2022 for a cost of $5.1 million for treating 3,000 GPM. Or $1.70 million per 1,000 GPM.

The bottom line is that the capital costs that LWD has experienced are three times the cost of what EPA portrays in the proposed rulemaking.

While these data points may be considered anecdotal, the magnitude of these examples of capital cost under-estimating is consistent with the broader findings of the American Water Works Association (AWWA) assessment of cost under-estimating in the proposed rule. The AWWA assessment also found that the typical PFAS treatment system is shown to cost 330% more than the estimated cost by the EPA's WBS Model.

EPA Response: The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $3.8 million to $6.4 million for 2,000 gallons per minute facility using GAC to treat groundwater. The commenter's reported cost of $3.3 million for the Ponders well site falls just below this range. For the Scott's wells site, the EPA's updated cost curves estimate a range of capital costs of approximately $5.1 million to $8.5 million for a 3,000 gallons per minute facility using GAC to treat groundwater. The commenter's reported cost of $5.1 million for this site falls within this range.

Lakewood Water District (LWD) (Doc. #1574, SBC-042750)

Operational Costs

Similar to capital cost estimates, operational cost estimates consistently underestimate the operational cost impact that water purveyors will face. LWD's annual Operation and Maintenance (O&M) cost for staff time, site visits, and sampling costs is $60,000 for two GAC treatment sites. Under the current Washington State SAL level of 10 parts per trillion (ppt) for PFOA and 15 ppt for PFOS, the estimated run time for replacing media is $400,000 per site

every five years. With the proposed EPA MCL of 4 ppt for PFOS and PFOA, LWD would have to replace the media every 2.5 years, which would double those costs.

EPA Response: Assuming these sites treat an average flow that is 50 percent of design flow (i.e., 1,000 to 1,500 gallons per minute) and given a replacement frequency of 2.5 years, the updated cost curves the EPA developed for the final rule estimate a range of annual O&M costs of approximately $224,000 to $324,000 per site per year. In comparison, the commenter's estimate converts to $190,000 per site per year ($60,000 per year / 2 sites = $30,000 per site per year; $400,000 per site / 2.5 years = $160,000 per site per year). This estimate falls just below the EPA's range.

New Hampshire Water Works Association, Inc. (NHWWA) (Doc. #1576, SBC-042449)

Approximately 150 community water systems – including two of our largest – are impacted by PFAS above New Hampshire's regulatory levels. Our legislature passed a law in June 2020 to provide $50M of funding to assist any system, including residential wells, so impacted. As capital costs continue to increase, these funds will fall short. In addition, ongoing operation and maintenance (O&M) costs are large, growing, and of long (decades) duration: our budget funds are insufficient to meet this need. Even with proposed federal support, funds for PFAS treatment at current NHDES drinking water standards are inadequate.

Please carefully consider the following points to help inform the pending rulemaking on this class of pervasive and persistent toxic chemicals:

• With several thousand systems impacted by the proposed MCLs and roughly three-quarters of them serving 10,000 customers or less, the proposed MCLs will disproportionately affect small systems. Many smaller systems lack the financial, staff and management resources to implement the proposed rules. In New Hampshire, where approximately 200 additional public water systems will be impacted, the estimated capital costs of ~$170M and annual O&M costs of $44M do not account for inflation, manufacturing and supply chain issues, or professional labor shortages.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

New Hampshire Water Works Association, Inc. (NHWWA) (Doc. #1576, SBC-042453)

EPA has not accurately estimated costs associated with treating PFAS to the proposed MCL. EPA's annualized costs for treatment are $772M per year, which contrasts with an American Water Works Association's estimate of $3,800M per year. A growing body of actual cost data indicate EPA's O&M estimates may be even further off, by up to an order of magnitude. It is important that projected costs be accurate to develop MCLs that balance health risk reduction, technical feasibility, and cost. With roughly 80% of PFAS exposures coming from non-drinking water sources, the proposed treatment standards only address a minority of the problem, at best.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments about the relative source contribution, please see section 4 2.5 of the EPA response in this *Response to Comments* document.

Santa Clarita Valley Water Agency (SCVWA) (Doc. #1578, SBC-042428)

On behalf of the Santa Clarita Valley Water Agency (SCV Water), we appreciate the opportunity to provide comments on the U.S. Environmental Protection Agency's (EPA) preliminary regulatory determination and proposed rule for certain per- and polyfluoroalkyl substances (PFAS Chemicals).

May 25, 2023

Ms. Radhika Fox

Assistant Administrator

Office of Water

U.S. Environmental Protection Agency

1200 Pennsylvania Avenue NW

Washington, DC 20460

RE: Docket ID No. EPA-HQ-OW-2022-0114

PFAS National Primary Drinking Water Regulation Rulemaking

Dear Administrator Fox:

On behalf of the Santa Clarita Valley Water Agency (SCV Water), we appreciate the opportunity to provide comments on the U.S. Environmental Protection Agency's (EPA) preliminary regulatory determination and proposed rule for certain per- and polyfluoroalkyl substances (PFAS Chemicals).

The health, well-being, and safety of our over 300,000 customers and community is of the utmost importance to SCV Water. Local water agencies play a critical role in achieving compliance with many federal laws, including the Safe Drinking Water Act and Clean Water Act, and this is a responsibility SCV Water takes seriously. SCV Water has firsthand knowledge of the impacts of the pervasiveness of PFAS Chemicals in the environment and is in the process of designing and constructing several treatment facilities. We feel compelled to provide our recent cost history and experience to help inform the rule making process. SCV Water General Manager, Matt Stone also provided testimony at the May 4th public hearing.

Real World Experience:

SCV Water has lost over 40% of its local groundwater capacity due to PFAS Chemicals. We are moving as quickly as possible to restore that lost capacity.

SCV Water has constructed and is operating two ion exchange treatment facilities to remove PFAS Chemicals, with a third currently under construction. The 1st project, the N-Wells facility was completed in December 2020 and treats up to 6,250 gallons per minute (GPM). The capital cost was $9.2 million or $1,474 per GPM of capacity. This facility was identified as the fastest and lowest cost project we could complete. We were fortunate to get ahead of inflationary price increases and already had three wells centrally connected to a treatment site property currently under SCV Water ownership.

The 2nd project, the Valley Center Well facility was completed in August 2022 and treats 1,200 GPM. The capital cost was $5.12 million or $4,267 per GPM of capacity. We saw increases in vessel cost, resin cost, and longer supply chain lead times for some items. This site also benefited from being located on property already under SCV Water ownership.

The 3rd project, the Santa Clara and Honby Wells facility is under construction with completion projected in early 2024 and will treat 2,000 GPM. The cost is $9.63 million or $4,813 per GPM of capacity. The final cost may be higher due to change orders. This project has experienced additional supply chain lead time issues as well. This site also benefited from being located on property already under SCV Water ownership. We believe the Valley Center Well and the Santa Clara and Honby Wells facilities reflect where costs and delivery times are today.

In addition to the extensive capital cost, there is also a significant operational and maintenance cost component for PFAS Chemical treatment facilities. Staffing, resin cost and disposal are the biggest operations and maintenance expenses, resulting in over $1.7 million in the first two years for the two facilities in operation.

EPA Response: The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $6.5 million to $9.4 million for a 6,250 gallon per minute facility using IX to treat groundwater. The commenter's reported cost of $9.2 million for the N-Wells facility falls within this range. The EPA's updated cost curves estimate a range of $2.2 million to $3.4 million for a 1,200 gallon per minute facility and $2.9 million to $4.5 million for a 2,000 gallon per minute facility. The commenter's reported costs of $5.12 million and $9.63 million for the Valley Center Well facility and the Santa Clara and Honby Wells facilities, respectively, exceed these ranges. However, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for this facility would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Santa Clarita Valley Water Agency (SCVWA) (Doc. #1578, SBC-042433)

Water Affordability:

SCV Water commissioned and completed a 3rd party PFAS Chemicals treatment feasibility study which indicated the capital cost of treatment for our impacted wells is estimated at $160 million

with an increase in operations and maintenance cost of over $11 million annually. These estimates are in 2022 dollars and subject to revision as more projects reach the design phase or as additional wells are impacted. These costs will be recovered from SCV Water customers.

On behalf of SCV Water, we request EPA take our and other testimony and letters related to cost experience and timeline projection under consideration for determining a final rule. We are dedicated to addressing the concerns related to PFAS exposure and protecting the health and well-being of our community. Thank you for considering these comments.

Sincerely,

Stephen L. Cole

Assistant General Manager

Santa Clarita Valley Water Agency

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

San Gabriel Valley Water Association (SGVWA) (Doc. #1580, SBC-042416)

Identified Best Available Technologies (BAT) may Prove Costly and Inadequate: As announced, the proposed MCLs will require public water systems to add advanced treatment to their current water production processes. States will have to review and approve the plans and specifications for this advanced treatment. In addition to the need for systems to conduct pilot testing of multiple treatment options, the costs associated with constructing, operating, managing, and sampling these systems can range from millions to hundreds of millions of dollars. However, if California and other states decide to adopt more stringent standards, the identified best available technologies may prove inadequate.

EPA Response: The EPA included pilot testing in the treatment capital cost estimates, as discussed in section 13.3.3 of the EPA response in this *Response to Comments* document. In response to the comment that states may adopt more stringent standards in the future and the BATs for the NPDWR may not be adequate to meet those standards, the EPA notes that SDWA does not prohibit States from promulgating more stringent drinking water regulations than the federal standards. However, whether states choose to do so at some time in the future is not reasonably forecastable nor is it within the EPA's control whether or not a state would choose to promulgate more stringent standards in the future. Even if the EPA were able to reasonably anticipate whether states might promulgate more stringent standards in the future, costs associated with potential future state standards more stringent than the NPDWR are outside of the scope of this rulemaking.

Missouri River Public Water Supplies Association (MRPWSA) (Doc. #1581, SBC-042412)

Estimated Treatment Costs — MRPWSA is concerned that the capital and O&M cost analyses included in the preamble to the proposed Rule significantly underestimate the likely cost impact from the proposed MCLs. MRPWSA believes it is likely that the U.S EPA has underestimated the number of drinking water facilities that will require treatment, as well as the cost to construct, operate and maintain treatment facilities.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Public Works Association (APWA) (Doc. #1584, SBC-047710)

These levels are also significantly lower than any state has proposed for PFAS chemicals, which would seem to indicate that even states highly concerned with PFAS contamination have arrived at different conclusions than EPA with regard to the cost and benefit analysis. Analysis that is fundamental to the 1996 amendments to the SDWA, which requires a detailed risk and cost assessment, and best available peer-reviewed science, when developing standards. We again request the EPA conduct a fuller analysis that more accurately captures the costs of compliance and if necessary, the agency collects more data to inform and address the gaps that currently exist.

Mandates, while well-intentioned, can entail complex and costly upgrades in combination with prescriptive procedures to demonstrate compliance. These requirements may imperil the financial sustainability and affordability of some water systems, which will warrant greater assistance in terms of funding. To not clarify the extent of these costs now would be a grievous mistake as water systems and governments across all levels budget for the future and may be forced into competing for limited federal dollars.

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document. In regard to the commenter's assertion that "even states highly concerned with PFAS contamination have arrived at different conclusions than EPA with regard to the benefit/cost analysis," the commenter provides no detail or references to support this statement. While no specific references were given, potential differences in conclusions could arise from differences in number entities included in the analysis, baseline levels of PFAS contamination, estimation of health risk reduction benefits, and the estimation of costs.

American Public Works Association (APWA) (Doc. #1584, SBC-042390)

Furthermore, while these levels are higher than what was proposed in the health advisories in June 2022 and are reliably testable that does not mean they do not pose a significant cost burden for water systems. The EPA's estimated costs of $777 million to $1.2 billion are very optimistic given the experience of systems such as the Cape Fear Public Utility Authority's estimated capital cost for its treatment, which alone was $43 million. This far exceeded its annual operating

cost of $3-5 million and if only about 16 utilities of similar size to Cape Fear nationwide had to implement comparable treatment techniques, the total cost would exceed EPA's estimate. We believe this is not out of the realm of possibility given a September 2022 Government Accountability Office (GAO) study of drinking water data collected from six states showed at least 18 percent of the 5,300 water systems studied had PFOA and/or PFOS exceeding the proposed MCLs of 4 ppt alone. Levels of initial noncompliance may be even higher than anticipated due to sampling bias since the proposed limits are the lowest level many laboratories can reliably detect, and some systems may not have already pursued such sensitive testing. In fact, we urge EPA to conduct a fuller analysis particularly given that the agency caveated its own work in the posting in the federal register, asserting:

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Furthermore, extrapolating from a single utility's experience is not an appropriate method to estimate national costs. See also section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments citing the GAO report mentioned by the commenter, please see the EPA response to comment Doc. #1729, SBC-043576 in section 6.5 in this *Response to Comments* document.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-042777)

5. Cost analysis

Underestimation of cost:

WSSC Water finds that EPA's analysis of costs for implementing the BATs for PFAS removal significantly underestimates the necessary capital and operational expenses. For instance, the capital cost of constructing a GAC process for our Potomac Water Filtration Plant (WFP) is estimated about $1.4 billion, including expenses for land acquisition, booster pumping, and engineering and legal fees. Our projected operating expenses cover the costs of replacement, disposal, and reactivation of spent GAC. To treat our average production at our 285 MGD rated plant, the operating cost alone is a large and continuing cost. Estimated to be about $38 million, O&M represents about 35 — 50% of the total annualized cost. Furthermore, operating costs may not be eligible for federal/state funding, in which case the cost must be borne solely by the public.

After annualizing the combined total of capital and operating costs over 30 years of the asset life cycle, we arrived at an estimated annual cost of $108 million for PFAS treatment with GAC. This figure is significantly higher than EPA's estimated annualized cost of $16 - 67 million for an average Type 2 System. We believe this difference is attributed to several factors. First, EPA's cost model does not include ancillary costs associated with capital improvements, such as costs to address site constraints. A GAC treatment system with adequate contact time for PFAS removal would be about four times the size of our existing high-rate filters, exceeding any available space at our treatment plant. Second, the EPA's cost model must be re-calibrated with a

scale-up factor for large treatment plant. The largest system size considered in EPA's cost model is >500,000 population served, about four times smaller than WSSC Water.

Additionally, we recommend that EPA revise all of its cost estimates to reflect current labor and material cost increases and supply chain and workforce issues, using $2023 dollars.

EPA Response: The commenter is referencing system costs presented in Table N-10: Results for Type 2 Systems for Medium PFAS Occurrence. These costs relate to the agency's assessment of system level incremental costs associated with removing PFNA, PFBS, and HFPO-DA in addition to removing PFOA, PFOS and PFHxS (i.e., a Type 2 system in the sensitivity analysis presented in the EA for proposal). The costs presented in the table should not be construed as the EPA's estimated costs for all systems serving greater than 500,000 people that exceed the MCLs. The EPA uses the WBS models to estimate cost using a detailed engineering build-up from the line-item costs of individual treatment system components. As described in detail in section 13.3.3 of the EPA response in this *Response to Comments* document and the *Technologies and Costs* document (USEPA, 2024d), the EPA has developed cost equations for treatment at surface and ground water systems across the range of bed life (5,000 to 75,000 BVs) and residuals management scenarios, including high, mid, and low-cost levels.

Additionally, the comment lacks sufficient detail to compare the commenter's estimated cost to those the EPA used for very large systems. Specifically, it does not include information on the influent PFAS concentrations expected at this facility. It also does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for this facility would be similar to the typical values assumed in the EPA's estimate. The EPA updated its equipment costs to 2022 dollars using current price indices. The EPA also collected new vendor price quotes for cost driver equipment components (e.g., pressure vessels, treatment media). Please see section 13.3.3 of the EPA response in this *Response to Comments* document. In regard to the availability of federal funding, please see section 2.4 of the EPA response in this *Response to Comments* document.

Security Water District, Security Water and Sanitation Districts/Enterprises (Doc. #1587, SBC-042781)

To date, about $35 million dollars has been spent on PFAS mitigation in the Security Water District — initially to obtain an interim water supply, and finally to install an Ion Exchange treatment system. For our system with a population of 20,000 people, this equates to $1,750 per person or about $5,000 per tap. As a result of our experience, we are concerned that the EPA cost model underestimates the cost of the proposed rule.

EPA Response: This comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Suffolk County Water Authority (SCWA) (Doc. #1589, SBC-043368)

4. Costs for Implementing Treatment Will be Significant

The cost to develop, install, operate and maintain treatment systems to implement the proposed regulation will be significant. As indicated above, so far the SCWA has installed more than 25 GAC systems in order to comply with New York's standards for PFOA and PFOS over the last four to five years so it has experience with the costs to install these systems. The SCWA estimates that the average cost for each new GAC system will be no less than $750,000. Because they are subject to freezing in the winter, each system also requires a building with average costs no less than $700,000 to $900,000, depending upon the type of building needed. These are historical costs, and they are likely to be much higher in the future. It is anticipated that inflation, supply chain issues, and nation-wide competition for new GAC systems upon adoption of the proposed regulation will cause substantial increases in these capital cost estimates. These factors are likely to cause a similar increase in the anticipated cost of GAC filter media.

A preliminary estimate of the capital costs of treatment systems for the SCWA to address PFOA and PFOS alone is in the hundreds of millions of dollars. SCWA has not yet estimated capital costs to treat the other four PFAS proposed for regulation. Operation and maintenance costs must also be considered. In SCWA's experience, the average GAC filter media must be changed at least once per year per treatment system. This would put operation and maintenance costs in the range of hundreds of millions of dollars as well.

The SCWA is a large water supplier and is able to purchase treatment systems and filter media with certain economies of scale. Consideration should be given to the fact that smaller systems will likely have much higher per unit capital costs, change out costs, and other costs in their efforts to comply with the proposed regulation.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. The EPA has considered costs impacts to systems of all sizes in the analysis, including small systems which the EPA agrees may not benefit for economies of scale.

New York Section American Water Works Association (NYSAWWA) (Doc. #1591, SBC-042374)

Cost/Affordability

10. New York State water suppliers have been working since 2020 to comply with State limits of 10 ppt for PFOA/PFOS. During this time, we have gathered a great deal data on the cost of treating for these compounds. Based on this experience, we believe that EPA's cost estimates for treatment are woefully inadequate. To date, our experience has demonstrated the financial impacts of meeting a 10 ppt MCL have exceeded $850 million in construction and $45 million in operating costs in New York State.

EPA Response: Please see sections 13.3.3 and 13.3 of the EPA response in this *Response to Comments* document.

Alameda County Water District (ACWD) (Doc. #1595, SBC-042348)

b. Cost estimates for treatment installation and analysis are low

The estimated capital cost curve included in the March 29th PFAS NPDWR public presentation indicated that the estimated capital costs for a 6 MGD granular activated carbon (GAC) PFAS treatment system were approximately $5M. The cost estimate included in the economic analysis for laboratory analysis using method EPA Method 533 is $376.

ACWD is in the late stages of designing a 6 MGD IX PFAS treatment system and the preliminary Class 2 construction cost estimate range (excluding planning, design, etc.) indicates actual construction costs could be more than three times the estimate provided in EPA's economic analysis. During our preliminary design stage, we also evaluated GAC treatment, which had a higher construction cost than IX. This difference in estimated cost of treatment installation compared to actual costs for treatment installation is substantial and indicates that the cost estimates within the economic analysis are unrealistically low.

The EPA's economic models used in the economic analysis for construction costs were last peer reviewed over 15 years ago, between 2005 and 2007, and may not provide an accurate basis for escalation. EPA should update the economic models for construction costs through a more current peer-reviewed process using current and realistic projected costs, to confirm the models still provide an accurate basis for economic analysis given current construction, parts, and materials costs post-pandemic.

EPA Response: The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $4.8 million to $7.1 million for a 6 million gallon/day facility using IX. Although the commenter's estimate appears to exceed this range, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for this facility would be similar to the typical values assumed in the EPA's estimate. WBS model development did not cease with the initial external peer review. The EPA has continued to maintain and update the models throughout the intervening years, including updates specifically for this final rule as described in section 13.3.3 of the EPA response in this *Response to Comments* document.

National Tribal Water Council-Tribal PFAS Working Group (NTWCTPWG) (Doc. #1598, SBC-042339)

Treatment

Tribal communities that are impacted by PFAS chemicals face a difficult situation. There are funding sources available to install equipment to treat PFAS in drinking water, but no clear

picture of what assistance will be available to operate and maintain those treatment facilities going forward. The treatment technologies have been evolving, which raises the question of installing treatment equipment, such as reverse osmosis / nano-filtration that can achieve removal, but that was not designed and developed specifically for PFAS removal, as compared to installing technology that has been or is being tested and scaled to specifically remove PFAS. The decision of how to proceed in these regards will be greatly affected by the timing of this regulation‘s implementation, together with funding availability and overall cost considerations.

The environment of competitive funding opportunities and the constantly evolving understanding of PFAS seems to cast a shadow over many factors that must be considered. There are capital, short-term and long-term cost implications of treatment technology(ies) being adopted for PFAS treatment. The operations and maintenance portion of the total costs should be considered “legacy costs” from the adoption of any given treatment technology to treat PFAS. We recommend that EPA consider in its economic analyses the tradeoff(s) between early adoption of expensive treatment methodologies that may be the only options available today, and less expensive alternatives that may be available in the near future. Regulatory language should speak to the utilization of emerging treatment technologies as well as to a thorough financial evaluation of the chosen treatment method’s cost over the lifecycle of the treatment approach and equipment selected. These treatment facilities require different levels of training/certification, maintenance, technical proficiency and scheduled operator hours to treat water to regulated levels of safe consumption. The cost that is incurred from these factors is not addressed in the funding available to install these facilities, thus passing significant financial burden on to the affected communities. The evaluation of liability of the parties responsible for the presence of these pollutants seems to be a logical next step in addressing this issue in a fair and equitable manner.

EPA Response: The EPA agrees that new technologies to treat PFAS, such as novel adsorptive media, may emerge in the near future. However, at this time, the EPA does not have sufficient data on the costs of these emerging technologies to include them in the EA. Nothing in the rule prevents water systems from adopting these technologies if they prove more cost-effective. For the EPA’s response to comments on funding availability for O&M costs specifically, please see section 2.4 in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-047712)

GAC media costs have been increasing steadily as illustrated in the following chart (GRAPHIC 4). We are concerned that costs will continue to rise for all PWSs who use GAC for treatment when there is a rush to provide it to systems for PFAS remediation across the nation.

[Figure 4: See Docket ID EPA-HQ-OW-2022-0114-1601]

GRAPHIC 4: Chart produced by MWWA Technical Advisory Committee plotting historical GAC costs.

A large PWS in Massachusetts, that uses GAC as part of their routine treatment process and not specifically for PFAS removal reported to MWWA that last fiscal year they used Carbon Activated (a GAC supplier) and replaced their media with virgin GAC at a cost of $194,450.00. This fiscal year, the bid for virgin GAC from Carbon Activated came in at $600,000.00, over triple the cost from last fiscal year. Due to this staggering increase, the PWS instead proceeded with regenerated GAC at a cost of $184,000.00 for their media replacement.

EPA Response: The EPA agrees that GAC prices have increased over time. For the final rule, the EPA updated its cost data to 2022 dollars, including collecting new vendor price quotes for GAC. As a result, the EPA's unit cost for virgin GAC ($2.46 per pound prior to any volume discounts) is higher than that shown in the commenter's Figure 4 for non-acid washed GAC. With regard to the impact of demand for GAC on future costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA does not dispute the commenter's reported costs for the large PWS in Massachusetts, but the comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042902)

Kleinfelder's survey of New England PWS (51 respondents) regarding capital costs for treatment per million gallons per day treated averaged $3.8 million. The survey reported yearly O&M for media replacement from $250,000-$373,000 [FN22: Presentation by Ben Powers, EIT, Kleinfelder, "PFAS Treatment in New England: A Regional Survey," April 2023, New England Water Works Association, Spring Conference].

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043658)

APPENDIX-C

Combined Impact on BWWB's Capital and O&M Budgets and Rates (Including the proposed PFAS Rule)

Based on water quality analysis performed to date on BWWB's various water source, BWWB believes that the proposed Rule may require the installation of the post-treatment GAC facility at the Shades Mountain Filter Plant. Therefore, the capital and O&M costs related to the proposed PFAS Rule that are presented in this Appendix are predicated on this assumption.

A preliminary estimate for the compliance costs associated with not only the LCRR, AWIA and NRW Control, but also the proposed PFAS Rule in the next 5 years, was added on the baseline budgets of BWWB to calculate the rate increase and affordability. Two scenarios were analyzed: costs associated with spent GAC considered as non-hazardous is shown in Table C1 and as hazardous waste is shown in Table C2 below.

Table C1. Baseline Capital and O&M Budget with LCRR, AWIA and NRW Control Compliance Costs and additional PFAS Rule (Non-Hazardous Waste) Compliance Cost

[Table C1: See Docket ID EPA-HQ-OW-2022-0114-1602]

Table C2. Baseline Capital and O&M Budget with LCRR, AWIA and NRW Control Compliance Costs and additional PFAS Rule (Hazardous Waste) Compliance Cost

[Table C2: See Docket ID EPA-HQ-OW-2022-0114-1602]

Table C3. Impacts on ratepayers and BWWB by LCRR, AWIA and NRW Control and the Proposed PFAS Rule Compliance

[Table C3: See Docket ID EPA-HQ-OW-2022-0114-1602]

EPA Response: Regarding the commenter's estimate of costs of compliance with the PFAS rule at the Shades Mountain Filter Plant, please see the EPA response to the commenter's Appendix A in the snippet below for Doc. #1602, SBC-043656. Regarding simultaneous compliance, please see section 10.4.2 of the EPA response in this *Response to Comments* document. Regarding the cost impacts of LCR, please see section 13.3 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043656)

APPENDIX-A

Comparison of Total Capital Cost and O&M Cost between EPA's Cost Model and Arcadis Case Studies

BWWB developed capital and O&M cost estimates for each of its filtration plants in order to support the evaluation of the proposed PFAS Rule. Cost estimates included in this Appendix are based on the selection of post-filter GAC as the BAT at each plant. Please refer to Table A1 below for the summary of the estimates.

BWWB's Technical Assumptions for the cost estimates are as follows:

• Water Source: Surface Water

• Size Category: Large (>10 MGD as defined by EPA)

• Component Level: Mid-level estimate

• Expected Bed Life in Bed Volume (BV): 60,000

The expected bed life was determined through one bench scale test at SMFP. While additional bench and/or pilot tests are needed to validate an accurate bed life for a full-scale GAC system, the bench test serves as a guide for conceptual design.

• Design type (gravity vs. pressure) was determined based on the plant design capacity.

o If the design capacity is >30 MGD, gravity was selected

o If the design capacity is <30 MGD, pressure was selected

Table A1. Summary of Capital Costs and O&M Costs for Installing GAC for PFAS Removal in BWWB's Four Filter Plants

[Table A1: See Docket ID EPA-HQ-OW-2022-0114-1602]

The development of the detailed estimates is presented below.

BWWB's Estimate Assumptions:

• BWWB's total capital costs are considered a Class 3 estimate; Class 3 estimates typically have an accuracy range of -15% to +20%, according to AACE Report (Aug 2020).

• A 20% margin has been added to the extrapolated construction cost in order to cover the cost of an intermediate pump station and associated site work.

• Site work, building, and concrete pad were included in BWWB's estimate due to site conditions and needs of the existing filter plants.

• 15% Engineering & Design and legal services was included in the total capital cost.

• USEPA's mid-cost option includes CPVC piping; steel piping is much more common. BWWB's estimate considered steel pipe and fittings.

• To escalate USEPA's cost in 2020 dollars to current dollars (2022 Q4), a 1.296 escalation factor was used, which was calculated based on the Construction Cost Index (CCI). x)

• City Index for Birmingham was 1.07, based on RSMeans City Cost Index (2019) to adjust the construction cost for a local project compared with national average.

• O&M cost was estimated based on media quantity generated by USEPA's WBS Model for GAC System Treatment. BWWB estimated that GAC replacement/reactivation costs account for 70% of the annual O&M cost. The other 30% O&M costs mainly cover maintenance (materials and labor) and electricity. BWWB assumed that GAC will be thermally reactivated off-site as non-hazardous waste. The current market price of virgin GAC is approximately $2/lb, which is subject to change based on the market conditions. BWWB considered the unit price of reactivated media to be $1.8/lb. Please note that mercury build-up in GAC media to a certain threshold may cause rejection by GAC reactivation facilities. Regular sampling of GAC media to monitor mercury levels is recommended to maintain media life and minimize the life-cycle O&M cost.

Actual Projects used as a Reference for Capital Cost Development:

1. NWTP Facility Upgrade and Reconstruction Project at Gilbert, AZ (Gravity GAC System)

Gilbert Project Considerations:

• Backwash Pump Station consists of a new concrete structure and all associated miscellaneous metals including hatch's and embeds. New process piping, sample pumps and vertical turbine pumps also installed with this new structure.

• GAC Facility is a new building consisting of an entirely new concrete structure with a large structural steel canopy and associated miscellaneous metals. New interconnecting piping installed along with new underdrains, GAC media, air scour blowers and associated turbine and centrifugal pumps.

• Maximum capacity of the GAC system is 65 MGD with 21.0 min Empty Bed Contact Time (EBCT).

Direct costs of the GAC Facility and Backwash Pump Station were extracted from the overall Gilbert direct costs. Extracted costs presented in Table A2 below; these costs represent a 60% design level.

[Table: See Docket ID EPA-HQ-OW-2022-0114-1602]

Formulas below used to calculate the total capital cost come from the Cost Summary for the entire NWTP Facility Upgrade and Reconstruction Project.

Subtotal 1 = Total Direct Cost * (1+0.0712)

• Provides an estimate of the cost of the work (direct costs and general condition costs) Subtotal 2 = Subtotal 1 * (1+0.06)

• Includes the Construction Manager at Risk Fee Subtotal 3 = Subtotal 2 * (1+0.0071+0.0164)

• Includes Bonds and Insurance Allowances

Subtotal 3 is the Guaranteed Maximum Price (GMP) excludes any sales tax and tax credits, which is considered as the Total Construction Cost for Gilbert's GAC facility. It is also used to estimate the Total Capital Costs for BWWB's filter plants.

Table A2, below, presents subtotal 1-3 calculations for Gilbert's GAC Facility. 'Subtotal 3' was then corrected from 2022 Q2 dollars to 2022 Q4 dollars using the appropriate Mortenson Construction Cost Index ratio (Table 2).

Table A2. Construction Costs (2022 Q4 dollars) for Gilbert GAC Facility and Backwash Pump Station

[Table A2: See Docket ID EPA-HQ-OW-2022-0114-1602]

Based on the CCI-corrected Subtotal 3 estimate in Table A2 above, an estimate for SMFP and WFP were calculated through extrapolation based on plant design capacity. Table A3 presents the total construction cost estimate (in 2022 Q4 dollars) for SMFP and WFP.

Table A3. Construction Costs (2022 Q4 dollars) for SMFP and WFP Extrapolated Based on Gilbert Case Study

[Table A3: See Docket ID EPA-HQ-OW-2022-0114-1602]

1: Includes 20% Margin to cover intermediate pump station and associated site work

2: Includes 15% Add-on Engineering & Design and Legal Service

2. Actual System in Upstate NY (Pressure GAC System)

• Flow = 13.8 MGD

• EBCT = 20 min

• Total quantity of GAC = 720,000 lb

• Standard pressure vessels

• Actual cost for contactors, plumbing & electrical: $5.1 million (2017 dollars); exclude extensive general construction, site work, building and concrete pad.

The construction cost was firstly corrected from 2017 Q4 dollars to 2022 Q4 dollars using the approporate Mortenson Construction Cost Index ratio. Then based on the CCI-corrected construction cost estimate, estimates for CFP and PFP were calculated through extrapolation based on plant design capacity, as shown in Table A4 below.

Table A4. Actual Cost for Contactors, Plumbing & Electrical (2022 Q4 dollars) for CFP and PFP Extrapolated Based on Actual Project Case Study

[Table A4: See Docket ID EPA-HQ-OW-2022-0114-1602]

1: In addition, building, concrete pad, and a considerable amount of site work will likely be needed at both CFP and PFP. Thus, additional construction costs were added to the extrapolated costs, which were calculated based on the automatic populated design factors from USEPA's WBS Cost Model, the unit price from AWWA (PFAS National Cost Model Report, March 2023), and price of construction materials from previous actual projects.

2: Includes 20% Margin to cover intermediate pump station and associated site work

3: Includes 15% Add-on Engineering & Design and Legal Service.

EPA Response: The tables below compare the estimated costs from the commenter's Table A1 to results from the updated cost curves the EPA developed for the final rule.

Capital Costs from Commenter's Table A1 Compared to Results from the EPA's Updated Cost Curves

Filter Plant	Design Capacity (MGD)	Design Type	Commenter's Capital Cost Estimate	EPA's Capital Cost Curves Lower Bound	EPA's Capital Cost Curves Upper Bound
SMFP	80	Gravity	$ 166,435,646	$ 38,650,025	$ 45,026,063

Filter Plant	Design Capacity (MGD)	Design Type	Commenter's Capital Cost Estimate	EPA's Capital Cost Curves Lower Bound	EPA's Capital Cost Curves Upper Bound
WFP	60	Gravity	$ 124,826,734	$ 30,866,248	$ 36,227,797
CFP	24.5	Pressure	$ 25,591,765	$ 16,627,489	$ 27,859,355
PFP	24	Pressure	$ 24,968,671	$ 16,359,836	$ 27,427,577

O&M Costs from Commenter's Table A1 Compared to Results from the EPA's Updated Cost Curves

Filter Plant	Design Capacity (MGD)	Design Type	Commenter's O&M Cost Estimate (non-hazardous waste)	Commenter's O&M Cost Estimate (hazardous waste)	EPA's O&M Cost Curves Lower Bound (non-hazardous waste)	EPA's O&M Cost Curves Upper Bound (non-hazardous waste)
SMFP	80	Gravity	$ 4,029,382	$5,558,955	$6,819,571	$6,887,420
WFP	60	Gravity	$ 3,116,171	$4,299,086	$5,138,924	$5,182,961
CFP	24.5	Pressure	$ 1,179,973	$1,627,897	$2,266,008	$2,336,178
PFP	24	Pressure	$ 1,118,357	$1,542,891	$2,222,121	$2,289,654

The commenter's O&M cost estimates, even those incorporating the assumption of hazardous waste disposal, are lower than the EPA's range for non-hazardous waste disposal. The commenter's estimated capital costs for the two pressure facilities fall within the EPA's range. The commenter's estimated capital costs for the two gravity facilities exceed the EPA's range. There are, however, several observations of the commenter's capital cost estimates that suggest they are overestimates. First, each of the estimates is based on linear extrapolation from a single case study. Linear extrapolation will overestimate costs because it does not account for economies of scale that exist with increasing treatment capacity. The commenter also applies a City Index of 1.07 to escalate the case study costs based on Birmingham's construction costs compared with the national average. It is not clear that the individual case studies used reflect national average or typical treatment costs. Finally, the commenter adds additional construction costs for buildings, concrete pad, and site work using the unit price from AWWA. As discussed in section 13.3.3 of the EPA response in this *Response to Comments* document, AWWA unit cost for buildings likely overestimates actual building costs.

Arlington County Virginia (Doc. #1603, SBC-043016)

2. Review of the cost modeling indicates significant misalignment between the report's assumption and our experiences with capital improvements and operating costs. For example, the EPA cost model utilizes the curve below to estimate the capital costs for Granular Activated Carbon. For our water provider, the Washington Aqueduct (WAD), the model as illustrated estimates a capital cost of $126.7M to install GAC.

[Figure 1: See Docket ID: EPA-HQ-OW-2022-0114-1603]

GAC was considered as a potential treatment upgrade at the WAD in 2013, and the capital cost of GAC at our two plants at that time was estimated at $200M. Utilizing a conservative inflationary estimate of 58% [FN1: Using the Census.gov Multifamily Housing Construction Index 2005-2022] indicates a present value of $316.6M, or a factor of 2.5 times the EPA's estimated cost of $126.7M.

We find a similar discrepancy in the estimated O&M costs for GAC, with our inflation adjusted annual O&M cost estimated at $31.6M as compared to the EPA model estimate of $10.1M. We were not able to find the comparable EPA cost curves for the other two recognized treatment processes (RO and IX), but we have 2013 estimates for the capital improvements and annual O&M cost for those technologies at our treatment plants and would welcome an opportunity to compare our estimates with the EPA model.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for further discussion.

Arlington County Virginia (Doc. #1603, SBC-043013)

Second, the assumptions on costs of the proposed rule seem to be drastically under-estimated.

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-043988)

• Rule Implementation – American Water has comments and concerns with various aspects of rule implementation that include initial monitoring, determining compliance, use of practical quantitation limits, reduced monitoring, use of previously collected data, and right-to-know provisions.

Specific Comments

Regulation of PFOA and PFOS

American Water supports the development of Maximum Contaminant Levels (MCLs) for PFOA and PFOS for the reasons provided in the rule preamble, including that the U.S. EPA has determined that these contaminants have carcinogenic endpoints. However, in order to establish appropriate regulatory levels, American Water believes the U.S. EPA must ensure that it is using accurate data, including estimates for the cost of compliance. Inaccurate estimates of the capital cost for installing treatment and the operating cost of maintaining this treatment will lead to an inaccurate cost-benefit analysis. American Water believes that the U.S. EPA is underestimating the overall cost of complying with the proposed MCLs of 4.0 parts per trillion (ppt) for PFOA and PFOS and urges the U.S. EPA to use the information provided in our comments as well as

comments submitted by the AWWA and others to re-evaluate its cost estimates, review the cost-benefit analysis, and determine appropriate regulatory levels for PFOA and PFOS. These cost levels must also be used when determining affordability and Federal funding assistance.

As part of our review of the proposed rule, American Water evaluated the projected costs associated with PFAS treatment at the proposed limits and the impact it could have on customers' bills. Using the data and approach as presented in a recent study conducted by Black & Veatch on behalf of the American Water Works Association, the estimated national cost to install treatment facilities and processes to remove PFOA and PFOS at drinking water facilities to levels required by EPA's proposal exceeds $47 billion, which is approximately $35 billion above what would be required to meet current state established PFAS limits. Further, it will require, on a national basis, more than $700 million annually for operating costs, which is approximately $500 million more than what would be required to meet current state established PFAS limits. These dollar values are significantly higher than EPA's cost estimates.

Based on initial estimates, American Water alone will likely have more than 100 of our existing drinking water treatment facilities that will need to be upgraded to provide PFAS removal capability, a 3 to 4-fold increase in the number of treatment plants than if the most stringent previously established state standards had been adopted nationwide. We estimate an investment in excess of $1 billion of capital to install additional treatment facilities over a 3 to 5-year period. Additionally, we estimate annual operating expenses related to testing and treatment could be near $50 million in today's dollars. These are preliminary estimates based on the proposed rule; our actual expenses may differ from these preliminary estimates and will be dependent upon multiple factors, including the final rule and effective date, as well as the completion of our system-by-system engineering analyses.

We strongly recommend that the U.S. EPA use this information to re-evaluate their cost estimates, review the cost-benefit analysis, and determine appropriate regulatory levels for PFOA and PFOS. These cost levels must also be used when determining affordability and Federal funding assistance.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA has considered all public comments prior to finalizing the PFAS NPDWR, including those referenced by the commenter.

American Water Works Company Inc. (Doc. #1608, SBC-043985)

Estimated Treatment Costs – American Water is concerned that the cost analyses included in the preamble to the proposed rule significantly underestimate the cost impact of the proposed MCLs. American Water believes that the U.S. EPA has underestimated the number of drinking water facilities that will require treatment, as well as the cost to construct, operate and maintain treatment facilities, impacting both the capital cost estimates and the operation and maintenance (O&M) cost estimates.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-043975)

While American Water had been anticipating and preparing for the rulemaking, our initial analyses were based on a federal PFAS standard more in line with the limits set by several states. We have carefully reviewed the U.S. EPA's proposed drinking water regulation to assess the 4.0 parts per trillion (ppt) requirements for PFOA and PFOS and the application of the Hazard Index approach for PFNA, PFBS, PFHxS, and HFPO-DA chemicals.

As part of our review of the proposed rule, American Water evaluated the projected costs associated with PFAS treatment at the proposed limits and the impact it could have on customers' bills. Using the data and approach as presented in a recent study conducted by Black & Veatch on behalf of the American Water Works Association, the estimated national cost to install treatment facilities and processes to remove PFOA and PFOS at drinking water facilities to levels required by the U.S. EPA's proposal exceeds $47 billion, which is approximately $35 billion above what would be required to meet current state established PFAS limits. Further, it will require, on a national basis, more than $700 million annually for operating costs, which is approximately $500 million more than what would be required to meet current state established PFAS limits. These dollar values are significantly higher than EPA's cost estimates.

Based on initial estimates, American Water alone will likely have more than 100 of our existing drinking water treatment facilities that will need to be upgraded to provide PFAS removal capability, a 3 to 4-fold increase in the number of treatment plants than if the most stringent previously established state standards had been adopted nationwide. We estimate an investment in excess of $1 billion of capital to install additional treatment facilities over a 3 to 5-year period. Additionally, we estimate annual operating expenses related to testing and treatment could be near $50 million in today's dollars. These are preliminary estimates based on the proposed rule; our actual expenses may differ from these preliminary estimates and will be dependent upon multiple factors, including the final rule and effective date, as well as the completion of our system-by-system engineering analyses.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see sections 13.3.3 and 13.3 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044002)

The U.S. EPA published a set of cost curves in its March 29, 2023, Technical Webcast, which are duplicated on the log-log graph presented in Figure 1 (See Appendix). According to the notes from the webcast, the U.S. EPA cost curves appear to estimate the cost to construct GAC-based PFAS treatment in a surface water treatment plant based on the plant's capacity. American Water was able to add the actual cost that it has incurred for the design, permitting, and construction of

more than a dozen PFAS treatment facilities that are already operating or are nearing completion. These facilities range in capacity from about 1 MGD to about 5 MGD, and all include pressure vessel-based GAC or AIX treatment media. Some facilities required the addition of pretreatment for iron and manganese removal to prevent fouling and shortened bed life for the GAC or AIX or the pre-treatment bag/cartridge filters recommended by AIX media suppliers. In addition, we added costs for several other PFAS treatment facilities constructed by other utilities, as reported in the media. All project costs were adjusted to mid-2022 values using HandyWhitman construction cost indices. As can be seen in Figure 1, some facility costs are below the amount estimated by the U.S. EPA curve, but most costs are above the curve. Since the curve is plotted at a logscale, even modest-looking offsets above the curve can represent a significant percent deviation in the cost of a facility. For example, "AW Plant 11" is a 3 MGD AIX treatment facility constructed in northern NJ. The final total project cost for this facility was approximately $5.5 million, adjusted to 2022 dollars. By comparison, the U.S. EPA cost curve would have projected that a 3 MGD PFAS treatment facility should only cost about $3.1 million. In this case, the actual cost of a 3 MGD PFAS treatment facility was more than 75% greater than the U.S. EPA cost curve would have predicted, and a new building was not required. Also, although the U.S. EPA cost curve presented in the webcast applies to surface water, it appears, based on explanations provided elsewhere in Document EPA-822-P-23-001, that the WBS models for AIX would have been even lower than the cost curves for surface water GAC treatment.

Figure 1 also includes an inflation-adjusted cost for the Cape Fear Public Utility Authority's (CFPUA) 44 MGD gravity GAC PFAS treatment facility that was recently constructed at the Sweeney WTP in Wilmington, NC. It was reported that CFPUA awarded a $35.9 million bid for construction of the facility in 2019. The $59 million value shown in Figure 1 includes an inflation adjustment factor of 26% based on the Handy-Whitman inflation index and an additional 30% allowance to estimate the total project cost to include fees for engineering design, permitting, legal, and other administrative soft costs. By comparison, the U.S. EPA cost curve estimates that a 44 MGD GAC surface water treatment facility should cost approximately $25 million. The projected cost of the Sweeney GAC facility in current dollars is more than two times higher than the U.S. EPA's estimate.

Based on American Water's experience, it is likely that a percentage of groundwater PFAS treatment facilities will require additional pretreatment for the removal of iron and manganese to prevent fouling of GAC or AIX resin, or the bag/cartridge filters that AIX manufacturers recommend be installed upstream of AIX resin beds. American Water has experience with several inline bag and cartridge filtration systems upstream of ion exchange treatment and has found they can be extremely expensive to operate and labor intensive to maintain when even moderate levels of iron or manganese are present in the source of supply. To further emphasize this concern, American Water prepared the unit cost curves presented in Figure 2 (See Appendix), which is the type of cost curve that American Water uses for developing preliminary budget estimates for its projects. The mid-capacity range section of the U.S. EPA's logarithmic cost curve from Figure 1 was transposed and included in Figure 2 for comparison to American Water's cost curves for GAC treatment of groundwater with and without pretreatment. Also

shown are the actual PFAS project costs incurred by American Water or reported in the media by several other utilities. As can be seen, the U.S. EPA's curve estimates unit costs that would average 50% less than American Water's "No Pretreatment Required" cost curve and more than 375% lower than American Water's "Pretreatment Required" range cost curve. Based on the data presented in Figures 1 and 2, American Water believes that the U.S. EPA should re-evaluate its economic analysis and provide additional metrics to show utilities the true cost of this proposed rule.

EPA Response: The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $3.0 million to $4.6 million for a 3 million gallon/day facility using ion exchange to treat groundwater. The cost curves estimate a range of capital costs of approximately $24.2 million to $45.2 million for a 44 million gallon/day facility using GAC to treat surface water. The commenter's estimates for these two examples exceed the EPA's updated ranges, but not as significantly as shown in commenter's Figure 1 and 2, which considered only one of the mid-cost curves used for the proposed rule, prior to the update. The commenter did not provide the underlying data for the other examples shown in the figures, so it is not possible to re-create these figures using the EPA's updated cost curves. In any case, the comment does not include information to confirm that (1) all the estimated costs for each example shown in the figures would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for the examples would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Regarding the cost of pretreatment, the EPA included the cost of cartridge filters for control of influent solids in its cost estimates for ion exchange. The EPA does not have quantitative data on the frequency with which systems might require pretreatment specifically for iron and manganese, but information from one treatment vendor suggests the need for this type of pretreatment might be limited. Please see section 10.1 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-043992)

GAC Treatment

While American Water concurs that GAC is generally a reliable treatment method for PFAS removal, we believe that the U.S. EPA has significantly underestimated both the initial capital cost and ongoing operational expense associated with using GAC for PFAS removal.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-043999)

Estimated Treatment Costs

American Water is concerned that the cost analyses included in the preamble to the proposed rule significantly underestimate the cost impact of the proposed MCLs. American Water believes that the U.S. EPA has underestimated the number of drinking water facilities that will require treatment, as well as the cost to construct, operate and maintain treatment facilities, impacting both the capital cost estimates and the operation and maintenance (O&M) cost estimates.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the estimated number of PWS expected exceed the MCLs, please see section 6.4 of the EPA response in this *Response to Comments* document.

Prince William County Service Authority (Doc. #1609, SBC-042840)

A study released by AWWA on March 7 found that the estimated national cost for water systems to install treatment systems to remove PFOA and PFOS to levels required by the EPA proposal would exceed $3.8 billion annually. Under EPA's proposal, virtually all of these treatment costs will be borne by communities and ratepayers, who are also facing increased costs to address other needs, such as replacing lead service lines, upgrading cybersecurity, replacing aging infrastructure and assuring sustainable water supplies.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Town of Lincoln Water Department (Doc. #1613, SBC-043022)

May 25, 2023

Mr. Michael S. Regan, Administrator

U.S. Environmental Protection Agency

EPA Docket Center, OLEM Docket, Mail Code 28221T 1200 Pennsylvania Avenue, NW

Washington, DC 20460

RE: Docket ID No. EPA-HQ-OW-2022-0114 • National Primary Drinking Water Regulation Rulemaking for per- and polyfluoroalkyl substances (PFAS)

Dear Administrator Regan:

I am writing to provide comments on the Environmental Protection Agency's (EPA) proposed National Primary Drinking Water Regulation Rulemaking for per- and polyfluoroalkyl substances (PFAS). The drinking water sector fully supports efforts to expand verified public health protections, but EPA needs to consider the challenges associated with its proposed

rulemaking and address the water sectors' implementation concerns before finalizing any standards.

I work for the Town of Lincoln Water Department. We provide drinking water to 5600 public water system customers. I am a member of the Massachusetts Water Works Association and New England Water Works, Inc. I am aware that they, and other water works organizations, are submitting more comprehensive comments. I would urge EPA to pay close attention to the points raised by these associations as they are comprised of individuals and companies with expertise in designing and operating Public Water Systems (PWS) and they have the best understanding of the challenges which will be associated with implementing any final rule EPA adopts. My major concerns are as follows:

EPA has very much underestimated the costs to PWSs to comply with the proposed rule. For example, Lincoln has a well that comprises about 33% of our water supply. The well has 13-14ppt PFOS levels, below the current 20ppt MCL. If the EPA adopts the new more strict MCLs, and the State of Massachusetts DEP follows suit, we will be forced to install treatment for PFOS at the well. Initial cost estimates are around $7,000,000 for this treatment at our 0.5mgd well. Operating costs would also skyrocket, with the increasing demand for activated carbon and disposal costs every two years. The Town of Lincoln has aging infrastructure, with 53 miles of water main that need replacing. 60% of this is AC pipe. Lowering the PFOS MCLs to these low limits (20 ppt is equivalent to 1 second every 1585 years) would bring very challenging financial conditions here in Lincoln, and hinder our ability to address existing infrastructure replacement needs.

EPA Response: The commenter did not specify the treatment technologies considered in its estimate. The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $550,000 to $1.3 million for a 0.5 million gallon/day facility using GAC or IX to treat groundwater. Adding RO/NF increases the upper bound of the EPA's estimated range to $3.2 million. Although the commenter's estimate of $7 million exceeds the EPA's range, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for this facility would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Averill Park Central School District (APCSD) (Doc. #1614, SBC-042924)

May 25, 2023

U. S. Environmental Protection Agency

EPA Docket Center

Office of Ground Water and Drinking Water Docket Mail Code 28221T,

1200 Pennsylvania Avenue NW,

Washington, DC 20460

Dear U.S. Environmental Protection Agency,

We write to you to express our concerns about the proposed EPA PFAS chemical regulation which will reduce the allowable level of PFAS chemicals found in water to 4 nanograms per liter (ng/L) being directed from the State without the necessary funding to accomplish this mandate.

When the regulation changed to 10 ng/L, the Averill Park Central School District (APCSD) was forced to use significant funds to bring the levels compliant and within the allowable limit. Specifically, the filter system that was installed with granular activated carbon (GAC) cost approximately $200,000. If the standards are lowered once again, APCSD will need to install three additional GAC filter systems at an approximate total cost of $600,000.

APCSD is already dealing with limited State Foundation Aid due to being considered a "Hold Harmless" District in regards to State funding. As a result of the limited State Aid, for the 2023-24 school year, the District faced a $1.3 million deficit. Having to bear the cost burden of the additional GAC systems will impact student programming and come at a significant cost to our local taxpayers.

As a Board of Education, we take our role as the financial stewards of our community very seriously and, therefore, respectfully request that the State fund any and all costs associated with complying with this change to the regulation.

Sincerely,

The APCSD Board of Education

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Aquarion Water Company (Doc. #1617, SBC-043372)

To comply with the proposed NPDWR, our preliminary evaluation indicates that we'll have to either install treatment (e.g., GAC or IX) or replace a source of supply for more than 40% of our sources of supply. Our planning level estimate of the capital cost of this work is $290 million. This equates to an annualized cost of approximately $14 million for just the capital costs associated with complying with the proposed regulation (using a 3% discount rate to be consistent with EPA's approach, and average useful life of 30 years).

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Calgon Carbon Corporation (Doc. #1620, SBC-042940)

• Our granular activated carbon technology is an affordable solution

o Based on a recent analysis of costs for PFAS treatment installation using granular activated carbon, Calgon Carbon estimates the average operations and maintenance cost of granular activated carbon to treat 1000 gallons of municipal drinking water is $0.18. Based on the average person using 60 gallons of water per day, this translates to an added cost of $1.64 per month for a household of 5 individuals.

In closing, Calgon Carbon is prepared to help utilities across the United States to comply with the draft MCL's when they are ratified and to ensure access to clean and safe drinking water through the deployment of granular activated carbon, equipment, and reactivation services.

Sincerely,

Jenalle Brewer Senior Vice President

Drinking Water Solutions, Innovative Carbon Technologies and Global Business Development

About Calgon Carbon Corporation

Calgon Carbon, a wholly owned subsidiary of Kuraray Co., Ltd. (TYO: 3405) (Kuraray), is a global leader in the manufacture and/or distribution of innovative coal-, wood- and coconut-based activated carbon products – in granular, powdered, pelletized and cloth form – to meet the most challenging purification demands of customers throughout the world.

Complemented by world-class activated carbon equipment systems and service capabilities, as well as diatomaceous earth and perlites, Calgon Carbon provides purification solutions for more than 700 distinct applications, including drinking water, wastewater, pollution abatement, and a variety of industrial and commercial manufacturing processes.

Headquartered in Pittsburgh, Pennsylvania, Calgon Carbon employs approximately 1,700 people and operates 17 manufacturing, reactivation, innovation and equipment fabrication facilities in the U.S., Asia, and in Europe, where Calgon Carbon is known as Chemviron.

Calgon Carbon was acquired by Kuraray in March of 2018. With complementary products and services, the combined organization will continue to focus on providing the highest quality and most innovative activated carbon and filtration media products, equipment, and services to meet customer needs anywhere in the world. For more information, visit calgoncarbon.com.

EPA Response: The EPA agrees that granular activated carbon can be an affordable treatment technology. Please see sections 13.3.3 and 13.10 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044048)

b. One large utility estimates their costs will increase by 200% if they are expected to meet 4.0 ppt levels, versus increasing by only 10% for meeting a 10 ppt MCL. The utility's yearly costs will increase from $250,000/yr to $550,000/yr at just one treatment plant that already has a GAC system in place. At the two facilities that need to construct a GAC treatment system it will cost their city $15 million initially with additional yearly operating costs of $550,000. These estimates do not consider inflation or potential increases in material costs as demand increases. One load of Calgon F300 GAC at 20,000 lbs costs $42,000.

c. Another utility has to change out each contactor annually plus take an extra 20-25% from their alternative source (with costs that can be upward of $2.5 million/year) to reach non-detect for PFOA and PFOS. This utility is relying on their wellfields with the lowest PFAS concentrations, some of which have water rights issues. They have estimated that if influent concentrations went above 500 ppt, they may need to change out one GAC contactor per day.

d. Another medium-sized utility is anticipating $180 million for installation of treatment, and a $5 million annual O&M increase.

e. EPA needs to remember that all these costs are borne by the utility's customers, and will impact lower income and disadvantaged communities the most.

EPA Response: The commenter's estimate of $42,000 for 20,000 lbs of GAC translates to a unit cost of $2.10 per pound. The EPA's GAC cost model, as updated for the final rule, estimates a nearly identical unit cost of $2.11 per pound for this quantity of virgin GAC. The comment lacks sufficient detail to compare the commenter's other estimates of costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043078)

EPA's Cost Estimates Are Significantly Underestimated and Need Revised

According to the Proposal, EPA anticipates that nearly 67,000 water systems will need to comply with the rule. These water systems will need to review and understand how to implement the rule, conduct initial monitoring of the regulated PFAS at each entry point to the distribution

system, and potentially work to install drinking water treatment systems or take another mitigation strategy.

According to the Proposal, EPA considered three treatment options that may be used by as many as 5,000 water systems to reduce PFAS levels to below the MCLs. These treatment options included granular activated carbon (GAC), ion exchange (IX), and reverse osmosis (RO) filtration facilities. Additionally, EPA considered other options to address PFAS levels in drinking water, such as interconnections, new wells, and point-of-use RO systems. To estimate the costs to install and operate these systems, EPA relied on their Work Breakdown Structure (WBS) for these strategies, which were developed more than a two decades ago and were updated as part of the Proposal

The American Water Works Association (AWWA) contracted with Black & Veatch to prepare a cost model (the BV Model) for PFAS treatment using GAC, IX, or RO using their national drinking water treatment expertise and with support from utilities and experts from across the sector. The AWWA / BV effort also included drinking water utilities to compile information on the costs to install PFAS treatment systems.

Comparison of the AWWA / BV costs from real data with EPA model show the EPA's WBS model significantly underestimates the costs associated with PFAS treatment using a GAC treatment facility. Data from the case studies in this range shows that the typical PFAS treatment system is shown to cost 330% more than the estimated cost by the EPA's WBS Model (based on 2021$). Aqua's own experience constructing several PFAS treatment systems show that the cost to construct can range from $2 to $6 per gallon treated per day which is several times greater than EPA's estimates. Most costs are not from the vessels or treatment systems but due to site related construction costs, piloting, sewer connection fees, meeting the various restrictions for permitting and zoning, and ensuring proper road access for media changeouts by large tractor trailers. The extent of the EPA's WBS Model's underestimation of cost is similarly demonstrated by the AWWA/BV Model (2022$). These patterns are similarly observed when looking at larger treatment facilities and other treatment technologies. Analysis of the EPA WBS model shows a lack of contingency costs in the estimates. The EPA should adjust this approach and include the appropriate levels of contingency to ensure that cost estimates are consistent with the level of project definition afforded by the available data.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Regarding contingency, the EPA updated its approach to incorporate a contingency factor of 5 to 10 percent depending on total project cost at all cost levels for systems installing treatment. The EPA also included a miscellaneous allowance of 10 percent, which can be considered a form of contingency. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-052828)

Accurately Reflecting Current Economic Conditions

Another limitation of the EPA's WBS Model is that it is reflective of costs based on construction costs in 2021. Additionally, the model relies on a variety of cost indices to scale the costs from a previous year to the relevant year of the analysis. It is reasonable to scale data from one year to another year using indices, but it is important to note that there is always a lag in the data for the most recent periods of time. It is also important that the Agency recognize that the previous two years, from 2021, have been shown to experience significant cost increases relevant to drinking water treatment systems.

These cost increases have stemmed from the COVID-19 pandemic, presently high inflation, and increasing interest rates for borrowing. Construction costs, for example, have increased steadily ranging from 15% to 30% in the past 2 years according to several different sources. A similar trend is observed in analysis of inflation since 2021, which has averaged 5.81% annually. The federal funds rate has also increased from 0.08% to 5.25%.

In addition to the increase in costs driven by recent economic conditions since 2021, it is also important to note the rule's impact on upwards of 5,000 water systems and increase demand for laboratories, engineering consultants, planners, contractors performing site investigation and construction work, and skilled treatment operators.

EPA should ensure that the final cost analysis is accurately reflecting these landmark increases in costs due to recent economic conditions and anticipated increases in demand that will drive the planning and construction costs of new facilities significantly higher than the current estimates.

EPA Response: The EPA updated its equipment costs to 2022 dollars using current price indices. The EPA also collected new vendor price quotes for cost driver equipment components (e.g., pressure vessels, treatment media). Please see section 13.3.3 of the EPA response in this *Response to Comments* document. In regard to the impact of demand created by the rule on prices, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-052829)

Recognizing the Importance of Ancillary Systems

Another potential limitation of the EPA's WBS Model is that it only considers capital upgrades related to the PFAS treatment process. This is a significant gap in that many systems will need to make improvements to other areas of the treatment facility to support the PFAS treatment process. For example, some systems installing GAC treatment may determine that the concentration and form of manganese or iron will cause problems in the vessel, requiring pre-treatment. A variety of other water quality characteristics may impact the need for pre-treatment and site-specific conditions may drive the need for significant upgrades to critical treatment support systems (e.g., pump stations, chemical feed systems, etc.). While the EPA's WBS Model

does not consider the need for these systems, it is not uncommon for upgrades for PFAS treatment to require these types of improvements.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Additionally, regarding the cost of pretreatment, the EPA included the cost of cartridge filters for control of influent solids in its cost estimates for ion exchange. The EPA does not have quantitative data on the frequency with which systems might require pretreatment specifically for iron and manganese, but information from one treatment vendor suggests the need for this type of pretreatment might be limited. Please see section 10.1 of the EPA response in this *Response to Comments* document for more information.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044897)

• Pilot testing costs do not appear to have been included in the cost estimates in the proposed rulemaking. However, DEP believes pilot testing will be even more important with inclusion of both short- and long-chain PFAS in the proposed rulemaking, and, with increasingly low levels of PFAS detections required, pilot testing will become ever more critical when planning for effective PFAS removal treatment. The BAT will remove all six PFAS included in this proposed regulation, but which PFAS will break through first will depend on the type of treatment, forms of PFAS, overall water quality, and potential presence of interferences such as total organic carbon (TOC), manganese, volatile organic chemicals (VOCs), etc. For effective operations, water treatment operators will need to know which PFAS are expected to breakthrough first and on what timeframe, with some level of consistency. Pilot testing will be critical in acquiring that knowledge, and the costs should be considered.

DEP would like to again thank you for the opportunity to comment on EPA's proposed PFAS National Primary Drinking Water Regulation Rulemaking.

Sincerely,

Richard Negrin

Acting Secretary

EPA Response: The EPA included pilot testing costs in the treatment capital cost estimates for the proposed rule and further updated these costs for the final rule. Abt Associates (2020a) provides technical details on the methodology used to derive pilot study costs. section 13.3.3 of the EPA response in this *Response to Comments* document and Section 7.1.4 of the *Technologies and Costs* document (USEPA, 2024d) describe how the EPA updated these costs for the final rule.

Water One - Water District No. 1 of Johnson County, Kansas (Doc. #1627, SBC-042328)

Cost and Logistical Implications

A permanent PFAS regulation across water utilities would result in significant financial and logistical implications and the costs developed by EPA are grossly understated. We are greatly concerned about the impact this would have on the national economy and impacts to water rates. Preliminary cost estimates to remove PFAS would result in significant rate impacts for our customers with no reprieve as O&M costs would drive the costs in perpetuity. This rule in addition to the ongoing Lead and Copper Rule Revisions will compound water rate affordability concerns.

WaterOne has conducted preliminary cost analysis specific to our operations. The conceptual capital cost to implement GAC treatment at WaterOne's Hansen and Wolcott Water Treatment Plants would be $170M (180 mgd capacity) and $46M (30 mgd capacity), respectively. The conceptual capital cost to implement ion exchange treatment at the two plants would be $182M and $44M, respectively. The conceptual total annual O&M cost to implement GAC treatment would be $19.2M and ion exchange treatment would be $8.6M. Based on a recent multidisciplined large scale project recently completed (180 mgd ozone facility at the Hansen WTP), the anticipated duration to implement PFAS treatment is 8 years. These are real costs that are clearly much higher than the estimates provided by EPA resulting from the rule. When ratepayers are faced with rate increases to meet these requirements, the public trust will be further degraded in utilities and the regulatory agency.

We encourage the EPA to take the necessary time to research further the cost and logistical implications this proposed regulation would have on water utilities retrofitting their facilities, and in many cases, drive the need for new treatment facilities. In some instances, water utilities would have to discuss new sources of water or adding other facilities, all of which requires significant time, consideration, and financial implications. Additional water rights and land availability potentially could become interwoven into the decision-making process too.

EPA Response: Please see sections 13.3.3 and 13.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenters characterization of the rule impacts, and that there will be significant water rate impacts nationally "with no reprieve;" for more information on funding availability, please see section 2.4 of the EPA response in this *Response to Comments* document. Regarding the LCR, please see section 13.3 of the EPA response in this *Response to Comments* document.

Regarding the cost figures provided by the commenter, the updated cost curves the EPA developed for the final rule estimate a range of capital costs for a 180 million gallon/day facility of approximately $79 million to $262 million using GAC and approximately $91 million to $121 million using IX. For a 30 million gallon/day facility, the EPA's cost curves estimate approximately $18 million to $33 million for GAC and approximately $18 million to $24 million for IX. Although some of the commenter's conceptual estimates for capital cost exceed the EPA's ranges, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for these facilities would be similar to the typical values assumed in the EPA's estimate. The commenter's

conceptual estimates for annual O&M cost lack sufficient detail to compare to the results of the EPA's WBS models.

Village of Woodbury (Doc. #1629, SBC-042952)

6. Estimated costs for treatment processes and operations and maintenance should consider: engineering, legal, and planning costs, disposal of media and backwash, and lab sampling & testing.

EPA Response: The EPA's EA included all of the costs identified by the commenter. Please see section 13.3.3 of the EPA response in this *Response to Comments* document and Chapter 5 of the EA for more information.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044129)

Costs for Small Public Water Systems

EPA's economic analysis does not accurately describe the economic impact on small public water systems and system customers. EPA is proposing Granular Activated Carbon (GAC), Anion Ion Exchange (AIX), and Nano-filtration/Reverse Osmosis as best available technology for PFAS removal from drinking water. GAC and AIX are the most likely to be implemented at small Texas systems. TCEQ estimates the initial installation of GAC at a small system will cost $175,000, while AIX is estimated to cost $1,050,000. On average, small systems (i.e., systems serving a population less than 3,300) in Texas serve 667 customers. EPA estimates a maximum annual maintenance cost per household for systems with a population of 501 to 3,301 of $700 per household for GAC—$332 for treatment and $368 for hazardous waste disposal—and $478 per household for AIX—$235 for treatment and $243 for hazardous waste disposal. Utilizing the average customer count, the combined annual maintenance and hazardous waste disposal costs are $466,900 for GAC and $318,826 for AIX. If a small water system with an average of 667 customers has a monthly water bill of $75 per customer, the annual revenue from billing is $50,025 which does not meet annual costs of maintenance and hazardous waste disposal for PFAS. Additional expense for quarterly monitoring requirements will further impact small systems operating on a limited budget. The PFAS NPDWR, as proposed, would significantly increase the annual cost of business for small systems and system customers, who already struggle.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Additionally, the updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $525,000 to $969,000 for a system serving 667 people using GAC to treat groundwater. The updated cost curves estimate a range of capital costs of approximately $377,000 to $730,000 for ion exchange. The commenter's estimate for GAC is substantially below the EPA's range. Although the commenter's estimate for ion exchange exceeds the EPA's range, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other

infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for this facility would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

The commenter's estimate of annual costs misinterprets the household costs presented in the EPA's analysis. The household cost for hazardous waste disposal is inclusive of annualized capital cost and all other treatment operating costs unrelated to hazardous waste disposal. It is not additive with the household costs presented for the non-hazardous disposal scenario. As a result, the commenter's estimated totals include double counting. In addition, the commenter has selected the maximum value from the EPA's range. This maximum would not be typical for most systems; even the minimum value incorporates conservative assumptions about PFAS occurrence.

Please see section 13.10 in this *Response to Comments* document for the EPA's response to comments on the affordability analysis and household cost impacts.

Orange County Water District (OCWD), California (Doc. #1634, SBC-043231)

EPA has utilized a Work Breakdown Structure (WBS) model to estimate installation and operating costs for PFAS water treatment systems. Utility surveys conducted by American Water Works Association (AWWA) clearly show that recent actual treatment construction costs are systematically more than 3x greater that the WBS estimates; this difference is consistent with OCWD's own recent treatment construction cost experiences. Furthermore, a treatment cost model developed by Black & Veatch (B&V) for AWWA also shows the WBS model to systematically underpredicts treatment costs. We suspect this is due to the WBS model's heavy reliance on treatment capacity, PFAS levels, and TOC levels as its primary inputs. The model's assignment of a 0% contingency budget to all projects less than 5.8 MGD capacity is a significant defect that does not reflect OCWD's experience nor the best engineering practices.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Regarding contingency, the EPA updated its approach to incorporate a contingency factor of 5 to 10 percent depending on total project cost at all cost levels for systems installing treatment. The EPA also included a miscellaneous allowance of 10 percent, which can be considered a form of contingency. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Orange County Water District (OCWD), California (Doc. #1634, SBC-052836)

Furthermore, the WBS model relies upon construction cost information from the calendar year 2021. Due to well documented factors such as significant inflation, labor shortages, global supply chain disruptions, and increased borrowing cost', OCWD's more recently bid PFAS treatment projects have come in progressively 15-25% higher than its initial projects contracted in 2021.

EPA Response: The EPA updated its equipment costs to 2022 dollars (which are the most recent data available), collected new vendor price quotes for cost driver equipment components, and made several other adjustments to WBS model assumptions. Taken together, these adjustments increased the system level capital cost estimates in the EPA's cost assessment by percentages that were generally greater than or equal to those reported by the commenter. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Orange County Water District (OCWD), California (Doc. #1634, SBC-043229)

In response to PFAS concentrations in our Groundwater Producers' wells exceeding State of California health-based advisory levels, OCWD has financed, designed, constructed, and/or is otherwise implementing more than 35 wellhead treatment projects to date for impacted public water systems. Planned capital expenditures for our existing treatment program are approaching $300 million, with anticipated long-term operating outlays expected to push total related treatment response costs to more than $1 billion. Based on our preliminary analysis, the EPA's proposed maximum contaminant levels (MCLs) for PFOA and PFOS of 4 nanograms per liter (ng/L) would increase the number of impacted wells in our service are in the near-term by 50 75%, with corresponding additional requirements for capital and operating expenditures for treatment or other interventions to achieve compliance. Additional wells in our service area are likely to be similarly impacted in the future.

Drawing upon our experience responding to PFAS impacts to our local groundwater basin, OCWD offers comments on the proposed regulation in the following areas: estimated cost, proposed implementation timeline, use of the Hazard Index, and alternative treatment technologies.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Town of Tewksbury, Massachusetts (Doc. #1637, SBC-043241)

May 30, 2023

Mr. Michael S. Regan, Administrator

U.S. Environmental Protection Agency

EPA Docket Center, OLEM Docket, Mail Code 28221T 1200 Pennsylvania Avenue, NW

Washington, DC 20460

RE: Docket ID No. EPA-HQ-OW-2022-0114 - National Primary Drinking Water Regulation Rulemaking for per- and polyfluoroalkyl substances (PFAS)

Dear Administrator Regan:

I am writing to provide comments on the Environmental Protection Agency's (EPA) proposed National Primary Drinking Water Regulation Rulemaking for per- and polyfluoroalkyl substances (PFAS). The drinking water sector fully supports efforts to expand verified public health protections, but EPA needs to consider the challenges associated with its proposed rulemaking and address the water sectors' implementation concerns before finalizing any standards.

I work for the Town of Tewksbury, MA Department of Public Works; we provide drinking water to approximately 30,800 customers. I am a member of the Massachusetts Water Works Association; I am aware that they, and other water works organizations, are submitting more comprehensive comments. I would urge EPA to pay close attention to the points raised by these associations as they are comprised of individuals and companies with expertise in designing and operating Public Water Systems (PWS) and they have the best understanding of the challenges which will be associated with implementing any final rule EPA adopts. My major concerns are as follows:

• EPA has very much underestimated the costs to PWSs to comply with the proposed rule. Our system would likely have to replace its granular activated carbon media in our filters more frequently than we currently do to ensure compliance with the proposed regulations. This can easily cost over $100,000 per changeout, of which we already do twice a year. This does not include the cost of any additional treatment systems that may need to be added or modifications to existing systems.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. The EPA has considered all public comments prior to finalizing the rule and made a number of adjustments to the cost models; please see section 13.3.3 of the EPA response in this *Response to Comments* document for more information.

National Rural Water Association (NRWA) (Doc. #1641, SBC-041)

1. EPA's Cost Estimate

EPA has significantly underestimated the costs of construction, monitoring, and remediation of PFAS. A recent study Black and Veach on behalf of AWWA and the WUC estimated the national cost for water systems [Link: https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14-102450-257] including capital costs, and operations and maintenance to be near $1 billion dollars nationally, for systems that serve populations of 101-500 people alone. For example, in Vermont, small water systems are averaging annual monitoring costs of nearly $2,000. Construction costs are in the millions as many small systems are not only burdened with the cost of constructing the actual equipment but in many cases must increase facility capacity to house filters, equipment, and other items necessary to remediate the PFAS.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. In regard to the total capital costs for small systems nationally, the EPA estimates that the total amount of initial capital treatment technology expenditures for small systems nationally ranges between approximately $1.8 and $3.5 billion. The commenter did not provide a directly comparable figure, but this may be consistent with the EPA's findings.

Additionally, it is not clear what costs are included in the statement "[f]or example, in Vermont, small water systems are averaging annual monitoring costs of nearly $2,000," but the EPA assumes this is an example of baseline sampling costs prior to PFAS rule promulgation. If so, the EPA acknowledges this but notes that these costs are outside of the scope of this rulemaking. Lastly, the EPA included the costs associated with buildings and other add-on capital costs in the cost analysis, for more information see Chapter 5 of the EA.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043270)

EPA's Request for Comments – NRWA appreciates EPA's request for comment on many specific aspects of the rule. Below are NRWA's responses to the requests the association is qualified to answer.

• EPA seeks comment on its PFOA and PFOS evaluation of feasibility for the proposal, including analytical measurement and treatment capability, as well as reasonable costs, as defined by SDWA.

• EPA seeks comment on its evaluation of feasibility for the proposed HI MCL finding, including analytical measurement and treatment capability, as well as reasonable costs, as defined by SDWA.

Response: Based on information from our members (where water systems have been required to comply with state regulations), EPA has grossly underestimated the costs of treatment (including treatment residual disposal) especially as it pertains to small rural systems serving a population under 10,000. The impact on the rate payers in these small systems will be far greater than those in larger systems for both capital improvements and ongoing maintenance. This rule will adversely affect systems sustainability.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document on treatment costs and section 13.10 of the EPA response in this *Response to Comments* document on affordability.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043490)

Technologies: In order to meet the 4ppt standard for PFOA and PFOS, rural water utilities will have to obtain and install new technologies. As outlined in the American Water Works Association's (AWWA) recent WITAF 56 Technical Memorandum: PFAS National Cost Model

Report, treatment strategies for PFAS in drinking water include both proven, commercially available technologies as well as emerging technologies. Commercially available technologies that have been demonstrated at full scale in the field to reduce concentrations of PFAS in drinking water are limited to the following:

• Granular activated carbon (GAC)

• Ion exchange (IX)

• Nanofiltration (NF) and reverse osmosis (RO)

Treatment considerations for the application of each of these technologies are described in the full report. While there are many variables that contribute to the specific costs associated with reaching the 4ppt standard, the report incorporates the most obvious operating costs into their cost models: media replacement, membrane replacement, power, maintenance, water disposal, chemical consumption, and labor. The report contains considerable explanation of their methodology and ultimately finds that the national cost for water systems to install treatment to remove PFOA and PFOS to levels required by this proposal will exceed $5.2 billion annually. These costs alone cannot be ignored and the uncertainty with testing availability and disposal methods only exacerbate our concerns with this rule.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Massachusetts Water Resources Authority (Doc. #1645, SBC-043288)

EPA should also take into consideration that this regulation will create significant demand for certain PFAS treatment and products, likely driving up the costs for the installation and maintenance of all PFAS treatment. In addition to the costs associated with the installation and maintenance of PFAS treatment, the costs for disposing of spent media are quickly escalating as traditional means for disposal of these media (e.g., landfilling, incineration, etc.) are becoming unavailable as a result of other state and federal regulations around PFAS. EPA should consider the full lifecycle of treatment, including the disposal/destruction of treatment residuals so that PFAS contaminated materials aren't simply moved from place to place. MWRA recommends that EPA ensure that the cost model takes into consideration the full lifecycle of treatment, from installation, operation and maintenance, to the disposal of residuals. MWRA also recommends that EPA consider cost escalators for the full lifecycle of PFAS treatment. MWRA is further concerned that EPA's significantly under-estimated cost model will act as a cap for PWSs seeking to recoup treatment and operation costs from responsible parties.

EPA Response: In response to the commenter's concerns that the rule will create demand that will drive up prices, please see section 13.3.3 of the EPA response in this *Response to Comments* document. The cost models do take into full lifecycle of treatment, from installation, operation and maintenance to the disposal of residuals as the commenter recommends. For the

EPA's response to comments on disposal and treatment residuals and response to comments on PFAS being moved "from place to place", please see section 10.4.1 of the EPA response in this *Response to Comments* document. In response to the commenter's concern that the EPA's cost estimates will "act as a cap for PWSs seeking to recoup treatment and operation costs from responsible parties", while beyond the scope of this action, the EPA would anticipate that a variety of information, including PWS site specific information, would be used to inform decisions about appropriate individual liabilities for responsible parties.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043165)

3. ACTUAL COMPLIANCE COSTS ARE EXPECTED TO BE MUCH HIGHER THAN EPA ESTIMATES

VMDWA appreciates EPA seeking additional compliance cost data. VMDWA believes that EPA's estimate of the cost of compliance with its proposed MCLs for PFAS is materially inaccurate and understated as proposed.

Black & Veatch recently conducted a national cost assessment on behalf of the American Water Works Association (AWWA) that found that MCLs set at 4 ppt for PFOA and for PFOS would trigger $3.2 billion in annualized national costs (capital, O&M, monitoring, etc.) for impacted facilities assuming a seven percent discount rate. [FN1: AWWA, WITAF Technical Memorandum Update, PFAS National Cost Model Report, Figure 7.2 (Summary of Annualized Costs) (May 26, 2023).] In contrast, at the same discount rate, EPA stated that it expects the total annualized cost of the proposal is $1.211 billion, with an uncertainty range for the total annualized costs of the proposed option is $1.103 billion to $1.353 billion. 88 Fed. Reg. at 18700. This is an astonishing nearly three-fold difference in costs between AWWA and EPA estimates. There are corresponding significant household-level cost consequences, with AWWA's estimate in the range of $200 to $225 per household per year for systems serving communities in a population range of 10,001 to 50,000 and $155 to $175 per household per year for systems serving communities in a population range of 50,001 to 100,000, for example [FN2: AWWA, WITAF Technical Memorandum Update, PFAS National Cost Model Report, Figure 7.1 (Annual Costs to Household for Removing PFAS from Drinking Water) (May 26, 2023).].

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-052834)

One VMDWA Member that has already obtained cost estimates support the findings by AWWA and Pennsylvania that the actual costs are likely to be significantly higher than EPA's estimate. This example is a 225 mgd facility with an existing treatment process that includes ozone and biological activated carbon (BAC). Capital costs for granular activated carbon (GAC) or ion exchange ranged from $180 million to $250 million (December 2021 dollars). The associated

annual operating cost increases are estimated at $10 million to $45 million, which using the midrange of $22.5 million, equates to a 20% increase in the utility's overall annual operations and maintenance expense (even assuming no impact of this regulation to a second water plant owned and operated by the utility).

EPA Response: The comment lacks sufficient detail to compare the commenter's estimated cost to those the EPA used for very large systems. Specifically, it does not include information on the influent PFAS concentrations expected at this facility. It also does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for this facility would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-052835)

VMDWA believes that costs are likely to increase even further due to the limited supply of engineers and contractors (our Members report that firms are already busy and their prices have been running very high and increasing due to high demand), ongoing supply chain challenges, worker shortages, the national inflation problem, and the adverse cost impacts of extremely high numbers of public utility and other infrastructure projects being attempted over the next five-to-ten years given high federal grant and loan appropriations activity in these areas. Recent experience of VMDWA Members includes the following severe price escalations:

• A Member's multi-year reservoir dam improvement and repair project received only a single bid of $24 million, which exceeded the engineer's estimate of $14 million by $10 million (71%).

• A Member's wastewater treatment plant upgrade received only two bids, with the lowest bid of $215 million exceeding the engineer's already revised (increased) estimate of $138 million by $77 million (56%).

• A review of a Member's capital projects identified an overall increase of 25 to 40 percent over the past three years.

• Multiple Members have reported concerns with GAC supply. One Member specifically reported a 17 percent increase in the cost of GAC over the past year (obviously this is prior to the proposed regulation taking effect).

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA updated its equipment costs to 2022 dollars (which are the most recent data available), collected new vendor price quotes for cost driver equipment components, and made several other adjustments to WBS model assumptions. Taken together, these adjustments increased the system level capital cost estimates in the EPA's cost assessment by percentages roughly consistent with those reported by the commenter.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043400)

3. ACTUAL COMPLIANCE COSTS ARE EXPECTED TO BE MUCH HIGHER THAN EPA ESTIMATES

MAMWA appreciates EPA seeking additional compliance cost data. MAMWA believes that EPA's estimate of the cost of compliance with its proposed MCLs for PFAS is materially inaccurate and understated as proposed.

Black & Veatch recently conducted a national cost assessment on behalf of the American Water Works Association (AWWA) that found that MCLs set at 4 ppt for PFOA and for PFOS would trigger $3.2 billion in annualized national costs (capital, O&M, monitoring, etc.) for impacted facilities assuming a seven percent discount rate. [FN1: AWWA, WITAF Technical Memorandum Update, PFAS National Cost Model Report, Figure 7.2 (Summary of Annualized Costs) (May 26, 2023).] In contrast, at the same discount rate, EPA stated that it expects the total annualized cost of the proposal is $1.211 billion, with an uncertainty range for the total annualized costs of the proposed option is $1.103 billion to $1.353 billion. 88 Fed. Reg. at 18700. This is an astonishing nearly three-fold difference in costs between AWWA and EPA estimates. There are corresponding significant household-level cost consequences, with AWWA's estimate in the range of $200 to $225 per household per year for systems serving communities in a population range of 10,001 to 50,000 and $155 to $175 per household per year for systems serving communities in a population range of 50,001 to 100,000, for example [FN2: AWWA, WITAF Technical Memorandum Update, PFAS National Cost Model Report, Figure 7.1 (Annual Costs to Household for Removing PFAS from Drinking Water) (May 26, 2023).].

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-052844)

MAMWA believes that costs are likely to increase even further due to the limited supply of engineers and contractors (our Members report that firms are already busy and their prices have been running very high and increasing due to high demand), ongoing supply chain challenges, worker shortages, the national inflation problem, and the adverse cost impacts of extremely high numbers of public utility and other infrastructure projects being attempted over the next five-to-ten years given high federal grant and loan appropriations activity in these areas.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

J.R. Simplot Company (Doc. #1661, SBC-044151)

III. Costs of the Proposed Rule Have Not Been Fully Determined and will be Detrimental, Especially to Small Communities

Feasibility (including costs) Must Considered

If EPA establishes an MCL for any contaminant, the combination of technology, treatment techniques, or other means required to meet the level must not be more stringent than feasible. Each NPDWR which establishes a MCL must list the technology, treatment techniques, and other means which EPA finds to be feasible for purposes of meeting the MCL. The term "feasible" is defined by SDWA as "feasible with the use of the best technology, treatment techniques and other means which [EPA] finds … are available (taking cost into consideration)." Notably, EPA is required to consider costs in its assessment of feasibility in setting an MCL.

Technology and Costs for Small Communities and NTNCWSs

When looking specifically at technologies and costs for small drinking water systems, EPA is proposing the Small System Compliance Technologies (SSCTs) of GAC (Granular Activated Carbon) and IX (Ion Exchange) as Best Available Technologies (BATs).

The installation and annual costs for GAC and IX are expensive, even for small systems, and EPA estimates an annual operating cost per household ranging from $376 to $727. In addition, EPA estimates that the annual disposal cost per household assuming hazardous waste disposal for spent GAC and Resin ranging from $397 to $827. During EPA's May 4 Public Hearing, it was mentioned that EPA is prioritizing research on PFAS disposal options. If spent GAC and Resin from small systems and large CWS are required to be disposed of as a hazardous waste, the disposal costs will be enormous, and treating PFAS in water will result in PFAS disposal to land.

Annualized Costs are Underestimated.

As proposed, EPA grossly underestimates the potential compliance costs of this rulemaking on the thousands of public water systems across the country, including non-transient, non-community water systems (NTNCWSs). As just one small example is that Tables 70 and 71 indicate that hazardous waste disposal for treatment media were not quantified in the Annualized Quantified Rule Benefits and Annualized Quantified Rule Costs evaluations. The exclusion of these disposal costs skews the Benefit/Cost ratio and significantly underestimates the Annualized Quantified Rule Costs.

EPA Response: Regarding feasibility, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA took cost into consideration when determining feasibility. Regarding disposal costs, the six PFAS included in this rulemaking are not RCRA listed. In response to stakeholder feedback, the EPA included a sensitivity analysis to determine the impact on this rule should systems be required to handle and dispose of PFAS treatment materials as hazardous waste in the future. The results of this analysis can be found in Appendix N.2 of the EA for the final rule. Please see section 10.4 in this *Response to Comments* document

for the EPA's response to comments regarding management of treatment residuals. Regarding total annualized costs, please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document. Finally, while the commenter is correct that the Tables references did not include the quantified costs of hazardous waste disposal, should that disposal method be used, the EPA did quantify those costs in the analysis referenced above and considered them in the Administrator's determination that the benefits of the rule justify its costs. For more information on that determination, please see section 13.8 of the EPA response in this *Response to Comments* document and section XII of the FRN for the final rule.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044436)

• PFAS treatment is expensive, and installation will likely involve pilot studies, which are essential to understanding the effectiveness of treatment, but will increase overall costs. BIL funding is available, but there are barriers to this funding.

• This rule does not explicitly consider costs associated with long-term operation and maintenance of treatment. Promising treatment methods require continual monitoring to assess the effectiveness of PFAS removal. This will potentially require additional operators and frequent replacement of filter media, which will be costly.

EPA Response: The EPA included pilot testing costs in the treatment capital cost estimates for the proposed rule and further updated these costs for the final rule, including the addition of a year of full-scale confirmation sampling. The EPA also included operator labor costs as well as media changeout costs in the cost analyses for the proposed and final rules. The EPA anticipates that the operational results from the pilot test and confirmation sampling will be a sufficient indicator of performance; therefore, water systems should not have to collect large amounts of performance samples indefinitely during the full-scale operation of treatment technologies. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Regarding BIL funding, please see section 2.4 of the EPA response in this *Response to Comments* document.

City of Hillsboro, Oregon (Doc. #1668, SBC-043121)

3. Implementation Cost for Utilities

Significant capital and annual operating costs will be needed to remove PFAS below the proposed MCL, especially given that utilities have such a small margin between detecting PFAS and potential MCL exceedances. The costs of the materials needed to install the treatment technologies to remove PFAS will increase due to the significant increase in demand for the materials as many utilities will need advanced treatment to ensure levels of PFAS meet the proposed MCL. Water utilities, including Hillsboro Water, are faced with investment challenges, as many utilities are already investing large amounts of funding into complying with other

proposed regulations, such as the Lead and Copper Rule Revisions, investing in new and resilient water supply infrastructure, and planned replacements of aging infrastructure. EPA has greatly underestimated the cost burden of this regulation for utilities (Black and Veatch, 2023).

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document regarding AWWA's comment letter and the impacts of demand on costs to comply with the rule. Please see section 5.1.3 of the EPA response in this *Response to Comments* document on feasibility and costs considerations in finalizing the MCLs. The EPA acknowledges that implementation timing associated with the final PFAS rule and the proposed LCRI has the potential to overlap, please see section 13.3 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043719)

According to a study done by Black and Veatch on behalf of AWWA, the costs of installing drinking water treatment for removing only PFOA and PFOS will exceed $3.8 billion per year nationally. This cost estimate uses data provided by water systems that have done their own cost studies. Compared to EPA's estimate, they estimate more impacted systems and higher costs than what EPA estimated. Aurora Water estimates yearly costs to increase from $250,000 to $550,000 for removing PFOA and PFOS to the proposed level of 4 ppt for one of the three treatment facilities. The other two facilities will need to construct treatment at a cost of approximately $15 million with ongoing O&M cost of about $550,000 per year, each. Aurora expects additional increases in treatment material costs, inflation and supply chain limitations.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. The EPA does not dispute the commenter's estimate of costs for its treatment facilities, but the comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

National Association of Water Companies (NAWC) (Doc. #1670, SBC-044159)

2. The proposal's economic analysis is deficient and fails to adequately recognize or address the costs that the rule will impose on water systems.

The proposal's economic analysis is deficient and fails to adequately recognize or address the costs that the rule will impose on water systems. A recent study by Black & Veatch on behalf of the American Water Works Association concluded that the projected costs associated with PFAS treatment at the proposed limits would exceed $47 billion dollars, which is orders of magnitude more than EPA's estimate.

The cost of the technologies to remove PFAS contaminants from drinking water supplies is substantial and far exceeds all the estimates EPA makes in the proposed rule. EPA must rely on the reports prepared by water industry experts that are based on actual case studies and then re-

evaluate how it balances the levels of reductions set with the cost to achieve those levels. As discussed below, how the technological changes necessary to achieve the levels set by EPA will be financed is a key component of this rulemaking.

EPA Response: As discussed in this section in this *Response to Comments* document and the preamble, the EPA has considered all the comments submitted on the EA for the proposed rule and made many changes to reflect these comments and the additional information on costs provided by the commenters. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Further, the EPA notes it is not reasonable to compare a one-time estimate of costs from AWWA's report to the EPA's national annualized costs in the proposal. Instead, a more reasonable comparison is AWWA B&V's annualized costs to the EPA's annualized costs, which are discussed in section 13.3.3 of the EPA response in this *Response to Comments* document. Please see section13.3 in this *Response to Comments* document for the EPA's response to the AWWA B&V present value estimate.

North Jersey District Water Supply Commission (NJDWSC) (Doc. #1673, SBC-044203)

In order to meet the new regulations, the Commission will need to construct a 60,000 SF GAC filter facility and a 4,200 SF intermediate pump station to convey water from their current conventional filters to the new facility, along with significant site, underground utility, and electrical improvement s. Current CAPEX estimates for these improvements, inclusive of project soft costs, are anticipated to be $195, 000,000. Annualized over 25 years at 4% interest, this will result in a yearly debt service payment of $12,500,000. OPEX estimates, inclusive of media replacement, O&M, energy administrative and sampling costs are anticipated to be $8,500,000 annually (2023 dollars). In total this will result in an increase of annual expenditures of $21,000,000, or $573 per million gallons per year. When this is compared to the current user rate of $851 per million gallons per year it represents an increase of nearly 67%. It is the North Jersey District Water Supply Commission's opinion that this significant of an increase in user charges to its member communities will result in an unachievable financial burden, especially to its underprivileged communities.

Lewis Schneider, Director Treatment, Residuals & Lab

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Regarding household level impacts, please see section 13.10 of the EPA response in this *Response to Comments* document.

A. O. Smith Corporation (Doc. #1674, SBC-043702)

b. Cost-effectiveness

As the EPA is aware, and evident in its Economic Analysis ("EA") of its proposed PFAS NPDWS, there are many options for treating drinking water at the point-of-use and each approach has unique capabilities and associated costs. [FN20: See, Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation, EPA Document No. EPA-822-P-23-001, March 2023.] Indeed, POU and POE systems can in fact provide a cost-effective approach to addressing health-based contaminants in drinking water including PFOA and PFOS. The annual costs of these systems can range depending upon the use and application, and the EPA's analysis does an adequate job at reflecting those costs. [FN21: 88 FR 18687 (Table 22)] However, from the Company's perspective there is additional cost data assumptions that it can share with the EPA under confidential business information ("CBI") rules that the EPA may find helpful as it completes the PFAS NPDWS.

The Company does recognize there are challenges when considering all the relevant factors in developing an analysis of the actual cost of implementing either POU or POE compliance solution will vary widely among small public water systems. This includes, for example, small public water systems that currently utilize POU RO systems to treat arsenic. These systems may only have to switch out postfilter cartridges to add in PFAS removal, which would have a negligible cost through updating and installing the filter through the current maintenance cycle. The cost estimates reflected in Table 22 for POU RO do not reflect this co-benefit and cost consideration to installing third-party certified POE and POU systems.

EPA Response: The EPA agrees that small PWSs that already have point of use (POU) programs in place for other contaminants may experience cost savings in using or retrofitting these programs to address PFAS. However, the EPA does not have data to quantify these potential cost savings. The EPA notes that POU devices are not currently a compliance option because the final rule requires treatment to concentrations below the current certification standard for POU devices. However, POU treatment is anticipated to become a compliance option for small systems in the future should National Sanitization Foundation/American National Standards Institute (NSF/ANSI) or another accredited third-party certification entity develop a new certification standard that mirrors (or is demonstrated to treat to concentrations lower than) the EPA's proposed regulatory standard.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044951)

The presence of microbiological activity in GAC filters is well documented in scientific literature. Although the presence of heterotrophic bacteria, including total coliform, is not necessarily a public health concern, these issues should be considered during design as well as during operation and maintenance depending on the influent quality. Overall, the presence of GAC filters may require changes in chemical dosages that could impact simultaneous compliance with both the lead and copper rule and the Stage 2 disinfectants and disinfection byproducts rule (Stage 2 DBPR) due to temporary increases in pH. Although these issues can be addressed with proper monitoring and operation, they also may impact the cost of treatment systems as well as operation and maintenance and should be addressed as an uncertainty.

13. The Department reviewed the Drinking Water Treatment Technology Unit Cost models, with particular interest in the granular activated carbon cost model and is concerned that the EPA has underestimated the cost of this proposal. This cost model does not include an evaluation for PFAS chemicals specifically but includes cost estimates for several organic contaminants. We recognize that there are weaknesses to using the standard design with linear interpolation for cost comparison purposes. We are using it only to illustrate the significant difference in cost between installations in the State of New York and the estimating tools available from EPA. Given the limited time provided for public comment, we were unable to do an in-depth evaluation of the economic analysis and customize the work breakdown structure (WBS) tool to determine if it was plausible to make modifications that would align the tool with New York State costs.

Table 3: New York State Costs for GAC Treatment Installed in the Newburgh Area

[Table 3: See Docket ID EPA-HQ-OW-2022-0114-1677]

[FN3: Estimate used standard design in WBS model with linear interpolation.] [FN4: Project did not include permanent enclosures.]

Each of the projects listed above were completed prior to the pandemic and prior to inflation experienced during the post-pandemic period. Nonetheless, the EPA estimated costs are considerably lower than the actual costs incurred by New York State prior to inflation.

Additionally, New York State compared data contained in preliminary engineering reports submitted for listing on the 2023 DWSRF Intended Use Plan Final Amendment #2 — Bipartisan Infrastructure Law Emerging Contaminants and compared those costs to the WBS model for organic compounds treating groundwater, using the standard design. New York State recognizes that most of these projects are on Long Island, where labor and construction costs can be higher than the remainder of the State.

Table 4: Cost Comparison of Projects Listed in IUP to EPA Cost Models

[Table 4: See Docket ID EPA-HQ-OW-2022-0114-1677]

[FN5: Estimate used standard design in WBS model with linear interpolation.] [FN6: Water system may benefit by reduction in TOC by GAC.] [FN7: Cost estimate evaluated based on 2.152 MGD standard design.] [FN8: Proposal includes 3 treatment systems at 1.5 MGD, 1.44 MGD and 1.73 MGD.] [FN9: Proposal includes 2 treatment systems at 2.0 MGD each.] [FN10: Proposal includes 2 treatment systems at 0.7 MGD each.]

While the cost difference can be partially due to increased construction costs in the New York City metropolitan area as well as inflation, it does not fully account for the discrepancy. Again, given the short timeframe states were given to provide comment, it was not feasible to conduct a thorough review of the economic analysis to determine if these discrepancies are addressed by EPA elsewhere in the proposal or in the cost estimating tools. Based on the information available, we estimate that the present value cost to New York State of the proposal based upon 551 supplies that may have violations, is approximately $1.6 billion with annual O&M of

approximately $50 million, While the Department appreciates additional funding through the IIJA, this funding accounts for a fraction of the total funding need. We recommend that EPA re-evaluate the cost estimate using data generated through Bipartisan Infrastructure Legislation Emerging Contaminant IUPs as well as current industry data and update estimates to ensure the tools utilized reflect real world current economic conditions and costs, including sector specific costs after inflation. We note that this rule will likely result in increasing inflation pressures on GAC and other construction materials, as well as in the needed labor force given the significant need for PWS treatment. The effect of cross cutters such as Buy American Build America Act (BABAA) is another uncertainty that deserves attention.

EPA Response: The costs discussed by the commenter are generally on the low-end range for what the WBS model might produce for removing non-PFAS organic contaminants. The EPA's estimates are based on values that the agency believes are necessary to remove PFAS and include ranges of estimates. Therefore, the estimates the EPA used for treatment in the EA are generally higher than the WBS estimates presented by the commenter. This is because the version of the WBS model used by the commenter to generate the WBS estimates in Tables 3 and 4 did not contain standard designs for PFAS. The commenter did not specify which of the other organic contaminants they selected, but the standard designs for most of these contaminants assume a single vessel with an empty bed contact time (EBCT) of 7.5 minutes. Typical designs for PFAS, including the standard designs in the current version of the WBS model used for this rulemaking, use two vessels in series with an EBCT of 20 minutes. These design parameters result in substantially higher capital costs for PFAS compared to other organic contaminants. Furthermore, if the commenter did not adjust the component level input in the WBS models, the resulting estimates would default to the low cost level. In estimating costs for the PFAS rule, the EPA considered the full range of cost levels (low, mid, and high). Finally, several of the examples listed present the total cost of installing GAC at multiple locations. The tables compare these costs to WBS outputs for installing GAC at a single location with a design capacity equal to the total of the multiple locations. Due to economies of scale and fixed costs that are incurred per installation, WBS outputs generated using this approach will underestimate costs for multiple, separate installations. Therefore, as discussed above, the WBS estimates presented in Tables 3 and 4 do not accurately represent the WBS outputs used to estimate costs for the final rule.

The tables below compare the reported or estimated costs from the commenter's Tables 3 and 4 to results from the updated cost curves the EPA developed for the final rule. Some of the commenter's reported or estimated costs fall within or below the EPA's range. Although others exceed the EPA's range, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for these facilities would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Costs from Commenter's Table 3 Compared to Results from the EPA's Updated Cost Curves

GAC Location	Design Capacity (MGD)	Commenter's Reported Capital Cost ($million)	EPA's Capital Cost Curves Lower Bound ($million)	EPA's Capital Cost Curves Upper Bound ($million)
Town of New Windsor Temporary GAC Butterhill WTP (2019)	2.1	1.4	3.2	5.3
Town of New Windsor Permanent GAC Butterhill WTP (estimate)	6.5	8.14	6.0	11.7
Town of New Windsor Permanent GAC Kroll (2019)	0.43	1.9	0.7	1.4
Town of Berlin Permanent GAC WTP (2017)	0.5	0.64	0.76	1.51
City of Newburgh Washington Lake Filter Plant (2018)	8.3	19.75	7.00	13.85

Costs from Commenter's Table 4 Compared to Results from the EPA's Updated Cost Curves

GAC Location	Design Capacity (MGD)	Commenter's Reported Capital Cost ($million)	EPA's Capital Cost Curves Lower Bound ($million)	EPA's Capital Cost Curves Upper Bound ($million)
Nyack Village PFAS treatment at water plant (19171)	3	4.7	3.8	6.6
Starr Ridge Manor Town of Southeast GAC treatment system (19496)	0.13	2	0.3	1.1
Birch Hill Acres Town of Southeast (19495)	0.06	1.2	0.2	1.1

Sands Point Water District wells 2A and 5A GAC treatment for PFAS removal (19012)	1.3	8.4	2.5	4.2

Notes: (a) total for 3 treatment systems of 1.33 MGD each; (b) total for 3 treatment systems of 1.5 MGD, 1.44 MGD, and 1.73 MGD; (c) total for 2 treatment systems of 2 MGD each; (d) total for 2 treatment systems of 0.7 MGD each

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044307)

Capital Costs Estimates:

The City of Vancouver hired a consulting firm to complete a treatment feasibility study based on levels detected in our groundwater supply. Capital and O&M costs for PFAS treatment systems were completed with this study. Vancouver has detected PFOS and PFOA levels in excess of the proposed 4 ppt regulation in 34 of our 40 wells, which represents six of our nine wellfields. Although the feasibility study estimated capital costs for treatment in order to meet the Washington State Action Level (SAL) of 15 ppt and 10 ppt for PFOS and PFOA, respectively, our estimate far exceeds what the EPA has established to meet 4 ppt. Vancouver estimated that it will cost $171.8 million in capital construction costs to meet the SAL for 52.6 MGD. The EPAs capital estimates to treat 52.6 MGD at the proposed 4 ppt is only about $23.5 Million. It will likely cost Vancouver upwards of $250 Million to treat the two additional sources of water that are under the SAL, but over the proposed MCL of 4 ppt. These estimates do not include the costs to treat new sources of supply that will be needed in the near future to meet the growth of the community.

Again, the Safe Drinking Water Act requires consideration of the costs and benefits, but in the case of PFAS, the EPA did a poor job of estimating the actual capital cost burden the proposed levels will have on rate payers. The EPA needs to adjust their capital cost estimates significantly.

O&M Costs Estimates:

Vancouver’s PFAS treatment feasibility study also included the estimated O&M costs to treat water at six of its nine wellfields to half the SAL, which amounted to about $1.237 million per year. Vancouver roughly estimates that adding two more wellfields at a lower limit of 4 ppt will likely increase O&M costs to approximately $3 million per year, but a more detailed analysis still needs to be completed and is currently under way. EPAs estimate of approximately $2.7

million per year to treat 30 MGD is likely very close based on Vancouver's O&M cost evaluation.

Unfortunately, it does not appear that the proposed rule explicitly considers costs associated with long-term operation and maintenance of treatment when setting the MCLs. The long-term O&M costs will be significant at such a low level and need to be a major component considered when setting the MCL as treatment systems will require additional operators and frequent replacement of filter media.

EPA Response: It is unclear how the commenter arrived at the conclusion that the EPA's capital and annual O&M estimates for the flow rates presented would be $23.5 million and $2.7 million, respectively. The commenter also did not specify the treatment technologies considered in its estimate. The updated cost curves that the EPA developed for the final rule estimate a range of capital costs of approximately $38 million to $86 million total to install six facilities, each treating approximately 8.77 million gallons/day (for a total of 52.6 million gallons/day). Although the commenter's estimates of $171.8 million and $250 million exceed the EPA's range, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for these facilities would be similar to the typical values assumed in the EPA's estimates. The commenter's estimates for annual O&M costs lack sufficient detail to compare to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Additionally, the EPA disagrees with the commenter's assertion that the agency did not consider costs associated with "long-term operation and maintenance of treatment when setting MCLs". The proposed and final rule explicitly considered costs associated with long-term operation and maintenance of treatment. The EPA's estimates of national annualized cost include long-term O&M costs such as operator labor and media replacement.

Horsham Water & Sewer Authority (HWSA) (Doc. #1686, SBC-043806)

Comments on Proposed Rule for Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (Docket ID No: EPA-HQ-OW-2022-0114)

Dear Administrator Regan,

The Horsham Water & Sewer Authority (HWSA) appreciates the opportunity to comment on the Environmental Protection Agency's (EPA's) "Proposed Rule for Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation". The HWSA is a medium sized water and sewer authority (~8,000 connections) that was one of three water systems severely impacted by PFAS contamination of its drinking water sources from the historical use of AFFF fire-fighting foam at the now closed Willow Grove Joint Naval Air Base and still active Biddle Air Guard station. Our systems combined to expose some of the worst PFAS contamination in the country in EPA's third Unregulated Contaminant Monitoring Rule (UCMR3).

Since the initial detection of Per- and Polyfluoroalkyl Substances (PFAS) contamination in our drinking waters in 2014, our utilities have been struggling to "fix" our water systems through the installation of PFAS treatment systems and restore confidence of our customers as our first and highest priority. Due to the evolving nature of health concerns from consuming PFAS, following the lowering of the EPA Health Advisory levels for PFOA and PFOS in 2016, Horsham Township adopted a "non-detect" standard for all PFAS substances in its drinking water, and tasked the HWSA with meeting this standard. As EPA is now proposing the laboratory Practical Quantification Level (PQL) of 4 parts per trillion (ppt) for these substances, EPA is essentially proposing the "Horsham Standard" for PFOA and PFOS for all water utilities to meet based on existing laboratory capabilities. We obviously have experience with achieving this level of performance and hope the agency will give our comments due consideration as such.

In January 2017, we began operation of our first two (2) wells with Granular Activated Carbon (GAC) treatment for PFAS removal. Currently we have eight (8) GAC treatment systems in place and have completed 26 GAC changeouts at these sites. We also have three (3) anion exchange (IX) treatment systems under construction. It should be noted that these IX systems are already well over their expected completion date due to supply chain issues. The construction contract period has now been extended to 500 days from award to substantial completion with no guarantee that this deadline will even be met. It should also be noted that the costs for the installation of the IX systems, as is occurring for all our capital contracts the last few years, is much higher than the engineering estimate.

As Horsham Township (Township) and HWSA committed to reducing PFAS levels to below the current analytical detection levels back in 2016 due to the concerns of the evolving nature of the science and that the community was subject to decades of PFAS exposure prior to its detection in the UCRM3 monitoring, we will not comment on the proposed Maximum Contaminant Levels (MCLs) for perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS). However, given our experiences as a "trail blazer" in installing PFAS treatment for drinking water and treating to “non-detect" levels for a number of years, our greatest concern with this proposed rule

is the feasibility of utilities across the country meeting the compliance timetables, and EPA's cost projections, both of which do not seem grounded in today's reality.

EPA Response: With respect to the commenter's concerns regarding treatment installation and associated costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document. For commenter concerns regarding practical quantitation limits, including implementation of the MCLs at the practical quantitation level (PQL), how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12.1 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Horsham Water & Sewer Authority (HWSA) (Doc. #1686, SBC-043809)

HWSA also believes EPA's estimates for capital and operating costs are both low. For instance, when looking at the capital costs, Horsham, and our neighboring townships of Warminster and Warrington, have all installed GAC installations on multiple wells and the total costs have all been approximately $1,000,000 per site for wells ranging from 0.1 MGD to 0.5 MGD. These actual costs are two (2) to four (4) times higher than EPA's cost estimates and these were all installed prior to the COVID-19 pandemic and before supply chain shortages resulted in on-going cost increases to the water industry. Further, our low bid price in 2021 for the construction of three anion exchange systems that is currently underway was 11% higher than the engineering estimate and this was as the supply chain related price increases were just beginning to materialize.

EPA Response: The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $0.3 million to $1.3 million for facilities using GAC to treat groundwater with a design flow ranging from 0.1 to 0.5 million gallons per day. The commenter's reported cost of $1 million falls within this range. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044334)

To date, 65 water systems have installed treatment to reduce levels of PFAS to comply with the state MCLs. Dozens of other public water system sources that have been contaminated with PFAS have been taken out of use. The MCLs proposed by USEPA are lower than NH's MCLs and would require that an additional 181 sources of water for public water systems be mitigated to comply with US EPA's MCL. The initial cost for installing treatment for the 181 sources is estimated to be $166 million and the annual operation and maintenance costs for the treatment systems are estimated to be $44 million.

Based on the ongoing work in NH and what we have learned since 2014, NHDES respectfully provides the enclosed comments. In addition to several comments relative to administrative

procedures and risk communication associated with rule implementation, our comments focus on three points.

First, NHDES believes that the US EPA's projected costs for administration, monitoring, treatment, operations and maintenance, etc. are vastly underestimated and that NH's cost alone may exceed the national estimate.

EPA Response: The EPA has considered all public comments on the cost analysis in the proposal and made changes to reflect those comments and information. The EPA's EA presents national level cost estimates that are annualized over the period of analysis and are therefore not directly comparable to the commenter's single year state-level estimate of capital costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Water Quality Association (WQA) (Doc. #1694, SBC-044987)

Cost Analysis and Small System Compliance

WQA believes that the EPA's cost analysis for deploying POU RO systems (found in Table 22 of the Federal Register notice [FN6: EPA-HQ-OW-2022-0114-0027, Table 22]) is conservative and that actual deployment would likely be more cost-effective than the table indicates. The association appreciates that the EPA views these systems as affordable but believes there are several factors in the analysis that led to a higher cost. This includes a slightly higher average price for a POU RO system and the absence of other POU/POE technologies that are effective and could increase savings. Additionally, since these products are certified using extremely high influent challenge levels, life expectancy for these products is expected to be longer. The analysis also doesn't account for community-wide maintenance agreements or the resources a small system may already have acquired to educate the public, including personnel.

The association understands it's difficult to consider all factors in a cost analysis and that the actual cost of implementing either POU or POE solutions will vary widely from one small system to the next. For example, a small system that is currently using POU RO to treat arsenic may only have to switch out post-filter cartridges to add in PFAS removal. The cost might be negligible if this change is phased in through the current maintenance cycle. The EPA only included cost estimates for POU RO in Table 22 of the Federal Register notice, but other technologies are also capable of meeting the proposed PFAS MCLs and may be less expensive in some situations. The EPA should encourage small systems to make their own "Fit for Purpose" analysis to determine if a POU or POE solution would be cost-effective for their situation.

EPA Response: Please see the EPA response to comment Doc. #1674, SBC-043702 in section 13.3.3 in this *Response to Comments* document.

Water Quality Association (WQA) (Doc. #1694, SBC-044981)

WQA believes that the EPA's cost analysis for deploying POU RO systems (found in Table 22 of the Federal Register notice) is high, and that actual deployment would likely be more cost-

effective and affordable than the table indicates. As with central treatment solutions, no model can account for all the variable conditions that could impact the treatment solution(s) of choice to meet individual water supply needs.

EPA Response: Please see the EPA response to comment Doc. #1674, SBC-043702 in section 13.3.3 in this *Response to Comments* document.

City of Lancaster, Pennsylvania (Doc. #1695, SBC4992)

1. Economic Impact: The initial assessment of the costs of implementing the removal of PFAS from drinking water are underestimated. Using currently available technologies for the City of Lancaster 12 MGD (million gallons per day) plant are estimated at $46.5 Million for Granular Activated Carbon (GAC) or $43.3 Million for ion exchange. Annual costs to operate are estimated at $2.5 million and $1.8 million dollars respectively. The costs are incredibly high and are in addition to the already rising operational costs due to supply chain limitations. Economically, this will be a significant cost burden for the City. These costs for operational costs assume only one media change out per year and it is highly likely it may be at least 2-3 times based on the source water, which makes the annual operational costs an extra $2-$4 Million.

For the City to treat PFOS, debt service repayments along with the operating costs for media change out and semiannual waste disposal, will increase the typical customer charge an estimated additional $260 Per year. for a GAC system. An Ion Exchange system is estimated at $190 per customer account. These costs would be very difficult for many households to take on financially and the impact it would have could be disastrous for many families, especially those struggling to make ends meet in these hard economic times. The cost is not justified since it will only help them to mitigate potentially 20%, at best, their PFOS exposure while allowing 80% or greater exposure from other foods and household items. If water was 80% of the source, then it would make sense to be so strict with water systems. However, allowing companies to continue to use these chemicals and profit while openly exposing the population to PFOS concentrations in food and consumer items at concentrations millions of times greater is regulating the wrong area. Water companies do not create PFOS but will be forced to treat them while they are continued to be used in our food and consumer products.

EPA Response: The updated cost curves that the EPA developed for the final rule estimate a range of capital costs for a 12 million gallon/day facility of approximately $9 million to $17 million using GAC and approximately $8 million to $12 million using IX. Assuming an average flow of 6 million gallons/day (50 percent of design flow) and one media changeout per year, the EPA's cost curves estimate annual O&M costs of approximately $1 million/year for GAC and approximately $1.7 million/year for IX. Although the commenter's estimates exceed the EPA's ranges, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for this facility

would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

With respect to the commenter's concerns that PFAS treatment will "increase the typical customer charge", please see section 13.10 of the EPA response in this *Response to Comments* document on the EPA's affordability analysis. With respect to the commenter's assertion that "the cost is not justified since it will only help them to mitigate potentially 20 percent, at best, their PFOS exposure while allowing 80 percent or greater exposure from others foods and household items", please see section 4.2.5 of the EPA response in this *Response to Comments* document for discussion of RSC and section 13.8 of the EPA response in this *Response to Comments* document for the EPA's comparison of costs and benefits, including the Administrator's determination that the benefits justify the costs of the rule. With respect to the commenter's concerns that "Water companies do not create PFOS but will be forced to treat them", please see section 15 of the EPA response in this *Response to Comments* document for the EPA's discussion of regulatory actions under different statutes, which are outside the scope of this rulemaking effort. While this drinking water rule was developed using the authorities of the SDWA, which is not the statutory authority to regulate use of chemicals in consumer and industrial products or regulate the remediation of contaminated sites, the EPA is taking action under other statutory authorities to reduce PFAS exposure and risk. Please see section 15 of the EPA response in this *Response to Comments* document discussing the EPA's PFAS Strategic Roadmap for further information.

City of Lancaster, Pennsylvania (Doc. #1695, SBC-044998)

PFOA and PFOS are everywhere including the clothing we wear and the food we eat due to wrappings and storage choices. Focusing on regulating water systems where the majority of levels are at background levels that are not causing ill health effects does not make sense. Additionally, treatment costs have been increasing at incredible rates. Chemical costs have doubled and even tripled over the last three years. To require an additional $ 9.2-million-dollar annual debt service and operating cost increase on a small system such as ours, to treat PFOS when the science on these chemicals is still very young and being tested is irresponsible. It is necessary to understand its effects and impacts before regulation. The scientific data is not available to set these limits and there has not been thorough testing to set the proposed limit. More data is also needed on the capital costs for large facilities and to ensure the proper treatment for all species of PFAS.

Thank you for your consideration of these comments. If you have any questions or require clarification, please contsterpa.com.

Sincerely,

James C Rieben Jr. Ph.D.

Water Treatment Manager

City of Lancaster PA

EPA Response: With respect to the commenter's concerns regarding treatment costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document. With respect to the commenter's concern about PFAS exposure through use of consumer products, the EPA notes that regulating consumer products is outside the scope of this rulemaking and the EPA's regulatory authority under SDWA. With respect to the commenter's assertion that "regulating water systems…does not make sense", once fully implemented, the final rule is anticipated to prevent thousands of deaths and reduce tens of thousands of serious PFAS-attributable illnesses. The Administrator has determined that the benefits of reducing PFAS in drinking water through this regulatory action justify the costs. See Chapter 7 of the EA for further discussion. For the quantified benefits analysis, the EPA relied on peer-reviewed literature and synthesis of multiple high-quality studies to evaluate the effects of PFAS exposure on human health. For responses to comments on the EPA's comparison of costs and benefits of this action, please see section 13.8 of the EPA response in this *Response to Comments* document.

With respect to the commenter's assertion that "the scientific data is not available to set these limits", the EPA disagrees as the EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; furthermore, as demonstrated by the record for this rulemaking and the many commenters who urged action regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Please see sections 3 and 4 of the EPA response in this *Response to Comments* document for discussions about the scientific health information used to inform this rule, sections 3 and 6 of the EPA response in this *Response to Comments* document for the occurrence information, section 10 of the EPA response in this *Response to Comments* document about the EPA's treatment technology evaluations, section 7 of the EPA response in this *Response to Comments* document about analytical methods, and this section (13) about costs and benefits information used to inform the regulation, among many other technical analyses and scientific sources used to inform this analysis. As demonstrated by the record for the rulemaking, which incorporates the data and information provided by commenters, the EPA has used best available science and information to inform this rulemaking and finalize the final rule's MCLGs and MCLs. The EPA also disagrees with the commenter's assertion that "the majority of levels are at background levels that are not causing ill health effects" As discussed in section IV of the final rule preamble and section 4 of the EPA response in this *Response to Comments* document, the EPA has determined that PFOA and PFOS are *Likely to be Carcinogenic to Humans* based on sufficient evidence of carcinogenicity in humans and animals (USEPA, 2024h; USEPA, 2024i). The EPA has also determined that a linear default extrapolation approach is appropriate as there is no evidence demonstrating a threshold level of exposure below which there is no appreciable cancer risk (USEPA, 2005b; USEPA, 2016b). Therefore, any increase in exposure would result in a linear increase in cancer risk which is very meaningful to public health. For further discussion of PFAS adverse health effects, please see sections II.B, III.B, and IV of the preamble for this action; for responses to comments related to PFAS occurrence data, please see sections 3.1.2, 3.2.2, and 6 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045048)

Specifically, monitoring costs for 1138 community and nontransient noncommunity water systems was estimated to be $2.1 million dollars per year. Costs of treatment, including costs for construction, operation, and maintenance, varied greatly based on the type of treatment selected, site conditions, initial concentration of the contaminant, the presence of other contaminants and organic materials in the raw water, the need for pre-treatment, and the size of the water system. Cost data submitted by water systems to NJDEP through construction permits and applications to the Drinking Water State Revolving Fund (DWSRF) shows a wide range of individual project costs for systems to install PFAS treatment, ranging between $3,000 and $77,000,000. Costs were project specific, ranging from simply replacing filter media in existing GAC vessels to full treatment plant construction and upgrades. Systems requiring a new treatment plant incurred higher costs for design, building and infrastructure construction, labor, and treatment components such as pumps, chemical storage and feed systems, monitoring instruments, and holding tanks.

Utilizing this permit data and project cost data submitted by water systems in applications to the DWSRF, NJDEP estimates that total capital costs for installation of PFAS treatment to meet EPA's proposed standards across the state could be as high as $1,065,000,000. This includes installation of treatment at an additional 350 or so water systems expected to be impacted by the proposed standards in New Jersey, based on currently available data. NJDEP is willing to share the data it has gathered and work with EPA to utilize this data in EPA's assessment.

EPA Response: The EPA's analysis presents national level cost estimates that are annualized over the period of analysis and are therefore not directly comparable to the commenter's single year state-level estimate of capital costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-045055)

II. EPA should consider costs and timing before settling its initial MCL at the PQL.

EPA is mandated to consider costs when setting the MCL. The standard is feasibility, which contemplates expense, rather than mere capability. The regulation as proposed is not feasible, nor is it capable of being met under EPA's proposed timeline.

A. MCLs at 4 ppt PFOA and PFOS are not feasible.

Under section 1412(b)(4)(B) of SDWA, EPA must conduct an economic analysis during the development of drinking water contaminant regulations. EPA must take costs into consideration when setting an enforceable MCL as close to the maximum contaminant level goal (MCLG) as feasible. The SDWA analysis on feasibility is only acceptable if it uses accurate assumptions for its inputs. EPA's cost estimate falls short.

The actual costs that water utilities will face for treatment are significantly higher than EPA's estimate. EPA's estimate of nationwide proposed costs to treat to 4 ppt PFOA and PFOS falls between $776M and $1.2B. This range is much too low. First, there are a few factors that will drive the true cost of meeting 4 ppt much higher. The first is inflation. Last summer, construction costs skyrocketed 25 to 30% higher than 2021 costs [FN1: Inflation Taking the Bite out of New Infrastructure Projects, US News and World Report article. June 19, 2022. Inflation Taking Bite Out of New Infrastructure Projects (usnews.com)]. EPA used 2021 dollars in its estimates so construction costs will already be 25 to 30% higher than the estimates used in the analysis.

EPA Response: The EPA does not agree with the commenter's interpretation of "feasibility;" please see the EPA's discussion in the preamble of what that term means. The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document (for laboratory considerations) and section 5.1.4 of the EPA response in this *Response to Comments* document (for treatment considerations).

With respect to the commenter's concerns about inflation, the EPA has updated its equipment costs to 2022 dollars (which are the most recent data available), collected new vendor price quotes for cost driver equipment components, and made several other adjustments to WBS model assumptions. Taken together, these adjustments increased the system level capital cost estimates in the EPA's cost assessment by percentages that were generally greater than or equal to those reported by the commenter. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-052961)

Second, supply and demand will force additional upward pressure on prices. Prices will increase significantly based on scarcity in the supply chain and labor force as 3,500 utilities nationwide hustle to comply [FN2: In the proposed rule, EPA estimates that 3,400-6,300 water systems will be impacted by the proposed regulation of 4 ppt for PFOA and PFOS with the 1.0 hazard index for the four other PFAS.]. This demand will continue to drive up prices on equipment, lab services, media, and reactivation.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-052969)

As part of its cost analysis, EPA also failed to recognize the factor of the opportunity costs of this regulatory action. As drinking water rates soar in response to the MCL and the required implementation of expensive treatment technologies, there is also an opportunity cost that will be realized by households and businesses. Consumers will have to make tough choices as they have less money. Businesses will raise prices to reflect their increased costs. Products and services

will then cost consumers more and they will have even less money for discretional spending. This cycle is exacerbated in Justice40 neighborhoods where there is already a lack of extra money and increases in the cost of basic needs results in going without basic necessities.

EPA Response: With respect to the impact of demand on costs, see section 13.3.3 of the EPA response in this *Response to Comments* document. For further discussion of opportunity costs, see section 13.9 of the EPA response in this *Response to Comments* document. Please see section 14.10 in this *Response to Comments* document for the EPA's response to comments on environmental justice; please see the EPA response to comment Doc. #1733, SBC-043892 in section 14.10 in this *Response to Comments* document for specific discussion of Justice40.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-052970)

EPA's acute underestimation is borne out in CDPU's numbers. In February 2023, CDPU received an estimate for the cost of implementing granulated activated carbon treatment at its water plants, which includes three existing plants and one plant currently in design [FN4: Engineers at Hazen and Sawyer produced a memo detailing the Cost of Implementation of GAC for PFAS Treatment at Columbus, OH Water Plants, dated March 9, 2023. Hazen and Sawyer is a National A/E firm which has worked in surface water and groundwater plants, developed solutions for meeting PFAS targets, installed granular activated carbon and ion exchange facilities, and researched innovative treatment approaches]. Estimated capital costs for CDPU's four plants falls between $338 million to $363 million, but could realistically approach $544 million. Additionally, the current estimate for annual operation and maintenance costs is between $29.4 million to $43.9 million, depending on whether virgin or reactivated carbon is used. To put that in perspective, CPDU—one public water system out of 3,500—may need to spend over half a billion dollars by 2030 to treat the very low levels of PFAS in our drinking water. The result would be an extreme cost for miniscule benefit. EPA's cost-benefit analysis is distorted because its nationwide estimate does not come close to being accurate.

EPA Response: This comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

California Farm Bureau Federation (Doc. #1704, SBC-045073)

Technologies

In order to meet the 4ppt standard for PFOA and PFOS, rural water utilities will have to obtain and install new technologies. As outlined in the American Water Works Association's (AWWA) recent WITAF 56 Technical Memorandum: PFAS National Cost Model Report, treatment strategies for PFAS in drinking water include both proven, commercially available technologies as well as emerging technologies. Commercially available technologies that have been demonstrated at full scale in the field to reduce concentrations of PFAS in drinking water are limited to the following:

• Granular activated carbon (GAC).

• Ion exchange (IX).

• Nanofiltration (NF) and reverse osmosis (RO).

Treatment considerations for the application of each of these technologies are described in the full report. While there are many variables that contribute to the specific costs associated with reaching the 4ppt standard, the report incorporates the most obvious operating costs into their cost models. These include media replacement, membrane replacement, power, maintenance, water disposal, chemical consumption, and labor. The report also contains considerable explanation of their methodology and ultimately finds that the national cost for water systems to install treatment to remove PFOA and PFOS to levels required by this proposal will exceed $5.2 billion annually.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs of the final rule. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045111)

Section XI – Treatment Technologies

1) Cost-effective compliance for GAC – additional guidance on applicable circumstances for GAC is needed.

GAC is the likely most cost-effective option, especially for small water systems. And as the preamble discusses, the Bipartisan Infrastructure Law provides considerable funding for the installation of treatment. However, it does not cover on-going costs, which are expected to be significant and likely increase in the next several years as the demand increases nationally nor does it cover compliance sampling costs. In Vermont our traditional approach is not to permit a new well if it has a human- introduced contaminant such as SOCs or VOCs, so there are very few sources that have treatment for these compounds in the state. However, given the emerging nature of PFAS, we do have contaminated sources, which increasingly require treatment. Often many small systems do not have access to other locations to develop a new source in an area outside of contamination, which would be the preferred option, however, many times it is not feasible. Additionally, we are very rural so connecting to a "nearby" system is likely to be incredibly cost prohibitive. That means treatment is a necessity. Based on our experience with PFAS to date, a community system serving approximately 400 individuals would spend approximately $30,000 per year on on-going treatment-related expenses including media disposal and replacement. These are expenses that are not "covered" by the traditional SRF program and would be borne by the system for potentially many years to work through the process of recovering costs from responsible parties. This will cripple the water system's user base due to the economy of scale.

As discussed previously in these comments, EPA needs to establish a post-treatment sampling framework.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document. With respect to concerns about funding for "on-going treatment-related expenses", please see section 2.4 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045090)

2) Feasibility on the proposal including analytical measurement, treatment capability, as well as reasonable costs.

a. Small system perspective/feasibility:

EPA should ensure that there is sufficient funding in the programs that the EPA has established for funding response to PFAS contamination at public drinking water systems with an emphasis on small systems and on-going Operations and Maintenance expenses. Vermont is comprised of many small water systems. Of the 592 Community and NTNC systems subject to the proposed regulation, 34 of them serve a population of 3,300 or greater, only 7 of them serving a population of over 10,000 with the biggest single system serving a population of 42,000 individuals. The proposed MCLs would likely impact 25 additional public water systems, based on analysis from single sample(s) and not a running annual average. This is in addition to the 16 systems in Vermont that have already exceeded the state MCL. All of the systems that are expected to exceed the proposed MCL serve a population less than 3,300. The preliminary estimate of capital costs associated with the installation of PFAS treatment for the 25 impacted systems to comply with EPA's draft MCL for Vermont is more than $200,000,000. This does not include on-going Operation and Maintenance (O&M) costs, as discussed below in these comments.

EPA Response: The EPA's analysis presents national level cost estimates that are annualized over the period of analysis and are therefore not directly comparable to the commenter's single year state-level estimate of capital costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. With respect to concerns about funding for ongoing O&M costs and funding available to small systems, please see section 2.4 of the EPA response in this *Response to Comments* document.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045733)

2. The cost estimates of the BATs developed by the EPA are based on incomplete or non-applicable information and more than likely represent an underestimation of the costs that will be borne by ratepayers.

There are several shortcomings in the cost estimation process for the BATs used by the EPA to justify the draft rule. First, cost curves require a significant number of case studies to develop, which does not appear to be present for surface water PWS. The EPA acknowledges in USEPA 2023g and "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation" (hereafter "Economic Analysis") that the BATs will perform differently for surface water and groundwater PWSs. In Section 5.3.1.2.2 of the Economic Analysis, the EPA acknowledges that the work breakdown structure (WBS) spreadsheet model for GAC was peer reviewed in 2006, the WBS IX model was peer reviewed in 2005, and the WBS RO/NF model was peer reviewed in 2007. However, from the list of full-scale installations in USEPA 2023g (Section 2.2.1 for GAC; Section 3.2.1 for IX; and Section 4.2.1 for RO/NF), no full-scale installations treating surface water for PFAS existed at the point when these models were created. PWD requests that EPA provide more information on how full-scale surface water treatment facilities were factored into the cost model.

EPA Response: With respect to the commenter's concerns about peer review of the WBS models, WBS model development did not cease with the initial external peer review. The EPA has continued to maintain and update the models throughout the intervening years, including updates specifically for this final rule as described in section 13.3.3 of the EPA response in this *Response to Comments* document.

With respect to the commenter's concerns that the EPA's cost curves do not rely on case studies for large surface water systems, the EPA notes that for unregulated contaminants like PFAS (and for many regulated contaminants), it is highly unlikely that even the most thorough literature search could find a peer-reviewed source for every possible combination of system size and source water with full-scale data on treatment performance and cost. Furthermore, the EPA did not develop its cost curves by extrapolating from case studies because parametric extrapolation can over or underestimate costs for water systems when it does not account for all factors that can vary among case studies. Instead, the EPA used results from the peer reviewed WBS models, which estimate cost using a detailed engineering build-up from the line-item costs of individual treatment system components. The WBS-based approach is a more robust approach than factored or parametric cost estimating methods, as it can be adjusted for desired treatment levels, raw water quality and a range of system parameters. Similarly, the EPA's evaluation of Best Available Technologies considered the complete body of scientific literature and was not based solely on case studies.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-053306)

Additionally, these WBS models do not account for the increased costs of construction in densely populated areas. Many urban WTPs are space-constrained and the likely need for additional land is both costly and politically tenuous. There are many additional costs that pose challenges to urban utilities, such as coordination, staging, utility relocation, that do not appear to be accounted for in the Economic Analysis. Section 2.4.4 of the documentation for each WBS model provides some clarification of how add-on costs, such as land acquisition, are estimated; however, this documentation does not provide adequate details around how the land cost estimates are generated or adjusted to account for land cost increases over time.

EPA Response: The EPA's analysis used unit costs for land acquisition that are scaled to a system's population served and reflect the fact that land costs are generally higher in more densely populated locations. Furthermore, within a given size category, these unit costs are weighted by the expected probability that a system is in an urban versus rural location. For the largest size category (greater than 100,000 people) these costs are heavily weighted (76 percent) to urban land values. Abt Associates (2020b) provides complete details on the methodology and data sources used to estimate unit costs for land. The EPA escalated the 2020 costs to 2022 dollars using the Gross Domestic Product (GDP) implicit price deflator. The resulting weighted average unit cost for land for the largest size category is more than $280,000 per acre after escalation to 2022 dollars.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-053312)

Fourth, the EPA recommends discharge of the concentrate stream from RO/NF into a non-potable body of water (brackish estuary or ocean) at less than 10,000 feet from the PWS. In December 2022, Assistant EPA Administrator Radhika Fox issued a memorandum to state regulatory agencies entitled "Addressing PFAS Discharges in NPDES Permits and Through the Pretreatment Program and Monitoring Programs", which details the implementation of technology-based effluent levels for PFAS discharges under the National Pollutant Discharge Elimination System (NPDES). The inclusion of NPDES discharge limits on PFAS would necessitate additional treatment on the concentrate stream. The cost for this additional treatment is not currently accounted for in the Economic Evaluation for the proposed NPDWR and should be included in any final cost assessments.

EPA Response: The EPA notes that in response to public comments about residual management concerns for high pressure membrane technologies, the EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the EA for the final rule. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments regarding residual management, including management of RO reject, please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-053313)

Finally, the addition of unit processes into the drinking water treatment train has the potential to pose hydraulic limitations which are not clearly accounted for in the Economic Analysis. The hydraulic restrictions from the addition of unit processes may necessitate the addition of raw water booster or mid-process pumping that is not accurately accounted for in the EPA's cost estimations. The documentation for the GAC and IX WBS models state that the assumption for small systems (<1 MGD) will require no additional pumping and the details of the method for determining additional pumps for larger systems is not clearly defined. Site-specific constraints may prevent the addition of booster pumps in existing raw water pumping stations and may necessitate the construction of a new building. It is not clear if the EPA is accurately accounting for the additional pumping that will be required to add these unit processes to treat for PFAS.

EPA Response: The EPA did not include booster pumps for pressure GAC systems or ion exchange, because the head loss associated with these treatment processes is typically low. The WBS models include booster pumps for gravity GAC systems, which are most likely to be used by large surface water systems and face hydraulic limitations. The models determine the number and size of these pumps based on the required design flow plus an additional safety factor. The models include the footprint of these pumps, plus required access space, in the calculation of treatment system footprint used to estimate the cost of buildings. See the *Technologies and Costs* document for more information (USEPA, 2024d).

Philadelphia Water Department (PWD) (Doc. #1709, SBC-053314)

There appear to be several issues with the Economic Analysis including an underestimate of the impact to large systems, which serve approximately 50% of the US population. Altogether, the Economic Analysis includes several shortcomings that potentially result in a underestimation of the cost that will be borne by ratepayers. PWD is requesting that the EPA recalibrate the WBS models used to form cost estimates, using case studies for large surface water PWS to more accurately estimate the financial burdens of the capital improvements required to comply with the draft NPDWR.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045906)

V. EPA's Cost Analysis Is Flawed, and it Is Infeasible for Regulated Entities To Comply with the Proposed MCLs

SDWA provides that, if EPA establishes an MCL for any contaminant, the MCL must be only as close to the MCLG as feasible. Further, the combination of technology, treatment techniques, or other means required to meet the level must not be more stringent than feasible [FN141: 42 U.S.C. 300g-1(b)(B)(5)(B)(ii).]. Each NPDWR that establishes a MCL must list the technology,

treatment techniques, and other means that EPA finds to be feasible for purposes of meeting the MCL [FN142: 42 U.S.C. 300g-1(b)(E)(4)(i).]. The term "feasible" is defined by SDWA as "feasible with the use of the best technology, treatment techniques and other means which [EPA] finds … are available (taking cost into consideration)."[FN143: 42 U.S.C. 300g-1(b)(B)(4)(D).] Notably, EPA is required to consider costs in its assessment of feasibility in setting an MCL. In proposing an MCL, EPA must publish an analysis of the compliance costs [FN144: 42 U.S.C. 300g-1(b)(3)(C)(i)(III).].

As proposed, EPA grossly underestimates the potential compliance costs of this rulemaking on the thousands of public water systems across the country, including non-transient, non-community water systems (NTNCWSs), that will be required to monitor, sample (with limited certified laboratory capacity), and treat six PFAS at infinitesimal, almost-zero levels. As proposed, there is a high level of uncertainty with even detecting PFAS at these levels.

The Chamber released a report in November of 2022 indicating that "the consensus is that Meeting PFAS drinking water standards will likely require substantial investment," and that if the MCL is 10 ng/L [FN145: 10 ng/L is 10 ppt.] or less, nationwide PWS treatment costs will be significant: "At 10 ng/L there is a 50 percent probability that costs exceed $16 billion, whereas the 50 percent probability is $32.5 billion for the 4 ppt scenario and $59.4 billion for the non-detect scenario [FN146: "Potential Costs of Meeting Safe Drinking Water Act (SDWA) Standards for PFOA and PFOS," U.S. Chamber of Commerce (November 7, 2022): https://www.globalenergyinstitute.org/potential-costs-meeting-safe-drinking-water-act-sdwa-standards-pfoa-and-pfos. Note this report only estimated costs for PFOA and PFOS.]. Also, the American Water Works Association (AWWA) published a report in March of 2023 [FN147: "PFAS National Cost Model Report," Black & Veatch Holding Company, prepared for the American Water Works Association (March 7, 2023): https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14-102450-257. See also AWWA statement on proposed PFAS drinking water standards: https://www.awwa.org/AWWA-Articles/awwa-statement-on-proposed-pfas-drinking-water-standards.] that provides national cost estimates for setting an MCL of 4 ppt for PFOA and PFOS. It found the national cost for water systems to install treatment to remove PFOA and PFOS to levels required by this proposal exceed $3.8 billion annually and the national cost burden for 4 ppt MCLs for PFOA and PFOS are over $5.2 billion The report analyzed costs for installation of each treatment technology, including granular activated carbon (GAC) gravity basins; GAC, IX and Manganese pre-treatment pressure vessels; reverse osmosis systems (low and high pressure feed pumps and associated building, storage tanks, brine disposal, decarbonation system, and chemical treatment system); operating costs, and life cycle costs (for a 20-year life).

AWWA concluded that a vast majority of these treatment costs will be borne by communities and ratepayers [FN148: See AWWA Press Release at: https://www.awwa.org/AWWA-Articles/awwa-statement-on-proposed-pfas-drinking-water-standards.]. Its report estimates that annual costs to households for removing PFAS from drinking water can range from $100 or more per year (for a

population of over 1 million) to even $10,000 (for a population of less than 100), which is reflective of communities where new treatment facilities will need to be installed and operated [FN149: Report at 32.]. And this estimate is just for compliance with PFOA and PFOS MCLs; it does not consider the costs for compliance with the other four PFAS and the burdens on water systems using of the newly proposed (and yet untested in any other MCL rulemaking) Hazard Index approach to determine compliance. While EPA accounts for capital costs, it fails to consider that most of the PFAS-related costs will be for ongoing operation and maintenance (O&M). EPA must consider the high costs of maintaining and replacing treatment technologies over time.

EPA Response: For the EPA's interpretation of the term "feasibility" and requirements for developing an MCL, please see the preamble. Section 1412(b)(5)(B)(ii) cited by the commenter is not relevant to this action as it only applies when the EPA is using the authority of that provision to set an MCL at a level other than the feasible level. For response to comments on the agency's consideration of feasibility, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA has considered costs in determining the feasibility of the MCLs, and the EPA has determined that MCLs of 4.0 ng/L for PFOA and PFOS, MCLs of 10 ng/L for PFHxS, PFNA, and HFPO-DA, and a Hazard Index MCL of 1 for mixtures of PFHxS, PFNA, HFPO-DA, and PFBS are all feasible, taking cost into consideration. In response to the commenter's assertion that "[a]s proposed, there is a high level of uncertainty with even detecting PFAS at these levels," the EPA disagrees; for discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. For additional discussion on implementing MCLs at the PQL or use of sample results below the PQLs to help operators manage their treatment operations, please see section V of the FRN and section 5.1.2 of the EPA response in this *Response to Comments* document. See the EPA response to this commenter's approaches and conclusions in the report "Potential Costs of Meeting Safe Drinking Water Act (SDWA) Standards for PFOA and PFOS" in snippet Doc. #1537, SBC-042649 in section 13.3.3 in this *Response to Comments* document. Further, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs; please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on AWWA's estimates of small system costs and household level cost impacts, please see sections 13.3.3 and 13.10, respectively, in this *Response to Comments* document. While the commenter is correct that AWWA's comment letter does not consider the costs of the Hazard Index MCL, the EPA has thoroughly evaluated and considered costs associated with the Hazard Index and individual MCLs for PFHxS, PFNA and HFPO-DA; please see section 13.3.2 of the EPA response in this *Response to Comments* document for more information. The commenter is incorrect when stating "[EPA] fails to consider that most of the PFAS-related costs will be for ongoing operation and maintenance (O&M);" The EPA has included O&M costs in the cost estimates, as detailed extensively in Chapter 5 of the EA.

HRSD (Doc. #1719, SBC-043546)

[We see the following recommendations as productive and protective strategies that EPA can utilize:]

Phased implementation coupled with reasonable policy choices can reduce capital and operational cost impacts to communities

HRSD developed estimates of its own increased costs to comply with the proposed MCLs based upon the treatment of 75 million gallons per day of SWIFT Water. As originally conceived, the driver for carbon replacement or regeneration in the SWIFT AWTs was based upon a treatment objective of 4 mg/L of Total Organic Carbon (TOC). Switching to a PFAS threshold of 4 ng/L each, PFOA and PFOS, will result in more than a 60% increase in quantity of virgin carbon utilized on an annual basis, an increase of more than 2,000 tons annually. The projected operational cost increase is approximately $10 million. The annual cost for virgin carbon alone within our SWIFT facilities is projected to be nearly $23 million. This estimate is for facilities that are already designed to utilize granular activated carbon as part of its treatment process. This cost, therefore, does not include the initial capital investment required to construct the facilities.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. While the EPA is not implementing phased implementation, the agency is granting a two-year extension to comply with the MCLs to allow for capital improvements: please see section 12.1 of the EPA response in this *Response to Comments* document. Additionally, the EPA notes that using the prices as updated for the final rule and including volume discounts, the EPA's cost model estimates approximately $25 million per year for the quantity of virgin carbon reported by the commenter. The commenter's projected cost of $23 million is slightly lower than the EPA's estimate. In short, commenter's estimate is generally in-line with the costs the EPA has projected for a facility of this size using carbon to comply with the PFAS NPDWR.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043592)

10. I am very concerned with EPA's cost estimates and believe they are too low and were based on surface water and not ground water sources. Our engineering estimates for treating a water system for 94 families is $1.1 million. The evaluation and estimates of three (3) jurisdictions in the chart below stated that O&M costs would be close to double between the SAL & MCL because of media replacement frequency. Sampling alone is roughly $300 per sample, on a well with PFAS detections requiring quarterly sampling that is $1,200 per year per well just in lab costs. PFAS treatment is going to be extremely costly and testing is just now rolling out to many systems in the state/nation. I think the number and prevalence of systems with measurable PFAS will be significant. When the MCL is adopted and systems are put on the clock it will become quite apparent that the EPA cost estimates are woefully insufficient. Costs are outlined approximately below on three Washington State water systems.

[Table 1: see docket ID EPA-HQ-OQ-2022-0114-1729].

Thank you for this opportunity to comment. I hope you will take these comments into consideration and modify the rule to accommodate these commonsense recommendations.

Respectfully,

John Weidenfeller, MBA

General Manager, Public Utility District No. 1 of Thurston County

jweidenfeller@thurstonpud.org

Attachment: Letter to EPA Administrator Michael Regan, Lakewood Water District, May 24, 2023 [see docket ID EPA-HQ-OW-2022-0114-1729]

EPA Response: The EPA's cost estimates considered both surface and groundwater sources. The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $0.2 million to $0.6 million facility using GAC or ion exchange to treat groundwater, assuming a design flow of approximately 0.1 million gallons/day based on applying the EPA's population-flow equations for a system with 94 households and an average of 2.53 people per household. The table below compares capital costs for the other examples presented by the commenter to results from the updated cost curves the EPA developed for the final rule. Some of the commenter's estimated or reported costs fall within the EPA's range. Although others exceed the EPA's range, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for these facilities would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. While the commenter estimates that O&M costs would "be close to double" at some facilities, the comment lacks sufficient detail to evaluate this conclusion in comparison to the results of the EPA's WBS models. Finally, regarding sampling costs, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Commenter's Tabulated Capital Costs Compared to Results from the EPA's Updated Cost Curves

Jurisdiction	MGD Plant Capacity	Commenter's Capital Cost	EPA's Capital Cost Curves Lower Bound	EPA's Capital Cost Curves Upper Bound
Lakewood #1	2.88	$3,300,000	$2,900,246	$6,388,393
Lakewood #2	4.32	$5,100,000	$3,782,467	$8,545,824
Yorba Linda, CA	25	$28,000,000	$15,020,224	$28,291,178
ENG Estimate Vancouver (future)	53	$172,000,000	$28,010,928	$53,662,660

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043578)

The proposed levels are significantly lower than any state has proposed for PFAS chemicals, which would seem to indicate that even states highly concerned with PFAS contamination have arrived at different conclusions than EPA with regard to the cost and benefit analysis. Analysis fundamental to the 1996 amendments to the SDWA requires a detailed risk and cost assessment, and best available peer-reviewed science when developing standards. These requirements are expected to imperil the financial sustainability and affordability of some water systems, which will warrant greater assistance in terms of funding. To not clarify the extent of these costs now would be a grievous mistake as water systems and governments across all levels budget for the future and may be forced into competing for limited and insufficient federal dollars.

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document. In regard to the commenter's assertion that "even states highly concerned with PFAS contamination have arrived at different conclusions than EPA with regard to the benefit/cost analysis," the commenter provides no detail or references to support this statement. While no specific references were given, potential differences in conclusions could arise from differences in number entities included in the analysis, baseline levels of PFAS contamination, estimation of health risk reduction benefits, and the estimation of costs. Additionally, the EPA notes that it has finalized this regulation to be consistent with the requirements of SDWA and numerous executive orders: these requirements may be different than those authorizing or mandating a given state to set standards. As discussed in this section and the preamble, the EPA considered public comments on the cost analysis in the proposal and made many changes in response to these comments and associated information; as a result, the EPA has used the best available peer reviewed information to support the EA for the final rule. For the EPA's response to comments on the affordability determination, please see section 13.10 of the EPA response in this *Response to Comments* document. For more information on federal funding availability, please see section 2.4 of the EPA response in this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043877)

Although the proposed NPDWR is vital to public health, Commenters are mindful that the cost of compliance will be substantial for public water systems. The proposed NPDWR would require a nearly five-fold increase in the number of EPs whose water will need treatment, when compared to the Pennsylvania regulations. However, this cost should not be a deterrent because the corresponding value in terms of health is high and the financial costs should be partially offset by federal funding.

Moreover, the exact costs are unclear, as demonstrated by, for example, the disparity between the cost estimates produced by the Commonwealth of Pennsylvania and those generated by EPA. When developing Pennsylvania's PFAS drinking water MCL rule, PA-DEP conducted an economic analysis to assess the treatment costs for PFOA and PFOS [FN22: 53 Pa.B. 350–60.] The analysis should be similar to the proposed economical analysis for the NPDWR, since the

monitoring and treatment technologies are the same for the state and the federal regulations, as noted above [FN23: It should be noted, however, that implementation of the NPDWR may require, for example, more frequent changing of the GAC or ion exchange materials, thereby increasing to a degree the annual costs.] The PA-DEP provided estimates for the annual costs of implementation as a function of the number of entry points requiring PFAS treatment, which could be fit to a linear function: Assuming 900 entry points in Pennsylvania (24% of the total) that will need PFAS removal under the proposed NPDWR, the economic analysis provided by PA-DEP suggests an annual cost of more than $395 million [FN24: Fitting the cost data in Tables 15 and 16 of the Pennsylvania drinking water regulation yields a linear fit for cost as a function of EPs needing PFAS treatment that is: annual cost (million $)=2.3+0.44*x, where x is the number of entry points affected. This means that $2.3 million/year is the cost of testing for the entire state, regardless of EP needing to implement treatment. The annual cost (in millions) for each EP that does require PFAS treatment is $0.44. See 53 Pa.B. 357, 359.]. This estimate is very high when compared to the economic analysis conducted by the EPA in the NPDWR, [FN25: See 88 Fed. Reg. 18689–729.] where the national annual cost of implementation is estimated to be of order $770–1,200 million [FN26: 88 Fed. Reg. 18724, Table 66]. These national costs are only 2–3 times higher than the PA-DEP estimate, despite Pennsylvania's population being only approximately 4% of that of the entire USA [FN27: Pennsylvania's population is 13 million, according to the census. U.S. Census Bureau, Section on Quickfacts, Pennsylvania, https://www.census.gov/quickfacts/PA (last visited May 24, 2023). Comparatively, the population is nearly 335 million for the entire United States. U.S. Census Bureau, U.S. and World Population Clock, https://www.census.gov/popclock/ (May 24, 2023).]. Even if the occurrence of PFAS in Pennsylvania drinking water is higher than the national average, it is not likely that Pennsylvania accounts for 30–50% of the national PFAS water pollution.

Detailed comparison of the economic analyses conducted by the EPA and the PA-DEP is outside the scope of these comments. However, it is likely that the EPA's numbers are more up to date and better represent current expenses: For example, PA-DEP used an average cost per sample of $616, [FN28: 53 Pa.B. 356.] while EPA used a value of $302–$376,[FN29: 88 Fed. Reg. 18698, Table 34.] which reflects the drop in costs over the last 5 years.

EPA Response: The EPA agrees that comparing the estimate of costs in Pennsylvania to the EPA's national cost estimates is complicated due to differences in discount rates applied and period of analyses for each estimate. The commenter's overall conclusion that the "EPA's numbers are more up to date and better represent current expenses" and the commenter's concurrence with the EPA's estimated sample analysis costs supports the final rule.

Michigan Section American Water Works Association (MI-AWWA) (Doc. #1734, SBC-044475)

Cost

Drinking water systems in Michigan have concerns regarding the short-term and long-term costs of upgrading treatment facilities and the disposal cost of PFAS impacted waste stream. The EPA

has significantly underestimated costs associated with the removal method based on unpredictable low concentrations. Further, this cost should be borne by chemical producers who make great profit on it rather than water utilities. For one community, the estimated cost for feasibility, final design, and construction within the next 2-5 years will impact rate payers by 1%-3% over the next 20 years for capital cost and operational cost increases.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Regarding the comment "[f]urther, this cost should be borne by chemical producers who make great profit on it rather than water utilities," please see section 15 of the EPA response in this *Response to Comments* document. While beyond the scope of this rulemaking, the EPA is also taking action outside of this NPDWR to address PFAS, and these actions can be found in the EPA's Strategic Roadmap outlined in section II.F of the FRN.

Arizona Corporation Commission (ACC) (Doc. #1735, SBC-045180)

The following example illustrates the potential cost of compliance with the proposed rule for an Arizona utility. The table below shows estimated construction costs from a Class A utility regulated by the ACC, which represents the largest utility class in Arizona with annual operating revenues exceeding five million dollars.

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1735]

[FN1: Media Changeout costs include replacement media, labor to replace media, and disposal of spent media.]

[FN2: Media changeouts are required annually for IX treatment. Spent media will be disposed using incineration. Costs for hauling, incineration, and environmental permitting are included.]

Note: Million Gallons per Day ("MGD"), Ion exchange ("IX"), Granular Activated Carbon ("GAC"), Reverse Osmosis ("RO")

Over the past five years, the Company's average construction expenditures were $39.9 million. The estimated cost to install ion exchange forever chemical remediation technology ("FCRT") for the Company's eight wells is estimated to be $38,391,500. This estimate indicates that the construction expenditure for the forever chemical containing wells in 2022 is approximately 96 percent of the Company's average capital costs over the past five years. Additionally, it costs around $5,909,000 to add an ion exchange facility to a 0.2 MGD or 138 gallons per minute ("GPM") well system.

In Arizona, smaller utilities are classified as Class D and E, serving populations ranging from five to 10,000 customers. These utilities typically have wells with flow rates between 50 GPM and 200 GPM (0.07-0.288 MGD). Class D utilities have operating revenues between $50,000 and $249,000, while Class E utilities have operating revenues of less than $50,000. In Arizona, Class D and E utilities comprise 228 of the approximately 266 regulated water utilities.

A 2018 study conducted by the Arizona Department of Environmental Quality ("ADEQ") tested 109 wells for PFOA and PFOS and found that 20 wells tested above the Maximum Contaminate Level ("MCL") as proposed, which is roughly 20 percent of the tested wells. The total number of Public Water Systems ("PWS") in Arizona is in excess of 1,500 systems. Assuming ADEQ's sampling represents the entire population, Arizona could potentially have over 275 systems impacted by the new standards. Given the nature of Arizona's water systems, the impact of the new rule would disproportionately impact the smaller rural communities.

EPA Response: The tables below compare the estimated costs from the commenter's table and text to results from the updated cost curves the EPA developed for the final rule. The commenter's estimated costs exceed the EPA's range. However, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for these facilities would be similar to the typical values assumed in the EPA's estimate. To fully evaluate the commenters' reported or estimated costs in comparison to WBS model results, the EPA would need itemized line-item cost details and engineering design parameters. To inform the cost estimates of the proposed and final PFAS NPDWR, the EPA conducted an extensive review of the literature. The EPA has further validated the unit costs in the PFAS rule with equipment cost information from 2023 from a major supplier of treatment media. While the EPA recognizes there are likely site-specific instances where costs exceed the EPA's cost ranges, there are also likely site-specific instances where costs are less than the EPA's cost ranges, and this level of accuracy is appropriate for a national level analysis. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Commenter's Estimated Capital Costs Compared to Results from the EPA's Updated Cost Curves

Project	Flow Rate	Type	Commenter's Capital Cost Estimate	EPA's Capital Cost Curves Lower Bound	EPA's Capital Cost Curves Upper Bound

		GAC	$ 700,000	$ 189,726	$ 206,120

In response to the comment regarding disproportionate impacts on smaller rural communities, In the EPA's Environmental Justice (EJ) analysis for the final rule, the agency examined the demographic distribution of costs across multiple water system size categories and found, as suggested by the commenter, that incremental household costs to all race/ethnicity and income groups generally decrease as system size increases, which is expected due to economies of scale. For more information on the findings of the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA, 2024b). To alleviate potential cost disparities identified by the EPA's analysis, there may be an opportunity for many communities to utilize BIL (P.L. 117-58) funding to provide financial assistance for addressing emerging contaminants. BIL funding has specific allocations for both disadvantaged and/or small communities and emerging contaminants, including PFAS, please see section 2.4 of the EPA response in this *Response to Comments* document for more information

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045994)

Treatment techniques also do not have the same efficacy for every PFAS chemical. Specifically, short chain PFAS generally break through more quickly than long chain. This provides less opportunity for adsorption unless the flow rate through the media is reduced. Treatment designs are typically contaminant specific, and while this may create opportunity for co-removal, the success is situation dependent. To remove additional PFAS compounds, modifications and additions would likely need to be made, further increasing project costs.

EPA Response: The EPA agrees that short chain PFAS generally break through more quickly than long chain PFAS. The EPA notes that the cost analysis reflects the assumption that water systems will target and treat for regulated PFAS; therefore, the estimated project costs are accurate. The EPA maintains that co-removal of some additional PFAS is likely because PFAS tend to co-occur and can be co-removed. These are important nonquantifiable co-removal benefits of this regulation, and why the rule, while protecting the public from regulated PFAS, also offers some protection from some other PFAS. See Chapter 6.2.4 of the EA for further discussion.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046032)

Attachment 2

The PFAS Challenge – May 2023

Monitoring and Planning for PFAS Treatment

Fairfax Water has been voluntarily monitoring for PFAS on a quarterly basis since 2021 and has posted its PFAS results on its website. Water treated from the Potomac River has so far tested below the proposed MCL's for PFOA and PFOS. Water from the Griffith plant slightly exceeds the proposed MCL's for PFOA and PFOS. Data from both plants is below the proposed HI.

[Table: see docket ID EPA-HQ-OW-2022-0114-1738]

The Griffith Water Treatment Plant (120 MGD) is sourced by the Occoquan Reservoir. The plant became operational in 2006, replacing three older treatment plants that were unable to meet the requirements of the D/DBP rule. Conventional treatment processes with the addition of ozone and biologically active carbon filtration were chosen for the Griffith Plant to meet D/DBP rules. An initial evaluation by engineering consultants has determined that additional treatment trains are necessary to remove PFOA and PFOS to the proposed MCL.

Construction cost estimates for GAC or Ion Exchange are initially estimated at between $180 and $250 million, with annual operating costs of between $10 and $45 million. A mid-range value of $215 million (capital) represents a 21% increase in Fairfax Water's 10-year capital improvement program. A mid-range value of $22.5 million for annual operating costs for PFAS treatment represents an increase of 20% in Fairfax Water's total annual operating budget.

[Figure: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $54 million to $136 million for a 120 million gallon/day facility using GAC or IX to treat surface water. Although the commenter's estimate of $180 to $250 million exceeds the EPA's range, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for this facility would be similar to the typical values assumed in the EPA's estimate. The

commenter's estimate for annual O&M cost lacks sufficient detail to compare to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046028)

Table 30: Annual Treatment Cost by CWS Size for Affected Systems ($M)

[Table 30: see docket ID EPA-HQ-OW-2022-0114-1738]

Table 31 below shows funding made available from the IIJA for the Emerging Contaminants Drinking Water State Revolving Fund in FY23 ($764 million) compared to the estimated annualized treatment costs for small and large CWSs [FN135: Black & Veatch, "WITAF 56 Technical Memorandum: PFAS National Cost Model Report," tbls. 6–3.]. National annualized CAPEX costs equate to 180 percent of the funding made available from the IIJA for small systems treatment and 750 percent for all systems. Even with the substantial increase in federal funding and even if the total amount was allocated to PFAS treatment, water systems and rate payers must pay six times more than the federal funding to purchase treatment systems. Rate payers are also responsible for all of the O&M costs to operate their systems. Therefore, while the federal funding provides some relief, the majority of the severe household effects still are expected to occur.

Table 31: Annual Treatment Costs as a Percentage of IIJA Funding for Emerging Contaminants in Drinking Water

[Table 31: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national capital costs required to comply with the rule; please see section 13.3 of the EPA response in this *Response to Comments* document for the EPA's response to comments concerning costs in comparison to the amount of BIL funding available. Please see section 2.4 in this *Response to Comments* document for the EPA's response to comment on federal funding available to help comply with the rule.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC6017)

1. Likely Compliance Strategies

To comply with EPA's proposed rule, drinking water systems that have PFAS detections exceeding one or more of the proposed MCLs will install limited or total system treatment technologies. Today's effective PFAS treatment systems include the following:

• Ionic exchange (IX). IX involves selective ion exchange in solution with ions bound to a resin matrix [FN101: Black & Veatch, "PFAS National Cost Model Report" (American Water Works Association, March 7, 2023), 6.]. IX resins have a limited capacity for adsorption and are

affected by contaminant concentrations and flow rates, similar to GAC. However, IX resins are highly selective toward PFAS removal, with minimal removal of other contaminants. The overall efficacy of IX for PFAS removal is specific to the water matrix, treatment goals, and system design.

• Granular activated carbon (GAC) [FN102: Black & Veatch, 3.]. GAC systems use carbon-based materials (e.g. coal) that, once activated, produce absorbent media with pores that organic compounds attach to and become absorbed onto. GAC has a finite capacity for compound adsorption and contaminants compete for adsorption sites. Disposal and reuse are considerations with this method, as reactivating GAC media contaminated with PFAS is expected to be more limited in drinking water applications.

• Reverse osmosis (RO) systems. RO is a membrane-based treatment process in which a semi-permeable barrier removes dissolved contaminants [FN103: Black & Veatch, 9.]. These treatment systems are more expensive than GAC or IX systems but are most viable when the GAC/IX replacement frequency requirements are cost-prohibitive due to high influent PFAS concentrations. Membrane elements are mounted into pressure vessels arranged in stages, banks, or arrays, the number of which depends on the specified recovery level.

Each treatment technology carries specific capital investment costs as well as operation and maintenance (O&M). Furthermore, installing treatment systems takes time. Temporarily shutting off a well while installation is completed means that a system will incur the opportunity cost associated with a decreased water supply capacity. With promulgation of EPA's final MCLs, hundreds of systems nationwide will be in non-compliance and require treatment. This sudden increase in demand will place a strain on supply chains and the labor force to meet the increased demand for equipment and labor. Water systems will bear near- term additional costs due to a scarcity in the labor force and in capital equipment.

Some systems that require treatment will also consider additional or alternative compliance strategies such as permanently shutting off a groundwater well and, subsequently, interconnecting raw water sources within the system. As with temporary well shut offs, these systems will incur opportunity costs of decreased water supplies. While shutting off wells will likely be one compliance strategy for some systems, we limit our analysis to the assumption that all systems will install treatment and, as a result, incur the following direct costs:

• Capital investment costs;

• O&M and labor costs;

• Near-term additional costs due to labor and capital equipment scarcity; and,

• Administrative costs such as reporting, permitting, and taxes.

In addition to costs with prices that can be measured in goods and services markets ("Market Costs"), EPA's rulemaking has costs that are not trade in markets ("Non-market Costs"). The analysis estimates the major market and non-market costs.

EPA Response: The commenter incorrectly suggests that immediately after the final rule is promulgated systems will be considered out of compliance., The rule provides for several years for water systems to come into compliance. All systems subject to the rule must comply with the MCLs by five years after the promulgation date, and all systems must comply with other requirements of the NPDWR, including initial monitoring, by three years after the promulgation date. Please see section 12.1 of the EPA response in this *Response to Comments* document for more information. Please see section 13.9 in this *Response to Comments* document for the EPA's response to comments regarding opportunity costs associated with the rule. With regard to the impact of demand on costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046039)

While results indicate very low levels of PFAS in our drinking water on average, the variability in testing results demonstrate vulnerability to potential non-compliance. The utility and our customers are faced with significant capital and operations cost burden. The only known methods to remove PFAS from drinking water are granular activated carbon, ion exchange, and reverse osmosis. The appropriate treatment options for WSSC Water's plants are being evaluated as part of our Water Quality and Treatment Master Plan that is currently under development where we are assessing the treatment measures to meet multiple and simultaneous compliance requirements. Initial estimates suggest that potential treatment changes are estimated to cost from $1.4 billion to $2.9 billion just for WSSC Water alone, and this does not include annual operating costs.

[Table: see docket ID EPA-HQ-OW-2022-0114-1738]

One Size Does Not Fit All

There are pros and cons to the different treatment alternatives. Without a comprehensive holistic approach to regulatory compliance based on science, the cost burden will increase exponentially for both SDWA and CWA compliance. Utilities need the time to plan, design, and implement solutions including the time to deal with existing plant constraints and the readiness for operations.

Source: Considering PFAS Treatment Alternatives with PFAS Rule in Mind, Adam Feffer, AWWA Webinar, 2023.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to simultaneous compliance comments, please see section 10.4.2 of the EPA response in this *Response to Comments* document

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046023)

Energy Consumption Data Sources

In one of EPA's background document for this rulemaking, EPA provides electricity consumption data per system size for three GAC and IX system sizes:

Table 18: Breakdown of Energy Costs in GAC and IX Systems [FN127: U.S. Environmental Protection Agency, "Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water," February 2023.]

[Table 18: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: The comment reiterates information provided in the EPA's background materials. Please see section 13.11 of the EPA response in this *Response to Comments* document.

LSP Association (LSPA) (Doc. #1742, SBC-043603)

Based on some point of entry treatment (POET) installations that have been installed in Massachusetts, we estimate that the costs associated with a POET installation are between $7100 - $8600 (that breaks down to $1,100 for the analytical data analysis +$6,000 - $7,500 for the system installation), with an annual maintenance cost of approximately $500 to $1600, not including additional analyses. With the anticipated increased demand for POET systems driven by the lowering of the MCLs, we anticipate that these costs will increase, and become a serious and perhaps insurmountable financial burden on individual homeowners.

EPA Response: The EPA did not include point-of-entry treatment costs in the EA for the proposed or final rule, as the agency did not identify point of entry (POE) treatment as a BAT or SCCT. The EPA notes that the final NPDWR does not require the use of any specific BAT and systems may choose other treatment or non-treatment approaches (e.g., connecting to new source waters) to comply with the rule. PFAS treatment option selection should consider conditions for a given utility, including water quality, available space, disposal options, local rules, and currently installed unit operations (for more information see section 10.1 of the EPA response in this *Response to Comments* document). To the extent water systems choose to use POE to comply with the final rule, the EPA assumes they will select that technology because it is cost effective for them compared to other technologies. Regarding the commenter's assertion that the final rule will increase demand for POEs and increase the costs of this technology, the EPA disagrees. As detailed in section 13.3.3 of the EPA response in this *Response to Comments* document, the EPA does not agree that the demand created by the rule will significantly increase the costs of any technology, in part because the demand created by the rule will be spread out among several compliance technologies. Further, due to practical limitations, the EPA anticipates that mostly small systems would consider implementing POEs to comply with the rule; therefore, the overall nationwide demand is likely to be small and spread out geographically.

Del-Co Water Company, Inc. (Doc. #1744, SBC-043620)

IV. Total costs to Drinking Water Plants is significantly underestimated

The EPA's estimated costs for PWSs to comply with the proposed rules range from $772 million to $1.2 billion. Based on the actual average capital expense received by Del-Co Water's preliminary engineering study (i.e., $67 million), the EPA range appears to significantly underestimate the potential costs to PWSs. The AWWA has estimated that 5,000 PWSs will have to install treatment to comply with the proposed rule and, if the average cost of $67 million is applied to all 5,000 PWSs, this is a total cost of $335 billion – an estimate which far exceeds the EPA's estimate top-range of $1.2 billion.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Furthermore, extrapolating from a single utility's experience is not an appropriate method to estimate national costs. See also section 13.3.3 of the EPA response in this *Response to Comments* document.

City of Thornton, Colorado (Doc. #1748, SBC-044785)

In addition, Thornton believes that EPA is severely underestimating supply costs. In 2022, Thornton already had difficulties in securing supplies of powdered activated carbon. Prices increased by 138% and the City could not find a supplier that could guarantee deliveries on the needed timeframe. Thornton anticipates the implementation of the PFAS rule will have a similar impact on the GAC market as demand for these products increases. Likewise, because EPA is underestimating the occurrence of PFAS compounds, their estimate of cost increases is insufficient due to exponentially increasing demand.

EPA Response: With regard to the impact of demand for GAC on costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document. Further, the EPA disagrees with the commenter's assertion that the agency underestimated the occurrence of PFAS compounds; for more information, please see section 6.5 of the EPA response in this *Response to Comments* document.

City of Thornton, Colorado (Doc. #1748, SBC-044783)

In Thornton's assessment of EPA's cost/benefit analysis, Thornton finds that the EPA has significantly underestimated the costs associated with treatment of PFAS. Thornton's preliminary engineering designs for installation of treatment systems at both of its WTPs to only meet the MCL (and not the MCLG) are estimated to cost approximately $125 million dollars and will necessitate an increase of $5-8 million in annual operations and maintenance costs (doubling our current O&M budget). This translates to a rate increase between 14 - 19% for our customers over the next decade, disproportionally impacting our disadvantaged residents. Thornton represents just one utility serving less than 0.04% of the national population but is 15% of the EPA's estimated cost.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comment on impacts across demographic and

income groups, please see section 14.10 of the EPA response in this *Response to Comments* document. The EPA further notes that the commenter's comparison of a single utility's capital cost estimate to the EPA's national cost estimate is not appropriate, as the EPA's estimates at proposal represent an annualized value of costs over the period of analysis (82 years).

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043920)

In response to Section XIII. Health Risk Reduction and Cost Analysis, EPA requests comment on the cost of treatment when additional co-occurring but not targeted PFAS chemicals are found in source water.

• Treatment of additional co-occurring chemicals could cause media to be spent more quickly and increase costs to the PWS. This potential increase in cost should be included in the WBS cost model.

EPA Response: The EPA acknowledges co-occurring contaminants could potentially result in more frequent media replacement for some systems. However, based on the EPA's review of the best available peer reviewed information on GAC performance, the agency did not find total PFAS concentration to be statistically significant, likely because competition among PFAS was overwhelmed by competition/fouling from TOC (which typically occurs in the milligrams per liter range compared to the nanograms per liter range for PFAS). Furthermore, for IX, the bed life equations incorporate total PFAS concentration along with percent removal of target contaminants and thus explicitly account for competition. Therefore, the EPA does not anticipate the presence of non-regulated PFAS will significantly increase treatment costs beyond the agency's national estimate for the final rule. Please see section 10.3 of the EPA response in this *Response to Comments* document for further discussion about co-removal of non-targeted compounds.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043918)

In response to Section XIII. Health Risk Reduction and Cost Analysis, EPA is requesting comment on the WBS models, including the range of component levels assumed in the input to the models, and the range of cost estimates for GAC, IX, and centralized RO.

• LCU agrees with the method for generating cost equation based on component levels assumed (low, medium, and high). However, LCU is unable to comment on the range of component levels as they are not defined in the documentation provided. LCU would like to comment on the range of cost estimates for GAC, IX, and centralized RO. However, the information/documentation provided does not include any information on the range of cost estimates for GAC, IX, and centralized RO. Utilization of centralized RO would require additional water rights to offset the brine water that will be generated as part of the process. RO brine discharge water will take away from the limited amount of water rights and available water here in the desert southwest.

EPA Response: The commenter's concurrence with the method for generating cost equations supports the final rule. The information the commenter describes as "not defined," was available in the docket for public comment. Specifically, Appendix C of the EA includes PWS level cost ranges, the *Technologies and Costs* document (USEPA, 2024d) details the cost ranges by technology, and the WBS models documentation was included in the docket and the models are available on the EPA's website at https://www.epa.gov/sdwa/drinking-water-treatment-technology-unit-cost-models. The EPA notes that in response to public comments about residual management concerns for high pressure membrane technologies, the EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the EA for the final rule. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045612)

EPA's WBS Model

According to the proposal, EPA considered three treatment options that may be used by as many as 4,300 water systems to reduce PFAS levels to below the MCLs. These treatment options included GAC, IX, and RO filtration facilities. Additionally, EPA considered other options to address PFAS levels in drinking water, such as interconnections, new wells, and point-of-use RO systems. To estimate the costs to install and operate these systems, EPA relied on their Work Breakdown Structure (WBS) for these strategies, which were developed more than two decades ago and were updated as part of the proposal.

As highlighted by the EPA's "Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water" document, there are full-scale facilities that are currently using these treatment technologies for PFAS removal. To support EPA's cost analysis, AWWA contracted with Black & Veatch to prepare a cost model (the BV Model) for PFAS treatment using GAC, IX, or RO using their national drinking water treatment expertise and with support from water systems and experts from across the sector (See full report in Appendix B). AWWA has also worked with water systems to compile information on the costs to install PFAS treatment systems.

The BV Model and the case studies were used to compare with the model outputs from the EPA's WBS Model for GAC and IX to better understand the accuracy of the EPA's WBS unit cost models. Figure 7-1 shows an example of a comparison of the available case study data to the BV and EPA cost models, specifically showing capital costs associated with installing GAC treatment facilities for PFAS treatment for systems up to 2.5 MGD.

[Figure 7-1: See Docket ID EPA-HQ-OW-2022-0114-1759]

Figure 7-1: Capital Expenses for PFAS Treatment Facilities using GAC Compared to EPA and BV Models

This range was selected as it represents more than 75% of the systems that would be impacted by the proposed rule. Appendix C provides supplemental figures showing a similar comparison for

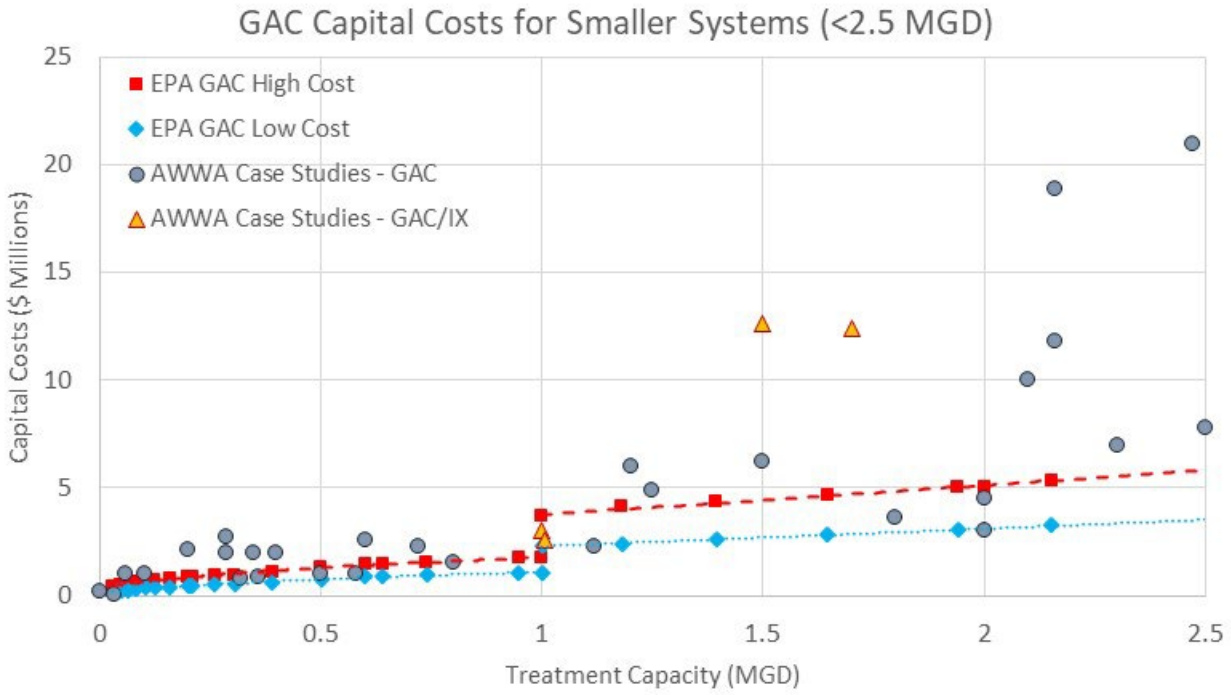
additional ranges of treatment capacity, types of treatment, and operating costs. This data was developed through the use of available data from the Black & Veatch cost model, the example model outputs provided by EPA in the supporting documentation, and more than 100 case studies that were collected earlier this year. For a full list of treatment case studies, refer to Appendix D.

As shown in this figure, the EPA's WBS model significantly underestimates the costs associated with PFAS treatment using a GAC treatment facility. Data from the case studies in this range shows that the typical PFAS treatment system costs 330% more than the estimated cost by the EPA's WBS Model (based on 2021$). The extent of the EPA's WBS Model's underestimation of cost is similarly demonstrated by the BV Model, which shows cost figures in 2022 dollars. These patterns are similarly observed when looking at larger treatment facilities, operating costs, and other treatment technologies. Refer to Appendix B and C for more information.

EPA Response: The EPA disagrees that the EPA's WBS model significantly underestimates the costs associated with PFAS treatment using a GAC treatment facility. The commenter's Figure 7-1 and the supplemental figures in Appendix C misrepresent the EPA's cost curves because they include only the example outputs from Appendix B of the EPA's *Technologies and Costs* document (USEPA, 2024d). The commenter's figures do not consider the full range of cost curves used to estimate national costs and presented in Appendix B of the *Technologies and Costs* document (USEPA, 2024d). Based on comments provided by this and other commenters, for the final rule, the EPA also updated its equipment costs to 2022 dollars (which are the most recent data available), collected new vendor price quotes for cost driver equipment components, and made several other adjustments to WBS model assumptions, as detailed in section 13.3.3 of the EPA response in this *Response to Comments* document.

To demonstrate that that commenter's figures do not accurately portray WBS output used in the cost estimates for this action, the figure below partially recreates the commenter's Figures 7-1 and A-13, comparing the commenter's case study costs to the EPA's updated cost curves. Some of the commenter's case studies fall within the range of costs bounded by the EPA's updated cost curves. While other case studies exceed the EPA's high-cost curve, the case study information provided lacks sufficient information for a detailed comparison to the EPA's WBS model. In addition, a portion of the case studies are anonymous, while many other case studies cite "AWWA, 2023b" which is simply a reference back to the comment letter, so the EPA cannot validate this information or decipher it in greater detail. The report provides no information about any of the systems, other than technology, flow, and cost, and does not clearly identify which cost figures are estimates and which are as-built costs. Furthermore, the commenter did not include information to confirm that (1) all the case study costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for the case study facilities would be similar to the typical values

assumed in the EPA's estimate.



Additionally, the commenter included several case studies labeled "GAC/IX" in the figures presenting GAC costs. The GAC/IX case studies include two of the highest cost examples. These examples may not accurately represent typical facilities using GAC alone. Finally, although the EPA's recreated figure does not show the data points or trendline associated with the B&V model, the EPA notes that this model overestimates costs for most of the commenter's case studies. For example, it results in higher capital costs for 28 of the 32 small GAC case studies shown in the commenter's Figure 7-1 (28 of 34 small GAC case studies reported in the commenter's Appendix D and shown in the EPA's recreated figure above).

The additional figures below recreate the commenter's Figures A-14 through A-24 using the EPA's updated cost curves. The EPA's conclusions regarding these figures are similar to those above. A number of the commenter's case studies fall within the range of the EPA's updated cost curves. The EPA notes that the majority of AWWA B&V report's case study information on O&M costs fall within or below the EPA's range. In general, while some case studies exceed the EPA's high-cost curve, others fall below the EPA's low-cost curve. Although the recreated figures do not show results from the B&V model, that model overestimates costs for many of the case studies, as discussed in section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-053001)

AWWA also compared the capital cost estimates for GAC under the proposed PFAS rule with the agency's estimates for the Stage 2 Disinfectants and Disinfection Byproducts Rule (EPA, 2005). Under the Stage 2 rule, EPA also estimated costs for systems installing GAC with a 20-minute empty bed contact time. The results of this comparison, Figure 7-1, show an alarming issue: EPA's cost estimate for PFAS removal in 2021 dollars is nearly the same as TOC removal in 2003 dollars. As a point of comparison, the Engineering News Record building cost index has increased from 6,654 in 2003 to 13,288 in 2023 representing a nearly double increase in construction costs alone, which do not include the additional cost increases water systems have been faced with (ENR, 2023).

[Figure 7-2: See Docket ID EPA-HQ-OW-2022-0114-1759]

Figure 7-2: Comparison of GAC Capital Costs for GAC for Stage 2 D/DBP and Proposed PFAS Rule

EPA Response: The commenter's Figure 7-2 misrepresents the EPA's cost curves because it includes only the example outputs from Appendix B of the EPA's *Technologies and Costs* document (USEPA, 2024d) and not the full range of cost curves used to estimate national costs and presented in Appendix B of the document. Furthermore, the EPA has considered all input from this and other commenters on the EPA's cost analysis and made a number of changes to the cost estimates, as detailed in section 13.3.3 of the EPA response in this *Response to Comments* document. Taken together, these adjustments increased the system level capital cost estimates in the EPA's cost assessment by a percentage that varied depending on the system size and treatment technology. For small systems using GAC and IX, the increase ranged from approximately 40 percent to 110 percent. For medium systems, the increase was approximately 20 to 60 percent; for large systems, 10 to 40 percent. Therefore, the EPA's capital costs for the final PFAS rule exceed the capital cost figures from Stage 2, as expected, in nearly every case. In addition, for large systems, the capital costs for Stage 2 included the installation of on-site reactivation facilities. This inclusion results in substantially higher capital costs in comparison to systems that use off-site reactivation. Under current economic conditions, off-site reactivation is likely to be more cost effective, so the EPA assumed systems installing treatment for PFAS would use this approach. Finally, for GAC, the Stage 2 rule relied on outputs from the Very Small Systems, Water, and W/W Cost models. These models were developed from the late 1970's through the early 1990's and had certain inherent limitations. Khera et al. (2013) summarized the models' limitations as follows: "These models lacked the flexibility to adapt to changes in technology, development of new construction materials, availability of new treatment media, automation, changes in manufacturing processes, and market competition. They were also difficult to update to reflect price changes and could not be adjusted for different combinations of treatment technologies and contaminants. Underlying assumptions in these models were not always readily apparent or easily modified, and outputs were often limited to a few lump-sum totals." It is because of these limitations that the EPA developed the WBS models, which are more robust and transparent than the older models. The level of component detail (and by

implication, design detail) in the WBS-based approach is more sophisticated, than the factored or parametric cost estimating methods used in the EPA's earlier efforts.

American Water Works Association (AWWA) (Doc. #1759, SBC-053002)

AWWA requested an extension of the public comment period to accommodate a more detailed analysis of the EPA's updated WBS. Given that the agency did not extend the comment period, an exhaustive review of the WBS could not be provided within the 60-day period for review and comment. However, in review of the data from Figure 7-1, Figure 7-2, and the supplemental figures, there is no question that the WBS struggles to accurately capture costs of new treatment facilities. There are some aspects of the WBS that are anticipated to cause a significant underestimation of the true costs of installing PFAS treatment systems. These are further described in the following sections. Given the central role that costs play in EPA's determination, and in order to provide an opportunity for meaningful public comment on the costs associated with this proposal, EPA should work with AWWA and other drinking water treatment experts to revise the cost analysis and provide for an additional comment period on the updated analysis.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document for why the EPA included a sixty-day public comment period instead of the statutory minimum of 30 days. In regard to the accuracy of the WBS model, please see section 13.3.3 of the EPA response in this *Response to Comments* document. Further, the EPA received extensive comments on the proposal's cost analysis, which the agency fully considered in revising the cost estimates for the final rule and in decision making on the final rule; as a result, additional comment on the cost analysis is unnecessary. For further discussion, see section 13.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-053003)

General Comments on EPA's WBS Model

Model Accuracy & Contingency

To estimate the costs associated with different treatment strategies, EPA's WBS model uses inputs to prepare a cost estimation for an individual water system. While the model is detailed with respect to potential costs that are considered, there are limitations of this approach, which may require the application of correction factors (similar to the toxicological uncertainty factors).

For each system, EPA estimates the service population using data available through the Safe Drinking Water Information System. The service population provides a reasonable estimate of the general water supply design requirements, which with some broad assumptions (e.g., daily per capita water use, peaking factor, etc) can inform an estimate of the overall water supply capacity needed for each entry point to the distribution system. Then, EPA relies on probabilistic

distributions of PFAS and TOC to determine specific unit operation costs for each system in a Monte Carlo Simulation.

Ultimately, the WBS model relies on three key system characteristics to drive the cost estimate: (i) water treatment flow capacity, (ii) PFAS levels, and (iii) TOC levels. This information is used by EPA to estimate the implementation costs for each water system, which is intended to cover planning, design, testing, perming, and construction of the system. While it is not uncommon for budgetary estimates to be prepared using a limited set of data, it is extremely rare for budgetary estimates of these systems to not recognize that the design is not exhaustive. Good engineering practice is to include an adequate contingency and to transparently describe the level of conservatism in the estimate based on uncertainty in the information available to prepare the cost estimate.

The American Association of Cost Engineering describes five classes of cost estimates that are distinguished by maturity level of project definition, end usage, methodology, and the expected accuracy range. A Class 1 estimate represents a level of project definition exceeding 50% where a detailed unit cost and detailed take-off have been used to estimate the costs and the cost could be as much as 15% higher. Alternatively, a Class 5 estimate represents a level of project definition of less than 2% where concepts are being screened and the use of parametric models were used and so the costs could be as much as 100% higher. In consideration of the data that are available for EPA to consider in estimating costs and given that site-specific conditions cannot be factored into the estimate, the EPA WBS Model is likely to be considered a Class 4 or Class 5 estimate where costs could be 50% or 100% higher.

EPA provides various example model outputs of their cost estimate for different systems, including the estimate of contingency. Table 7-1 provides an overview of the contingency for each of these estimates. As shown in the table, the vast majority of the model outputs show cost estimates for systems with 0% contingency included. This is for 100% of the systems with a treatment capacity below 5.809 MGD, which is pertinent to more than 75% of the water systems that EPA anticipates will be impacted by this rule. For the remaining example outputs, a very low level of contingency is included. This is inconsistent with recommended best practices for cost estimators and is expected to be a major contributor to the EPA WBS' failure to accurately capture costs for PFAS treatment facility implementation.

Table 7-1: Assumed Contingency in EPA WBS Model Example Outputs

[Table 7-1: See Docket ID EPA-HQ-OW-2022-0114-1759]

Therefore, the minimal level of contingency, or lack thereof, in the WBS cost estimates wildly overestimates the WBS' ability to capture system-specific water quality, site conditions, community needs, and the overall cost factors for the new treatment facility. The EPA should adjust this approach and ensure that the appropriate levels of contingency are included to ensure that cost estimates are consistent with the level of project definition afforded by the available data in keeping with sound engineering practice.

EPA Response: The EPA disagrees with commenter that the American Association of Cost Engineering (AACE) cost estimate classification system is an appropriate approach to use for national level drinking water regulatory cost estimates. The AACE cost estimate classification system is applicable to estimates used in screening, planning, and budgeting for specific projects. It is not specifically designed to guide economic analysis involving national level cost estimates. Additionally, the WBS models are not factored or parametric models of the type referenced in AACE Class 4 and 5. They estimate costs using a detailed engineering build-up from the line-item costs of individual treatment system components. Furthermore, for purposes of national cost estimating, it is appropriate to reflect actual realized contingency costs at project completion, as opposed to contingencies incorporated in planning and budgeting. A Construction Industry Institute (2001) study found that projects of $100 million or less incurred only 74 percent or less of the contingency initially budgeted. Nevertheless, in response to public comments, the EPA updated the contingency factors incorporated in the WBS models as discussed in section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-053004)

Accurately Reflecting Current Economic Conditions

Another limitation of the EPA's WBS Model is that it reflects outdated 2021 construction costs. Additionally, the model relies on a variety of cost indices to scale the costs from a previous year to the relevant year of the analysis. It is reasonable to scale data from one year to another year using indices, but EPA fails to account for the fact that there is always a lag in the data for the most recent periods of time. The agency must recognize that the past two years, from 2021, have shown significant cost increases relevant to drinking water treatment systems.

These increases in costs have stemmed from the COVID-19 pandemic, high inflation, and increasing interest rates for borrowing. Construction costs, for example, have increased steadily by more than 15% to 30% in the past 2 years according to several different sources (Mortenson, 2023; Turner Construction, 2023; USBR, 2023). By comparison, construction costs during 2020 only increased by less than 1.5%. A similar trend can be observed in analysis of inflation since 2021, which has averaged 5.81% annually. The federal funds rate has also increased from 0.08% to 5.25%, which will also drive up the costs for water systems to secure financing for new projects. EPA's analysis must reflect these increases to properly account for the costs of implementation.

In addition to the increase in costs driven by economic conditions since 2021, it is also important to note that the proposal itself will further increase the costs; 67,000 systems conducting monitoring and upwards of 4,300 water systems installing treatment facility will increase demand for laboratories, engineering consultants, planners, contractors performing site investigation and construction work, and skilled treatment operators.

In order to comply with its statutory obligations, including under the SDWA [FN25: 42 U.S.C. 300g-1(b)(B)(4)(D).], EPA should ensure that the cost analysis of any rule is accurately

reflecting costs due to economic conditions and anticipated increases in demand that will drive the planning and construction costs of new facilities significantly higher than the current estimates.

EPA Response: As explained in this section and the preamble, the cost analysis for the final rule is consistent with the EPA's obligations under SDWA 1412(b)(3)(C) to consider quantifiable and nonquantifiable costs as part of its HHRCA analysis and to determine "feasibility" for purposes of setting the MCLs in this rule. The EPA updated its equipment costs to 2022 dollars (which are the most recent data available), collected new vendor price quotes for cost driver equipment components, and made several other adjustments to WBS model assumptions. Taken together, these adjustments increased the system level capital cost estimates in the EPA's cost assessment by percentages that were generally greater than those reported by the commenter. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for further details. With regard to the impact of demand on costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-053005)

Recognizing the Importance of Ancillary Systems

Another potential limitation of the EPA's WBS Model is that it only considers capital upgrades for PFAS removal from water. This is a significant analytical gap because many systems will likely need to make improvements to other areas of the treatment facility to support the PFAS treatment process. For example, some systems installing GAC treatment may determine that the concentration and form of manganese will cause problems in the vessel, requiring pre-treatment. A variety of other water quality characteristics may impact the need for pre-treatment and site-specific conditions may drive the need for significant upgrades to critical treatment support systems (e.g., pump stations, chemical feed systems, etc.). It is not uncommon for upgrades for PFAS treatment to require these types of improvements, none of which EPA's WBS Model takes into account.

EPA Response: Regarding the cost of pretreatment, the EPA included the cost of cartridge filters for control of influent solids in its cost estimates for ion exchange. The EPA does not have quantitative data on the frequency with which systems might require pretreatment specifically for iron and manganese, but information from one treatment vendor suggests the need for this type of pretreatment might be limited. Please see section 10.1 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-053006)

Lifespan of Treatment Equipment

The proposal provides inconstant information related to the total number of years that are used for the annualization of costs. In the Economic Analysis, EPA notes that both costs and benefits

are annualized over 82 years. Alternatively, the example outputs for each treatment system in the Technologies and Costs document lists useful life for each piece of equipment that is included in the capital costs. In the same document a system-specific useful life is listed as part of the cost equations. The supporting documentation from the EPA does not provide a clear explanation of how costs are annualized. Additionally, the useful life varies for equipment from as low as 7 years to as long as 35 years; it is unclear from the supporting documentation the methodology EPA used to substantiate these assumptions. This approach is not consistent with previous practice; the agency's approach to annualizing costs under the Arsenic Rule was based on a 20-year useful life for equipment (EPA, 20XX). In order to fulfill its obligations under the APA, AWWA recommends that EPA provide this information during a supplemental comment period prior to finalizing any PFAS rule. Failing to do so or failing to acknowledge this change in the assumption for treatment facility lifespan and providing a reasoned explanation for the change, would violate the APA.

EPA Response: The treatment system useful life reported with the cost equations and used to annualize total capital costs is calculated from the useful life of the individual equipment components. The calculation uses a reciprocal weighted average approach, which is based on the relationship between a component's cost I, its useful life (L) and its annual depreciation rate (A) under a straight-line depreciation method. The formula below shows the reciprocal weighted average calculation:

$$\text{Average Useful Life} = \frac{\sum_{n=1}^{N} C_n}{\sum_{n=1}^{N} A_n} = \frac{C}{A}$$

where: C_n denotes the cost of component n, n=1 to N; C denotes total cost of all N components; A_n denotes the annual depreciation for component n, which equals C_n/L_n; and A denotes total annual depreciation for the N components.

When calculating the present value of costs over the 82-year period of analysis, the EPA uses the useful life of the technology to determine when the capital components will need to be replaced. So, for example, if a PWS installs a technology in year 7 of the analysis that has an average useful life of 18 years, and costs $1M, the PWS accrues capital costs of $1M in each of the following years: 7, 25, 43, 61, and 79. It also accrues O&M costs every year of the analysis beginning in year 7.

The EPA notes that the concept that individual components of treatment technologies have different useful lives is well-known and accepted and a commonly applied concept in drinking water engineering (USEPA, 2003). Therefore, the EPA disagrees with the commenter that the agency should maintain previous approaches (e.g. the Arsenic Rule's uniform assumption of 20 years) and make a blanket assumption about useful life when information and modeling capabilities exist to support more accurate approaches to capture the known variation in useful life among components. As discussed in the EPA response to comment Doc. #1759, SBC-045612

in this section and section 13.3.3 of the EPA response in this *Response to Comments* document, as the science has matured, the EPA has further developed and refined cost models since proposal of rules 20 or more years ago. EPA notes that during the peer review of the WBS models, EPA asked peer reviewers for their input on the specific useful lives assigned to individual items of equipment (for more information see SAIC, 2006a; SAIC, 2006b; SAIC, 2006c; USEPA, 2007b; USEPA, 2012). The EPA provided information on the calculation of total annualized cost in Section 2.4.6 *Total Annualized Costs* in each of the technology specific WBS documents, available in the docket[8] and on the EPA's website at https://www.epa.gov/sdwa/drinking-water-treatment-technology-unit-cost-models. See also Chapter 2.2.3 *Annualization* of the EA, where the EPA provides the equation used to annualize future costs and benefits. EPA strongly disagrees that there is a need to hold a supplemental comment period on this straightforward component of the analysis, for which the EPA included complete documentation on in the proposal (as noted above see Chapter 2 of the EA and the WBS documents for each technology and non-treatment options). The EPA further notes that this is not a novel application; this exact functionality was included in the EAs for the proposed and final LCRR.

American Water Works Association (AWWA) (Doc. #1759, SBC-046166)

5.5 Life-Cycle Costs

The model determines 20-year life-cycle costs, which combines the capital costs and annual operating and maintenance costs. Life-cycle costs provide a means of comparing the costs of alternative technologies over the life cycle of the equipment. The life-cycle costs in the body of this report were calculated assuming a 20-year lifespan and a discount rate of 3 percent. A comparison of annualized NPDWR costs by system size at 3 and 7 percent is included in Table A-5 of Appendix A . While typical practice to determine life-cycle costs may incorporate other factors, such as the inflation and loan interest, the discount rate was used to match the approach that is standard practice for the EPA in promulgating national primary drinking water regulations.

6.0 National Cost Assessment Methodology

The conceptual framework for assessing the national costs is as follows:

• Assess capital, annual O&M, and life-cycle costs for each EPTDS in every water system for which potential regulatory limits for PFAS may require treatment.

• Average the costs by system size category and system type (ground or surface water).

• Multiply those average costs by the total anticipated number of systems of each type impacted in each system size category based on the percentage of systems in the database impacted by a proposed regulatory limit for PFAS.

[8] See documents: EPA-HQ-OW-2022-0114-0041, EPA-HQ-OW-2022-0114-0039, EPA-HQ-OW-2022-0114-0042, and EPA-HQ-OW-2022-0114-0040 in docket No. EPA-HQ-OW-2022-0114.

The following subsections summarize the process and details associated with the national cost estimation methodology.

6.1 Estimating National Costs Using Model Outputs

Due to the difference in number of EPTDS for groundwater and surface water systems, the national cost calculations were completed separately for groundwater and surface water systems. The following methodology was utilized for each source water classification:

1. Using the treatment facility costs for systems from the occurrence database, the costs were binned by system size, and average EPTDS costs per system size bin were calculated.

2. Using the occurrence database, the number of impacted systems per size category was calculated, and the corresponding percent of the systems in the database was determined.

3. To estimate the number of impacted systems nationally, the percentage of impacted systems in the occurrence database was multiplied by the total number of systems in SDWIS for each size category.

4. The estimated number of impacted systems per size category multiplied by the average cost per EPTDS and the assumed number of entry points yields the total cost per size category. The sum of all costs per size category yields the estimated national cost of removing PFAS to a potential regulatory limit.

A summary output is included in Table 6-1, which displays the costs associated with a achieving a maximum contaminant level (MCL) in drinking water of 4 ppt for PFOA and 4 ppt for PFOS for groundwater systems only.

Table 6-1 Example Summary Capital Cost Table for an MCL of 4 ppt for PFOA and PFOS (Groundwater Systems Only)

[Table 6-1: Docket ID: EPA-HQ-OW-2022-0114-1759]

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and therefore with the costs presented in the commenter's Table 6-1. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For explanation why a fixed 20 year lifecycle estimate is a simplification compared to the EPA's peer-reviewed WBS models, and why the EPA believes this is a less precise tool than the EPA's WBS models, please see the EPA response to comment Doc. #1759, SBC-045612 in section 13.3.3 in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046155)

3.2.2 Assumptions for Cost Estimation

The costs for IX Contactors depend on the contactor type, size, number, and ancillary processes such as backwash pumps/recovery basins and contactor influent pumps/wetwells. The primary process design assumptions for each of these factors are summarized in Table 3-2.

Table 3-2 IX Design Process Assumptions

[Table 3-2: Docket ID: EPA-HQ-OW-2022-0114-1759]

EPA Response: The EPA disagrees with several of the assumptions presented in the commenter's Table 3-2. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046158)

3.3.2 Assumptions for Cost Estimation

The costs for RO systems depend on the number of trains, permeate flow, and ancillary processes such as the RO feed tank, low-pressure feed pump, high-pressure feed pump, chemical pretreatment, chemical post-treatment, flush pump/tank, clean-in-place (CIP) system, decarbonation system, building requirements, and brine disposal. The primary process design assumptions for each of these factors are summarized in Table 3-3.

Table 3-3 RO Design Process Assumptions

[Table 3-3: Docket ID: EPA-HQ-OW-2022-0114-1759]

EPA Response: The EPA disagrees with several of the assumptions presented in the commenter's Table 3-3. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045639)

The cost analysis for drinking water treatment is demonstrably underestimating the impacts of the rule based on case study data and a model by Black & Veatch, which was crafted leveraging long-standing national PFAS treatment design expertise.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046082)

b) Did EPA consider the costs and timing of the analysis that needs to occur to decide if and what kind of treatment may be necessary? Table 35 of the Proposal estimates a range of 3 hours to 42 hours to "notify, consult, and submit a permit request for treatment installation." This does not appear to include – or if it does, it grossly underestimates – the costs of evaluating potential

treatment options, designing and pilot testing a treatment system, etc. Some systems will be starting with no baseline information whatsoever. Many of these have not had to sample for PFAS before.

EPA Response: The EPA included pilot testing costs in the treatment capital cost estimates for the proposed rule and further updated these costs for the final rule. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046079)

E. Concerns and questions regarding EPA's analysis of treatment technologies and costs need to be considered and addressed.

The Coalition has reviewed the information in the Proposal and, as time has allowed, in the supporting document "Technologies and Costs for Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water" (February 2023), Dkt. No. EPQ-HQ-OW-2022-0114-0038. We have a number of questions and comments on EPA's analysis of treatment options and costs, which are set forth below.

a) Can EPA provide more basis for its estimates of the range of bed volumes included in its analysis of GAC and IX? EPA presents very large ranges but no details about the information on which the estimates are based. Based on our members' experience, the numbers appear high, which would equate to unduly low operational expenses of GAC systems. In particular, EPA has likely underestimated the quantity of spent GAC that will require treatment. In the Proposal, EPA identified proposed Bed Volumes for GAC that exceed the values that AWWA identified in their analysis. The generation rate of spent carbon is a function of bed volume and replacement frequency. EPA's cost estimate basis for bed volume was a range of 5,000 to 150,000 for GAC. 88 FR 18695. AWWA's analysis limited the carbon life to a maximum of 40,000 bed volumes for GAC. Bed volumes directly impact operating costs of these systems; EPA's assumptions of longer bed volumes would result in incurring lower costs due to less frequent media exchange and disposal.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For each entry point installing treatment, the EPA estimated bed life within the range using equations that incorporate percent removal required for each target contaminant along with influent TOC concentration (for GAC) or total PFAS concentration (for IX). The EPA's *Technologies and Costs* document (USEPA, 2024d) describes these equations and the data sources on which they are based in detail. The EPA used the ranges cited by the commenter to bound the results of the equations. Based on this and other comments, for the final rule, the EPA decreased the upper bounds of these ranges to 75,000 bed volumes for GAC and 260,000 bed volumes for IX. The EPA selected these maximum bed volumes to avoid intervals between replacement of greater than approximately five years. This upper bound ensures that media will be replaced within a reasonable service life even if its capacity has not been exhausted. Whether the EPA's assumptions result in a bed life that is longer or shorter than AWWA's will depend on

the water quality characteristics of a given entry point. However, AWWA's approach is likely to underestimate GAC bed life for entry points with low TOC because it does not scale with TOC and is based on data from a single pilot study with relatively high TOC.

PFAS Regulatory Coalition (Doc. #1761, SBC-053405)

b) The recovery rates for RO appear higher than what our members' experience suggests. We believe that EPA has underestimated the reject quantities that would be expected with the proposed pretreatment units identified by EPA. EPA should assume rejection rates of 25-30% when developing disposal costs for RO units.

EPA Response: The scientific literature reviewed in the EPA's *Technologies and Costs* document (USEPA, 2024d) reports recovery rates ranging from 78 to 92 percent for the low-pressure (or "loose") RO membranes and high-pressure (or "tight") nanofiltration (NF) membranes found to be effective for PFAS. These recovery rates convert to rejection rates of 8 to 22 percent. The commenter's members' experience may involve higher pressure RO membranes used for desalination or industrial purposes, which have higher rejection rates. The EPA notes that in response to public comments about residual management concerns for high pressure membrane technologies, the EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the EA for the final rule, as discussed in section 13.3.3 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-053406)

c) EPA should consider remineralization costs. Remineralization is sometimes needed for RO or IX treated water before it can be used again. EPA identified two full-scale applications of RO to treat PFAS in drinking water systems. The industrial facilities that the Coalition represents have experience using Reverse Osmosis units in their facilities (non-PFAS specific applications). From this experience, EPA did not adequately address costs associated with the need for remineralization of RO permeate to make it non-corrosive to downstream piping and to make it suitable for consumption as a drinking water. Technologies and Cost for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water, Fed. 2023, Dkt. No. EPQ-HQ-OW-2022-0114-0038.

EPA Response: While the EPA acknowledges the commenter's input regarding remineralization, the agency notes this input is moot for purposes of the cost analysis. In response to public comments about residual management concerns for high pressure membrane technologies, the EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the EA for the final rule, as discussed in section 13.3.3 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-053407)

d) Does EPA have any more data large surface water treatment plants regarding treatment technologies and costs? It appears there are limited data points and case studies on which to evaluate available technologies or to form a representative cost curve.

EPA Response: The commenter is incorrect; the EPA did not develop its cost curves by extrapolating from case studies. The EPA used results from the WBS models, which estimate cost using a detailed engineering build-up from the line-item costs of individual treatment system components. Similarly, the EPA's evaluation of Best Available Technologies considered the complete body of scientific literature and was not based solely on case studies. See also section 13.3.3 of the EPA response in this *Response to Comments* document and Chapter 5 of the EA for more information on the EPA's cost analysis.

Riverside Public Utilities, Riverside, CA (Doc. #1762, SBC-044227)

The following comments are submitted for consideration in the proposed EPA rulemaking:

Increase cost of treatment compared to EPA's Cost Model

The City hired a consulting engineer to determine an optimized long-term approach to treat PFAS in its drinking water supply. The study identified multiple alternatives that range from $24M to $85M in capital costs for new treatment plants and other modifications and between $108M and $238M for operation and maintenance over their expected 20-year life cycle, depending on treatment capacity. These costs are substantially higher than the EPA's economic analysis of both the capital costs and the operation and maintenance cost estimates as shown on the March 29, 2023, EPA's presentation slides (31 and 32).

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The presentation slides the commenter referenced were two examples of the many cost curves developed by the EPA to illustrate WBS model output and represented mid-level costs for surface water systems using GAC.

Southwest Regional Water District (Doc. #1772, SBC-044726)

May 30, 2023

Michael S. Regan Administrator

Environmental Protection Agency 1200 Pennsylvania Avenue, N.W. Washington, DC 20460

RE: Proposed National Primary Drinking Water Regulations (NPDWR) for the Following Per- and Polyfluoroalkyl Substances (PFAS): [POFA, PFOS, PFNA, HFPO-DA (GenX), PFHxS, and PFBS]

Public Docket ID: EPA-HQ-OW-2022-0114-0027

To United States Environmental Protection Agency,

Southwest Regional Water District appreciates the opportunity to provide comments to the USEPA regarding the proposed drinking water rules on PFAS contaminants. Public participation is vital to making the rulemaking process successful.

Southwest Regional Water District is a political subdivision of the state of Ohio organized under Chapter 6119 of the Ohio Revised Code. The District serves safe drinking water to approximately 15,200 customer connections within its service area, which primarily includes western Butler County, Ohio, but also includes parts of Hamilton, Preble and Warren Counties. The District's water system includes more than 650 miles of water mains, two water production plants and twenty-five water storage facilities all maintained by a staff of less than 40 employees.

The District is aware of the importance of monitoring for potentially harmful contaminants in public drinking water systems, including PFAS substances. In anticipation of regulatory changes, an estimate was acquired to better understand what the cost to the District and it's customers would be to retrofit one of our treatment facilities. The upgrades would be for a Granular Activated Carbon (GAC) facility. The estimated cost was $9 million for construction and $540,000 annually for operations and maintenance. This project would be for one treatment plant, in one PWS, in one state in the county.

The USEPA has projected that for all public water systems (PWS) in the United States it would be about $772 million annually. The District suspects that other PWSs throughout the country are receiving similar cost estimates and those totals would at least triple the estimate from USEPA. These proposed drinking water standards are just one of the many current and upcoming regulatory rules where compliance is required or will be required for PWSs. The current funding available for all these treatment and operational changes will only go so far. Especially as more utilities become aware of contaminants in their systems through additional sampling from UCMR5. We urge the USEPA to thoroughly review the estimated costs and what funding will be made available to PWSs as we tackle the removal of PFAS substances.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA notes that the agency's total national cost estimates are annualized over the period of analysis (82 years). Please see section 13.3 of the EPA response in this *Response to Comments* document and section XII of the FRN for the EPA's updated cost estimates for the final rule. Regarding funding availability, please see section 2.4 of the EPA response in this *Response to Comments* document.

Uttara Jhaveri (Doc. #1778, SBC-045446)

COST OF IMPLEMENTING THE TECHNOLOGICAL CHANGES

Water systems with PFAS levels that exceed the proposed MCLs would need to take action to provide drinking water which meets the NPDWR by the compliance dates established in the rule when final. [FN18: Environmental Protection Agency, supra note 4.] The Safe Drinking Water Act states that the technology proposed by the regulations should be "technologically and economically feasible." [FN19: THE SAFE DRINKING WATER ACT, 42 U.S.C. (1974),w.govinfo.gov/content/pkg/CPRT-106SPRT67528/pdf/CPRT-106SPRT67528.pdf.] Since conventional treatment technologies are unable to remove PFOS, PFOA, PFNA, PFHxS, PFBS, or HFPO–DA from drinking water to meet levels protective of public health (McCleaf et al., 2017), the public water utilities would have to adopt and install other available technologies effectively to remove the abovementioned PFAS and other PFAS. [FN20: Environmental Protection Agency, supra note 4.]

The proposed standards are to be enforced via the BATs technology, and the agency proposed the GAC, AIX, and High-Pressure membranes (RO and NF) technology. [FN21: Id.] The GAC and AIX system has been proposed as the most efficient technology to remove PFAS. EPA also suggests other options, such as source remediation or connecting to an uncontaminated water system. [FN22: Id.] However, installing the required technology to achieve the proposed MCLs will be time-consuming and costly.

EPA Response: The EPA does not "enforce" or require the use of any specific technology to meet MCLs. With respect to the costs of the rule, please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document.

Ohio Water Utility Council (OWUC), Ohio American Water Works Association (OAWWA) (Doc. #1782, SBC-044721)

May 30, 2023

Michael S. Regan Administrator

Environmental Protection Agency 1200 Pennsylvania Avenue, N.W. Washington, DC 20460

RE: Proposed National Primary Drinking Water Regulations (NPDWR) for the Following Per- and Polyfluoroalkyl Substances (PFAS): [POFA, PFOS, PFNA, HFPO-DA (GenX), PFHxS, and PFBS]

Public Docket ID: EPA-HQ-OW-2022-0114-0027

To United States Environmental Protection Agency,

The Ohio Section of the American Water Works Association (OAWWA) represents over 4,500 water utilities that serve Ohio's population of 11.5 million. The Ohio Water Utility Council (OWUC) of the OAWWA has a primary purpose of advocating on matters that affect the water industry, treatment and delivery of safe, clean drinking water.

The OWUC appreciates the opportunity to provide comments on the proposed drinking water standards for PFAS substances to the United States Environmental Protection Agency (EPA) during this comment period of the rulemaking process. We recognize the importance of a collaborative effort between the EPA and the water utilities in United States and Ohio when evaluating the impacts of these rules. OWUC is focused on providing operational context to the regulatory requirements being proposed by EPA.

OWUC is aware of the importance of monitoring for potentially harmful contaminants in the public drinking water systems in Ohio and throughout the county, including PFAS substances. Our member utilities have begun evaluating the needs of their PWSs with respect to these substances. In anticipation of the regulatory changes being proposed cost estimates have been obtained. The OWUC is sharing some of those estimates to illustrate the real costs to Ohio utilities and the customers we serve.

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1782]

Each of these estimates are for one treatment facility in one public water system in one state in the country. Based on these examples it is very clear that the estimates from EPA of $772 million for the entire country are significantly low and likely would not cover the costs for the state of Ohio.

EPA Response: The EPA disagrees with the commenter's statement that the EPA's national cost estimates at proposal "likely would not cover the costs for the state of Ohio." Please see section 13.3 in this *Response to Comments* document for the EPA's response to comments about the total national costs of the rule.

The tables below compare the estimated capital costs from the commenter's table to results from the updated cost curves the EPA developed for the final rule, assuming the use of GAC or ion exchange to treat of groundwater with design flow estimated by applying the EPA's population-flow equations to the commenter's reported population served for each facility. Two of the three examples presented by the commenter fall within the EPA's range. The commenter's third example is elevated compared to the EPA's range. Unfortunately, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for these facilities would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3. The comment lacks sufficient detail to compare the commenter's O&M cost estimates to the results of the EPA's WBS models.

Commenter's Estimated Construction Costs Compared to Results from the EPA's Updated Cost Curves

Utility	Customers	Estimated Design Flow (MGD)	Commenter's Estimated Construction Costs ($millions)	EPA's Capital Cost Curves Lower Bound ($million)	EPA's Capital Cost Curves Upper Bound ($million)
Utility A	12,000	4.34	5 to 10	3.8	8.6
Utility B	16,000	5.71	9.6	4.6	10.6
Utility C	50,000	16.97	70	10.9	21.4

Fairfax Water (Doc. #1789, SBC-045306)

Fairfax Water's existing treatment process at both plants includes ozone and biological activated carbon (BAC). This treatment was selected for both facilities to ensure compliance with the Disinfectants and Disinfection Byproducts rules (D/DBP). In 2021 Fairfax Water engaged a consulting engineer to evaluate potential PFAS treatment technologies for our facilities under several different assumptions of potential MCLs. Our consulting engineer reviewed GAC, Ion Exchange (IX), and Reverse Osmosis (RO) and developed capital cost ranges and annual operating cost ranges for the three treatment alternatives as additions to Fairfax Water's existing treatment trains. In 2022 the review was updated following the publication of the revised health advisory levels for PFOA and PFOS. That update most closely relates to the current EPA proposal - MCLs effectively set at the level of detection.

For the plant sourced by the Occoquan, which would not meet the proposed rule based on available data, capital costs for GAC or IX ranged from $180 million to $250 million (December 2021 $), with annual operating costs of $10 million to $45 million. A mid-range capital cost of $215 million represents a 21% increase to Fairfax Water's ten-year capital improvement program (CIP).

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1738, SBC-046032 in section 13.3.3 in this *Response to Comments* document.

Fairfax Water (Doc. #1789, SBC-045308)

A mid-range of our projected annual operating costs for PFAS treatment at our Occoquan facility alone is $22.5 million. This represents an increase of 20% over Fairfax Water's total annual operations and maintenance expense budget - to comply with a single regulation. If RO treatment is required to meet the proposed rule (or a future PFAS regulatory requirement including constituent additions to the Hazard Index calculation), capital costs range from $720 million to $1.54 billion with annual operating costs of $30 million.

For our plant sourced by the Potomac, which meets the proposed rule based on available data but has source detections for PFAS and is located downstream from both Federal and non Federal

sites with known or suspected PFAS, capital costs for reverse osmosis treatment are estimated at $1.21 billion to $2.59 billion with annual operating costs of $55 million. None of the aforementioned capital or operating costs include mitigating potential future regulations for PFAS in water treatment residuals.

The potential increase in operating expenses for PFAS treatment comes at a time when the drinking water industry has seen double and triple-digit percentage increases in essential supplies such as chemicals and ductile iron pipe. These cost increases are borne by the ratepaying public. While our production has been flat, since January 2020, Fairfax Water's chemical budget has increased 52%. Our costs for sodium hypochlorite (disinfectant) in that time have increased 175% and costs for poly-aluminum chloride (coagulant) have increased 67%. Costs for ductile iron pipe, used in our distribution system to replace aging infrastructure, have on average increased 54% for 4-inch to 36-inch pipe and 128% for 42-inch and 48-inch pipe. Purchased power costs have increased 31% since July 2022. We urge EPA to re-evaluate the cost to implement the proposed rule to ensure the cost increases utilities are experiencing, which far outpace inflation, are accurately reflected in its analysis.

EPA Response: To the extent the commenter's expectation of costs are based on hypothetical future PFAS NPDWR, the EPA cannot speculate on the costs of future rules, especially since the EPA does not currently have rulemakings underway for additional PFAS. Based on this and other comments, the EPA updated its equipment costs to 2022 dollars (which are the most recent data available), collected new vendor price quotes for cost driver equipment components, and made several other adjustments to WBS model assumptions. Taken together, these adjustments increased the system level capital cost estimates in the EPA's cost assessment by percentages that were generally consistent with those reported by the commenter. Please see section 13.3.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1738, SBC-046032 in section 13.3.3 in this *Response to Comments* document.

Vermont Rural Water Association (Doc. #1798, SBC-045331)

GAC treatment costs for very small systems were estimated by EPA to be $25,000. Vermont's very small systems have been seeing total project remediation costs around $125,000, on average. For community systems that may have to construct treatment buildings to house the necessary filters and equipment, those costs can range into the millions. In addition, supply chain issues, skyrocketing construction and transportation costs, and unknown media disposal fees have been increasing the actual cost of remediation compared to preliminary estimates.

EPA Response: The commenter is incorrect; the EPA did not apply single point estimate of $25,000 to very small systems as a category. As described in the supporting documentation, the EPA developed cost curves that generate a range of costs based on individual entry point flow rates. The comment lacks sufficient detail for the EPA to compare the costs for small systems in Vermont to the results of the EPA's WBS models. The EPA updated its equipment costs to 2022

dollars (the most current data available) using current price indices. The EPA also collected new vendor price quotes for cost driver equipment components (e.g., pressure vessels, treatment media). Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Additionally, the specific cost elements mentioned by the commenter, including building costs and media disposal costs (both non-hazardous disposal options, as well as hazardous disposal included in a sensitivity analysis detailed in Appendix N.2 of the EA) are included in the cost models. In response to the commenter's statements about supply chain issues and increasing prices, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Massachusetts Municipal Association (MMA) (Doc. #1800, SBC-043764)

One municipality estimated that $15.8 million – in capital costs alone – will be required to install the necessary PFAS treatment infrastructure to supply the community with safe drinking water. Ongoing costs for the maintenance, operation, and staffing of the town's treatment plants are not yet known, but the financial impact will inevitably be borne by residents and taxpayers. Water rates have already increased 10% per year since remediation efforts began, and will continue to do so in order to meet the state PFAS6 20 ppt standard. It's important to highlight that these sizable investments have been made to comply with a more lenient regulation than what is currently being proposed by the EPA.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Laurens County Water and Sewer Commission (LCWSC) (Doc. #1805, SBC-043743)

May 30, 2023

By Electronic Submission: Docket EPA-HQ-OW-2022-0114

U.S. Environmental Protection Agency

EPA Docket Center

PFAS: PFOA and PFOS National Primary

Drinking Water Regulation Rulemaking,

Mail Code 28221T

1200 Pennsylvania Avenue NW Washington, DC 20460

Dear Sir/Madam:

Laurens County Water and Sewer Commission (LCWSC) [SC3020001] appreciates the opportunity to comment on USEPA's proposed National Primary Drinking Water Regulation and

health-based Maximum Contaminant Level Goals (MCLG) for PFOA and PFOS, as well as PFHxS, HFPO—DA and its ammonium salt, PFNA, and PFBS and their mixtures.

LCWCS serves approximately 40,000 people in Laurens County, SC, a Tier Ill semi-rural county in Upstate South Carolina.

EPA's proposed MCLs for PFAS have the potential to impose great costs to our rural community. And while we are committed to protecting the health of all those who enjoy our water, we have significant reservations that the United States is proposing excessively low levels of chemicals that are actively being sold and used by our citizens and businesses. If the concern was an acute concern, then these chemicals would be banned, and the need to remove them from the drinking water supply would be reduced and would involve dealing with legacy levels of chemicals instead of ongoing constituent loads.

We believe EPA's cost estimate may understate true compliance costs. For our system, we believe the most likely treatment available would be Granular Activated Carbon (GAC), with an estimated capital cost of $20M.

EPA Response: Regarding the comment "And while we are committed to protecting the health of all those who enjoy our water, we have significant reservations that the United States is proposing excessively low levels of chemicals that are actively being sold and used by our citizens and businesses. If the concern was an acute concern, then these chemicals would be banned, and the need to remove them from the drinking water supply would be reduced and would involve dealing with legacy levels of chemicals instead of ongoing constituent loads," please see section 15 of the EPA response in this *Response to Comments* document regarding other EPA actions to address PFAS. In response to the commenter's characterization of the proposed rule at "excessively low levels of chemicals," please see section 5 of the EPA response in this *Response to Comments* document regarding the EPA's MCLs. The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Florida Rural Water Association (FRWA) (Doc. #1806, SBC-044695)

GAC/Resin treatment costs for very small systems were estimated by EPA to be $25,000. FRWA engineers estimate that very small systems are realizing a total project remediation cost around $125,000, on average. For community systems that may have to construct treatment facilities to house and support the necessary filters and equipment, costs can range into the millions. An example, a Florida system with a max daily demand of 2 MGD is incurring a cost of $3 million just for GAC filters.

EPA Response: The commenter is incorrect; the EPA did not apply single point estimate of $25,000 to very small systems as a category. As described in the supporting documentation, the EPA developed cost curves that generate a range of costs based on individual entry point flow rates. The commenter's estimate of an average $125,000 for very small systems in Florida lacks

sufficient detail to compare this estimate to the results of the EPA's WBS models. Regarding the more specific example, the updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $3 million to $5 million for a 2 million gallon/day facility using GAC. The commenter's reported cost of $3 million falls within this range.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045481)

In addition, Advocacy is concerned that EPA also underestimates the compliance costs for small water systems. Small entities and their representatives have shared that the cost of setting up and running treatment systems is four to five times higher than EPA's projections. For example, a Small Entity Representative to the SBREFA panel, presented the results of a case study at Advocacy's environmental roundtable showing that the capital expenses for a granular activated carbon (GAC)[FN9: Granular activated carbon (GAC) is a treatment technology used to remove PFAS. GAC is a separation process where contaminants become attached to specially treated carbon with a high surface area.] showed that there was over a 300% percent difference compared to EPA's predicted cost of treatment for PFOA and PFOS. Small entities have also expressed concern about the availability and rising costs of treatment technologies due to the expected increase in demand in anticipation of these proposed regulations.

EPA Response: This comment, and specifically the claim that "cost of setting up and running treatment systems is four to five times higher than the EPA's projections" lacks sufficient detail to compare these costs to the results of the EPA's WBS models. In response to this commenters reference to information shared by a Small Entity Representative, specifically AWWA, please see section 13.3.3 of the EPA response in this *Response to Comments* document. Finally, regarding the impacts of demand on costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Analysis of the USEPA Proposed PFAS National Primary Drinking Water Regulation Treatment Costs and Comparison to the AWWA National PFAS Cost Model Report

Prepared by Elin Betanzo, Safe Water Engineering, LLC

Executive Summary

The presence of per- and polyfluoroalkyl substances (PFAS) in drinking water sources has emerged as a pressing environmental and public health concern over the last decades. These persistent and bioaccumulative chemicals, commonly found in firefighting foam, nonstick cookware, and numerous other consumer products, have been linked to various adverse health effects. As a result, the United States Environmental Protection Agency (EPA) has undertaken the task of proposing regulations to limit the concentration of PFAS in drinking water.

The proposed regulation would establish enforceable maximum contaminant levels (MCLs) of PFAS in drinking water supplies. This analysis, requested and paid for by the Natural Resources Defense Council, focuses on the potential financial burden of installing treatment to comply with the EPA's proposed PFAS regulation. This analysis also includes a comparison with the American Water Works Association (AWWA) PFAS National Cost Model Report (AWWA, 2023), which provides an industry perspective on the costs associated with PFAS treatment.

These analyses seek to understand realistic treatment costs that would be triggered by the regulation. Furthermore, comparing the EPA's cost estimates to those provided by the AWWA National PFAS Cost Model Report will offer valuable insights into the potential variations and discrepancies between regulatory projections and industry-based assessments. This exploration of the intricacies of these analyses will help inform the overall Economic Analysis to ensure costs are assigned to the rule that will realistically allow water systems to install treatment and achieve the public health benefits anticipated for the new requirements.

Although the USEPA analyzed complete compliance costs for the proposed rule, including sampling and state oversight, this present analysis focuses only on the cost of treatment installation and annualized operations and maintenance (O&M). When AWWA published their analysis, the published proposed rule was not yet available. AWWA estimated the cost of 3 potential compliance options. Although the first AWWA compliance scenario, MCLs of 4 ppt for PFOA and PFOS, does not match the EPA proposed rule (which also includes a Hazard Index of 1.0), it does match USEPA’s Option 1a. Because the same modeling methods are used in all options presented in each report, this analysis compares EPA’s Option 1a to AWWA’s first compliance scenario.

Table 1: EPA and AWWA Modeled Annualized Water System Treatment Costs for Achieving 4.0 ppt for PFOA and PFOS

[Table 1: Docket ID: EPA-HQ-OW-2022-0114-1808]

Estimating national costs for drinking water rules requires applying assumptions and professional judgement, especially when there are limitations in availability of occurrence data. Although it is a tricky task, it is a necessary task to estimate the necessary funding for protecting public health. Both cost estimates inform and help move the conversation forward. This memo attempts to identify the sources of the $3.1 billion difference between these two cost estimates and identify which modeling assumptions are more likely to reflect a realistic compliance forecast and reasonable engineering judgement.

EPA Response: The EPA agrees with some of the commenter's conclusions about the sources of differences between the EPA's estimate and the AWWA B&V report estimates. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046175)

[The analysis that follows shows that the $3.1 billion dollar difference in annualized cost can be explained by the following primary factors:]

6. Cumulative impact of cost assumptions for small systems (serving <10,000). The EPA model assumes that package plants, at a lower cost point, are available for entry points <1 MGD. Package plants have been an option for reducing costs for small systems for decades (National Drinking Water Clearinghouse, 1997), but this option is not described as incorporated in the AWWA estimate. The EPA estimate for cost savings from package plants may be conservative as some package plants may be available up to 6 MGD flows and PWSs typically seek the lowest cost option available for compliance. The cumulative impact of the points raised here: lack of package plants, higher than actual design flows, treatment of unnecessary entry points, and lack of non-treatment options means that AWWA does not provide a realistic cost estimate for small systems.

EPA Response: The EPA agrees that the AWWA B&V report does not provide a realistic cost estimate for small systems and that package plants can be a cost saving measure for some systems. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046174)

5. Differences in flow calculations. EPA and AWWA use different average flow assumptions. EPA uses inventory data, and AWWA assumes 150 gpd per person with published populations to calculate average flow. According to the USGS (Dieter et al., 2018), the AWWA assumption of 150 gpd per person is high, compared to their estimate of 82 gpd. This indicates that EPA flows may be more appropriate. The AWWA estimate also does not reflect regional differences in water use. Even though essentially the same peaking factors are used, AWWA ends up with higher design flows for systems serving <10,000 compared to EPA (Appendix E). The higher AWWA flows result in larger capital and O&M costs relative to actual flow requirements and are magnified even further when applied to the overestimate of entry points requiring treatment in small systems. On the other hand, Appendix E shows that for ground water CWSs serving

>=10,000 EPA flows are higher than AWWA estimated flows. This is not an apples-to-apples comparison because the EPA estimate does not include surface water CWSs, but it means there may not be a differential impact in costs for systems serving >=10,000. The total magnitude of the net impact of differences in flow between the two estimates is unclear because equivalent datasets are not available. However, the AWWA excess flows assumed for small systems likely results in net larger magnitude costs in AWWA compared to EPA.

EPA Response: The EPA generally agrees the commenter's conclusions about the sources of differences between the EPA's estimate and the AWWA B&V report estimates. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046172)

[The analysis that follows shows that the $3.1 billion dollar difference in annualized cost can be explained by the following primary factors:]

3. Treatment of Entry Points. EPA calculates treatment and O&M cost per entry point to the distribution system (EPTDS) that exceeds the MCL using modeled system and flow characteristics. Some PWSs have more than one entry point that requires treatment; costs are assigned per entry point that exceeds the MCL. AWWA calculates the number of PWSs that exceed the MCL, assumes that every PWS that exceeds the MCL has the average number of entry points per system for a system in that size category, and assumes every entry point in that system will require treatment regardless of whether a given entry point exceeds the MCL. This assumption results in 3,645 more entry points with treatment installation in the AWWA analysis that may not actually require treatment, and impacts both capital and O&M costs. A conservative estimate of the overall impact of this assumption, using the number of PWSs that AWWA estimated exceed the MCL along with EPA's metric of 1.3 entry points exceeding the MCL per PWS for small systems and 3.1 for large systems, is an overestimate of $1.4 billion (Appendix C).

EPA Response: The EPA generally agrees with the commenter's conclusions about the sources of differences between the EPA's estimate and the AWWA B&V report estimates. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046109)

EPA's analysis of treatment costs associated with the Proposed Rule is also well supported and more accurately forecasts costs than the competing analysis submitted by the American Water Works Association ("AWWA"). [FN111: Betanzo 2023; see Am. Water Works Ass'n, PFAS National Cost Model Report (Black & Veatch 2023).] For example, in contrast to AWWA, EPA properly screened the PFAS occurrence data incorporated into its treatment cost assessment to avoid bias in the data set from non-public water system PFAS samples and samples collected by water systems investigating known PFAS contamination. [FN112: Betanzo 2023 at 4, 6.] EPA also appropriately calculated treatment costs based on the number of water system entry points

with modeled MCL violations, whereas AWWA assumed without justification that every entry point within a water system will require treatment if any entry point within the system violates the MCL. [FN113: Id. at 4–5.] Critically, EPA also incorporated detailed estimates of the compliance strategies that water systems are likely to select—including non-treatment options — and associated costs. [FN114: Guignet 2023 at 4; Betanzo 2023 at 2–3, 9–11.] EPA's cost estimates also rely appropriately on inventoried flow rates, whereas AWWA utilizes a standardized 150 gpm/person flow rate that is biased high and fails to account for regional water-use differences. [FN115: Betanzo 2023 at 5, 12.] Overall, EPA's cost estimate is "robust" and "there is no evidence that EPA is consistently underestimating occurrence or costs," while AWWA's estimate includes excess treatment costs of at least $2.6 billion. [Fn116: Id. at 22.]

EPA Response: The EPA agrees with the commenter's regarding the appropriateness of the EPA's handling of data and screening of samples and cost analysis done at the EP level, rather than making the assumption that all EPs within a system will install treatment, as AWWA's B&V report did. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046176)

[The analysis that follows shows that the $3.1 billion dollar difference in annualized cost can be explained by the following primary factors:]

7. Magnitude of treatment cost inputs. EPA's Economic Analysis (2023a), Technologies and Costs document (2023b), and Work Breakdown Structure Model documents (e.g., 2021a) provide hundreds of pages of documentation of the EPA cost analysis process whereas AWWA 2023 provides 36 pages with no references. The difference in documentation makes it impossible to compare cost inputs one to one, but it is possible to insert AWWA's flow assumptions into the EPA model to explore the net magnitude of underlying cost assumptions by comparing average systems. Appendix F shows that for small system capital costs, AWWA estimates treatment for a single entry point up to two times higher than EPA (e.g., $2.2 million compared to $1.1 million per entry point for systems serving 500-1,000 people). For large system capital costs, the EPA model for midlevel ground water CWS costs generates larger costs than the AWWA published averages. In Appendix G, application of the EPA model using AWWA average flows generates annual O&M cost estimates that are the same or larger than AWWA's average cost estimates, indicating that AWWA O&M cost inputs may be lower than EPA's. AWWA does not provide a treatment forecast showing the percent of systems expected to implement any given treatment. This analysis provides limited insight on determining the cumulative difference of cost inputs between the EPA and AWWA analyses. The relative magnitude of underlying costs is unknown, but nonetheless has a major impact on the net outcome of total national costs.

The evidence provided in this memo demonstrates that the EPA cost estimate is robust. While there are several items that could not be directly compared to the AWWA cost model, there is no

evidence that EPA is consistently underestimating occurrence or costs. According to calculations shown in Appendix G, if AWWA's O&M costs are accurate ($30,000-125,000 per entry point), this could mean that EPA's O&M cost estimates ($27,000-2,515,000) are larger than necessary and may be lower in practice. If Michigan's rate of non-treatment options is relevant nationwide, the total EPA cost would fall even further.

The EPA cost estimate of $658.5 million appears to be the more realistic result based on the calculations and findings presented here.

While professional judgement must be used in applying cost modeling assumptions, it appears that several of the assumptions in the AWWA cost model are too conservative. These assumptions consistently result in higher capital and O&M costs for treatment, especially for systems serving fewer than 10,000. As shown in Table 2, the analyses presented here demonstrate the AWWA estimate includes at least $2.6 billion in excess costs. Many of these overestimates have cascading effects that could not be modeled with available data. The cumulative impact of these corrections is likely even larger than estimated here. Subtracting the excess costs from AWWA's total estimate would result in a maximum annual cost of $1.2 billion for treatment installation and O&M.

Table 2: Total Magnitude of Quantified Excess Costs in the AWWA Cost Model

[Table 2: Docket ID: EPA-HQ-OW-2022-0114-1808]

Analysis

Tables are presented below that compare the two cost modeling approaches and outcomes. These evaluate occurrence data, public water system (PWS) inventory data, capital cost data and analytical approaches, and O&M.

Table 3: Occurrence Factors

[Table 3: Docket ID: EPA-HQ-OW-2022-0114-1808]

Table 4: Capital Treatment Selection and Costs

[Table 4: Docket ID: EPA-HQ-OW-2022-0114-1808]

Table 5: Operations and Maintenance Costs

[Table 5: Docket ID: EPA-HQ-OW-2022-0114-1808]

A case study for actual costs incurred can be identified from the AWWA analysis. Table 6-3 quantifies one PWS serving >1,000,000 that installed treatment in response to state PFAS MCLs with an AWWA estimated capital cost of $407.5 million and an annualized cost of $47 million. The water utility was identified via UCMR3 monitoring data. Information on this water system (O'Connell and Kilcommons, 2023) states the following: "Through a mix of blending, GAC treatment, and taking wells offline that have contaminant detections over the MCL that they are

currently in compliance with the state requirements. This PWS anticipates additional treatment may be needed to meet the proposed federal requirements." To date, they have spent:

• $15.0 million from 2016 – 2022 on PFAS related work

• $36.2 million on Emerging Contaminant Work

• $21.2 million on 1,4-Dioxane work

Although this is not the complete capital cost for the work (as more is pending), and some of the emerging contaminant and 1,4-Dioxane work may result in PFAS reduction benefits, the cost to date is significantly less than the estimated capital cost of $407.5 million presented in AWWA Table 6-3. Even if the $15 million is the actual annualized cost of PFAS treatment alone, it would be less than one third of the annualized cost shown in AWWA Table 6-3.

EPA Response: The EPA generally agrees with the commenter's observations about AWWA's B&V report and the case study. The EPA also agrees with this commenter's conclusions about the sources of differences between the EPA's national cost estimates and the estimates included in AWWA's B&V report. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046178)

Conclusion

As discussed throughout this memo, assumptions used in AWWA cost modeling of the proposed PFAS drinking water rule result in higher annualized capital and O&M costs for treatment, especially for systems serving fewer than 10,000. While AWWA cost inputs for O&M may be lower than EPA's inputs, the larger number of entry points installing treatment per AWWA result in cumulative increased O&M costs. Although several details that are not provided cannot be quantified, the source of $2.6 billion in excess costs are clearly identified in this analysis and in Table 2. Many of these overestimates have cascading effects that are not readily calculated without access to the underlying cost models, so the cumulative impact of these corrections is likely even larger than estimated here. Subtracting the overestimates from the AWWA cost estimate results in a revised AWWA annual estimate of $1.2 billion for treatment and O&M to comply with the proposed MCLs. While there is a possibility that the actual result lies between the EPA and AWWA cost estimates, the calculations here indicate it is more likely to be closer to the EPA estimate.

The evidence provided in the executive summary and Tables 3-5 demonstrate that the EPA cost estimate is robust. While there are several items that could not be directly compared between the EPA and AWWA cost models, there is no evidence that EPA is consistently underestimating occurrence or costs. When looking toward which cost estimate is likely to better reflect future

compliance decisions, the EPA cost estimate appears to be more realistic based on the calculations and findings presented here.

If AWWA's apparent lower O&M cost inputs are accurate, this could mean that EPA's O&M cost estimates are higher than necessary and will be lower during implementation. If Michigan's rate of non- treatment options is relevant nationwide, the total EPA estimated cost would fall even further. The EPA $658 million annual treatment cost projection is realistic, and there are several opportunities for actual costs to turn out even lower upon implementation.

EPA Response: The EPA agrees with the commenter's conclusions about the sources of differences between the EPA's national cost estimates and the estimates submitted via public comment by AWWA. The EPA also agrees with the commenter that the EPA cost estimates are robust. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Please see section 13.3 of the EPA response in this *Response to Comments* document regarding the EPA's cost total national cost estimates for the final rule.

Wet Weather Partnership (Doc. #1820, SBC-044582)

We believe that EPA's implementation cost estimate may be upwards of an order of magnitude too low. EPA must revise and update its cost of compliance estimate and, using that significantly higher cost estimate, reevaluate the MCL levels. We believe the result of that reevaluation will yield a higher MCL for both PFOA and PFOS.

The number of facilities impacted by the proposed rule underscores how inaccurate the EPA cost estimate is and where there is need for more time and stakeholder input. In the proposed rule, EPA states "the entities potentially affected by the proposed PFAS regulation are primacy agencies and PWSs." 88 Fed. Reg. at 18690. The agency thinks around 66,000 water systems will be subject to the proposed rule and that around 3,400-6,300 systems will exceed one or more MCL. [FN2: EPA, Proposed PFAS National Primary Drinking Water Regulation (March 2023).] AWWA has publicly shared that a member facility (Cape Fear Public Utility Authority) estimated its PFAS treatment costs at $43 million with annual operating costs around $3-5 million, commenting that it would only take around 16 similarly sized utilities to go past the EPA cost figure. We estimate that 40-50 percent of the water systems nationwide will require PFAS barrier technology. In North Carolina, the State recently sampled 50 different water systems and concluded that 42 out of 50 exceed the 4 ppt MCL proposed for PFOA and/or PFOS. In South Carolina, the State sampled statewide and found 26 drinking water plants exceeded the federal limits. These numbers will increase with additional sampling.

EPA Response: This comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. The EPA notes that the commenter is comparing total capital costs at a single system to the EPA's annualized costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for why this is inappropriate and misrepresentative of the EPA's analysis. The EPA disagrees with the commenter's unsupported claim that 40-50 percent of water systems nationwide would need to install treatment. This far exceeds the EPA's or any other known data-driven analysis' estimates of the number of water systems nationally expected to exceed the MCLs. It is also inconsistent with empirical observations from nearly all of the states that conducted non-targeted monitoring which demonstrate widely varying percentages of systems exceeding the MCLs, See Section 2.4.2.2 of the *Occurrence Technical Support Document* (USEPA, 2024a) and section 6.2 of the EPA response in this *Response to Comments* document for more information about state occurrence data. Furthermore, while the analyses are preliminary, this is wholly inconsistent with the partial results from the EPA's UCMR 5 monitoring effort. Please see section 6.8 of the EPA response in this *Response to Comments* document for further discussion. The EPA has used a nationally representative peer reviewed model to inform the number of water systems expected to install treatment. Please see section 6.5 of the EPA response in this *Response to Comments* document for more information on the EPA's national occurrence model. Furthermore, extrapolating from a single utility's experience is not an appropriate method to estimate national costs. See also section 13.3.3 of the EPA response in this *Response to Comments* document.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044670)

We believe that EPA's implementation cost estimate may be upwards of an order of magnitude too low. EPA must revise and update its cost of compliance estimate and, using that significantly higher cost estimate, reevaluate the MCL levels. We believe the result of that reevaluation will yield a higher MCL for both PFOA and PFOS.

The number of facilities impacted by the proposed rule underscores how inaccurate the EPA cost estimate is and where there is need for more time and stakeholder input. In the proposed rule, EPA states "the entities potentially affected by the proposed PFAS regulation are primacy agencies and PWSs." 88 Fed. Reg. at 18690. The agency thinks around 66,000 water systems will be subject to the proposed rule and that around 3,400-6,300 systems will exceed one or more MCL. [FN2: EPA, Proposed PFAS National Primary Drinking Water Regulation (March 2023), Link:w.epa.gov/system/files/documents/2023-03/PFAS%20NPDWR%20Public%20Presentation_Overview_3.16.23_508.pdf] AWWA has publicly shared that a member facility (Cape Fear Public Utility Authority) estimated its PFAS treatment costs at $43 million with annual operating costs around $3-5 million, commenting that it would only take around 16 similarly sized utilities to go past the EPA cost figure. We estimate that 40-50 percent of the water systems nationwide will require PFAS barrier technology. In North Carolina, the State recently sampled 50 different water systems and concluded that 42 out of 50 exceed the 4 ppt MCL proposed for PFOA and/or PFOS. In South Carolina, the State sampled statewide and found 26 drinking water plants exceeded the federal limits. These numbers will increase with additional sampling.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1820, SBC-044582 in section 13.3.3 in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044648)

We believe that EPA's implementation cost estimate may be upwards of an order of magnitude too low. EPA must revise and update its cost of compliance estimate and, using that significantly higher cost estimate, reevaluate the MCL levels. We believe the result of that reevaluation will yield a higher MCL for both PFOA and PFOS.

The number of facilities impacted by the proposed rule underscores how inaccurate the EPA cost estimate is and where there is need for more time and stakeholder input. In the proposed rule, EPA states "the entities potentially affected by the proposed PFAS regulation are primacy agencies and PWSs." 88 Fed. Reg. at 18690. The agency thinks around 66,000 water systems will be subject to the proposed rule and that around 3,400-6,300 systems will exceed one or more MCL [FN2: EPA, Proposed PFAS National Primary Drinking Water Regulation (March 2023).]. AWWA has publicly shared that a member facility (Cape Fear Public Utility Authority) estimated its PFAS treatment costs at $43 million with annual operating costs around $3-5 million, commenting that it would only take around 16 similarly sized utilities to go past the EPA cost

figure. We estimate that 40-50 percent of the water systems nationwide will require PFAS barrier technology. In North Carolina, the State recently sampled 50 different water systems and concluded that 42 out of 50 exceed the 4 ppt MCL proposed for PFOA and/or PFOS. In South Carolina, the State sampled statewide and found 26 drinking water plants exceeded the federal limits. These numbers will increase with additional sampling.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1820, SBC-044582 in section 13.3.3 in this *Response to Comments* document.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044626)

We believe that EPA's implementation cost estimate may be upwards of an order of magnitude too low. EPA must revise and update its cost of compliance estimate and, using that significantly higher cost estimate, reevaluate the MCL levels. We believe the result of that reevaluation will yield a higher MCL for both PFOA and PFOS.

The number of facilities impacted by the proposed rule underscores how inaccurate the EPA cost estimate is and where there is need for more time and stakeholder input. In the proposed rule, EPA states "the entities potentially affected by the proposed PFAS regulation are primacy agencies and PWSs." 88 Fed. Reg. at 18690. The agency thinks around 66,000 water systems will be subject to the proposed rule and that around 3,400- 6,300 systems will exceed one or more MCL. [FN2: EPA, Proposed PFAS National Primary Drinking Water Regulation (March 2023).] AWWA has publicly shared that a member facility (Cape Fear Public Utility Authority) estimated its PFAS treatment costs at $43 million with annual operating costs around $3-5 million, commenting that it would only take around 16 similarly sized utilities to go past the EPA cost figure. EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1820, SBC-044582 in section 13.3.3 in this *Response to Comments* document.

Wet Weather Partnership (Doc. #1820, SBC-044580)

Below are examples of different water system estimated costs to install PFAS barrier technology.

South Carolina

• One drinking water system in South Carolina, which is a member of the SC Water Quality Association, has estimated the cost of PFAS barrier technology installation would be $150-$200 million. On top of that, annual operation and maintenance costs would be $24 million.

• Another SC utility that also operates a large drinking water system has a preliminary estimate of $335 million to install granulated activated carbon technology. Complicating matters, the utility may have to add transfer pumping and additional standby power generation for the GAC contractors as there may not be a current suitable location near the flow train or available head loss. This would raise the cost closer to $500 million or more. Due to the potential frequency of GAC media change out, the utility might also have to install a rail spur to manage the logistics of handling that amount of GAC.

North Carolina

• In North Carolina, a utility estimates $43M in capital costs for a GAC system and $1-5M annually for GAC renewal/replacement and O&M.

• Another North Carolina utility estimates $15M in anticipated PFAS-related projects.

• A relatively small North Carolina water system has contracted for a GAC upgrade in the $25 million range.

Other

• A Virginia utility estimates its installation of GAC vessels will have a $21.4 million project cost.

• The City of Nashville received between $500-900M in funding for GAC at its two water plants (including $315M in WIFIA loans in Sept. 2022).

• The Orange County Water District in California received $131 million in WIFIA loans for a $267 million project to remove PFAS from groundwater.

EPA needs more cost information and input from states, SDWA SRF program managers, and public utilities in order to develop a legally valid cost assessment. In addition to actual project awards, the EPA SDWA SRF Program staff should include PFAS barrier projects that were proposed for funding but were not accepted/deferred.

EPA Response: This comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. As detailed in section 13.3.3 of the EPA response in this *Response to Comments* document, to fully evaluate the commenters' reported or estimated costs in comparison to WBS model results, the EPA would need itemized line-item cost details and engineering design parameters. The EPA has further validated the unit costs in the PFAS rule with equipment cost information from 2023 from a major supplier of treatment media. While the EPA recognizes there are likely site-specific instances where costs exceed the EPA's cost ranges, there are also likely site-specific instances where costs are less than the EPA's cost ranges, and this level of accuracy is appropriate for a national level analysis. The EPA has thoroughly considered all public comments submitted on the proposed PFAS rule and incorporated a number of recommendations from public commenters into the agency's cost models that are reflected in the cost analysis for the final rule. Finally, the EPA disagrees with the commenter's assertion that the EPA has not conducted a "legally valid cost assessment" as the agency has used the best available peer reviewed science to inform a HRRCA pursuant to SDWA requirements. Please see section 13.3.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1675, SBC-044933 in section 13.3.2 in this *Response to Comments* document for further discussion of why the EPA fulfilled its obligations under SDWA 1412(b)(3)(C) and performed a robust cost analysis meeting all SDWA requirements.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044668)

Below are examples of different water system estimated costs to install PFAS barrier technology.
South Carolina

• One drinking water system in South Carolina, which is a member of the SC Water Quality Association, has estimated the cost of PFAS barrier technology installation would be $150-$200 million. On top of that, annual operation and maintenance costs would be $24 million.

• Another SC utility that also operates a large drinking water system has a preliminary estimate of $335 million to install granulated activated carbon technology. Complicating matters, the utility may have to add transfer pumping and additional standby power generation for the GAC contractors as there may not be a current suitable location near the flow train or available head loss. This would raise the cost closer to $500 million or more. Due to the potential frequency of GAC media change out, the utility might also have to install a rail spur to manage the logistics of handling that amount of GAC.

North Carolina

• In North Carolina, a utility estimates $43M in capital costs for a GAC system and $1-5M annually for GAC renewal/replacement and O&M.

• Another North Carolina utility estimates $15M in anticipated PFAS-related projects.

• A relatively small North Carolina water system has contracted for a GAC upgrade in the $25 million range.

Other

• A Virginia utility estimates its installation of GAC vessels will have a $21.4 million project cost.

• The City of Nashville received between $500-900M in funding for GAC at its two water plants (including $315M in WIFIA loans in Sept. 2022).

• The Orange County Water District in California received $131 million in WIFIA loans for a $267 million project to remove PFAS from groundwater.

EPA needs more cost information and input from states, SDWA SRF program managers, and public utilities in order to develop a legally valid cost assessment. In addition to actual project awards, the EPA SDWA SRF Program staff should include PFAS barrier projects that were proposed for funding but were not accepted/deferred.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1820, SBC-044580 in section 13.3.3 in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044646)

Below are examples of different water system estimated costs to install PFAS barrier technology.
South Carolina

• One drinking water system in South Carolina, which is a member of the SC Water Quality Association, has estimated the cost of PFAS barrier technology installation would be $150- $200 million. On top of that, annual operation and maintenance costs would be $24 million.

• Another SC utility that also operates a large drinking water system has a preliminary estimate of $335 million to install granulated activated carbon technology. Complicating matters, the utility may have to add transfer pumping and additional standby power generation for the GAC contractors as there may not be a current suitable location near the flow train or available head loss. This would raise the cost closer to $500 million or more. Due to the potential frequency of GAC media change out, the utility might also have to install a rail spur to manage the logistics of handling that amount of GAC.

North Carolina

• In North Carolina, a utility estimates $43M in capital costs for a GAC system and $1-5M annually for GAC renewal/replacement and O&M.

• Another North Carolina utility estimates $15M in anticipated PFAS-related projects.

• A relatively small North Carolina water system has contracted for a GAC upgrade in the $25 million range.

Other

• A Virginia utility estimates its installation of GAC vessels will have a $21.4 million project cost.

• The City of Nashville received between $500-900M in funding for GAC at its two water plants (including $315M in WIFIA loans in Sept. 2022).

• The Orange County Water District in California received $131 million in WIFIA loans for a

$267 million project to remove PFAS from groundwater.

EPA needs more cost information and input from states, SDWA SRF program managers, and public utilities in order to develop a legally valid cost assessment. In addition to actual project awards, the EPA SDWA SRF Program staff should include PFAS barrier projects that were proposed for funding but were not accepted/deferred.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044624)

Below are examples of different water system estimated costs to install PFAS barrier technology.

South Carolina

• One drinking water system in South Carolina, which is a member of the SC Water Quality Association, has estimated the cost of PFAS barrier technology installation would be $150-$200 million. On top of that, annual operation and maintenance costs would be $24 million.

• Another SC utility that also operates a large drinking water system has a preliminary estimate of $335 million to install granulated activated carbon technology. Complicating matters, the utility may have to add transfer pumping and additional standby power generation for the GAC contractors as there may not be a current suitable location near the flow train or available head loss. This would raise the cost closer to $500 million or more. Due to the potential frequency of GAC media change out, the utility might also have to install a rail spur to manage the logistics of handling that amount of GAC.

North Carolina

• In North Carolina, a utility estimates $43M in capital costs for a GAC system and $1- 5M annually for GAC renewal/replacement and O&M.

• Another North Carolina utility estimates $15M in anticipated PFAS-related projects.

• A relatively small North Carolina water system has contracted for a GAC upgrade in the $25 million range.

Other

• A Virginia utility estimates its installation of GAC vessels will have a $21.4 million project cost.

• The City of Nashville received between $500-900M in funding for GAC at its two water plants (including $315M in WIFIA loans in Sept. 2022).

• The Orange County Water District in California received $131 million in WIFIA loans for a $267 million project to remove PFAS from groundwater.

EPA needs more cost information and input from states, SDWA SRF program managers, and public utilities in order to develop a legally valid cost assessment. In addition to actual project awards, the EPA SDWA SRF Program staff should include PFAS barrier projects that were proposed for funding but were not accepted/deferred.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

South Carolina Water Quality Association (Doc. #1819, SBC-044602)

Below are examples of different water system estimated costs to install PFAS barrier technology.

South Carolina

• One drinking water system in South Carolina, which is a member of the SC Water Quality Association, has estimated the cost of PFAS barrier technology installation would be $150-$200 million. On top of that, annual operation and maintenance costs would be $24 million.

• Another SC utility that also operates a large drinking water system has a preliminary estimate of $335 million to install granulated activated carbon technology. Complicating matters, the utility may have to add transfer pumping and additional standby power generation for the GAC contractors as there may not be a current suitable location near the flow train or available head loss. This would raise the cost closer to $500 million or more. Due to the potential frequency of GAC media change out, the utility might also have to install a rail spur to manage the logistics of handling that amount of GAC.

North Carolina

• In North Carolina, a utility estimates $43M in capital costs for a GAC system and $1-5M annually for GAC renewal/replacement and O&M.

• Another North Carolina utility estimates $15M in anticipated PFAS-related projects.

• A relatively small North Carolina water system has contracted for a GAC upgrade in the $25 million range.

Other

• A Virginia utility estimates its installation of GAC vessels will have a $21.4 million project cost.

• The City of Nashville received between $500-900M in funding for GAC at its two water plants (including $315M in WIFIA loans in Sept. 2022).

• The Orange County Water District in California received $131 million in WIFIA loans for a $267 million project to remove PFAS from groundwater.

EPA needs more cost information and input from states, SDWA SRF program managers, and public utilities in order to develop a legally valid cost assessment. In addition to actual project awards, the EPA SDWA SRF Program staff should include PFAS barrier projects that were proposed for funding but were not accepted/deferred.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1820, SBC-044580 in section 13.3.3 in this *Response to Comments* document.

Mississippi Farm Bureau Federation (Doc. #1826, SBC-044268)

We expect that the costs associated with testing and the potential need for filtration will be significant, especially for some of the rural water systems that can ill afford it.

EPA Response: Regarding treatment costs, including costs for small systems, please see section 13.3.3 of the EPA response in this *Response to Comments* document. Regarding sampling costs, please see section 13.3.4 of the EPA response in this *Response to Comments* document. Please see section 13.10 of the EPA response in this *Response to Comments* document on the EPA's affordability analysis.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045776)

Based on our experience, the EPA cost model significantly underestimates the capital and O&M costs associated with PFAS treatment. We recommend that EPA reevaluate its cost estimates and consider inflation and supply chain issues likely to result from the Proposal in its revised evaluation.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-04'770)

EPA's Estimates Underestimate the Actual Cost of PFAS Treatment

EPA's cost analysis is critical to the health risk reduction and cost analysis (HRRGA) and household affordability analysis. Inaccurate cost estimates will result in mischaracterization of the Proposal's merits.

[Figure 1: see docket ID EPA-HQ-OQ-2022-0114-1829]

Review of the cost modeling shows significant misalignment between the Proposal's assumption and our experiences with capital improvements and operating costs. For example, the EPA cost model utilizes the curve below to estimate the capital costs for granular activated carbon (GAG). Our water provider, the Washington Aqueduct, operates two surface water treatment facilities, Dalecarlia and McMillan. EPA's model estimates that it would cost approximately $103.4M to install GAG at these two facilities.

GAG was considered as a potential treatment upgrade at the WAD in 2013, and the capital cost of GAG at our two plants at that time was estimated at $200M. Utilizing a conservative inflationary estimate of 58% [FN1: Using the Census.gov Multifamily Housing Construction Index 2005-2022] indicates a present value of $316.6M, or a factor of more than 3 times the EPA's estimated cost of $103.4M.

Our analysis notes a similar discrepancy in the estimated O&M costs for GAG, with our inflation adjusted annual O&M cost estimated at $31.6M as compared to the EPA model estimate of $10.1M.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for further discussion.

American Chemistry Council (ACC) (Doc. #1841, SBC-044841)

EPA Has Underestimated the Cost of Treatment Systems and Residual Disposal

EPA's cost model for treatment systems included several assumptions that do not appropriately characterize water treatment costs and disposal of spent residuals. EPA assumes that the majority of the drinking water systems that will require treatment will utilize granular activated carbon (GAC). EPA's estimates of a 2-year lifespan of the activated carbon in these systems is likely overstated.

EPA Response: The commenter is incorrect; the EPA did not make a blanket assumption of a 2-year lifespan for activated carbon. The EPA estimated GAC bed life individually for each entry point based on the percent removal required to comply with the rule, given each entry point's estimated influent PFAS concentrations. See Chapter 5.3.1 of the EA for more information.

American Chemistry Council (ACC) (Doc. #1841, SBC-052936)

Similarly, EPA's cost model for reverse osmosis (RO) systems does not include the requirement to remineralize RO permeate to protect downstream distribution piping from corrosion and make the water suitable for human consumption. Where facilities use RO systems, EPA should not assume blending with other finished waters is an available option.

EPA Response: The EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the EA for the final rule. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. Regarding the commenter's mention of blending, the comment is moot as the EPA is not forecasting the use of RO as a result of this rule. However, if it were not moot, the EPA notes that no specific technology, technique, or process is required under this rule in order to meet the MCLs and all options have potential tradeoffs. The EPA recommends that utilities and primacy agencies evaluate all options according to site-specific needs and circumstances. For more information, please see the EPA response to comment Doc. #2793, SBC-046610 and Doc. #1699, SBC-045043 in section 10.2 in this *Response to Comments* document.

Santa Clarita Valley Water Agency (Doc. #3072-20, SBC-046350)

Thank you. My name is Matt Stone. I am the general manager of the Santa Clarita Valley Water Agency, also known as SCV Water. We serve 300,000 residents in northwest Los Angeles County, California. I want to thank EPA for its effort to establish a national safe drinking water standard for PFAS chemicals. About half of our water supply portfolio comes from two local groundwater aquifers. Since California first set response levels for PFOA and PFOS in 2018, it continues to refine and add additional PFAS related RLs. We have removed approximately 40% of our groundwater production capacity from service. As we work to restore that capacity, we have gained experience with the cost to implement ion exchange PFAS treatment systems, which

I will share with you. Our N Wells facility was completed in December 2020, treats 6,250 gallons per minute, had a capital cost of $9.2 million, or about $1,474 per GPM of capacity. This project was identified as the fastest and lowest-cost project we could complete, and we were fortunate to get ahead of price increases, and already had three wells connected to the treatment site. Next, the Valley Center facility was completed in August of 2022, treats 1,200 gallons per minute, with a capital cost of $5.12 million, or $4,267 per GPM of capacity. For that project, we saw increases in vessel costs, resin costs, and long supply chain lead times for some items. Last, Santa Clara and Honby Wells Facility is now under construction, and should be completed in early 2024. It will treat 2,000 gallons per minute, and the cost is $9.63 million, or $4,813 per GPM of capacity. We experienced additional supply chain lead time issues here as well. We believe these two recent projects reflect where costs and delivery times are today. Project delivery time was three and a half years for Valley Center, and is expected to be four years for Santa Clara Honby. We currently estimate the cost to restore total impacted capacity to meet state and federal PFAS standards could reach $160 million in capital, and an annual operating cost of $11 million. These are in 2022 dollars, and may be revised as more projects reach design phase, and as additional wells are impacted. Thank you for the opportunity to provide comment.

EPA Response: The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $6.5 million to $9.4 million for a 6,250 gallon per minute facility using IX to treat groundwater. The commenter's reported cost of $9.2 million for the N-Wells facility falls within this range. The EPA's updated cost curves estimate a range of $2.2 million to $3.4 million for a 1,200 gallon per minute facility and $2.9 million to $4.5 million for a 2,000 gallon per minute facility. The commenter's reported costs of $5.12 million and $9.63 million for the Valley Center Well facility and the Santa Clara and Honby Wells facilities, respectively, exceed these ranges. However, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for this facility would be similar to the typical values assumed in the EPA's estimate. The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046167)

6.2 Accounting for State Level Regulatory Costs

The model includes consideration of state regulatory actions that may have driven PWSs to remove PFAS already. Consideration of state regulatory actions is necessary to characterize the compliance costs of a potential NPDWR for PFAS. All state regulations incorporated into modeled cost output are shown in Table 6-2

Table 6-2 State Maximum Contaminant Levels Modeled for State Regulatory Cost Estimate

[Table 6-2: Docket ID: EPA-HQ-OW-2022-0114-1759]

To differentiate federal regulatory costs from costs incurred because of existing state regulations, the cost tool includes an input sheet for all existing state MCLs as either individual limits or group totals. The Visual Basic Script references both the state MCLs and the projected federal MCLs. In the absence of a federal regulation (or if the state MCL is more stringent than the federal MCL), the cost tool generates costs for treatment to comply with the state MCLs on the input sheet. An example of this is shown in Table 6-3, which displays treatment costs incurred as a result of state regulations shown in Table 6-2.

Table 6-3 Summary of Estimated Costs Associated with State PFAS MCLs

[Table 6-3: Docket ID: EPA-HQ-OW-2022-0114-1759]

EPA Response: Although the commenter includes these estimates of the costs to PWSs to comply with existing state PFAS regulations, it does not assume that PWSs are already in compliance with state standards. This approach overestimates federal rule compliance costs for water systems in states with existing state standards. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046162)

5.1.2 Water Quality Considerations Incorporated

5.1.2.1 Influent and Effluent PFAS Levels

For each PWS in the occurrence database, any single PFAS monitoring result above either existing state or potential regulatory limit was assumed to incur a capital expenditure for treatment. Data down to the resolution of each individual source was not considered for this modeling effort; instead, the number of projected water treatment facilities per system was based on the EPTDS factors as summarized in the previous section. Maximum PFAS monitoring data were assumed to compel treatment for the PWS as a whole and, thus, all the projected water treatment facilities. The average PFAS monitoring data were used to estimate long-term costs of removal (annual O&M costs).

The target effluent PFAS levels for treatment was determined as an input percentage of a potential regulatory limit. For example, treatment could be triggered at 80, 90, or 100 percent of the potential regulatory level. For this work, a threshold of 80 percent was used in alignment with previous practice for estimating costs of potential regulations for drinking water, since water systems will target and operate below this threshold to ensure that the limit is not exceeded if the water quality suddenly increases.

5.1.2.2 Other Water Quality Considerations

Other water quality contaminants may impact PFAS treatment performance (and therefore costs), such as TOC and manganese. The longevity of GAC media, IX resin, and membrane operations are significantly affected by the quality of the source. Differences in source water quality parameters not specifically included (e.g., TOC, sulfate, pH, alkalinity, etc.) with pertinence to

design or performance were reflected in cost by varying design parameters and treatment system performance according to probability functions using Monte Carlo analysis. This is primarily controlled through variation of the treatment performance factors (e.g., EBCT, surface area loading rate) to reflect less or more challenging water quality characteristics. The methodology for the Monte Carlo Simulation is covered in Section 5.2. Work is in progress to estimate costs associated with removing manganese and will be made available at a later date.

EPA Response: The EPA disagrees with some of the assumptions used by the commenter with regard to PFAS occurrence and media bed life. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046160)

5.0 Individual Treatment Facility Cost Methodology

The next step in estimating the national costs to remove PFAS from drinking water is to use the occurrence database to estimate the costs associated with treatment for individual PWSs. The following subsections summarize how capital, operating, and life-cycle costs are calculated for each system and for each technology.

The spreadsheet tool developed to perform this task accepts inputs for individual or combined target effluent levels for the six PFAS compounds represented in the database. After both occurrence data and potential regulatory levels are input, Visual Basic scripts within Excel may be initiated by a user to run a Monte Carlo analysis and generate a 10th percentile, 90th percentile, and most probable costs for the capital, operations and maintenance (O&M), and life-cycle costs for a typical entry point to the distribution system (EPTDS) for each PWS in the database. For each system, the tool selects the treatment technology with the lowest life-cycle cost.

This methodology assumes installation of a treatment system at each EPTDS associated with PWSIDs where the maximum PFAS concentration is greater than the potential regulatory level for the corresponding PFAS. The details of individual system and EPTDS cost methodology are described in the following subsections. A list of output fields generated by the cost modeling tool for each PWS with occurrence data is shown in Table 5-1.

Table 5-1 Model Outputs for Individual PWS with Occurrence Data

[Table 5-1: Docket ID: EPA-HQ-OW-2022-0114-1759]

EPA Response: The EPA disagrees with the commenter's assumption that every EPTDS at a system will require treatment if not every EPTDS at a system exceeds the MCL. For example, if a utility has four entry points, but only one entry point exceeds an MCL, only that entry point must be treated (or other action must be taken). Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046164)

5.3 Capital Cost Calculation

Capital costs were calculated for each EPTDS of a PWS based on the design flow per EPTDS (refer to Equation 1). The design flow was used for capital costs estimates since equipment should be sized for peak treatment flow rates. Costs were independently calculated for IX, GAC vessels, GAC basins, and RO as described in the following subsections. Capital costs generated for individual systems represent a Class 5 Association for the Advancement of Cost Engineering (AACE) estimate, at approximately 1 to 2 percent maturity level of deliverable definition.

5.3.1 Major Hardware Components

5.3.1.1 GAC Gravity Basins

The major cost components incorporated into the capital cost estimate for this option are the concrete basins themselves, an influent pump station, media for the initial fill, and a building to house the system. The design assumptions for each element are summarized in Subsection 3.1.2.

The concrete basin includes costs for influent and effluent piping, isolation valves, and monitoring instruments. Using the design flow rate and the SLR, a required surface area for filtration is calculated and used to determine the appropriate number of basin cells and anticipated basin dimensions for costing.

Once number and size of basins are calculated, the design flow and specified EBCT is used to determine the volume of media needed. Cost of media was determined by converting volume to mass using an average GAC density of 0.5 g/cc and an average cost per pound of $1.40. It should be noted that cost changes were not projected into the cost model resulting from increased demand for adsorbent media.

The pump station includes costs for influent pumps, backwash pumps, an influent wetwell, and a backwash recovery basin. The independent design inputs for the influent pumps are total dynamic head (TDH) and total number of pumps. The independent design parameters for backwash pump and backwash recovery basin calculations are backwash loading rate, backwash duration, backwash frequency, and backwash pump TDH. Costs for backwash pumping include a single duty pump and a single standby pump.

The sum of the square footage required for the contactor basins was multiplied by a sizing factor of two to account for the ancillary equipment and space for access and maintenance. Pump station square footage, including all pumps and the wet well, was estimated by benchmarking design flow against previous designs. Building area was assumed to be the sum of contactor facility area (including sizing factor), pump station area, and backwash recovery basin area (assumed to be indoors). The building cost was assumed to be $200/sf.

Black & Veatch utilized empirically derived cost curves as a function of size from several decades of infrastructure project design and delivery to estimate cost for these major

components. A curve for concrete basins provides cost as a function of square footage. A curve for steel tanks provides costs as a function of volume in gallons, and a curve for pumps provides cost as a function of horsepower.

Installation fees were included at 20 percent for all major equipment components, as summarized in Table 5-5. These cost factors are identical to those for GAC and IX pressure vessels.

Table 5-5 GAC and IX Equipment Installation Cost Factors

[Table 5-5: Docket ID: EPA-HQ-OW-2022-0114-1759]

5.3.1.2 GAC, IX and Manganese Pretreatment Pressure Vessels

Capital equipment costs were calculated using the total contactor footprint, contactor building footprint, and media volume required. Capital costs were calculated for the ancillary pump stations using the building footprint, number and size of influent pumps, backwash pumps, influent wetwell, and backwash recovery basin. The model incorporated a building cost of $200/ft2. The installation fees for the various components are the same as those summarized in Table 5-6.

Calculated capital cost for manganese pretreatment for each system was considered a stand-alone output and was not included in the capital, operational, or life-cycle cost outputs for PFAS treatment.

5.3.1.3 Reverse Osmosis

Capital costs were calculated for the RO system and building, low- and high-pressure feed pumps and their associated building, storage tanks, cartridge filters, chemical treatment system, decarbonation system, and brine disposal. The model incorporated a building cost of $200/ft2. The installation fees for the various components are summarized in Table 5-6.

Table 5-6 RO Equipment Installation Cost Factors

[Table 5-6: Docket ID: EPA-HQ-OW-2022-0114-1759]

5.3.1.4 Additional Capital Costs

In addition to equipment costs, the capital costs for GAC, IX, RO, and manganese pretreatment included additional project costs (site work, yard piping, electrical, and instrumentation and controls), contractor markup costs, and non-construction costs. The multipliers used for each of these factors are summarized in Table 5-7.

Table 5-7 Additional Capital Cost Assumptions

[Table 5-7: Docket ID: EPA-HQ-OW-2022-0114-1759]

5.4 Operating Cost Calculation

The operational costs for GAC, IX, and RO were calculated using the average flow rate for each EPTDS, as represented by the average flow per water system divided by the number of EPTDS. Whereas capital costs were driven by maximum PFAS levels, the operating costs incurred were driven by the average influent PFAS concentrations to reflect long-term operating conditions. The tool allows entry of a treatment goal expressed as a percent of the potential regulatory limit, and the resulting target concentration serves as the effluent concentration trigger for replacement of media. This target may be expressed either as a concentration of a single PFAS compound or as a combination of compounds.

Operating costs that were considered for this work included replacement costs (using the calculated bed volumes to breakthrough or media replacement frequency), power consumption in the pumps and buildings, maintenance costs, waste disposal, and labor costs. Analytical monitoring costs were not included in the life-cycle cost calculations. Table 5-8 provides an overview of the O&M cost assumptions.

Table 5-8 O&M Cost Assumptions

[Table 5-8: Docket ID: EPA-HQ-OW-2022-0114-1759]

EPA Response: The EPA disagrees with many of the assumptions presented in this section of the comment and the AWWA's B&V that was used to develop the commenter's cost estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document which discusses specifically why the EPA disagrees with many of these assumptions.

American Water Works Association (AWWA) (Doc. #1759, SBC-046168)

7.0 Summary of Results

A summary of the cost model results for various potential federal MCL alternatives on the national and household level is presented in this section.

7.1 National Cost Estimates

The national cost modeling tool was used to evaluate both the national financial burdens on communities from PFAS drinking water contamination (the National Burden) and the costs for water systems to comply with a potential NPDWR for PFAS (NPDWR Compliance Costs).

The National Burden is reflective of the total, cumulative impact to water systems and communities across the United States from PFAS contamination of drinking water. It is calculated by estimating the drinking water PFAS treatment costs associated with the number of systems with PFAS occurrence data above the target limit. The National Burden assumes the same target limit for water systems across all states and includes systems in states with existing drinking water regulations for PFAS. The NPDWR Compliance Costs are determined by estimating the national financial burden and excluding costs for systems already triggered into treatment by existing drinking water regulations at the state level. The difference between the

National Burden and the NPDWR Compliance Costs is therefore calculated using the data presented in Table 6-3.

The National Burden and NPDWR Compliance Costs were estimated for two different scenarios. The first scenario is based on a target PFOA and PFOS level of 4 ppt each. The second scenario is based on target PFOA and PFOS levels of 10 ppt each.

An overview of the present value of the life-cycle cost for the National Burden and NPDWR compliance cost for each of these scenarios is displayed on Figure 7-1.

[Figure 7-1: Docket ID: EPA-HQ-OW-2022-0114-1759]

Figure 7-1 Summary of Present Value of Life-Cycle Costs for National Burdens and NPDWR Compliance Costs for Each Scenario based on a 3% discount rate

Annualized costs were also calculated using Formula 3. An overview of the National Burden and NPDWR Compliance Annualized Cost for each of these scenarios is presented on Figure 7-2.

[Formula 3: Docket ID: EPA-HQ-OW-2022-0114-1759]

[Figure 7-2: Docket ID: EPA-HQ-OW-2022-0114-1759]

Figure 7-2 Summary of Annualized Costs for National Burdens and NPDWR Compliance for Each Scenario based on a 3% discount rate

A more detailed breakdown of these costs by system size is presented in Appendix A.

7.2 Household Financial Impacts

As part of this analysis, the annual financial impacts to individual households from costs associated with the installation and operation of drinking water treatment facilities for PFAS were determined. The financial impacts to individual households will vary by specific PFAS levels, system size, and other factors. Additionally, the impacts to individual households arising from a potential NPDWR will differ depending on whether there is an existing state regulation for PFAS in drinking water. Table 7-1 shows the individual household impacts as a function of system size for each of the three scenarios discussed in Section 7.1. These household level cost impacts are based on the annualized costs for each system size and an average of 2.6 persons per household and incorporate estimated average service populations for each size category based on SDWIS data. The range of household level costs in the table is reflective of communities where new treatment facilities will need to be installed and operated.

Table 7-1 Annual Costs to Household for Removing PFAS from Drinking Water

[Table 7-1: Docket ID: EPA-HQ-OW-2022-0114-1759]

Appendix A. Modeled Cost MCL and Discount Rate Comparison Tables

Table A-5 Annualized NPDWR Costs by System Size per Discount Rate

[Table A-5: Docket ID: EPA-HQ-OW-2022-0114-1759]

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and therefore with the costs presented in this section of the comment. Please see section 13.3.3 of the EPA response in this *Response to Comments* document which discusses specifically why the EPA disagrees with many of these assumptions.

American Water Works Association (AWWA) (Doc. #1759, SBC-046152)

3.1.2 Assumptions for Cost Estimation

The cost model includes capital costs, annual operating and maintenance costs, life-cycle costs, and annualized costs. The assumptions that drove the results of those cost estimates are summarized in this section.

The costs for GAC contactors depend on the contactor type, size, number, and ancillary processes such as backwash pumps/recovery basins and contactor influent pumps/wet wells. The primary process design assumptions for each of these factors are summarized in Table 3-1.

Table 3-1 GAC Design Process Assumptions

[Table 3-1: Docket ID: EPA-HQ-OW-2022-0114-1759]

EPA Response: The EPA disagrees with several of the assumptions presented in the commenter's Table 3-1. Please see section 13.3.3 of the EPA response in this *Response to Comments* document which discusses why the EPA disagrees with many of the assumptions in this table.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042815)

LCA understands there are some significant concerns regarding EPA's methods to evaluate costs and benefits of this proposed rule, including calculations of household affordability and other concerns discussed in more detail in comments to be provided by the American Water Works Association (AWWA).

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the affordability analysis, please see section 13.10 in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042897)

Cost:

MWWA believes that EPA has grossly underestimated the costs associated with compliance with the proposed rule. We believe the technical memorandum [FN21: WITAF 56 TECHNICAL MEMORANDUM, PFAS National Cost Model Report, B&V PROJECT NO. 409850w.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=202303-14-102450-257] prepared by Black & Veatch on behalf of American Water Works Association (AWWA WITAF 56) is a more accurate depiction of the costs that will be incurred. For example, the most recent estimate by Black & Veatch suggests that the annualized costs of the rule could exceed $3.2 billion based on a PFOA and PFOS MCL of 4 ppt each.

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043634)

ATTACHMENT 1:

Detailed Technical Comments

Detailed Technical Comments on the Proposed PFAS National Primary Drinking Water Regulation

May 26 2023

Attachment 1:

Detailed Technical Comments on the Proposed PFAS National Primary Drinking Water Regulation

May 26, 2023

1) Cost Benefit Analysis

1. The USPEA Economic Analysis (March 2023) significantly underestimated the cost impact of the proposed Rule on utilities. EPA costs are significantly less than the number presented in the independent analysis conducted by AWWA and cost estimates conducted for BWWB.

EPA Response: Please see section 13.3.3 in this *Response to Comments* document for the EPA's response regarding the EPA's estimates of national treatment costs and response to AWWA's B&V report. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. While the EPA has considered the input from the AWWA report and other public comments about the EPA's estimated rule costs, the EPA does not think it accurate to describe the AWWA report as "independent." Please see the EPA response to comment Doc. #1841, SBC-044850 in section 5.1.3 in this *Response to Comments* document for further discussion.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043637)

C. There is no safety factor guidance offered by the proposed PFAS rule. Many utilities consider a safety factor with regards to MCLs as a critical piece of their strategic planning. If a safety factor is considered, it is possible that a greater number of utilities will necessitate PFAS treatment technology, potentially increasing national compliance costs. It is recommended that the USEPA consider, in its cost model, that utilities are likely to employ a safety factor and implement treatment at PFAS levels below the proposed MCLs.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document for the EPA's response to comments on the EPA's national cost estimates. Additionally, the EPA would like to clarify that as stated in Chapter 5 of the EA, the EPA does consider a margin of safety, and assumes all PWS installing treatment to comply with the rule will target finished water concentrations at 80 percent of the MCLs.

Massachusetts Water Resources Authority (Doc. #1645, SBC-043287)

e. EPA's Cost Model Underestimates the Cost of the Proposed Rule

EPA underestimates the cost of drinking water treatment to remove PFOA and PFOS. Cost models prepared for AWWA by Black & Veatch, as well as examples of previously built PFAS treatment systems differ significantly from EPA's model. EPA's benefit cost analysis must accurately evaluate the cost impact of the rule to make a sound decision on the appropriateness of the rule requirements. In Massachusetts alone, the Massachusetts Department of Environmental Protection (MassDEP) estimates that 29 percent of all community (COM) and non-transient non-community (NTNC) systems would be impacted by this proposed rulemaking. There are almost 1,600 COM and NTNC systems in Massachusetts; approximately 450 of these PWSs would need to install treatment under EPA's proposed rule. Massachusetts has committed $209 million in State Revolving Fund loans to fund 24 PFAS treatment projects. That means that

costs for the installation of PFAS treatment in Massachusetts alone could be $4 billion. The proposed rule also fails to fully consider the detrimental implications associated with additional electricity usage, carbon emissions, fuel consumption and disposal costs; these are added costs to rate payers and to the environment.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document regarding the AWWA B&V report and the EPA's estimates of national treatment costs for the final rule. The EPA notes that based on state occurrence data described in the *Occurrence Technical Support Document* (USEPA, 2024a), Massachusetts has one of the higher rates of PFAS occurrence compared to other states for which the EPA has state data. Furthermore, extrapolating from individual utilities or states' experience is not an appropriate method to estimate national costs. In addition, the comment lacks sufficient detail to compare these costs to the results of the EPA's WBS and SafeWater models. With respect to the commenter's suggestion that the rule consider implications associated with electricity use, carbon emissions, fuel consumption and disposal costs, please see section 13.11 of the EPA response in this *Response to Comments* document.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043327)

Comment 3

EPA's proposed cost model includes treatment equipment; however, it does not appear to adequately include the added costs of compliance, site developments, engineering, pilot-testing, etc. Costs incurred by publicly owned treatment systems with costs ultimately transferred to residents relying on these essential services.

EPA Response: Please seesections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document. The commenter is incorrect that the WBS models do not include costs for land, permits and pilot testing, equipment installation, process engineering and contractor's overhead and profit. The WBS models do include costs for land, permits and pilot testing, equipment installation, process engineering and contractor's overhead and profit; see Chapter 5 of the EA for more information.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045918)

F. EPA's models used in its cost assessment are flawed

EPA's models underestimate the costs of installed groundwater systems, surface water systems, GAC systems, reverse osmosis, or ion-exchange systems, and they do not come close to a comparable model by a major engineering firm that designs and installs PFAS treatment systems. One principal reason that EPA's models may deviate from reality is because they are outdated—they were developed from 2006 to 2012 [FN171: U.S. EPA, "Best Available Technologies and Small System Compliance Technologies for Per- and Polyfluoroalkyl Substances (PFAS) in

Drinking Water," February 2023.]. Another reason could be the lack of adequate independent peer review. EPA sought a three-person, letter peer review of the GAC model around 2006 and then made additional changes to the model that have not been peer reviewed [FN172: U.S. EPA, "Work Breakdown Structure-Based Cost Model for Granular Activated Carbon Drinking Water Treatment," February 2023.]. EPA states that the IX model received even less of a comprehensive review since reviewers did not review a complete model – more than 10 years ago [FN173: U.S. EPA, "Work Breakdown Structure-Based Cost Model for Ion Exchange Treatment of Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water," February 2023.]. EPA must use more up to date modeling and inputs in its cost estimates.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC6081)

1. EPA needs to provide more information as to several aspects of its cost analysis.

We have a number of questions and comments concerning EPA's compliance cost analysis, which are set forth below.

a) Did EPA consider the costs for installing new or expanded public water systems (PWS)? In EPA's cost/benefit model, the Agency includes the costs of monitoring/ compliance/treatment for PWS and non-community, non-transient water systems (NCNTWS) but it does not include any review of the potential compliance costs for new or expanding systems. This should include consideration of situations where, in response to PFAS concerns, municipal water supplies are being extended to rural areas that primarily had relied on individual drinking water wells. For example, centralization is part of the Biden Administration's strategy for addressing PFAS in drinking water and the Bipartisan Infrastructure Law provides funding that can be used for such purposes. FACT SHEET: Biden-Harris Administration Combatting PFAS Pollution to Safeguard Clean Drinking Water for All Americans (June 15, 2022), available atw.whitehouse.gov/briefing-room/statements-releases/2022/06/15/fact-sheet-biden-harris-administration-combatting-pfas-pollution-tosafeguard-clean-drinking-water-for-all-americans/. OMB Circular A-4 requires agencies to include in its baseline consideration of the evolution of the impacted market. Circular A-4, at 15. At a minimum, EPA should conduct a sensitivity analysis to evaluate the impact of the capital investments as well as the ongoing operation/maintenance costs for new and expanded systems, as well as increased treatment costs due to increased volumes. These costs will likely be significant – millions or tens of millions of dollars per facility, depending on the size of the system. EPA must include an analysis of these costs – and the benefits - at the different levels of proposed MCLs (4 ppt, 5 ppt, 10 ppt), since the level chosen could greatly affect the scope of any new or expanded system and the related costs.

EPA Response: Please see section 13.3 of the EPA response in this *Response to Comments* document. The EPA included in its cost analysis non-treatment options, such as new sources of water including regionalization. The costs of these non-treatment options were

included in the cost of the rule. The EPA disagrees that it should consider the cost of system expansion to serve new customers as a cost of the rule when the expansion is not required under the rule.

American Water Works Company Inc. (Doc. #1608, SBC-044001)

Further, the U.S. EPA's reporting of only annualized cost makes it very difficult to compare to more typical utility metrics. American Water recommends that the U.S. EPA's cost analysis provide a simple comparison of total capital cost for facilities in each capacity range, as well as a "cost per million gallons" of water treated. This will facilitate more direct comparison to the cost metrics that utilities typically utilize for rate impact analyses.

According to the backup document entitled "Economic Analysis for the Proposed PFAS NPDWR (EPA822-P-23-001)" available through the U.S. EPA's website, almost 3,500 individual cost equations were developed using the U.S. EPA's Work Breakdown Structure Cost Model to derive the estimated cost impact. Although the U.S. EPA provides copious written documentation on the methodologies used, it is difficult to understand how the U.S. EPA converted the combined capital and operating costs for the estimated 3,400-6,300 systems it projects may be impacted by the proposed rule into an annual cost of $772 million to $1.20 billion. This total represents an average of $120K to $350K per year per system based on this range of costs and systems, but $11 - $12 per person per year based on the 70 to 94 million people referenced as being affected in Section VI.F in the Supplementary Information section of the draft rule. Assuming there are approximately three people per household, this means the average annual customer bill impact would be less than $40 per household. By comparison, Table 22 reports the annual cost per household could range between $121 and $727 depending on system size and whether GAC or AIX is the technology selected. It is difficult to understand the basis for the total cost annual cost of $772 million to $1.20 billion when expressed this way.

EPA Response: Please see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document. With regard to presentation of costs in the EA, the EPA presents results as annualized national and system level costs in order to readily compare results to the quantified national benefits of the rule. Please see the EPA response to comment Doc. #1738, SBC-046008 in section 5.1.3 in this *Response to Comments* document, which includes WBS results presented in dollars per mgd. Additionally, the EPA provided two tables of household costs. The first includes all households that are served by CWSs. The second only included households that are served by CWSs that exceed one or more MCLs and must take action to comply with the rule. This information was provided to increase transparency of the cost impacts of the rule. However, not all compliance costs are attributable to residential customers as most water utilities also serve commercial and industrial customers. Therefore, to calculate household costs for a PWS, the EPA first calculates the cost of compliance per gallon of water produced. Then, to calculate household costs the EPA multiplies the cost per gallon by the average annual household water consumption.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045914)

D. EPA has not appropriately considered costs and implications for NTNCWSs

EPA's proposed rule will impact over 17,000 NTNCWSs that EPA intends to hold to the same regulatory requirements, including monitoring, sampling, and compliance, as community water systems (CWS). EPA recognizes that 99 percent of all NTNCWSs serve 3,300 or fewer people, with only two NTNCWSs serving more than 50,000 people [FN159: See EPA Economic Analysis of the Proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances, 2023, at page 4-7 and Table 4-3.]. Given the small size of the NTNCWSs and the costly monitoring and treatment that will be required, relative compliance costs will be greatly increased under this proposed rule. In fact, in some rural NTNCWS that serve remote industrial or other needs, the costs could threaten the viability of these systems and the users that depend on them. Additionally, EPA's assessment does not consider the amount of water used by NTNCWSs or the potential treatment costs. NTNCWSs are a diverse group, including agricultural operations, industrial facilities, and many other businesses, which may use water far in excess of what may be expected based on the number of personnel each NTNCWS serves. Thus, any analysis of the potential cost impacts for treatment must be based on the volume of water needed to be treated, not merely the number of people served. The cost of treatment for many of these locations may far exceed the treatment to be expected based solely on the number of ratepayers.

Yet, EPA chose not to specifically analyze the proposed rule's economic impact on NTNCWSs [Fn160: Id. at 9-10.] and instead, based on a 2008 EPA Assessment, placed the cost of SDWA compliance at less than 1 percent of NTNCWS revenue [Fn161: Id. at 9-10.]. And EPA assumes, with no supporting data, that the rise in compliance costs for the NTNCWSs will be no more than an additional 1 percent [Fn162: Id. at 9-10.]. EPA's choice to forego actual analysis of impacts to the smallest systems is inappropriate. Detailed analysis on the impacts to NTNCWSs should be conducted to inform the cost/benefit analysis. For example, treating PFAS with GAC at the low levels proposed is much more costly than current treatment for currently regulated contaminants, and a 2008 study is not a reliable indicator of future costs. Lack of both actual data on occurrence in these systems and reliable information on cost of compliance makes finalizing the MCL as to NTNCWSs too uncertain.

EPA Response: Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA disagrees that the agency has not analyzed the impacts of the PFAS NPDWR on NTNCWS. The EPA has used both "actual data on occurrence" at NTNCWSs from UCMR 3 and state data, as well as "reliable information on costs" to NTNCWSs using the WBS treatment cost models to assess the impact of the rule on NTNCWSs. As the EPA stated in the proposal, the EPA lacks information on the volume of water produced or revenues of NTNCWS, therefore the agency does not take the same approach used for CWSs in the Significant Economic Impact on a Substantial Number of Small Entities (SISNOSE) screening analysis where costs are compared to 1 and 3 percent of revenues. Instead, the EPA used the best

available data, the EPA's Assessment of the Vulnerability of Noncommunity Water Systems to SDWA Cost Increases (USEPA, 1998), which showed that NTNCWSs are less vulnerable to SDWA related increases than a typical CWS. The EPA proceeded with the SBAR Panel process, for more information please see section XIII.C of the FRN.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046019)

Cost Estimates

EPA Cost Estimates

The analysis then analyzes EPA's cost estimates at system size levels. To estimate a combined annualized cost per CWS estimate across both water source types, the following approach is employed. First, using the CWS inventory values by water source and system size, the analysis estimates, for each system size category, the percentage of total systems that rely on GW and those that rely on SW (see Table 11). These percentages are applied to EPA's estimated mean annualized cost per CWS and water source.

Table 11: CWS ratios

[Table 11: see docket ID EPA-HQ-OW-2022-0114-1738]

[FN107: U.S. Environmental Protection Agency, 4–7; U.S. Environmental Protection Agency, "SDWIS Federal Reporting Services Fourth Quarter 2021 Dataset."]

[FN108: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation Appendices," March 2023, tbl. C–9.]

[FN109: EPA does not present average or specific costs for systems >1 M. EPA identified 25 PWSs serving >1M people based on SDWIS/Fed estimates. Rather than model treatment costs using the MCMC model PFAS values, UCMR3 data & system consumer confidence reports are used to obtain entry point PFAS values. U.S. Environmental Protection Agency, app. N.1.]

Black and Veatch Cost Estimates

Black and Veatch (B&V) recently developed a national cost estimate for water systems to remove PFOA and PFOS from drinking water and comply with a proposed NPDWR using cost data and design methodology to capture accurate system-level cost estimates for drinking water treatment [FN110: Black & Veatch, "PFAS National Cost Model Report."]

Relying on B&V's cost estimates for systems presents two main advantages. First, it relies on recent data inputs, overcoming the dollar year limitation of EPA's EA discussed earlier in the report. Producer prices have risen as a result of supply shortages, global trade disruptions, and financial stimulus for the economy during the pandemic. Thus, B&V's analysis is more consistent with current conditions. The second advantage to using B&V's cost estimates is that

the inputs and results are based on more recent engineering experience with building and designing treatment systems:

The spreadsheet tool developed to perform this task accepts inputs for individual or combined target effluent levels for the six PFAS compounds represented in the database. After both occurrence data and potential regulatory levels are input, Visual Basic scripts within Excel may be initiated by a user to run a Monte Carlo analysis and generate a 10th percentile, 90th percentile, and most probable costs for the capital, operations and maintenance (O&M), and life-cycle costs for a typical entry point to the distribution system (EPTDS) for each PWS in the database. For each system, the tool selects the treatment technology with the lowest life-cycle cost [FN111: Black & Veatch, 14.].

Moreover, the capital costs for a CWS are based on the design flow per entry point to the distribution system (EPTDS) [FN112: Black & Veatch, 20.]. The design flow was used for capital cost estimates since equipment should be sized for peak treatment flow rates. Costs were independently calculated for IX, GAC vessels, GAC basins, and reverse osmosis (RO). Capital costs generated for individual systems represent a Class 5 Association for the Advancement of Cost Engineering (AACE) estimate, at approximately one to two percent maturity level of deliverable definition.

As shown by the expert analysis by a water sector engineering firm, EPA's cost models substantially underestimate the installation and operating costs of PFAS treatment systems. While EPA's cost estimates range from $16,000 to $3.2 M, B&V's estimates are between $250,000 and $11 million [FN113: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation Appendices," tbl. C–9; Black & Veatch, "PFAS National Cost Model Report," tbl. A-1.]. As shown in Table 12, B&V's estimates are between four and 16 times larger than EPA's estimates for the same system size.

These ratio differences are stark. Assuming 100 gallons of water used daily per person and based on average population served by CWS size, we estimate total annual gallons per CWS. We compare this to the annualized cost per CWS using both EPA and B&V estimates and include the results in Table 12. For the smallest systems serving populations <100 people, the additional annual cost per thousand gallons of water as a result of EPA's proposed rule is approximately $110 based on B&V's cost estimates, compared to $7.1/1,000 gallons/year based on EPA's cost estimates.

Table 12: Annualized Cost per CWSs that Treat or Change Water Source: Comparison between EPA's and B&V's Estimates

[Table 12: see docket ID EPA-HQ-OW-2022-0114-1738]

Annualized Treatment Costs

To calculate total annual treatment cost for the proposed rule, the analysis multiplies the cost estimates from B&V by the estimated number of systems requiring treatment from EPA's

affected population estimate. Table 13 summarizes the estimated annualized treatment costs by CWS size for systems that will have to install treatment under EPA's proposed rule. Treatment costs are greatest for systems serving between 10,000 and 50,000 people ($2.4 billion) and those serving between 100,000 and 1 million people ($1.4 billion). Nationally, across all 4,400 estimated affected systems, costs are estimated at $6.4 billion each year.

Table 13: National Annual Treatment Cost by CWS Size for Affected Systems

[Table 13: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA disagrees that there are "two main advantages" to relying on the B&V estimates. First, the EPA has updated the dollar year in the WBS cost curves to 2022 dollars for the final rule, removing commenter's objection to using 2020 dollars in the WBS models (the most recent values/indices available when the EPA developed the proposed rule and at the time of rule proposal: please see section 13.3.3 of the EPA response in this *Response to Comments* document for further discussion). Secondly, the EPA's unit cost estimates are based on the best available cost data and rely on recent information from treatment technology vendors; for more information, please see section 13.3.3 of the EPA response in this *Response to Comments* document. Finally, the EPA strongly disagrees with this commenter's overall statements about the costs of the rule nationally (i.e., costs of $6.4 billion dollars a year) as discussed in the Policy Navigation Group (PNG) report. The PNG report claims to rely on the B&V annual treatment cost per affected PWS. However, the EPA's review of the PNG report finds substantial discrepancies between the annual treatment costs cited and the values presented in the B&V report that indicate the PNG report may produce unreliable estimates. As shown in the table below, the EPA has calculated the average annual cost per affected PWS based on the B&V report. For most system size categories, the annual treatment cost per affected PWS used by PNG is significantly greater than the values presented in the B&V study. The PNG provides no documentation or other information that explains where these extensive cost increases originate. Therefore, from the information provided in the commenter's letter, it's not clear how the PNG reportedly used B&V cost values and arrived a national cost estimate more than double that of the B&V study, which concludes national treatment costs of the NPDWR would be 2.5 billion to 3.2 billion at the 3 and 7 percent discount rates respectively.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046029)

3. CONCLUSIONS

This report assessed EPA's approach to estimate the social benefits and costs of its proposed rule to federal requirements for regulatory analysis and best practices in the field. We determine that EPA's cost models substantially underestimate the installation and O&M costs of PFAS treatment systems. We provide data from experts in the water sector engineering field to show how substantial the costs of EPA's proposed rule will actually be. We also provide evidence from actual cost data from AMWA members to show the extent of EPA's underestimation. EPA also fails to account for other social costs such as additional costs from water rate increases and the non-market costs of greater greenhouse gas emissions.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA also disagrees with the Association of Metropolitan Water Agencies' (AMWA's) representation of national costs associated with the rule, please see the EPA response to comment Doc. #1738, SBC-046019 and SBC-046008 in section 13.3.3 in this *Response to Comments* document for more information. For the EPA's response to comments on greenhouse gas emissions associated with the rule, please see section 13.11 in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046008)

2. Evaluation of EPA's Benefit-Cost Methodologies Costs

While there are numerous individual problems with EPA's cost models, the sum of these issues is more important than the laundry list of flaws. As the saying goes, "all models are wrong; some models are useful." The fundamental problem with EPA's model is that it is not useful – it fails to predict actual, installed treatment systems' costs by a substantial margin. EPA's models underestimate the costs of installed groundwater systems, surface water systems, granular activated carbon (GAC) systems, reverse osmosis, or ion-exchange systems. It does not come close to a comparable model by a major engineering firm that designs and installs PFAS treatment systems.

One principal reason that EPA's models may deviate from reality may be their vintage. As EPA states, the models were developed from 2006 to 2012 [FN13: U.S. Environmental Protection Agency, "Best Available Technologies and Small System Compliance Technologies for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water," February 2023.]. Another reason could be the lack of adequate independent peer review. According to the background documents, EPA sought a three-person, letter peer review of the GAC model around 2006 and then made additional changes to the model that have not been peer reviewed [FN14: U.S. Environmental Protection Agency, "Work Breakdown Structure-Based Cost Model for Granular Activated Carbon Drinking Water Treatment," February 2023.]. EPA states that the IX model received even less of a comprehensive review since reviewers did not review a complete model – more than 10 years ago [FN15: U.S. Environmental Protection Agency, "Work Breakdown Structure-Based Cost Model for Ion Exchange Treatment of Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water," February 2023.].

The AMWA and the AWWA surveyed its members to obtain recent cost data on installed PFAS treatment systems at drinking water treatment plants. Figure 1 plots the ratio of capital costs per the treatment system capacity (in millions of gallons per day) reported by 60 systems. Figure 1 also provides EPA's estimated capital costs for the comparable treatment technique and system size. As shown, EPA's values are most often below reported capital costs. On average across the 60 systems, EPA's estimate is 2.9 times lower than reported values.

Figure 1: Comparison of the Capital Costs of Actual Installed Treatment Systems with EPA Model Results ($/MGD)

[Figure 1: see docket ID EPA-HQ-OW-2022-0114-1738]

The discrepancy is greater for small treatment systems, the ones most likely to be installed due to this regulatory action. Figure 2 shows the detail of Figure 1 for systems below 50 MGD. For systems under 1 MGD, the average ratio between actual system capital expenditures and EPA's is 5.1. For systems under 2 MGD, EPA's models underestimate actual capital expenditures by a factor of 3.6.

Figure 2: Comparison of the Capital Costs of Actual Installed Treatment Systems with EPA Model Results for Systems Below 50 MGD ($/MGD)

[Figure 2: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA also omits other, non-market social costs. Consuming real resources like activated carbon, electricity, and transportation services have costs that are not captured in their market price. EPA strives to reduce the adverse human health and environmental effects of the non-market social costs of pollution. By requiring treatment for certain PFAS, EPA's rule will lead to increased pollution from transportation, electricity generation, and other construction and operations activity. While the social costs of this additional pollution may be justified by the rule's benefits, EPA must estimate these social costs to demonstrate this claim.

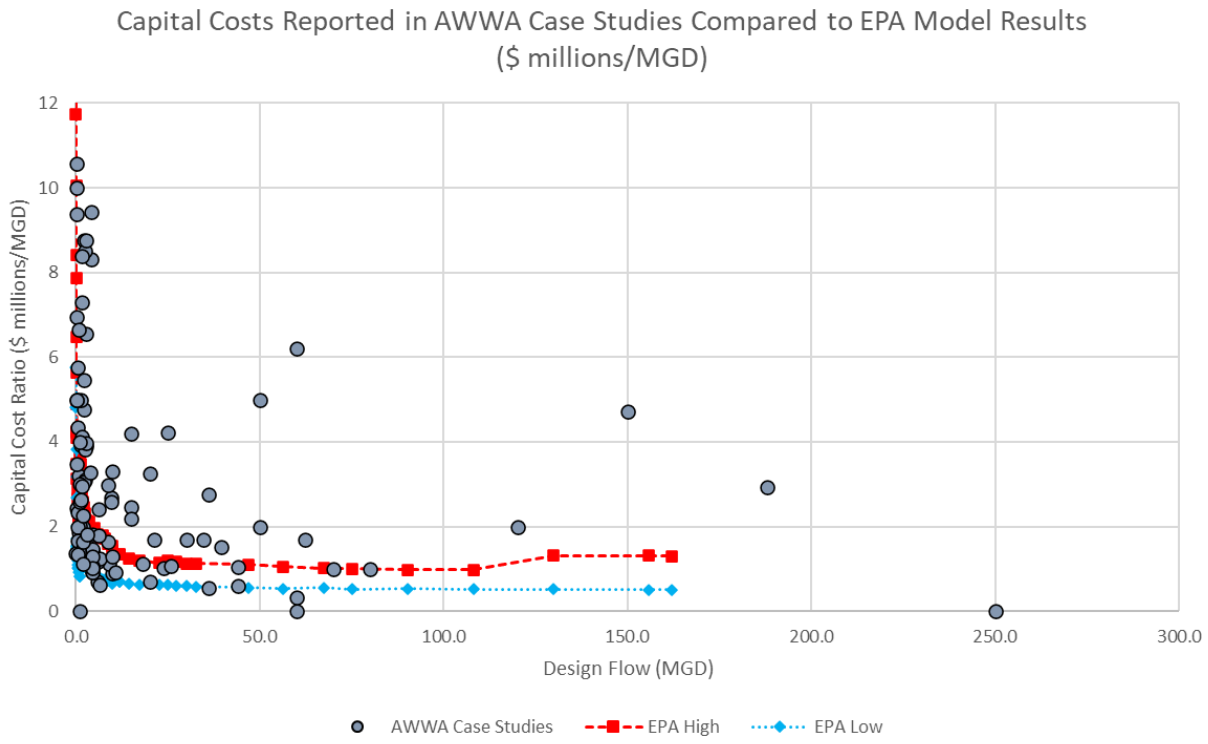
EPA Response: Regarding the commenter's assertion that the EPA's models are outdated, please see section 13.3.3 of the EPA response in this *Response to Comments* document. For the final rulemaking, the EPA included an analysis of the costs of greenhouse gases. Please see section 13.11 of the EPA response in this *Response to Comments* document.

The commenter's Figures 1 and 2 purport to compare the EPA's cost estimates with cost data from a survey conducted by the commenter and the AWWA. However, the EPA observed several issues with the commenter's figures. The figure titles indicate the data shown are in units of dollars per million gallons per day treatment capacity ($/MGD). The y-axis of Figure 1 is labeled in units of dollars ($). Based on the range of values shown, it appears the data are actually in units of million dollars per million gallons per day treatment capacity ($ millions/MGD). Also, the commenter states that "…Figure 2 shows the detail of Figure 1 for systems below 50 MGD." The data for "actual installed treatment systems" shown in Figure 2 are clearly not the same data shown in Figure 1. Based on the shape of the curve and lack of scatter in the data, Figure 2 appears to show the results of a parametric cost model, not the capital costs of actual installed treatment system.

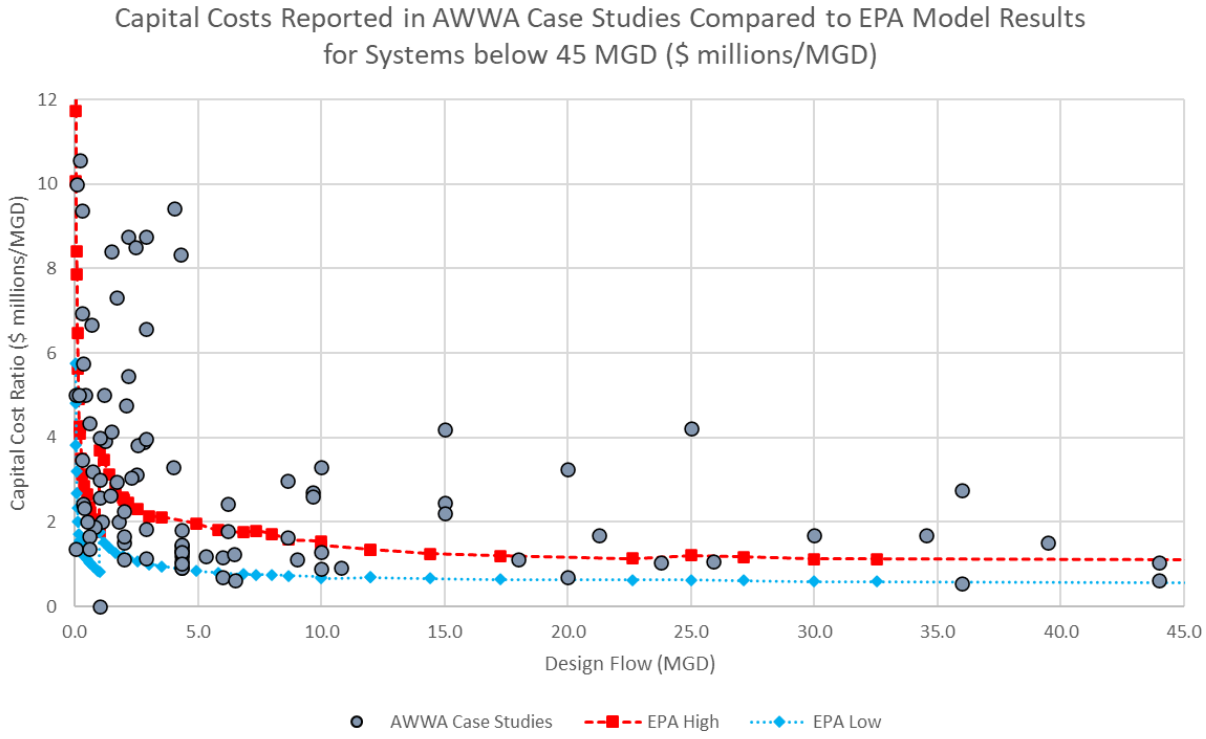
The commenter did not provide the underlying data supporting Figures 1 and 2, so it is not possible to conclusively resolve these discrepancies. The commenter also did not provide details on how they obtained the "EPA model results" shown in Figures 1 and 2. However, it appears that the figures misrepresent the EPA's cost estimates. Specifically, given that there is only one EPA data point for each "actual" data point, the figures clearly do not consider the full range of cost curves used to estimate national costs and presented in Appendix B of the EPA's *Technologies and Costs* document (USEPA, 2024d). For the final rule, the EPA updated its equipment costs to 2022 dollars (which are the most recent data available), collected new vendor price quotes for cost driver equipment components, and made several other adjustments to WBS model assumptions, as discussed in section 13.3.3. Considering all these factors, the EPA disagrees with the commenters assertion that the EPA's estimates are 2.9 to 5.1 times lower than actual.

The figures below recreate the commenter's Figures 1 and 2, attempting to correct for the issues identified above. Because the commenter did not provide their underlying data, the recreated figures use the data provided in public comments from AWWA (Doc. #1759, SBC-045612). The AWWA data set appears to be similar to the commenter's data set but is not identical. The EPA cost data shown in the recreated figures reflect the underlying WBS model outputs used to

generate the high- and low-cost curves for GAC and ion exchange.[9] Some of the AWWA case studies fall within the range of costs bounded by the EPA's updated cost curves. Other case studies exceed the EPA's high-cost curve. However, the commenter did not include information to confirm that (1) all the case study costs would be directly associated with PFAS treatment, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., empty bed contact time) for the case study facilities would be similar to the typical values assumed in the EPA's estimate. Again, after recreating the figures presented by this commenter, the EPA disagrees with the commenter's overall conclusions about the EPA's costs estimates in comparison to the commenter's information.



[9] The EPA's WBS have a maximum design flow of 162 MGD. The EPA data points show a shift in capital cost at 1 MGD, which corresponds to the change in model assumptions that the EPA used to reflect the use of package treatment systems below this threshold.



Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046027)

The B&V report provides estimated capital expenditure (CAPEX). The analysis subtracts the average O&M costs per system from the annualized per-system cost and multiplies the remainder by the estimated number of systems [FN134: Black & Veatch, "PFAS National Cost Model Report," tbls. 6–3.]. Capital cost is lowest among smaller systems, ranging between $150 and $370 million per year, and highest among systems serving 10,000 to 50,000 and 100,000 to 1,000,000 people ($290 million to $2.1 million).

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045987)

Section 8.2: Assessment of EPA's cost estimates

EPA's analysis grossly underestimates the costs of the rule in several ways, including not accounting for inflation and the social cost of carbon. First, EPA prepared its cost estimates before the full effect of inflation and supply chain constraints took hold. As a result, water utilities, like other businesses and consumers, continue to see major price increases. Inflation and supply chain issues continue to drastically impact the American economy, including the water

sector. AMWA members have reported price increases from 20-120% (Attachment 2), with water supply chemicals seeing the highest increases. GAC costs also continue to rise.

A June 2022 US News and World Report article, Inflation Taking the Bite out of New Infrastructure Project [FN21: Associated Press. (2022, June 1). Inflation taking bite out of new infrastructure projects. https://www.usnews.com/news/business/articles/2022-06-19/inflation-taking-bite-out-of-new-infrastructure-projects], stated that construction project costs are at least 25-30% higher than in 2021. The article specifically cited the costs of ductile iron pipes and fittings at 25% higher than the previous year. EPA estimated its cost projections in 2021 dollars, so at a bare minimum, construction costs are likely 25-30% higher than agency estimates. Additionally, these estimates using 2021 data will not take into account potentially higher prices, driven by increased demand as a result of this rule promulgation.

In addition, energy costs are also on the rise, as seen in Attachment 2. In its proposal, EPA neglected to include the social costs of carbon – both the benefits and disbenefits – to calculate the economic impacts associated with the rise in greenhouse gas emissions due to the implementation of treatment technologies to address PFAS at drinking water utilities. GAC, the treatment technology many utilities will install to meet this NPDWR, is also typically derived from bituminous coal and reactivated in multiple hearth furnaces operating at high temperatures using fossil-fuel energy. In addition, transport to and from the reactivation facility is done over long distances with diesel trucks. EPA must take these costs into account to make accurate estimations to influence informed decision-making.

AMWA would like to highlight a study prepared for the American Water Works Association (AWWA) by Black & Veatch that assesses more accurate costs of this proposed rule implementation using current real-world data [FN22: AWWA. (2023 March 7). WITAF 56 Technical Memorandum. PFAS National Cost Model Report. https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14-102450-257]. While EPA's estimated range of annualized costs is around $770 million to $1.2 billion, this Black & Veatch study uses real-world data to assess the economic impact of this proposal, finding that the costs of this rulemaking could exceed $3.2 billion annually.

Section 8.3: Methodology of cost analysis

PNG's analysis uses cost data from surveys taken of AMWA and AWWA's members in March-April 2023. Information from 60 systems was incorporated into the analysis to further illustrate the real-world costs associated with PFAS treatment. Information was also included to show other social costs of rule implementation. As reported in the PNG analysis, "AMWA and the AWWA surveyed its members to obtain recent cost data on installed PFAS treatment systems at drinking water treatment plants. Figure 1 plots the ratio of capital costs per the treatment system capacity (in millions of gallons per day) reported by 60 systems. Figure 1 also provides EPA's estimated capital costs for the comparable treatment technique and system size. As shown, EPA's

values are most often below reported capital costs. On average across the 60 systems, EPA's estimate is 2.9 times lower than reported values." AMWA has copied this figure below.

PNG's analysis shows the discrepancy between actual costs and EPA's estimate is greater for small treatment systems, the ones most likely to be installed due to this regulatory action. For systems under 1 MGD, the average ratio between actual system capital expenditures and EPA's is 5.1. For systems under 2 MGD, EPA's models underestimate actual capital expenditures by a factor of 3.6.

Figure 1 (PNG, 2023): Comparison of the Capital Costs of Actual Installed Treatment Systems with EPA Model Results ($/MGD)

[Figure 1: see docket ID EPA-HQ-OW-2022-0114-1738]

Below is the figure shown above reframed for systems with a design capacity from 0-45 MGD.

[Figure 2: see docket ID EPA-HQ-OW-2022-0114-1738]

As stated in PNG's report, "EPA also omits other, non-market social costs. Consuming real resources like activated carbon, electricity, and transportation services have costs that are not captured in their market price. EPA strives to reduce the adverse human health and environmental effects of the non-market social costs of pollution. By requiring treatment for certain PFAS, EPA's rule will lead to increased pollution from transportation, electricity generation, and other construction and operations activity. While the social costs of this additional pollution may be justified by the rule's benefits, EPA must estimate these social costs to demonstrate this claim."

Section 8.4 Need to assess costs of greenhouse gases/social cost of carbon

While EPA did not assess the costs of greenhouse gasses in this proposal, the agency has performed this analysis for other rulemakings - specifically its proposed rule for the New Source Performance Standards for the Synthetic Organic Chemical Manufacturing Industry and National Emission Standards for Hazardous Air Pollutants for the Synthetic Organic Chemical Manufacturing Industry and Group I and Group II polymers and Resins Industry (the Hazardous Organics NESHAP, or HON) [FN 23: EPA. (2023, April 25). 88 FR 25080. https://www.federalregister.gov/documents/2023/04/25/2023-07188/new-source-performance-standards-for-the-synthetic-organic-chemical-manufacturing-industry-and]. In the Regulatory Impact Analysis (RIA) [FN24: EPA. (2023, March). Regulatory impact analysis. https://www.epa.gov/system/files/documents/2023-04/Proposed_HON_RIA_final_2023-03.pdf] on the proposed rule, EPA included the social cost of carbon for the electricity required to operate the air pollution controls in its proposal.

Additionally, in EPA's 2023 Proposed Rule: New Source Performance Standards for Greenhouse Gas Emissions from New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units (EGUs), the RIA includes an appendix with economy-wide modeling results [FN25: EPA. (2023, May 5). https://www.epa.gov/system/files/documents/2023-05/FRL-8536-02-

OAR%20111EGU%20NPRM%2020230504_Admin.pdf]. EPA finds that including these additional costs for the social cost of carbon increases the social cost of the rule by 35 percent. We note that EPA's estimate of the engineering costs for this proposal is roughly the same as EPA's estimate for the PFAS MCL.

EPA should do the same analysis for the PFAS MCL that it has done in these other rulemakings and reflect these additional costs and benefits in its analysis. This will allow EPA to make a well-informed decision that will take substantial costs into consideration while still presenting the opportunity for meaningful health risk reduction.

EPA Response: Regarding the commenter's statements regarding rising construction prices, the effects of rising inflation, and the EPA's alleged underestimates of costs please see section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see the EPA response to comment Doc. #1738, SBC-046008 in section 13.3.3 in this *Response to Comments* document regarding AMWA/PNG's presentation of results and conclusions based on survey data. Further, for the final rulemaking, the EPA included an analysis of the costs of greenhouse gases. Please see section 13.11 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046125)

2. EPA uses an equally thorough, data-driven approach for estimating what treatment and non-treatment technologies would be adopted to comply with the rule.

EPA recognizes that there would likely be variation in what technologies PWSs adopt to comply with the proposed rule, and as such they did not simply assume all PWSs with PFAS levels above the proposed MCLs would adopt the seemingly cheapest technology. Instead, based on system and source water-specific parameters, EPA estimated systems' choices of treatment and non-treatment technologies based on data of past technology adoption choices. More specifically, a decision tree was developed to determine what treatment technologies or non-treatment approaches are feasible based on entry point, water source, and system characteristics, as well as the regulatory option being considered. Then among the feasible options, the estimated compliance approach is randomly chosen for each PWS based on the probability distribution of recently observed choices made by PWSs. In other words, holding all system and water-source characteristics constant, if a certain technology has tended to be chosen more often in practice, then that increased likelihood is accounted for in EPA's technology adoption models and subsequent cost estimates.

EPA then developed over 3,500 individual cost equations to estimate the costs of the chosen technologies based on key factors, including the corresponding technology bed life (i.e., the length of time that a technology can maintain a target pollutant removal percentage), water source, flow, etc.

Overall, this detailed, data-driven approach to estimate treatment and non-treatment approaches towards compliance, and the subsequent costs, strengthens the analysis because the cost estimates are based on empirical evidence (i.e., observed choices made by PWSs), rather than theoretical assumptions and subjective best judgements. The randomization of PWS compliance choices and subsequent costs based on the observed distribution of PWS adoption choices is layered on top of the Monte Carlo simulations discussed in comment #1, and thus further exhibits all the advantages of such an approach that are discussed above.

EPA Response: The EPA agrees with the commenter's characterization of the estimation of treatment and non-treatment costs as data-driven. Please see sections 13.3.3 and 13.3.6 of the EPA response in this *Response to Comments* document.

Del-Co Water Company, Inc. (Doc. #1744, SBC-043619)

III. Del- Co Water average capital cost to meet the proposed PFOA MCL is approximately

$67 million for just one (of four) Water Treatment Plants

Del-Co commissioned a preliminary engineering study to retrofit its largest WTP and the capital costs for completion came in at an average of $67 million. Further, it is anticipated that Del-Co will need to upgrade a second WTP, which would likely cost $10 – $20 million. These estimates do not include annual operational costs, nor do they include inflationary expenses. Taking into account the information in Section II, Del-Co questions whether this funding could be allocated to other priorities (e.g., replacing lead service lines, upgrading cybersecurity, replacing aging infrastructure, and assuring sustainable water supplies) which would provide greater benefit, risk reduction, and public health protection to the ratepayers.

EPA Response: Please see response section 13.3.3 of the EPA response in this *Response to Comments* document. Additionally, see the EPA response to comment Doc. #1744, SBC-043620 in section 13.3.3 in this *Response to Comments* document. The EPA has reaffirmed the Administrator's determination at proposal that the benefits of the rule justify the costs; see response section 13.8 of the EPA response in this Response to Comments document for more information.

13.3.4 Water System Costs - Monitoring

Summary of Major Public Comments and EPA Responses

Commenters disagreed with the EPA's laboratory costs claiming that EPA Method 533 was more expensive than analyzing PFAS using EPA Method 537.1. The EPA used sample costs associated with Method 537.1 based on the assumption that, while both methods provide the required data to demonstrate compliance, water systems will select the least costly analytical method (which is Method 537.1). Two commenters incorrectly suggested that the cost of the field reagent blank (FRB) was not included in the EPA's monitoring cost calculations. For any samples that are above detection, the final rule requires the system to analyze the FRB samples collected at the

same time as the monitoring sample. The EPA included the costs associated with analyzing the FRB when samples are above detection in the EA for both the proposed and final rule.

Some commenters disagreed with the EPA's cost per sample for EPA Method 533 and EPA Method 537.1. Specifically, one commenter noted that "This difference in laboratory analysis costs is significant and may contribute to unrealistically low-cost assumptions." Some of these commenters provided information on costs per sample such as "$350 - $500 per sample," "$525+ per sample," "500 per sample, with an average being about $450" and "$300-$500/sample." These commenters stated that the costs the EPA used in the proposal were too low. One commenter stated they believe the EPA's sample costs in the proposal "…are generally on par with current pricing for large commercial labs." Another commenter noted that costs were "roughly $300 per sample." To support the analysis for the proposed and final rule, the EPA used the cost estimates developed in the UCMR5 rule and adjusted the costs to $2022 dollars for the final rule. To estimate sampling costs under UCMR5, the EPA determined the average analytical cost for assessment monitoring by averaging estimates provided by four drinking water laboratories (USEPA, 2022a). The EPA believes this is the most representative dataset to inform the sampling costs estimates of the rule.

For the national cost analysis, the EPA assumes that systems with either UCMR 5 data or monitoring data in the State PFAS Database (see Chapter 5 in USEPA, 2024b) will not conduct the initial year of monitoring as allowed by the final rule. One commenter stated that they believed it is not appropriate to exclude the sampling costs for water systems participating in UCMR5 from the analysis even if the EPA deems they can use these data for rule compliance. This commenter stated "[w]hile all systems serving more than 3,300 are currently already required to monitor for PFAS in accordance with UCMR 5, many of these systems may need to conduct additional monitoring to comply with the rule and to meet the timeline for compliance set by EPA." The EPA disagrees with the commenters assertion that many water systems that participate in UCMR 5 will need to conduct additional monitoring to comply with the rule. Though large groundwater systems will be required to collect two additional samples to supplement their UCMR 5 monitoring and meet the required number of samples under the final rule initial monitoring requirements, for these and all other water systems conducting UCMR 5 monitoring, the EPA has clearly specified in the rule that all data collected in the UCMR5 effort can satisfy initial monitoring requirements and expects the majority of these water systems (approximately 85 percent) will have all the data required. As a simplifying assumption for the cost analysis, the EPA assumes all systems serving a population of greater than 3,301 have UCMR 5 data and those with 3,300 or less do not. In the EA for the proposed rule, the EPA noted these simplifying assumptions may result in a small underestimate of initial monitoring costs for systems serving greater than 3,301 persons. The EPA recognizes this is, in part, because both the large (greater than 10K) groundwater systems under UCMR 5 will need to collect two additional samples under the PFAS NPDWR, and also because the systems that have existing state monitoring data may or may not have enough to fully satisfy their initial monitoring requirements (i.e., 2 or 4 samples). However, the EPA notes that it has likely overestimated monitoring costs for systems serving less than 3,300 as the EPA is aware of numerous states

which have led monitoring programs for some or all of their regulated systems of this size. Additionally, many small systems have had data collected by federal agencies (e.g., the EPA, DoD) as a result of other programs.

In the proposed rule, the EPA asked for public comment on the underlying assumptions that, under UCMR 5, individual water systems would be able to request the full release of data from the labs for use in determining their compliance monitoring frequency and that PWSs may be able to use these lab analyses to demonstrate a "below trigger level" concentration using the UCMR 5 analyses by following up with the lab for a more detailed results report. Some commenters expressed concern about acquiring data below the PQL. Under UCMR 5, individual water systems would be able to request the full release of data from the labs for use in determining their compliance monitoring frequency. PWSs may be able to use these lab analyses to demonstrate a "below trigger level" concentration using the UCMR 5 analyses by following up with the lab for a more detailed results report. For UCMR 5 purposes, laboratories analyzing UCMR 5 samples only report data at or above minimum reporting levels (MRLs) to the EPA; however, results for the Laboratory Reagent Blank (LRB), a required method quality control sample, must not exceed 1/3 the MRL. Additionally, laboratories may have PWS data below the PQL in its Laboratory Information Management System (LIMS), the software that manages commercial laboratory sample processing, analysis, and reporting. It is typically a matter of data reprocessing to retrieve those results. Several factors, such as the LIMS software itself, the abilities of the LIMS management team, and the laboratory pricing structure, will all dictate the likely cost. The agency has encouraged laboratories to extend this evaluation to samples, working with their PWS clients to accommodate PWS requests for data below the UCMR 5 MRLs (and final NPDWR PQLs), to potentially support the PWS's future determination of NPDWR monitoring frequency on a reduced monitoring schedule.

One commenter asserted that water systems would have to "pay twice" to acquire data below the PQL. The pricing that each laboratory would charge to retrieve that data for its client may differ significantly from one lab to another. However, the EPA notes that UCMR small systems contract labs, which also handle a large number of large systems' analysis, have provided feedback to the EPA that additional costs for the EPA to query results below the UCMR MRL would not be financially burdensome. The EPA cannot comment on the specific data provisions between each UCMR lab and their clients; however, based on labs that the EPA has surveyed, the EPA does not expect that it will be a common occurrence that labs will "pay twice for results" as suggested by the commenter. Additionally, this commenter stated they were told they would "need to perform an entirely separate sampling event due to QAQC considerations." The EPA disagrees with this assertion, and as stated above, the results are already available in the LIMS. This action would not require a "separate sampling" as the original analysis data would be used (i.e., no recollection, no re-analysis).

Some commenters expressed concern for small systems monitoring costs in particular. The EPA notes that as a mechanism to reduce the burden of the final rule requirements on small entities the EPA has promulgated compliance flexibilities for small CWSs serving 10,000 or fewer persons. These flexibilities include the use of previously collected PFAS monitoring data to

satisfy initial monitoring requirements, allowing reduced initial monitoring for small groundwater systems serving 10,000 or fewer, the addition of annual monitoring to the ongoing compliance monitoring framework, and modified rule trigger levels for reduced monitoring eligibility.

Individual Public Comments

COMM Water Department (Doc. #1577, SBC-042435)

May 30, 2023

Mr. Michael S. Regan, Administrator

U.S. Environmental Protection Agency

EPA Docket Center, OLEM Docket, Mail Code 28221T

1200 Pennsylvania Avenue, NW

Washington, DC 20460

RE: Docket ID No. EPA-HQ-OW-2022-0114 - National Primary Drinking Water Regulation Rulemaking for per- and polyfluoroalkyl substances (PFAS)

Dear Administrator Regan:

I am writing to provide comments on the Environmental Protection Agency's (EPA) proposed National Primary Drinking Water Regulation Rulemaking for per- and polyfluoroalkyl substances (PFAS). The drinking water sector fully supports efforts to expand verified public health protections, but EPA needs to consider the challenges associated with its proposed rulemaking and address the water sectors' implementation concerns before finalizing any standards.

I work for C.O.MM Water Department; we provide drinking water to 38,000 customers. I am a member of the Massachusetts Water Works Association; I am aware that they, and other water works organizations, are submitting more comprehensive comments. I would urge EPA to pay close attention to the points raised by these associations as they are comprised of individuals and companies with expertise in designing and operating Public Water Systems (PWS) and they have the best understanding of the challenges which will be associated with implementing any final rule EPA adopts. My major concerns are as follows:

• EPA has very much underestimated the costs to PWSs to comply with the proposed rule. We have had to increase the budget 20% to sample our twenty groundwater wells.

EPA Response: The EPA disagrees it underestimated monitoring costs. Please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Alameda County Water District (ACWD) (Doc. #1595, SBC-042349)

ACWD is currently conducting PFAS monitoring using EPA Method 533 and has experienced costs for this analysis of up to $500 per sample, with an average being about $450. EPA's economic analysis assumes estimated costs of analysis using method 533 of $376 per sample. This difference in laboratory analysis costs is significant and may contribute to unrealistically low-cost assumptions. EPA should validate the cost of PFAS analysis and update the economic analysis as appropriate.

EPA Response: The EPA disagrees that it underestimated analytical monitoring costs. Please see section 13.3.4 of the EPA response in this *Response to Comments* document for discussion of how the EPA estimated analytical monitoring costs.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044091)

ASDWA recommends EPA address laboratory training and expanding capacity needs to ensure costs are considered as a part of the economic analysis in the final regulation.

The amount and variety of costs and resources needed to set up and certify laboratories and access supplies, to have laboratories analyze the water system PFAS samples, and to ensure accurate reporting for regulatory compliance will impact laboratories, primacy agencies, and water systems. ASDWA estimates a cost of $1 million to set up a laboratory, obtain certification, and prepare to analyze drinking water samples for PFAS using EPA Methods 537.1 and 533. This estimate includes the costs for PFAS-clean rooms, equipment, nitrogen, consumables, service agreements, staff, and more. In addition, laboratory infrastructure changes may be needed, such as plumbing nitrogen lines, running new electrical circuits, and ensuring adequate ventilation for new instruments. PFAS will be the first SDWA-regulated compounds to be analyzed using tandem mass spectrometers (LC/MS/MS) or triple quadrupole mass spectrometers (triple quads) that are very costly (from $400,000 -$700,000) and more difficult for laboratory staff to use.

Laboratories will incur additional costs and need training and resources to prepare for reporting sample results electronically to the state's data reporting system (e.g., SDWIS). Primacy agencies will also incur additional costs to develop templates, guidance, and SOPs for laboratory staff to ensure that water system violations are accurately calculated using the running annual average (RAA) for the new PFAS MCLs.

The water system costs for laboratories to analyze PFAS are expensive and increase significantly when laboratories run the field reagent blanks (FRBs). Laboratory costs for analyzing PFAS using EPA Method 533 are also more expensive than costs for analyzing PFAS using EPA Method 537.1.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document. In response to the commenter's recommendation that the EPA should include the costs of establishing new laboratories and associated laboratory training costs in the EA for the final rule, the EPA disagrees that those costs should be estimated and included. The

sampling costs the EPA included in the cost analysis are derived from a set of current labs and reflect the market price at the time of the survey. New labs entering the market would likely be competing with currently operating labs that have the option to expand their services. Expanding labs will likely lower their unit sample costs given the potential for shared existing overhead like billing platforms/other systems in general, floor space, or trained personnel, therefore potential new labs could not charge significant per sample rates above the current labs in the market. The costs to larger water systems considering creating a new lab would be equal to or less than the market rate charged by commercial labs already in the market.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043211)

Additionally, the cost for operation of the system does not seem to account for the initial year of sampling that could well cost more than the installation of the POUs.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document and Chapter 5 of the EA (USEPA, 2024b). The initial year sampling costs are included for all water systems.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044431)

Page 18731. Section XIII – HRRCA

EPA requests comment generally on its estimation of sampling costs. The Agency is also specifically requesting comment on the ability of systems to demonstrate they are reliably and consistently below 1.3 ppt for PFOA and PFOS and 0.33 ppt for PFAS regulated by the HI to qualify for reduced monitoring.

• EPAs use of trigger levels set at 1/3 the PQL increase the estimated cost of sampling while increasing variability in sampling data. Setting the trigger at ½ the PQL would increase the number of laboratories that can meet QA/QC levels bringing down the cost of sampling and provide better data for decision making. Washington supports using the EPA's suggested alternative trigger level of ½ the PQL. Currently laboratories are charging for both the PWS sample, and if there are detections, for testing the field reagent blank, effectively doubling the cost for PWSs with detections. It is unclear if EPA considered this in their cost estimates.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document. In addition, in the final rule the EPA set the trigger level equal to ½ of the MCLs after considering public comments received. Please see the EPA response to comment Doc. #1692, SBC-044744 in section 13.3.4 in this *Response to Comments* document and section 8.8 of the EPA response in this *Response to Comments* document for further discussion of the trig level.

A. O. Smith Corporation (Doc. #1674, SBC-043697)

The Company does however have some concerns relative to current national laboratory capacity and the economic impacts the proposed PFAS NPDWS testing regime may have on testing costs, given supply and demand across a limited number of certified labs, as well as a shortage of seasoned and trained laboratory technicians. As the EPA points out in its analysis, the anticipated annual cost of sample testing across covered public water systems assumes a total annualized cost at $105,000,000 at a 3% discount rate and $109,000,000 at a 7% discount rate. [FN13: 88 FR 16672] From the Company's perspective, sample testing costs for its products – as well as the combined time to certify systems – will increase under the proposed MCL for PFOA and PFOS. Those costs will potentially increase further if broader laboratory capacity does not increase.

EPA Response: For the EPA's response to comments on laboratory capacity, please see section 8 in this *Response to Comments* document. The EPA disagrees that laboratory sampling costs will increase significantly as result of heightened demand created by the rule because, as discussed in more detail in section 13.3 of the EPA response in this *Response to Comments* document, the EPA believes there is or will be sufficient lab capacity to support the rule.

American Council of Independent Laboratories (ACIL) (Doc. #1692, SBC-044744)

7. Additional Quality Control and Associated Costs

Related to our comments on the lowered reporting limits needed to support reporting at or below the trigger value, we note that on page 18698, the Agency has estimated a price per sample of $375 for Method 533 and $302 for Method 537.1. These prices are likely to be an underestimate and may not reflect the actual differences between 537.1 and 533. In addition to inflation in the cost of reagents and labor, there are likely to be additional quality control, calibration, and other associated costs that arise from calibrating and reporting down to the trigger values. We strongly recommend that EPA clarify that, while it provided approximate monitoring costs, in the NPRM, water utilities are likely to find the costs are higher than the costs that EPA found when conducting its UCMR study.

EPA Response: The EPA disagrees that it underestimated analytical monitoring costs. Please see section 13.3.4 of the EPA response in this *Response to Comments* document for discussion of how the EPA estimated analytical monitoring costs. In addition, in the final rule the EPA set the trigger level equal to ½ of the MCL after consideration of public comments received. This is anticipated to reduce overall national monitoring burden; see Chapter 5 of the EA for more information on the EPA's estimates of monitoring costs for the final rule. Please see section 8.8 of the EPA response in this *Response to Comments* document for the EPA's responses as to why it adjusted the trigger level.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045120)

As discussed above, a clear post-treatment sampling protocol needs to be established in the regulation. The mid-point sampling is industry norm, but many small systems cannot afford to pay the $525+ per sample cost (the current rate available to many Vermont water systems) twice per quarter or monitoring period – once for treatment efficacy and the other for compliance. Since the mid-point sampling will not "count" for compliance, which is defined as being at the entry point to distribution, this would require multiple samples per quarter, at a cost of nearly $4,000/year on top of the treatment and disposal costs.

EPA Response: For the EPA's response to comments on per sample monitoring costs, please see section 13.3.4 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on performance monitoring, i.e., "mid-point sampling" see section 13.3.3 in this *Response to Comments* document. In response to the commenter's recommendation that the EPA establish "a clear post-treatment sampling protocol," see monitoring requirements section VIII.A of the final rule preamble and section 8.1.2 of the EPA response in this *Response to Comments* document on compliance monitoring requirements.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043921)

In response to Section XIII. Health Risk Reduction and Cost Analysis, EPA requests comment generally on its estimation of sampling costs. The Agency is also specifically requesting comment on the ability of systems to demonstrate they are reliably and consistently below 1.3 ppt for PFOA and PFOS and 0.33 ppt for PFAS regulated by the HI in order to qualify for reduced monitoring.

• Hall Environmental Analysis Laboratory in NM, prices range from $350 - $500 per sample depending on the method requested and the number of PFAS compounds requested. EPA's assumed costs for samples are extremely low.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045610)

Monitoring Requirements for Systems Participating in UCMR 5

Under the proposed rule, community water systems and non-transient non-community water systems will need to conduct initial monitoring, unless the state primacy agency approves the use of previously collected monitoring data. AWWA appreciates the agency's interest in providing this flexibility for water systems that may have already collected PFAS monitoring data for UCMR 5 or state monitoring programs. As part of the compliance cost analysis for the proposal, EPA did not include the monitoring costs associated with certain systems that may be eligible to

take advantage of this flexibility. While it is reasonable to assume that some systems may potentially avoid initial monitoring for PFAS, it is not appropriate to exclude these costs from the analysis. While all systems serving more than 3,300 are currently already required to monitor for PFAS in accordance with UCMR 5, many of these systems may need to conduct additional monitoring to comply with the rule and to meet the timeline for compliance set by EPA. Examples of these systems may include:

• Large groundwater systems (serving more than 10,000 persons): Large groundwater systems will be required to collect quarterly samples while UCMR 5 requires the collection of two samples for all groundwater systems. There are more than 1,650 systems in this category that would need to collect additional samples beyond UCMR 5 to take advantage of this flexibility. Additionally, systems that are actively collecting samples during 2023 are unlikely to have the opportunity to adjust monitoring plans.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Uttara Jhaveri (Doc. #1778, SBC-045447)

In addition, the water systems will have to conduct compliance monitoring to demonstrate that the finished drinking water does not exceed the MCLs for regulated PFAS. Systems that exceed the proposed MCLs for regulated PFAS will be monitored quarterly, and the PFAS will be determined by running annual averages at the sampling point. [FN23: Id.] The monitoring and communication costs of the proposed regulation will be high, especially for the water sources that fail to meet the proposed MCLs. Furthermore, the sharp decrease of the MCLs from the current limit of 70 ppt [FN24: Environmental Protection Agency, FACT SHEET PFOA & PFOS Drinking Water Health Advisories, (2016), https://www.epa.gov/sites/default/files/2016-06/documents/drinkingwaterhealthadvisories_pfoa_pfos_updated_5.31.16.pdf.] may lead to several water sources in the country failing to meet the proposed limits.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document. The EPA notes that the 2016 PFOA and PFOS Health advisories are beyond the scope of this rulemaking. The 2016 Health Advisory level of 70 ppt was and are not legally enforceable federal standards and HAs are subject to change as new information becomes available. In response to the commenter's reference to the communication costs associated with the rule, please see section 13.3.5 of the EPA response in this *Response to Comments* document on administrative costs of the rule, as well as section 1.2 in this *Response to Comments* document on the EPA's response to comments on risk communications associated with the rule.

Vermont Rural Water Association (Doc. #1798, SBC-045330)

Based on the experiences of Vermont's small systems, EPA has significantly underestimated the costs of monitoring and remediation. Engineering analyses did not recommend POU treatment systems as a remediation option, even for NTNCs and TNCs. Monitoring costs for very small

systems with any detectable level of PFOA or PFOS will average over $2000 per year (EPA estimates $900). For Vermont's small systems, this is a greater expense than all of their other annual monitoring costs combined.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document for response to comments on monitoring costs. For the EPA's response to comments on POU devices, please see section 10 in this *Response to Comments* document. The commenter does not provide any information to support the claim that "monitoring costs for very small systems with any detectable level of PFOA or PFOS will average over $2000 per year," and it is unclear how this number was derived. The estimated annual costs per system varies in the EPA's analysis depending on the monitoring frequency and the number of EPTDS in the systems. The commenter's suggestion that the EPA estimates $900 dollars for every small system is not correct. Please see the EPA response to comment Doc. #1692, SBC-044744 in section 13.3.4 in this *Response to Comments* document for information about burden reduction anticipated with adjusting the trigger level. Additionally, based on public comments, the EPA has added an additional burden reducing monitoring option for those utilities whose regulated PFAS concentrations are above the trigger level, but reliably and consistently below the MCLs: please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Palm Beach County Water Utilities Department (Doc. #1802, SBC-045338)

Page 18698, Table 34:

PBCWUD Comment: Current sampling and subcontracting costs to a certified lab is approximately $300-$500/sample (hours, travel,bottles, testing) with a TAT of 3-4 months. It is difficult to make data driven decisions when TAT is 3-4 months currently. Approximate cost to analyze PFAS in house at PBCWUD lab would be around $500,000 for new equipment, method development, training, and personnel.

Please contact myself, our Director, or our Deputy Director directly with any questions or comments. Our contact information is below.

Sincerely,

Bret Hammell, P.E.

Environmental, Health and Safety Manager, PBCWUD

bhammell@pbcwater.com

cc: Ali Bayat, P.E., Director, PBCWUD, ABayat@pbcwater.com

Krystin Berntsen, Deputy Director, PBCWUD, KBerntsen@pbcwater.com

Stephanie Weder, PBCWUD, Laboratory Manager, SWeder@pbcwater.com

Diana Perez, PBCWUD, Environmental Program Supervisor, DPerez3@pbcwater.com

Keresha Whittingham, PBCWUD, Regulatory Compliance Specialist, KWhittingham@pbcwater.com

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document and response to comments on monitoring requirements and laboratory capacity in section 8 in this *Response to Comments* document.

Florida Rural Water Association (FRWA) (Doc. #1806, SBC-044694)

Based on the experiences of Florida small systems, EPA has significantly underestimated the costs of monitoring and remediation. Engineering analyses did not recommend POU treatment systems as a remediation option, even for NTNCs and TNCs. Monitoring costs for very small systems with any detectable level of PFOA or PFOS will average close to $2000 per sample (counting all costs) (EPA estimates $900).

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document for response to comments on monitoring costs. For the EPA's response to comments on POU devices, please see section 10 in this *Response to Comments* document. The commenter does not provide any information to support the claim that "monitoring costs for very small systems with any detectable level of PFOA or PFOS will average over $2000 per year," and it is unclear how this number was derived. The estimated annual costs per system varies in the EPA's analysis depending on the monitoring frequency and the number of EPTDS in the systems. The commenter's suggestion that the EPA estimates $900 dollars for every small system is not correct. Please see also the EPA response to comment Doc. #1692, SBC-044744 and Doc. #1798, SBC-045330 in section 13.3.4 in this *Response to Comments* document for discussion about additional monitoring burden reduction the EPA has incorporated into the rule based on public comment.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045482)

In addition, small entities shared that the cost of PFAS sampling will add significantly to their testing expenses (e.g., $700-$800 per sample).

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document. This commenter's per sample costs are significantly higher than the EPA's and all other public commenters. It's possible this commenter's cost estimate includes the administrative burden associated with collecting the samples. If so, the EPA notes that the hours per sample to travel to sampling locations, collect samples, record any additional information, submit samples to a laboratory, and review results are captured in the EPA's cost analysis, see Chapter 5.3.2 of the EA for more information.

Groundwater Resources Association of California (Doc. #1831, SBC-045352)

Groundwater sampling and analysis costs will likely be higher than costs calculated for analysis at potable water treatment systems due to specialized consumables (pump components, tubing, sample vials) and additional background, blank, and spiked samples required for quantification of PFAS at ppt levels in outdoor and/or remote locations.

EPA Response: Sampling is only required at the EPTDS. Raw water sampling is not required under the final rule. As discussed in section 13.3.4 of the EPA response in this *Response to Comments* document, the EPA included the costs of FRB when samples exceed the detection limits in the cost analysis.

Vanderbilt University Drinking Water Justice Lab (Doc. #3072-97, SBC-047409)

Okay, so my name is Yolanda McDonald and I am the lead investigator for the Vanderbilt University Drinking Water Justice Lab. And I first want to say, Katie, your comments are extremely moving and part of the reason that our lab is conducting research in PFAS and trying to develop machine learning methods whereby small water systems can assess presence of PFAS because of the concerns of the regulation whereby there's a random sampling of systems that are less than 3,301. I understand that the majority of people in the United States do receive their water from large systems, but I think that there is an oversight in the current legislation and what we're going to do about these small water systems. And we have to ensure that there's allocation beyond the initial UCMR 5 to have testing done in small systems that is affordable to the community without requiring there to be high rate increases just to make water affordable and safe for those citizens. And I do also want to point out, this may have been discussed earlier and I apologize, I wasn't able to make the entire meeting.

EPA Response: The EPA agrees with the commenter that it is important to understand the level of contamination regardless of system size. Under the final NPDWR, all community and non-transient non-community public water systems will be required to sample for PFAS.

New Mexico Rural Water Association (Doc. #3072-98, SBC-047412)

$500 a sample for testing in New Mexico is a bit too steep for most small systems. Others have already commented on this. Having access to BIL funds is nice, but we need the money to be available to small systems even if they don't qualify by state rules like a current audit. Half of our systems are political subdivisions of the state, and most are under 500 in population.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document for the EPA's response to comments on monitoring costs. Please see section 2.4 in this *Response to Comments* document for the EPA's response to comments on available funding for water systems to help comply with the PFAS NPDWR.

Santa Clarita Valley Water Agency (SCVWA) (Doc. #1578, SBC-042429)

We have also invested in equipping our own laboratory with the ability to analyze PFAS Chemicals through the purchase and ELAP certification of an LCMSMS ($550,000). This has allowed SCV Water to proactively manage analytical costs and maintain timely results with our samples. But this has also resulted in additional staff costs to oversee and run the laboratory equipment.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043114)

5. Analytical Costs

Related to our comments on the lowered reporting limits needed to support reporting at or below the trigger values, we note that the EPA has estimated a price per sample of $376 for 533 and $302 for 537.1. There are likely to be additional quality control, calibration and other associated costs that arise from calibrating and reporting down to the trigger values. These extra cautions will probably increase the costs due to the extra steps the laboratory will have to take to lower contamination (if even possible) to a level that would allow them to report data at 1.3 ng/L.

The EMC recommends that EPA clarify that, in order to perform the Economic Impact Assessment, it approximated monitoring costs based on costs it incurred during UCMR studies conducted several years ago. These estimates may underestimate the actual analytical and overall monitoring costs by a significant amount due to the need for the additional quality control steps, lower quantitation levels, and overall inflation.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document. In addition, in the final rule the EPA set the trigger level equal to ½ of the MCL in response to comments received. Please see the EPA response to comment Doc. #1692, SBC-044744 in section 13.3.4 in this *Response to Comments* document.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043322)

5. Analytical Costs

Related to our comments on the lowered reporting limits needed to support reporting at or below the trigger values, we note that the EPA has estimated a price per sample of $376 for 533 and $302 for 537.1. There are likely to be additional quality control, calibration and other associated costs that arise from calibrating and reporting down to the trigger values. These extra cautions will probably increase the costs due to the extra steps the laboratory will have to take to lower contamination (if even possible) to a level that would allow them to report data at 1.3 ng/L.

The EMC recommends that EPA clarify that, in order to perform the Economic Impact Assessment, it approximated monitoring costs based on costs it incurred during UCMR studies conducted several years ago. These estimates may underestimate the actual analytical and overall monitoring costs by a significant amount due to the need for the additional quality control steps, lower quantitation levels, and overall inflation.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document. In addition, in the final rule the EPA set the trigger level equal to ½ of the MCL in response to comments received. Please see the EPA response to comment Doc. #1692, SBC-044744 and Doc. #1798, SBC-045330 in section 13.3.4 in this *Response to Comments* document for discussion about additional monitoring burden reduction the EPA has incorporated into the rule based on public comment.

Missouri Department of Natural Resources (Doc. #1563, SBC-042539)

EPA requests comment on the underlying assumptions that, under UCMR 5, individual water systems would be able to request the full release of data from the labs for use in determining their compliance monitoring frequency and that PWSs may be able to use these lab analyses to demonstrate a ‘‘below trigger level’’ concentration using the UCMR 5 analyses by following up with the lab for a more detailed results report.

EPA based its assumption on water systems contracting with a lab to perform analysis. In Missouri, the state procures the contract for UCMR analyses for large systems. As the water system is not the client of the laboratory, the system has no legal right to the release of data from the lab. Likewise, small system analyses are procured by EPA, and do not have legal right to the release of the data from labs secured by EPA. This was recently experienced by the Department as UCMR 5 proficiency testing (PT) results were requested from EPA and we were informed those results are not available to the public.

Thank you for the opportunity to provide comments on this proposed rule. The Department looks forward to continuing to work with the EPA to improve the protection of public health and the implementation of the national primary drinking water regulations. If you have any questions regarding these comments, please contact David Lamb, Public Drinking Water Branch Chief, at P.O. Box 176, Jefferson City, MO 65101, by email at david.lamb@dnr.mo.gov, or by telephone at 573-751-0124.

Sincerely,

WATER PROTECTION PROGRAM

John Hoke

Director

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document. Further the EPA is in the process of obtaining the data below UCMR 5

MRLs for the small water systems that had their UCMR 5 samples analyzed by an EPA contracted laboratory. The EPA doesn't foresee any challenges procuring the data at this time. In the situation the commenter describes, primacy agencies may explore procuring the data on behalf of the water systems and sharing that data after receiving it.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044051)

31. EPA requests comment on the underlying assumptions that, under UCMR 5, individual water systems would be able to request the full release of data from the labs for use in determining their compliance monitoring frequency and that PWSs may be able to use these lab analyses to demonstrate a "below trigger level" concentration using the UCMR 5 analyses by following up with the lab for a more detailed results report.

a. See number 21. CWUC absolutely does not agree with EPA's assumption. Eurofins Eaton Analytical will not send UCMR5 data to customers below the EPA established RLs, per their direction from EPA. Further, it is irrational to think that laboratories will re- send every single lab report to every single system nationwide to re-include the MDL data which was previously not allowed due to EPAs direction. This is an unrealistic and incredible burden to UCMR5 contract laboratories nationwide. EPA needs to immediately rescind the requirement that labs cannot report UCMR data for PFAS to less than the established PQLs.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document. In addition, there is no EPA requirement that labs cannot report data from UCMR 5 below the PQLs directly to water systems. The EPA does realize that the UCMR 5 reporting system ("SDWARS 5") will not accommodate results below UCMR 5 MRLs, since the UCMR MRLs must be held consistent over the monitoring timeframe. However, the EPA, through a memo to UCMR 5 laboratories sent in August 2023, encouraged UCMR 5 laboratories to evaluate or reprocess results below UCMR 5 MRLs and work with their water system clients to accommodate requests for data below the UCMR 5 MRLs (and proposed NPDWR PQLs), to potentially support a water system's future determination of NPDWR monitoring frequency. Any "lower level" data provided to water system clients for potential NPDWR monitoring-frequency determinations should be considered a separate action outside of UCMR 5 and managed separately.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043714)

EPA is assuming that individual water systems can request a full release of data collected during UCMR 5 from laboratories for determining compliance with the proposed monitoring trigger level that is below the PQL. Laboratories would be concerned with liability issues therefore it will be unlikely they would release a full report of data that includes measurements below the PQL. Aurora Water does not agree with EPA's assumption that sample results below the PQL could be acquired from commercial laboratories.

EPA Response: Please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045219)

4. EPA requests comment on the underlying assumptions that, under UCMR 5, individual water systems would be able to request the full release of data from the labs for use in determining their compliance monitoring frequency and that PWSs may be able to use these lab analyses to demonstrate a ''below trigger level'' concentration using the UCMR 5 analyses by following up with the lab for a more detailed results report.

CT DPH agrees that individual water systems can obtain a more detailed results report to demonstrate a below trigger level concentration, depending on the analytical capabilities of the laboratory. CT DPH requests that EPA clarifies whether trigger levels are based off the annual average calculation or if the intent for labs to routinely report to this level. CT DPH requests EPA to specify if labs are allowed to provide provisional or "J" flagged data for trigger level screening purposes or if all labs will be required to meet 1.3ppt.

EPA Response: For the EPA's assumptions that water systems can request all UCMR 5 data from laboratories for use in satisfying some or all of the NPDWR's initial monitoring requirements and determination of compliance monitoring frequency, please see section 13.3.4 of the EPA response in this *Response to Comments* document. Regarding trigger levels and determination of monitoring frequency, including data reporting, please see section 8.8 of the EPA response in this *Response to Comments* document. The determination of monitoring frequency is based on individual sample results, not averages.

13.3.5 Water System Costs – Administrative (including Public Notification)

Summary of Major Public Comments and EPA Responses

Many commenters expressed concerns with the EPA's assumption of full compliance with this rulemaking and thus the EPA's decision not to include quantified public notification costs in its national cost estimates. The EPA recognizes that these activities do have an associated burden for systems but disagrees that these costs should be included in the EA. The EPA assumed 100 percent compliance for its national level analysis in the EA for the final rulemaking because the EPA has determined that the final rule is feasible given known occurrence concentrations and efficacy of the technologies available. Further, this is consistent with the approach taken in EAs for other NPDWRs (USEPA, 2005a; USEPA, 2019; USEPA, 2020a). Additionally, the EPA notes that the assumption of full compliance with the final rule will not necessarily underestimate the annualized cost of the rule as suggested by several commenters. While it is correct that noncompliance would require PWSs to incur public notification costs, it would also reduce annualized treatment costs due to the delay in treatment initiation. Therefore, the EPA believes that the assumption of full compliance is appropriate and the impact on national cost estimates is

likely not significant. For approximate estimates of the potential burden associated with Tier 2 and 3 Public Notifications (PNs), please see Section 5.3.2.4 of USEPA (2024b).

A couple of commenters raised concerns that the EPA did not sufficiently capture the administrative costs (e.g., monitoring, reporting, and recordkeeping) of the rule. The EPA disagrees with these commenters as the agency has accounted for a wide range of administrative costs borne by water systems in its EA, including administrative costs associated with implementation, sampling costs, and administrative costs associated with treatment. The EPA's estimated implementation administration costs capture the costs anticipated for systems to read and understand the rule and attend training provided by primacy agencies. The EPA's estimated treatment administration costs capture the costs anticipated for systems to obtain permits for treatment and non-treatment actions taken to comply with the rule, compile data for and review treatment efficacy with primacy agencies during triennial sanitary surveys, and obtain permits for source water changes or alternative methods.

Additionally, the labor associated with designing pilot test protocols, installing and testing equipment as well as collecting operational data (monitor and adjust the pilot system and collect samples) is captured in the EPA's cost analysis, within the cost estimates for pilot studies, rather than in the EPA's PWS administrative costs. In addition, compliance monitoring costs and related costs associated with notification to the primacy agency are included separately in the EPA's sampling cost estimates. For more information on the EPA's estimates of water system administrative and monitoring costs, please see Section 5.3.2 of the EA (USEPA, 2024b). For comment responses on the EPA's monitoring cost estimates, please see section 13.3.4 in this *Response to Comments* document.

Individual Public Comments

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-047693)

AMWA would, however, like to comment on EPA's assumption of full compliance with the proposed rule and subsequently not include any costs related to public notification in the cost-benefit analysis.

Historically, health-based violations of drinking water regulations have increased immediately after new regulations are enacted as utilities work to perfect treatment operations or finish capital improvement projects [FN18: Allaire, M., Wu, H., and Lall, U. (2018). National trends in drinking water quality violations. Proceedings of the National Academy of Sciences, 115(9), 2078-20823. https://www.pnas.org/doi/10.1073/pnas.1719805115.]. It is not practical to assume full compliance when a rule of this magnitude will result in water systems having to plan and implement large capital improvement projects that will likely not be finished in the short three-year compliance time span EPA has proposed. These public notification requirements can result in significant costs to utilities that are taking all necessary actions to be in compliance with the rule but are not given enough time to carry out and finish projects. Therefore, AMWA suggests

EPA include some costs related to public notification in its economic analysis to more accurately portray the overall costs that the agency's proposed rule will pass to ratepayers.

EPA Response: Please see section 13.3.5 of the EPA response in this *Response to Comments* document. Additionally, with respect to the commenter's assertion that "it is not practical to assume full compliance when a rule of this magnitude will result in water systems having to plan and implement large capital improvements projects that will likely not be finished in the short three-year compliance timeline", the EPA notes that for the final rule, the agency is providing compliance flexibility by means of a two-year capital improvements extension of the MCL compliance deadline allowed by Section 1412(b)(10) of SDWA. For more discussion of the two-year MCL compliance deadline extension, please see section 12 of the EPA response in this *Response to Comments* document.

Robert Hollander (Doc. #1516, SBC-042714)

7. 88 FR 18694, Table 27

Are costs of monitoring, reporting, and recordkeeping (for compliance purposes) included in O&M Costs? Many larger utilities have separate [administrative] staff performing these duties, therefore, maybe Administrative Costs, should be included as an additional Cost Category.

EPA Response: Please see section 13.3.5 of the EPA response in this *Response to Comments* document for response to comments on administrative costs and section 13.3.4 in this *Response to Comments* document for response to comments on monitoring costs. With respect to the commenter's question about the costs of monitoring, reporting, and recordkeeping, the EPA has quantified these costs separately from treatment O&M costs; please see Section 5.3.2 of the EA (USEPA, 2024b) for more information on the EPA's estimates of PWS administrative and monitoring costs, which include administrative costs associated with implementation, sampling costs, and administrative costs associated with treatment.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044433)

EPA requests comment on the discussion of estimated PN costs provided in the proposed rule.

• Currently, PN can run from $50,000 – 100,000 per quarter for a larger PWS. It would be beneficial if EPA published some options for electronic delivery methods for tier 2 PN. Consider that different types of communication methods may reach different audiences. Such options could require a balance of methods to both save on costs for repeat PN while attempting to ensure more customers maintain awareness.

EPA Response: Please see section 13.3.5 of the EPA response in this *Response to Comments* document.

With respect to the commenter's recommendation for the EPA to publish "options for electronic delivery methods for tier 2 PN", the EPA agrees that using a mix of delivery methods is

beneficial for reaching different audiences; however, revising the form and manner of PN delivery is outside the scope of this action. Under the existing PN Rule, public water systems must provide the notice in a form and manner reasonably calculated to reach all persons served. The existing PN Rule includes posting on the internet for community water systems or sending an e-mail for non-community water systems as example supplemental delivery methods in addition to direct delivery. The EPA encourages systems to use supplemental delivery methods, for example, social media or other forms of electronic communications, in addition to their primary delivery methods, to widely distribute the PN [40 CFR 141.203(c)(1)(ii), 40 CFR 141.204(c)(1)(ii), 40 CFR 141.203(c)(2)(ii) and 40 CFR 141.204(c)(2)(ii)].

Under special primacy requirements in 40 CFR (Code of Federal Regulations) 142.16(a)(2), a primacy agency may set alternate notification requirements with respect to the form and content of PN. The alternative requirements must provide the same type and amount of information required under 40 CFR 141 Subpart Q. This special primacy requirement addresses state flexibility to approve in writing the use of a substitute delivery method not already listed in the PN rule. The EPA recognizes the need to tailor any additional methods of delivery used to the specific situation. Primacy agencies may make this determination in writing on a case-by-case basis [40 CFR 141.202(c)(4), 141.203(c)(1) and (2), and 141.204(c)(1) and (2)]. Primacy agencies were required to establish enforceable requirements and procedures for adding to or changing the form and manner of delivery requirements for Tier 1, 2, and 3 public notices in their PN regulations [40 CFR 142.16(a)(2)(v)]. A primacy agency also has the option of establishing by rule, after notice and comment, alternate PN form and manner requirements that provide the same type and amount of information required under the EPA's PN regulations. For further discussion of the public notification requirements for this rule, please see section 9.2 of the EPA response in this *Response to Comments* document.

<u>New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045052)</u>

Public Notice Cost

EPA requests comments on the discussion of estimated PN costs provided in the proposed rule. In review of PN costs in NJ, a typical PN cost in New Jersey is estimated at $0.50 - $1.00 per service connections per quarter. The cost range for a community water system to issue a typical Tier 2 PN in New Jersey is $20.00 for the smallest systems to as much as approximately $100,000 of its largest systems per quarter.

EPA Response: Please see section 13.3.5 of the EPA response in this *Response to Comments* document. For discussion of the public notification requirements for this rule, please see section 9.2 of the EPA response in this *Response to Comments* document.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045739)

6. EPA significantly underestimated the costs associated with Public Notifications for this rulemaking by assuming that all systems would be in compliance with the NPDWR.

EPA should re-evaluate its assessment of costs and benefits of their proposed rulemaking to ensure consistency in its assumptions of compliance with the proposed rulemaking to ensure an accurate balance between the two. In section XIII.G, EPA assessed the health benefits that would occur through the reduction in Disinfection By-Products (DBPs) via the implementation of PFAS removal treatment technologies. In this assessment, EPA used its occurrence model to estimate the number of PWSs that would exceed one of the three proposed MCLs to determine how many would install PFAS treatment. This estimate was then used to estimate the health benefits associated with co-removal of DBPs. In EPA's Economic Analysis for the Proposed PFAS NPDWR, it is estimated that over 25% of large systems will exceed one of the three proposed MCLs. However, in section XIII.C.1.h, EPA states that its "cost analysis assumes full compliance with the rule throughout the period of analysis and, as a result, EPA does not estimate costs for the [Public Notification (PN)] requirements in the proposed rule". The assumption stated in section XIII.C.1.h appears to directly contradict the underlying assumption made in section XIII.G. If EPA estimates that 25% of large water systems will exceed one of the three proposed MCLs there are likely to be significant costs associated with issuing the required PNs. It is recommended that EPA re-evaluate their cost assessment in a manner that maintains consistent assumptions throughout the process.

EPA Response: Please see section 13.3.5 of the EPA response in this *Response to Comments* document. For discussion of the public notification requirements for this rule, please see section 9.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that the agency does not maintain consistent assumptions in its EA; the EA assumes that systems that exceed one or more of the MCLs for the final rule will take action to comply with the final rule (e.g., installation of treatment technologies or non-treatment alternatives) by the compliance deadline and, as a result, would not incur violations under the final rule.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045916)

EPA assumed administrative startup costs incorporated a total of 4 hours per PWS to read the rule and 16-32 hours per PWS to attend a training on the rule [FN166: 88 Fed. Reg. at 18697, Table 32.]. EPA further assumed treatment administrative costs of 3 to 42 hours per entry point for a system to notify, consult, and submit a permit request for treatment [FN167: 88 Fed. Reg. at 18699, Table 35.]. This does not appear to include the costs associated with evaluating potential treatment options, design, or piloting treatment.

The times allotted by EPA do not appear to sufficiently capture the administrative time that PWSs will require to be prepared for this rulemaking. These times further do not consider that the majority of treatment system serving less than 3,300 people were not included in UCMR 3 of UCMR 5, and do not have an established baseline of PFAS in their PWS. To properly assess treatment needs, these systems will have to dedicate more time to develop new sampling plans, specifically understating the sample collection methodologies required of analytical methods for which they may not be familiar, and to understand the laboratory results.

With regards to primacy agencies, EPA has assumed there would be no costs related to reporting violations to EPA as result of this rule, which is not a realistic assumption. EPA also assumed that agencies would spend 1 hour per sample to review results; however, EPA did not assume the PWSs would require time to review their own analytical results.

EPA Response: Please see section 13.3.5 of the EPA response in this *Response to Comments* document. The EPA disagrees that the agency has not sufficiently captured the administrative time required of PWSs to comply with the rule. The labor associated with designing the pilot test protocols, installing and testing equipment as well as collecting operational data (monitor and adjust the pilot system and collect samples) are captured in the EPA's cost analysis, within the cost estimates for pilot studies, rather than in the PWS administrative costs. These pilot study costs include labor for initial setup and ongoing operation of the pilot. The EPA applies a generalized labor rate for civil engineers to these hours to reflect that at least some of these activities might be conducted by a 3rd party contractor. This labor rate is higher than the PWS labor rates used in the rule and, therefore, reflects a conservative estimate for those activities that would be conducted by PWS operators.

While not all systems serving less than 3,300 people have been included in UCMR 3 or UCMR 5 sampling, the EPA disagrees that these systems will not have an established baseline. This is because the rule's initial monitoring requirements are intended for water systems to establish their baseline PFAS concentrations and have been costed in the rule appropriately. As part of the final rule, the EPA is also allowing a flexibility for systems to utilize previously collected PFAS drinking water data from UCMR 5 and/or state or other appropriate monitoring efforts to satisfy these initial monitoring requirements and provide baseline PFAS concentrations. Therefore, the EPA has appropriately accounted for the sampling burden and resulting costs anticipated to result from the final rule. For more information on the EPA's monitoring cost estimates, please see Section 5.3.2.2 of the EA (USEPA, 2024b). The EPA notes that the agency also captures costs

associated with traveling to sampling locations, collecting samples, recording additional information, submitting samples to a laboratory, and reviewing results. Additionally, the EPA notes that the agency intends to prepare a Small System Compliance Guide to help small entities comply with the final rule; this resource will be developed in the first three years following rule promulgation and will be made available on the EPA's PFAS NPDWR website.

With respect to the commenter's concern about costs to primacy agencies, please see section 13.3.1 in this *Response to Comments* document for response to comments received on primacy agency costs.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046021)

Multiplying the hourly labor rate by the number of hours per entry point for a system to notify, to consult, and to submit a permit request for treatment installation gives an estimate of the cost per system. Multiplying these figures by the total number of ground water and surface water EPTDSs that exceed one or more MCLs gives the total cost for each system size. This same methodology is used to determine costs per entry point for source water changes or alternative method permitting requests.

Table 14: Implementation Startup Costs

[Table 14: see docket ID EPA-HQ-OW-2022-0114-1738]

Table 16: Treatment Administration Costs

[Table 16: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: Please see section 13.3.5 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045997)

Section 8.10: Public notification costs

AMWA would like to reiterate concerns outlined in section 6.1 with EPA's assumption of 100% compliance with this rulemaking, resulting in no estimation of public notification costs. It is unreasonable for EPA to assume no system will be in non-compliance, especially as the agency is proposing only a three-year compliance deadline. Historically, there are spikes in non-compliance after a regulation takes effect as water systems work to address the issue as quickly as possible. EPA should look at non-compliance from previously NPDWRs and estimate non-compliance and public notification costs. Public notification costs can be significant, particularly if translation and other services are also required.

EPA Response: Please see section 13.3.5 of the EPA response in this *Response to Comments* document. For discussion of the public notification requirements for this rule, please see section 9.2 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043923)

In response to Section XIII. Health Risk Reduction and Cost Analysis, EPA requests comment on the discussion of estimated PN costs provided in the proposed rule.

• Public notifications are not currently factored into the costs developed by EPA. PN costs should be added at some percentage rate considering that achieving compliance by treatment may not be achieved by the compliance deadlines.

EPA Response: Please see section 13.3.5 of the EPA response in this *Response to Comments* document. For discussion of the public notification requirements for this rule, please see section 9.2 of the EPA response in this *Response to Comments* document.

13.3.6 Water System Costs – Non-treatment costs

Summary of Major Public Comments and EPA Responses

Many commenters pointed out that the availability of interconnection[10] and new wells as compliance options will vary greatly on a system-specific or regional basis. Some commenters pointed out that non treatment options would be particularly challenging in regions where water is scarcer; stating "[r]eplacement water is not readily available to most agencies in the arid west." One commenter agreed "…that some systems could potentially decide to install an interconnection if it is a viable alternative. Regionalization may have benefits for consecutive systems and can help provide smaller systems with access to economies of scale." Another noted that interconnection may not be a viable option for many water systems, "…but the option should exist to allow interconnections as a potential compliance avenue." Consistent with these comments, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. Specifically, for design flows up to 10 million gallons per day, the EPA assumed that 7 percent of systems with design flows 1 million gallons a day or less and 6 percent of systems with design flows between 1 and 10 million gallons a day would choose interconnection and 2 percent would choose new wells. For larger flows, the EPA assumed 0 percent of systems would choose non-treatment options. While the EPA recognizes there are likely some regions where non-treatment options would be available to fewer systems, there are also likely regions where these options are more prevalent. For example, one commenter pointed out that Michigan expects up to 26 percent of water systems to interconnect with other systems to comply with their state standard. The EPA is also aware of a number of water systems that have elected to drill a new well to reduce PFAS concentrations in supplied water.

Several commenters stated that the EPA underestimated the costs associated with interconnection. Commenters pointed out that "…systems considering interconnections will need to thoroughly investigate this option and determine if it is both cost effective and appropriate

[10] Interconnection is when a system replaces their contaminated water source by purchasing water from another nearby system that is in compliance. Booster pumps can be needed when the pressure from the supplying system is lower than required at the purchasing system and also to overcome pressure losses due to friction in interconnecting piping.

given the water quality impacts." These commenters identified the following issues that might be faced by individual systems pursuing interconnections: water quality and chemistry concerns (e.g., elevated water age, nitrification, DBPs, compatibility of secondary disinfectants); technical and engineering requirements (e.g., spill containment, mixing and storage tanks, water quality monitoring devices, water main upgrades); additional miscellaneous costs (e.g., buy-in fees, emergency use surcharges); and simultaneous compliance with existing drinking water standards (e.g., Lead and Copper Rule Revisions, Microbial Disinfection Byproduct Rules, and dealing with regulatory matters (e.g. getting local and state approval).). The EPA agrees that there are many considerations for water systems pursuing interconnections, as pointed out by commenters; however these considerations are not quantifiable. For example, water quality and chemistry concerns and simultaneous compliance with existing laws and drinking water standards, and public perceptions of source water type are not direct or indirect costs that can be quantified. Other considerations such as technical and engineering requirements and the labor and time associated with dealing with regulatory matters are likely to vary significantly between systems, and data does not exist to incorporate these costs at the national level. The EPA further notes that water systems that evaluate these quantifiable and non-quantifiable considerations and find that pursing interconnection would require extensive additional costs, such as disinfectant conversion facilities or water main upgrades, would likely not find interconnection cost-effective and elect a different compliance option. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. Regarding the costs to the small number of water systems that do chose interconnection to comply with the rule, based on input received through public comments the EPA incorporated contingency costs at all cost levels and increased the complexity factor applied to estimate contingency for systems using non-treatment options. Increasing the complexity factor increased the overall cost estimate for interconnections and can account for a range of potential site-specific considerations and costs that cannot be captured in a national level analysis. Taken together with the escalation to 2022 dollars and the addition of booster pumps discussed below, these changes increased the system level capital costs for interconnection by approximately 60 to 100 percent. One commenter stated that it was "unrealistic to assume that booster pumps are unlikely to be necessary. Pressure loss associated with friction could be significant, especially for an interconnection that may span 10,000 feet or more," and recommended that the EPA include booster pumps in the cost estimate. The EPA agrees that booster pumps may be needed and added the costs of booster pumps designed to account for friction loss in interconnecting piping.

A few commenters shared some information about the costs that they have incurred at a system level for non-treatment options. However, many of these comments lacked supporting details, such as information to confirm that all of the reported costs were directly associated with replacement of the PFAS contaminated source, as opposed to other infrastructure improvements (e.g., capacity expansion, administrative facilities, distribution system improvements) that happened to be completed as part of the same project. To fully evaluate these estimates in comparison to the WBS model outputs, the EPA would need itemized line-item cost details and engineering design parameters. While the EPA recognizes there are likely site-specific instances where costs exceed the EPA's cost ranges, there are also likely site-specific instances where costs

are less than the EPA's cost ranges, and this level of accuracy is appropriate for a national level analysis.

Individual Public Comments

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042739)

Regional connections are a possibility to achieve compliance, but interconnections with neighboring communities to provide an alternative water source may pose challenges in terms of cost and time required to design, permit, and construct the needed infrastructure, as well as potential incompatibility with that water. [FN2: See Appendix D which outlines challenges and considerations with interconnections.] It is important to note that there are many water systems in New England where interconnections or participation in regional supplies will just not be possible and that is likely the case across the nation, but the option should exist to allow interconnections as a potential compliance avenue.

EPA Response: The EPA has included in the cost analysis the cost and time required to design, permit, and construct the needed infrastructure associated with interconnections. Regarding, "potential incompatibility with that water," please see the EPA response to comment Doc. #1601, SBC-042906 in section 13.3.6 in this *Response to Comments* document and section 13.3.6 of the EPA response in this *Response to Comments* document. The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

Lakewood Water District (LWD) (Doc. #1574, SBC-042748)

Further, EPA's cost estimates for drilling new wells dramatically underestimate the costs. EPA estimates the cost of bringing a new well online to be less than $1,000,000. As described previously, the LWD PFAS mitigation program also includes drilling new wells to replace contaminated wells. LWD's actual experience with the cost of drilling and bringing online one new well is closer to $3.8 million. Keep in mind that the hydrogeology for LWD is more favorable for developing new wells. Nevertheless, LWD's actual experience with the cost of new wells is nearly four times the cost estimate presented by EPA in the proposed rules.

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Please see sections 13.3.3 and 13.3.6 of the EPA response in this *Response to Comments* document.

National Tribal Water Council-Tribal PFAS Working Group (NTWCTPWG) (Doc. #1598, SBC-042343)

Water Source Alternatives

The proposed regulation speaks to an approach to mitigation that makes use of water source alternatives, bypassing the implementation of treatment measures. However, this approach is not available in a large portion of affected tribal communities due to a variety of reasons, including the changing climate impacts on the environments. Tribal communities are often located in areas that see a disproportionate amount of these impacts. Funds should be made available to explore alternative sources and build new facilities before installing new treatment techniques to reduce the long-term impacts on the affected communities. This would be a step towards a holistic assessment of the needs of the affected community's solution to addressing PFAS.

EPA Response: The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

In regard to funding available to explore alternative sources and build new facilities, the EPA notes that the commenter's suggestion is a valid use of DWSRF funding to deal with PFAS. The following are examples of valid DWSRF BIL EC projects; see the EPA's memo on Implementation of the Clean Water and Drinking Water State Revolving Fund Provisions of the Bipartisan Infrastructure Law (USEPA, 2022b).

- Emerging contaminants costs associated with the construction of a new treatment facility or upgrade to an existing treatment facility that addresses emerging contaminants.
- Development of a new source (i.e., new/replacement well or intake for a public water system) that addresses an emerging contaminant issue [Note: water rights purchases must still meet the criteria in the Class Deviation for Water Rights].
- Consolidation with another water system that does not have emerging contaminants present or has removal capability.
- Costs for planning and design and associated pre-project costs.
- Infrastructure related to pilot testing for treatment alternatives.
- Creation of a new community water system to address unsafe drinking water provided by individual (i.e., privately-owned) wells or surface water sources.

Finally, as part of the EPA's environmental justice analysis, the agency examined baseline PFAS exposure and the anticipated distribution of benefits and costs of the rule across various demographic groups, including American Indian or Alaska Native subpopulations. For more information on the findings of the EPA's analysis, please see Chapter 8 of the EA. For the EPA's response to comments about financial assistance available for water systems, please see section 2.4 in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042906)

APPENDIX B - INTERCONNECTION PROCESS Summary of Interconnection Process:

Activities, Regulatory Requirements, Timeframes, and Costs

As the move to regulate PFAS in drinking water in Massachusetts has commenced, a number of public water systems have needed to confront the issue due to PFAS detections from voluntary or past regulatory testing. One option for systems with detects at levels of concern is to utilize an alternate source of water obtained through interconnections with neighboring water systems. While this may be a viable and reasonable option, the use of interconnections as a short or long-term solution to PFAS contamination is not a simple alternative and is beset with issues and concerns.

How quickly an interconnection can be activated and used to replace a PFAS contaminated source is very dependent on site-specific issues. The table below summarizes some of the circumstances that are present and the impact on activation timelines. This summary is not all inclusive; there are numerous combinations of situations that influence the time it would take to activate an interconnection.

[Table 3: See Docket ID EPA-HQ-OW-2022-0114-1601]

Factors that need to be considered in development of the interconnection option include:

• Getting Local Approvals

o Both the supplying system and the receiving system need to agree to make the interconnection option viable. That process of agreement may involve town meeting, city council approval, votes of District commissioners or other formal authorization following a legally established procedure. Approvals by legislative bodies may only happen at certain times, thus subjecting the interconnection activation to schedules driven by other parties and/or statutes.

o Prior to any formal votes or approval actions, the interconnection concept would have to be at least partially developed. That planning process would need to involve engineers from both sides along with directors, commissioners and upper management. The planning process along with preliminary design, authorization to proceed, budget approvals, regulatory guidance and creation/approval of an intermunicipal or inter-district water supply agreement could take 1-3 years (or more).

o Historical relationships between the supplying system and the receiving system play a critical role in creation of a viable interconnection. It is not unusual for there to be “bad blood” between the two sides that stems from some perceived transgression which occurred decades earlier. Sometimes those ill feelings resurface and prevent an otherwise viable interconnection from being developed.

• Regulatory matters and state approvals

o Prior to construction and activation of a new interconnection and in some cases use of an existing interconnection, a number of regulatory hurdles must be overcome. These include:

*Drinking water approvals from MassDEP-the drinking water program would need to review and approve a new interconnection and may have some say in approving use of an existing interconnection.

*Water Management Act-How an interconnection impacts an existing WMA permit needs to be well understood. This is especially the case for the supplying system as the added demand may impact permitted withdrawal volumes, potentially push a withdrawal above its baseline or even result in a permit exceedance. If mitigation becomes necessary the supplying system needs to understand who would be responsible for mitigation and include appropriate language in an interconnection agreement. The supplying system also needs to know how much of its permitted (or registered) withdrawal remains after providing water to a PFAS impacted system and whether that remaining volume is sufficient to allow for growth within the supplying system

*Interbasin Transfer Act-The Interbasin Transfer Act may apply to a new or existing interconnection if the source water is in a different river basin than the receiving system or if the receiving system's wastewater is discharged to a river basin different than the supply system's source water. Interbasin Transfer Act approvals are through the Water Resources Commission and typically involve multiple meetings with IBTA staff to identify and resolve issues before a hearing with the WRC.

*Wetlands Protection Act-For interconnections requiring new infrastructure near wetlands and other water resources, a filing with the local Conservation Commission would be needed. This process typically includes a public hearing followed by issuance of an Order of Conditions. The entire process could take two months or more.

*MEPA Filing-If the interconnection trips certain thresholds, an Environmental Notification Form (ENF) would have to be filed. That could potentially be followed by preparation of an Environmental Impact Report (EIR). The ENF could take 3-6 months while the EIR could take 6 months to 2 years. Public meetings and site visits would also be part of this process.

*Procurement-Purchasing and installing materials and equipment needed for a viable interconnection will typically involve procurement under Massachusetts law. Most often equipment and services will need to be bid, usually after design and preparation of specifications by a consulting engineer. The procurement process adds time to the overall development of the interconnection and the process can be further delayed through litigation brought by parties who are dissatisfied with the bid outcome.

• Technical/engineering concerns

o Water pressure at the interconnection will, in part, determine the need for pumping. If the receiving system needs to pump water into parts of its system the design, construction and operation of the system will be much more complex and costly.

o Available flow rates, in addition to pressure, will drive complexity and costs for the receiving system. Distribution system design (pipe size, storage) is generally driven by fire flows. While pressures at the interconnection may be adequate, existing pipe size and condition in both the supplying system and receiving system may be flow limiting. Extensive water main upgrades may be required in order to meet both water use needs and fire flows in the receiving system and prevent low pressures and system disruptions (Rusty water, main breaks) in the supplying system.

o The supplying system needs to determine whether it has the physical capacity to supply the volume requested by the receiving system. This is a matter of water source capacity (well pumping rates, surface water and treatment facility capacity) and transmission capabilities (pumping stations and storage) along with regulatory limits on available volumes (WMA).

o The physical interconnection needs to be considered in terms of pipe size, materials, valves, metering, meter vault, SCADA controls, chemical injection (disinfection, corrosion control), alarms and pumping stations.

Having the space to construct the needed infrastructure is also critical. Land acquisition and/or easements may be necessary to actually build the interconnection.

• Water Quality concerns

o Using an interconnection between two water systems is not as simple as opening a valve if impacts on water quality for the receiving system are not well understood.

*Conflicting water chemistry-Treated water from the supplying system may not be compatible with the water in the receiving system. This could result is precipitation of iron or other elements that causes discoloration. Worse yet, corrosive water from the supplying system could cause lead and copper to leach from pipes, services and plumbing in the receiving system, as occurred in Flint, MI.

*Poor water quality at periphery of supplying system-

Interconnections are often located at the periphery of the supplying system where water age can increase the likelihood of water quality problems including bacterial growth, low disinfectant residuals, elevated iron, elevated disinfection byproducts, tastes and odors. Eliminating elevated PFAS in exchange for elevated THMs or HAAs or generally poor water quality would not be a desired outcome of an interconnection that may have already contributed to higher water rates.

*Public perception-Customers in the receiving system may not be pleased to receive water with high dissolved solids, poor taste, high chlorine levels and discoloration that comes through the interconnection. While the new supply may meet all water quality standards, it may not meet with satisfaction from the customers who use it. This is especially true if the receiving system had previously had soft, surface water and will now get hard, groundwater with high dissolved solids.

• Costs

o There are many cost factors that need to be considered

*There may be substantial buy in fees

*Utilities may have to payer higher per unit charges than if they were utilizing their own supply

*There may be emergency use surcharges

EPA Response: The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. The EPA recognizes there may be regulatory limitations as to whether an interconnection can occur, potentially including the regulatory factors such as the interbasin transfer act, wetlands protection, water management act, local and state approvals, or other legal limitations that would prevent or limit interconnection options. The EPA also recognizes that there are many considerations for water systems to evaluate when considering compliance options, including those described by this commenter such as technical and engineering concerns, water quality concerns, and public perception of the source water types. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options; please see section 13.3.6 of the EPA response in this *Response to Comments* document for more information. The EPA believes it has accurately estimated costs for non-treatment options because, among other things, many of the engineering/technical concerns mentioned by the commenter are explicitly addressed in the WBS costs, including land acquisition and physical interconnection components such as pipe size, materials, valves, metering, meter vault, and SCADA controls. For the final EA, based on this and other comments, the EPA added the costs of booster pumps designed to account for friction loss in interconnecting piping. The only physical equipment costs that the commenter mentions that the EPA didn't consider are chemical injection and distribution system upgrades. These needs are highly system specific. In the case of distribution system upgrades, they include general infrastructure improvements that may be required even in the absence of the PFAS rule. The EPA also agrees that there are many other considerations for water systems pursuing interconnections and therefore the EPA incorporated contingency costs at all cost levels and increased the complexity factor applied to estimate contingency for systems using non-treatment options. Taken together with the escalation to 2022 dollars and the addition of booster pumps, these changes increased the system level capital costs for interconnection by approximately 60 to 100 percent. Please see section 13.3.6 of the EPA response in this *Response to Comments* document. The EPA also agrees that utilities may have to pay higher unit costs for purchased water than for their own supplies. The EPA explicitly included the cost of purchasing water in the cost estimates. While the EPA did not quantify the potential cost savings in the cost analysis because of uncertainties, the unit cost for purchased water that the EPA used may, in fact, overestimate the marginal cost of purchasing water to replace a contaminated source because it does not account for the avoided cost of pumping and performing non-PFAS-related treatment on the abandoned source.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042890)

Regional connections are a possibility to achieve compliance, but interconnections with neighboring communities to provide an alternative water source pose challenges in terms of the cost and time required to design, permit, and construct the needed infrastructure, as well as potential incompatibility with that water [FN20: See Appendix B which outlines challenges and considerations with interconnections.]. It is important to recognize that there are many PWS in Massachusetts where interconnections or participation in regional supplies will just not be possible, and that is likely the case across the nation, but the option should exist to allow interconnections as a potential compliance avenue.

EPA Response: The EPA has included in the cost analysis the cost and time required to design, permit, and construct the needed infrastructure associated with interconnections. Regarding, "potential incompatibility with that water," please see the EPA response to comment Doc. #1601, SBC-042906 in section 13.3.6 in this *Response to Comments* document and section 13.3.6 of the EPA response in this *Response to Comments* document. The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043079)

Interconnections

The Proposal considers that some water systems may take non-treatment actions to mitigate PFAS levels, such as the installation of an interconnection. Aqua agrees that some systems could potentially decide to install an interconnection if it is a viable alternative. Regionalization may have benefits for consecutive systems and can help provide smaller systems with access to economies of scale. Alternatively, regionalization can have unintended consequences on the water quality for the consecutive system, such as elevated water age and disinfection byproducts, and corrosion control impacts. For this reason, systems considering interconnections will need to thoroughly investigate this option and determine if it is both cost effective and appropriate given the water quality impacts. For the analysis, EPA estimates that upwards of 7% of small systems will install an interconnection to comply with the PFAS MCLs.

In review of the EPA's approach, Aqua recommends that the following challenges are recognized by the EPA and that the Agency incorporate these challenges into the cost analysis if interconnections will be retained in the final rule as a compliance option. These challenges include:

• Compatibility of Disinfectants: The use of disinfectants for drinking water treatment varies by system and not all systems use the same disinfectant chemical to maintain distribution system residuals (if they are required). The selection of a disinfectant for maintaining a residual is not

solely a regional decision and varies on several other factors (e.g., water source, finished water quality, distribution system size, water supply capacity, etc.). Subsequently, there is a significant likelihood that a purchasing system may be using a different disinfectant than a supplying water system, which would require the installation of a facility that can either convert free chlorine to chloramine, or vice versa.

• Simultaneous Compliance with Lead and Copper Rule: In 2021, the Lead and Copper Rule (LCR) Long-Term Revisions became effective, which require water systems to provide enhanced protections for the public when adding new sources of water to the system.

• Simultaneous Compliance with Microbial and Disinfection Byproduct Rules: As noted previously, regionalization can have negative impacts on water quality particularly because of increased water age. For systems that install a consecutive system, a thorough investigation will be necessary to determine if water age will be an issue and whether disinfection byproducts (DBPs) may need addressed at the point of connection. This could potentially require systems installing interconnections to install GAC filters. Similarly, systems may determine that there is an inadequate disinfectant residual present in the water to support the longer water age and thus requiring a boosting station.

EPA Response: The EPA agrees that there are many considerations for water systems pursuing interconnections, including those discussed by the commenter such as compatibility of disinfectants and simultaneous compliance with LCR and MDBPRs. Therefore, the EPA increased the complexity factor applied to estimate contingency for systems using non-treatment options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document for more information about the complexity factor and the treatment of compatibility of disinfectants. For the EPA's response to comments on simultaneous compliance, please see section 10 in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-052830)

• Pressure Differences: Pressure loss associated with friction could be significant, especially for a typical interconnection that may span 10,000 feet. For an interconnection of this distance, the pressure loss associated with water flow through an appropriately sized pipe (to maintain water velocity from 5 to 7 feet per second), would lead to a pressure loss of approximately 50 psi. The inclusion of purchasing booster pumps, at minimum, should be included as part of this analysis.

EPA Response: The EPA agrees that booster pumps may be needed for interconnecting systems. For the final EA, based on this and other comments, the EPA added the costs of booster pumps designed to account for friction loss in interconnecting piping. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-052831)

• Unit Cost of Purchased Water: According to the Proposal, an assumed average cost of purchased water is $3.00 per thousand gallons (2021$) based on wholesale rates that were available online. Currently there are 3,258 water systems in SDWIS categorized as wholesaler systems. These systems range in service population size from 25 to up to 2.5 million persons, which represents a significant range in the ability for the system to produce and sell finished drinking water at economy of scale. Aqua's current purchased water interconnects range from $2.33 to $16.0 per thousand gallons with an average cost of $5.32 per thousand gallons (2022$) and thus the EPA is significantly underestimating the costs of interconnections. It is not clear what data was used to estimate the national average cost of purchased water and whether this data is nationally representative. It is possible that the available data may only be from cities with a water supply that is inexpensive to treat and supply to purchasers. Additionally, some systems that consider an interconnect may not be purchasing water from a large system that has achieved an economy of scale. Transparency on this data is necessary to ensure that this unit cost is accurate and reflective of the national perspective.

EPA Response: For the final rule, the EPA used a cost for purchased water of $3.17 in 2022 dollars, based on unit costs from 6 wholesalers collected between 2019 and 2022. Although this rate is lower than the commenter's average, it may still overestimate the marginal cost of purchasing water to replace a contaminated source because it does not account for the avoided cost of pumping and performing non-PFAS-related treatment on the abandoned source.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-052832)

• Available Capacity Without Improvements: Finally, the EPA's approach assumes that these water systems will be able to identify a supplier water system that has existing available capacity to provide finished drinking water with PFAS levels below the MCL without needing to install treatment. It is highly likely that a supplier will need to install additional drinking water treatment systems to accommodate the purchasing water system's water supply capacity. This is an especially important consideration for regions of the U.S. where drought is creating water supply challenges already as well as areas where source waters are becoming increasingly challenging with respect to accessibility and ease of treatment. On top of this challenge, there is a high likelihood that the PFAS contamination impacting a purchasing water system may be impacting the supplying water system, especially given the low levels of concern identified by the Proposal. In this case, the supplying water system would need to install PFAS treatment for their current water supply capacity in addition to the purchasing water system's demands.

EPA Response: The EPA recognizes that interconnection is only a viable option in some cases and dependent on identifying a supplier with available capacity, as discussed by the commenter. Therefore, the EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a

limited number of systems nationwide would be able to choose these options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043726)

EPA should also consider region specific challenges when proposing this rule. In the arid west it will be an extreme challenge to find new sources of water if the system's current sources are high in PFAS chemicals. Many western water systems simply cannot afford to turn off a source because it is high in PFAS and move to another source. There may not be another source available. Water systems such as Aurora Water are in a better position than many smaller water providers and could still struggle to be able to replace certain sources. Furthermore, shutting down certain sources could potentially jeopardize the water right itself. Water is scarce and becoming scarcer in the arid west. The cost of replacement supplies could easily be exorbitant.

EPA Response: The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. The EPA also recognizes that in areas with limited water resources, finding new sources or interconnections may pose particularly significant challenges. However, these limitations are not applicable for much of the country (e.g., Michigan). As discussed in section 13.3.6 of the EPA response in this *Response to Comments* document, the EPA assumed that only a limited number of systems nationwide would be able to choose these options.

Horsham Water & Sewer Authority (HWSA) (Doc. #1686, SBC-043810)

Additionally, as a utility that has had to use increased purchase of water from neighboring utilities while our wells have been out of service for installation of PFAS treatment and has recently drilled a new well hoping to replace an existing one (unrelated to PFAS as no water supply well can be drilled in Horsham Township that is not impacted by the PFAS contamination), EPA's cost estimates for the use of purchase water and drilling new wells as alternates to treatment are low as well. It should also be noted that the availability of a neighboring utility with unused capacity to sell and/or the ability to drill a new well far enough removed from contamination in an aquifer is a luxury many utilities will not have available to them, and we believe EPA is overestimating the number of utilities that will be able to use these mitigation options. Purchasing water most likely will not be an option for a system that is not adjacent to a larger surface water supplied system and in many such cases, the secondary disinfection residuals are not compatible (free chlorine vs. chloramines) and will require additional capital expenditures not accounted for to avoid blending of residuals.

EPA Response: The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. The EPA also agrees that there are many considerations for water systems pursuing interconnections, including secondary disinfection, and therefore the EPA increased the complexity factor applied to estimate

contingency for systems using non-treatment options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document. Regarding the cost of purchased water, please see the EPA response to comment Doc. #1623, SBC-052831 and Doc. #1759, SBC-045615 in section 13.3.6 of the EPA response in this *Response to Comments* document. Regarding the costs to drill a new well, the EPA has made adjustments described in section 13.3.6 of the EPA response in this *Response to Comments* document that have increased the cost estimates for drilling a new well.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045051)

In addition to the overall concern the NJDEP has with the National Cost Estimate, the NJDEP recommends that EPA evaluate its estimate of the number of public water systems that would feasibly be able to select non-treatment options. Section 5.3.3.1 (Decision Tree for Technology Selection) in this document outlines the process that EPA used to determine what treatment technology or non- treatment option a public water system would select based on the three inputs the decision tree accepts. Table 5-8, located in this section, notes that 8% of public water systems, both those with design flows less than one MGD and those with design flows of one to ten MGD, would opt for interconnection or new wells, both non-treatment options. While this outcome may be accurate in a theoretical setting, regional differences in geology and local governance issues render it far harder for many small systems in certain regions of the US to opt for non-treatment options.

The NJDEP urges the EPA to take into consideration these issues raised regarding the choosing of non- treatment options in the model. This gap could possibly be bridged by including additional inputs for the decision tree that would account for varying geology (and how those differences may limit the drilling of new wells) and a measure of distance to the next available PWS to determine the feasibility of interconnection.

In no way should NJDEP comments concerning estimated costs be construed as a lack of support for the proposed standards, which NJDEP finds to be a critical measure necessary to better protect public health, safety, and the environment from the myriad and significant risks associated with PFAS.

EPA Response: The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. The EPA did not have sufficient data to incorporate variations in geology or distance to the nearest PWS in the model. Furthermore, given that the EPA assumed that a limited number of systems nationwide would be able to choose non-treatment options, it is not clear that the inclusion of these additional variables would significantly change the results. Please see section 13.3.6 of the EPA response in this *Response to Comments* document for further discussion of factors the EPA considered when estimating the number of systems that would opt for interconnections or new wells.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045115)

b. Alternatives such as drilling a new well and installing it should be evaluated from a cost perspective. In Vermont, the cost per source is ~$100,000-200,000 assuming you own the property, and the well is not very deep. The yield of the source will influence the unit (cost/household).

EPA Response: The comment lacks sufficient detail to compare these costs to the results of the EPA's WBS models. Even a rough comparison would require information on well capacity (i.e., design flow). Also, although the comment indicates the well is "not very deep," it provides no quantitative information for comparison with the EPA's default assumption of 250 feet. See also sections 13.3.3 and 13.3.6 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043913)

In response to Section XI-Treatment Technologies, EPA requests comment on whether there are additional technologies which are viable for PFAS removal to the proposed MCLs as well as any additional costs which may be associated with non- treatment options such as water rights procurement.

• Additional costs for non-treatment options could include easements, land acquisition, in order to obtain necessary water rights. Planning, design, and construction costs would also be incurred for either interconnection or new well options, there may be a need to seek new water sources outside of the local area which would require large transmission lines, large amount of energy consumption and fossil fuels to be used, in order for the water to be delivered to the residents of Las Cruces.

EPA Response: The EPA's cost estimates for new wells explicitly include land acquisition. The land area purchased is based on the well and building footprint plus buffer space for access around all sides. The EPA does not have nationally representative information to estimate additional easement costs beyond the purchase price of land. The cost estimates for interconnection explicitly include 10,000 feet of transmission piping sized to accommodate the required design flow. The cost estimates for both options include planning, design, and construction costs, specifically mobilization and demobilization, geotechnical evaluation, process engineering, construction management, and general contractor overhead. To account for other site-specific considerations for water systems pursuing non-treatment options, the EPA also increased the complexity factor applied to estimate contingency. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

In response to comment on costs for water rights procurement, the EPA did not have sufficient data to incorporate these potential costs. Further, it is reasonable to assume that water systems that may face prohibitively high water rights procurement associated costs would elect a more cost effective option, including the treatment options available to comply with the rule. While the

EPA notes water scarcity issues are a challenge in parts of the country, other parts of the country do not have these limitations to nearly the same degree. Irrespective of whether the EPA's estimate of 2 percent of systems nationwide would seek a new source is accurate, inclusion of these potential additional costs would not significantly change the national results.

Please see section 13.11 in this *Response to Comments* document for the EPA's response to comments on greenhouse gas emissions associated with the rule.

American Water Works Association (AWWA) (Doc. #1759, SBC-045615)

• Unit Cost of Purchased Water: According to the proposal, an assumed average cost of purchased water is $3.00 per thousand gallons (2021$) based on wholesale rates that were available online. Currently there are 3,258 water systems in SDWIS categorized as wholesaler systems. These systems range in service population size from 25 to up to 2.5 million persons, which represents a significant range in their economy of scale. The WBS for non-treatment options and the documentation that is provided does not clearly illustrate what data were considered to estimate the national average cost of purchased water and whether those data are nationally representative. It is possible that if the available data may be only from cities with a water supply that is relatively inexpensive to treat and supply to purchasers. Transparency on this data is necessary to ensure that this unit cost is accurate and reflective of the national perspective. EPA should therefore provide the underlying analysis and an explanation for the model provided in order to allow for a meaningful opportunity for public comment.

To further illustrate this, a report by the Department of Energy from 2017 assessed water rates nationally and estimated that in 2016 the average water rate was $3.38 per thousand gallons (DOE, 2017). More recent data from Circle of Blue similarly analyzed water rates nationally and estimated that average national water rate in 2019 to be $6.22 per thousand gallons (Circle of Blue, 2019). These national data points highlight a stark difference between the EPA's data and highlight that water rates have increased substantially as water supplies have become more severely impacted by drought and water quality challenges. Additionally, it is important to note that both reports do not reflect water system cost increases related to LCRR, the economic effects of the COVID-19 pandemic (e.g., increased price of chemicals, materials, and labor).

These cost increases have been previously described in this letter. EPA should clearly communicate the sources of the wholesale water rate data so that additional supporting data can be provided to improve EPA's analysis.

EPA Response: For the final rule, the EPA used a cost for purchased water of $3.17 in 2022 dollars, based on unit costs from 6 wholesalers collected between 2019 and 2022. The DOE data cited by the commenter appear to be rates charged to retail commercial or industrial users. The Circle of Blue data (https://www.circleoofblue.org/waterpricing/) are retail residential rates. Neither of these sources reflect wholesale rates charged to interconnected water utilities and are therefore not appropriate for inclusion in the EPA's costs analysis.

American Water Works Association (AWWA) (Doc. #1759, SBC-045613)

• Simultaneous Compliance with LCRR: LCRR became effective in 2021 and water system compliance with all provisions of the current LCRR will be required in October 2024. Water systems are required to fully evaluate and ensure adequate corrosion control when adding or changing sources of water. Specifically, LCRR expands on existing requirements to include this assessment when adding new sources as previously described. The challenges posed by LCRR will impact the number of systems for which purchased water from wholesale supplier is a viable near-term option. Furthermore, if both systems are using CCT, the compatibility of each CCT must be considered.

• Simultaneous Compliance with Microbial and Disinfection Byproduct Rules: As noted previously, regionalization can provide benefits but can also have negative impacts on water quality particularly because of increased water age. For systems that install an interconnection to a consecutive system, a thorough investigation will be needed to determine if water age will be an issue and whether DBPs may need to be addressed at the to prevent MCL violations. This could potentially require systems installing interconnections to install GAC filters and/or transition to a different disinfectant residual. Similarly, systems may determine that inadequate disinfectant residual is present in the water to support the longer water age and so a boosting station is required.

EPA Response: Regarding simultaneous compliance considerations when evaluating interconnection as a compliance option, please see section 13.3.6 of the EPA response in this *Response to Comments* document. For the EPA's response to simultaneous compliance generally comments, please see section 10.4.2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-053040)

• Available Capacity Without Improvements: Finally, the EPA's approach makes a blanket assumption that these water systems will be able to identify a supplier water system that has existing available capacity to provide finished drinking water with PFAS levels below the MCL without needing to install any treatment. It is highly likely that a supplier will need to install additional drinking water treatment systems to accommodate the purchasing water system's water supply capacity. This is an especially important consideration for regions of the U.S. where drought is creating water supply challenges already as well as areas where source waters are becoming increasingly challenging with respect to accessibility and ease of treatment. On top of this challenge, there is a significant possibility that the PFAS contamination impacting a purchasing water system is also impacting the supplying water system, especially given the low levels of concern identified by the proposal. In this case, the system providing water supply would need to install PFAS treatment capacity for their current water supply capacity in addition to the purchasing water system's demands.

EPA Response: The EPA agrees that the availability of alternative water sources will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to purchase water as a compliance option. The EPA further assumed that the purchased water would be from a source that does not need to treat for PFAS. The EPA recognizes this may result in a slight underestimate of national compliance costs. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-053042)

Finally, in review of the EPA's example outputs for interconnections, the projected costs for a 1 MGD interconnection with mid-cost components were estimated to be less than the projected costs for a 0.5 MGD interconnection with low-cost components. It's unclear whether the model requires correction. Nonetheless, EPA is encouraged to review the model and subsequent cost analysis to ensure that this and other potential errors are addressed prior to using this analysis to support any final rule.

EPA Response: The commenter is correct that costs for the larger, mid-cost example were lower than for the smaller, low-cost example. The EPA reviewed the model and determined that this counter-intuitive result was not caused by an error in calculation. Instead, it was an artifact of the minimum size of interconnecting piping, limited choice of acceptable materials, and default assumptions about indirect costs. Specifically, direct capital for these two systems were identical because equipment sizes and materials were the same. Indirect capital was slightly lower for the larger system because of the lower process engineering and mobilization/ demobilization percentages assumed for medium systems, resulting in a lower total cost. In the final rule, the EPA has added the cost of booster pumps for interconnecting systems, which eliminates this discrepancy in the example outputs. Please see section 13.3.6 of the EPA response in this *Response to Comments* document for discussion of the addition of booster pumps.

American Water Works Association (AWWA) (Doc. #1759, SBC-053045)

Development of New Wells

EPA also estimates that some water systems will develop new wells instead of installing treatment. The development of new wells also relies on assumed conditions that may make the development of new wells to be more cost effective than treatment. One key assumption is that the PFAS contamination impacting the water system's current groundwater source is not impacting another local source where a new well can be constructed. This is a flawed assumption and likely overestimates the number of water systems for which this is a viable option.

EPA Response: The EPA continues to believe that the record supports the assumption that 2 percent of small water systems nationwide will be able identify a new well that is contaminated to a lesser degree than their current groundwater source; this is supported by the record for the proposal (see Chapter 5 of the EA for proposal) as well as public commenters who

provided information on drilling a new well to reduce PFAS concentrations in supplied water. The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-053047)

This option also appears to be underestimating the costs for performing this task. In review of the example cost model outputs for a new well of 0.5 MGD, several aspects of the cost estimate are significantly low. A recent budgetary estimate for a water system in Pennsylvania for a new well with a capacity of 0.144 MGD is approximately $1.5 million, which does not include planning and design services totaling another $532,000 (Horsham, 2023a).

The referenced budgetary estimate was compared with EPA's model output for the development of a new 0.5 MGD well. Several aspects of the project are substantially low compared with the referenced estimate. Construction management, for example, is estimated to be less than $16,000 by EPA'S WBS whereas the construction management services for this recently developed well will exceed $175,000. The overall cost of this well will exceed EPA's estimate by a factor of 5 for a well that has less than a third of the capacity. Another water system in Washington submitted comments to the EPA similarly illustrating that these costs are underestimated by a factor of 4 (LWD, 2023).

In order to provide an accurate assessment of costs, EPA must therefore re-evaluate the WBS for new wells and address errors in its estimates prior to using its new well costing analysis to support any final rule.

EPA Response: The updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $272,000 to $587,000 for a 0.144 million gallon/day new well. Although the commenter's budgetary estimate exceeds the EPA's range, the comment does not include information to confirm that (1) all the estimated costs would be directly associated with replacement of the PFAS-contaminated source, as opposed to other infrastructure improvements, and (2) that design parameters (e.g., well depth, distance to distribution system) for this facility would be similar to the typical values assumed in the EPA's estimate. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-053010)

Interconnections

EPA anticipates that some water systems may take non-treatment actions to respond to PFAS levels above the MCLs, such as the installation of an interconnection. Overall, AWWA agrees that some systems could potentially decide to install an interconnection if it is a viable alternative. Regionalization may have benefits for consecutive systems and can help provide

smaller systems with access to economies of scale. Alternatively, regionalization can have unintended consequences on the water quality for the consecutive system, such as elevated water age, nitrification, and DBPs. For this reason, systems considering interconnections will need to thoroughly investigate this option and determine if it is both cost effective and appropriate given the water quality impacts.

For the analysis, EPA estimates that upwards of 7% of small systems will install an interconnection to comply with the PFAS MCLs, it is unclear from the supporting information how this assumption was made, and EPA should provide additional information. The potential use of an interconnection to comply with the proposed rule has not previously been included as part of a drinking water rule's compliance analysis and the EPA's approach poses significant issues that exclude significant cost factors. AWWA is providing the following recommendations for necessary considerations for installing interconnections.

• Compatibility of Secondary Disinfectants: The use of disinfectants for maintaining a residual in the distribution system varies by system and not all systems use the same disinfectant chemical to maintain distribution system residuals (if they are required to). The selection of a disinfectant for maintaining a residual is not regionally uniform and varies on a number of other factors (e.g., water source, finished water quality, distribution system size, water supply capacity, etc.). Subsequently, there is a significant likelihood that a purchasing system may be using a different disinfectant than a supplying water system, which would require the installation of a facility that can convert free chlorine to chloramine, or vice versa. Some systems may need pH adjustment as well. EPA's cost analysis for interconnections does not consider this. If needed, disinfectant conversion facilities require substantially more upgrades than the EPA's WBS for interconnection considers. Costs for these facilities will need to include, at a minimum:

o Land purchasing,

o Building construction, Chemical feed pumps, storage tanks, and spill containment,

o Mixing and storage tanks, and

o Water quality monitoring devices.

EPA Response: The EPA agrees that there are many considerations for water systems pursuing interconnections, please see section 13.3.6 of the EPA response in this *Response to Comments* document for more information. Based on this and other comments, the EPA incorporated contingency at all cost levels and increased the complexity factor applied to estimate contingency for systems using non-treatment options. The EPA did not explicitly include the cost of disinfectant conversion facilities because the need for these facilities, along with the associated design and operating requirements is highly system specific. Systems with extensive such needs would likely not find interconnection cost-effective. Accordingly, the EPA assumed only a small percentage of systems could use this option.

American Water Works Association (AWWA) (Doc. #1759, SBC-045614)

Pressure Differences: In Table 5-15 of the Economic Analysis, the EPA notes that booster pumps and/or pressure reducing valves are included as direct capital costs by the WBS cost model. The agency later notes, however, that to generate cost equations for interconnections the agency has assumed a minimal pressure difference between each water system so that neither booster pumps nor pressure reducing valves are needed. AWWA understands that it may be impossible for the agency to surmise the average pressure difference between two water systems, however it is nonetheless unrealistic to assume that booster pumps are unlikely to be necessary. Pressure loss associated with friction could be significant, especially for an interconnection that may span 10,000 feet or more. For an interconnection of this distance, the pressure loss associated with water flow through an appropriately sized pipe (to maintain water velocity from 5 to 7 feet per second), would be approximately 50 psi. The inclusion of purchasing booster pumps, at minimum, should be included as part of this analysis.

EPA Response: The EPA agrees that booster pumps may be needed for interconnecting systems. For the final EA, based on this and other comments, the EPA added the costs of booster pumps designed to account for friction loss in interconnecting piping. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043948)

C. Alternative Water Supplies

EPA requested additional comments on whether there are additional technologies which are viable for PFAS removal to the proposed MCLs, as well as any additional costs which may be associated with "non-treatment options," such as water rights procurement. [FN29: 88 Fed. Reg. at 18731.] EPA selected an economic model to evaluate costs of certain non-treatment options as part of its EA, including the construction of replacement groundwater wells in an uncontaminated aquifer or purchasing replacement water from other public water systems. [FN30: EA at 5-9–5-40]

WUWC is concerned that the selected modeling does not adjust for regional differences in alternative water supply costs and availability. In the arid western United States, where the majority of WUWC members reside, periods of prolonged drought, population growth, and other stressors have constrained water supplies to a greater degree than experienced in other areas of the country.

For example, in areas of the western United States that are reliant on groundwater for a significant portion of their water supply, our members report that the costs to produce and treat groundwater to potable quality are already rising. Aquifers stressed by drought and population growth in many areas of the West have experienced significant drawdown, meaning that new or replacement water supply wells must be drilled deeper, increasing water utilities' drilling costs and energy expenditures to pump groundwater. [FN31: See, e.g., U.S. Geological Service,

Groundwater Decline and Depletion (June 6, 2018), available at https://www.usgs.gov/special-topics/water-science-school/science/groundwater-decline-and-depletion#overview.] One of our members has reported that, where an aquifer serving as a primary water supply became contaminated with PFAS, the infrastructure and incremental operational costs of replacing that supply totaled approximately six million dollars. That capital cost translated to an approximately $300 per person increase ($882 per tap) over a two-year period, the effect of which is ultimately borne by ratepayers.

Water utilities in the West have increasingly been looking to diversify water supplies through commissioning recycled water projects, including projects supported by EPA funding opportunities. Our members report that recycled water projects can be capital intensive and difficult to achieve to due significant hurdles with permitting, environmental review, and agency staffing limitations. The Proposed Rule will only make utilities' water supply diversification strategies more expensive. To the extent that EPA's financial modeling supporting the Proposed Rule has not considered these differences, WUWC believes EPA has not conducted sufficient analysis to draw conclusions about the economic feasibility of obtaining alternative water supplies.

EPA Response: The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. The comment lacks sufficient detail to compare the provided costs to the results of the EPA's WBS models. Please see section 13.3.6 of the EPA response in this *Response to Comments* document for discussion about considerations that water systems are likely to evaluate when selecting a non-treatment option, and the EPA response to comment Doc. #1753, SBC-043913 in section 13.3.6 in this *Response to Comments* document for discussion about limitations for obtaining other water supplies.

Eastern Municipal Water District (EMWD) (Doc. #1780, SBC-043821)

EPA's cost assessment does not fully capture the costs that will be borne by water agencies and ratepayers. As an agency that provides water, wastewater, and recycled water services, we have a deep appreciation for the severe and far-reaching impacts that can occur when PFAS is detected. EMWD has shut off three wells due to PFAS contamination, and we were compensated by the Department of Defense to bring one of those wells back in to service as the cause of contamination was legacy fire fighting training on a U.S. Air Force Base. EPA's Proposed Rule discusses replacement water as an alternative to treatment, which is not a viable option. Replacement water is not readily available to most agencies in the arid west, and when additional supplies can be developed, those new projects are very expensive. EMWD is already maximizing all available local resources such as recycled water and brackish groundwater. Developing new replacement water would be very expensive, and for EMWD, importing additional water as a replacement source would place a greater burden on the Colorado River and the Sacramento San Joaquin Delta.

EPA Response: The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046173)

[The analysis that follows shows that the $3.1 billion dollar difference in annualized cost can be explained by the following primary factors:]

4. Non-treatment compliance options. AWWA assumes all PWSs that exceed the MCL will install treatment at every entry point, and EPA assumes that small systems will explore interconnections with other complying systems and new sources before installing treatment. As one example, Michigan Department of Environment, Great Lakes, and Energy (EGLE) personnel have indicated that it is policy to investigate safe water options before considering installation of treatment on a source that exceeds an MCL (Smith, Personal Communication 2023). Michigan's analysis exploring the existing Michigan MCLs and the proposed EPA rule indicates that EPA's estimates of systems opting for non-treatment are reasonable and may even be low (Smith, Personal Communication 2023). Michigan anticipates that up to 26% of PWSs requiring treatment may be able to establish a new connection with another PWS that already meets the MCLs. In this case, both the EPA and the AWWA cost estimate for treatment may be high. Using EPA's assumptions for establishing new interconnections or new sources would result in at least $159 million in savings compared to AWWA. (Appendix D).

[The analysis that follows shows that the $3.1 billion dollar difference in annualized cost can be explained by the following primary factors:]

EPA Response: The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. For this reason, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document. The EPA also agrees with the commenter's conclusions about the sources of differences between the EPA's estimate and the AWWA B&V report estimates. Please see section 13.3.3 of the EPA response in this *Response to Comments* document.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045771)

We also note the optimistic nature of the assumptions associated with those systems who may opt to purchase water from a wholesaler through an interconnection rather than install and operate treatment.

Interconnections may be a more economical solution than treatment for some small systems. However, the assumptions made by EPA are overly simplistic. Interconnects are not without their challenges. Compatibility of the new water supply and the existing supply must consider the

secondary disinfectant (free chlorine or chloramines), corrosion control treatment (do the systems both practice the same corrosion control treatment), water age impacts, pressure, and supply redundancy (need for storage). The assumption that an interconnection can be made by simply connecting one water system to another is likely the exception rather than the rule. It should be assumed that booster pumping, storage, and disinfectant boosting are required at all interconnects to appropriately account for the costs of interconnections for small water systems.

The accuracy of the Proposal's cost evaluation is the foundation to an accurate NRRCA and affordability evaluation. Based on our experience, the EPA cost model significantly underestimates the capital and O&M costs associated with PFAS treatment. We recommend that EPA reevaluate its cost estimates and consider inflation and supply chain issues likely to result from the Proposal in its revised evaluation.

EPA Response: The EPA agrees that there are many considerations for water systems pursuing interconnections and therefore the EPA increased the complexity factor applied to estimate contingency for systems using non-treatment options. The EPA also added the costs of booster pumps designed to account for friction loss in interconnecting piping. Please see section 13.3.6 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on water treatment costs, please see section 13.3.3 in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-045391)

Regional connections are a possibility to achieve compliance, but interconnections with neighboring communities to provide an alternative water source may pose challenges in terms of cost and time required to design, permit, and construct the needed infrastructure, as well as potential incompatibility with that water. It is important to note that there are many water systems in New England where interconnections or participation in regional supplies will just not be possible and that is likely the case across the nation, but the option should exist to allow interconnections as a potential compliance avenue.

EPA Response: The EPA has included in the cost analysis the cost and time required to design, permit, and construct the needed infrastructure associated with interconnections. Regarding, "potential incompatibility with that water," please see the EPA response to comment Doc. #1601, SBC-042906 in section 13.3.6 in this *Response to Comments* document and section 13.3.6 of the EPA response in this *Response to Comments* document. The EPA agrees that the availability of non-treatment options will vary greatly on a system-specific and regional basis. The EPA acknowledges that interconnections and new sources may not be a viable or the most cost-effective option in many cases. For these reasons, the EPA assumed that only a limited number of systems nationwide would be able to choose these options. Please see section 13.3.6 of the EPA response in this *Response to Comments* document.

13.4 Method for Estimating Quantified Benefits

Summary of Major Public Comments and EPA Responses

The EPA received comments from industry groups and organizations representing water utilities about the EPA's methodology for estimating quantitative benefits associated with the NPDWR. While some commenters supported the EPA's analysis, a few commenters stated that the agency overestimated quantified benefits. These commenters asserted that the EPA overstated the benefits of the rule and that the HRRCA is flawed because the existing health evidence does not support the quantified benefits.

The EPA disagrees with commenters that the existing evidence does not support the EPA's estimate of quantified benefits from avoided adverse health effects likely to occur as a result of drinking water treatment and that these benefits are overstated. The EPA reviewed the best available science on health effects associated with exposure to the PFAS considered in the rulemaking. Among other things, the EPA has used the best available science in three key respects: by 1) considering relevant peer-reviewed literature identified by performing systematic searches of the scientific literature or identified through public comment, 2) relying on peer-reviewed, published EPA human health risk assessment methodology (USEPA, 2022c), and 3) utilizing peer-reviewed methodologies to valuing and quantifying avoided adverse health outcomes. Specifically, the EPA identified the full range of expected human health outcomes, including quantified benefits associated with co-removal of co-occurring contaminants (i.e., disinfection byproducts (DBPs)). This process was built upon multidisciplinary research, including hazard identification and dose-response analysis, exposure assessment, and economic valuation methods recommended by the EPA's Guidelines for Preparing Economic Analyses (USEPA, 2016a) and updated Circular A-4 Guidance (OMB, 2023) to enumerate all beneficial outcomes, identify beneficiaries, and determine human health endpoints that can be valued. The EPA employed state-of-the-science reviews and weight of evidence assessments to identify and select studies for dose-response information in the EA. The risk assessment guidance and best practices serve as the basis for the PFOA and PFOS health effects systematic review methods used to identify, evaluate, and quantify the available data (USEPA, 2022c). In addition to using the most current literature, the EPA relied on state-of-the-art approaches for synthesizing information from the available studies (e.g., regression-based meta-analysis of studies reporting associations between PFOA/PFOS and total cholesterol). The EPA also carefully examined the critical aspects of the dose-response functions such as type of the effect (e.g., change in risk factor such as total cholesterol), temporal nature of the effect (e.g., lifetime risk or risk by a certain age), eligible population (e.g., persons without prior cardiovascular disease history). To model a chronic/persistent health effect associated with PFAS exposure (i.e., cardiovascular disease, cancer) the EPA relied on lifetable-based modeling to account for population overall survival trends and competing risk of death from other causes. To ensure soundness of its analysis, the EPA has considered the input of numerous outside reviewers (between the Science Advisory Board's (SAB) review, the letter peer reviews, and the journal peer reviews, the EPA

notes that dozens of outside peer-reviewers have shared their input on various underlying components of this economic analysis).

One commenter criticized the EPA's evidence integration strategy, asserting that toxicogenomic data are useful for identifying genomic evidence to support risk analyses. The EPA disagrees with this commenter's evidence integration strategy. The commenter cites Chen et al. (2022), which claims to have integrated toxicological and Physiologically-Based Pharmacokinetic (PBPK) modeling for PFOS. This study used "available human in vitro and mouse in vivo toxicogenomic data" to identify genomic evidence. Unlike the EPA's Toxicity Assessments (USEPA, 2024h; USEPA, 2024i), the study does not incorporate study quality evaluation or other strength of evidence metrics. This study's reliance on toxicogenomic data is also in contrast to the EPA's approach as recommended in the EPA's Benchmark Dose Technical Guidance document (USEPA, 2012). The Integrated Risk Information System (IRIS) handbook is clear in its recommendation that human data are generally preferred for the derivation of toxicity values, compared to laboratory or animal data (USEPA, 2022c). For detail on the strength of the human epidemiological evidence supporting analyses of renal cell carcinoma (RCC, birth weight, and cardiovascular disease (CVD), see sections 4.1.4 and 4.2.1 of the EPA response in this *Response to Comments* document, as well as the EPA response to comment Doc. #1774, SBC-045685, SBC-053211, SBC-053281, SBC-045682, and SBC-045683. Moreover, Chen et al. (2022) also notes that there are limitations to using toxicogenomic data for traditional risk assessments. For these reasons, the EPA does not think that this study relies on the best available science, nor is it appropriate for the EPA to consider when evaluating avoided adverse health outcomes and benefits for purposes of the PFAS NDPWR.

The EPA assesses potential benefits quantitatively where (1) there is indicative (likely) evidence of a relationship between exposure and a health effect response, (2) it is possible to link the health outcome (e.g., CVD) to risk of a health effect (e.g., increased total cholesterol [TC]), and (3) there is no overlap in effect with another quantified endpoint in the same outcome group. The EPA's quantification of health benefits resulting from reduced PFAS exposure in drinking water is driven by the availability of PFAS related occurrence estimates, pharmacokinetic (PK) models, information on exposure-response relationships, and economic data to monetize the impacts.

One commenter developed a benefits estimate that used a bounding estimate of the benefits of reducing PFOS in drinking water. First, the commenter assumed that a 10 percent genomic or cellular change leads to a person suffering a disease. The EPA disagrees with this assumption as it appears to be an arbitrary assumption of the model in the source paper that the analysis cites (Chen et al., 2022). Additionally, citing Chen et al. (2022) and Chou and Lin (2020), this commenter makes another bounding assumption that "there is little significant biological activity at doses below 20 ng/kg/day" for PFOS and consequently excludes those exposed below 20 ng/kg/day from the benefits estimation. The EPA disagrees with this approach and the commenter's rationale for this assumption. Currently, the EPA's peer-reviewed methodology does not provide guidance or recommendations for using in vitro/mechanistic data for risk assessment, as is also acknowledged by Chen et al. (2022) who state that "the methodology to

incorporate toxicogenomic data into a PBPK model to inform risk assessment remains to be developed." Furthermore, the analyses in Chen et al. (2022) and Chou and Lin (2020) are based on outdated RfD information (e.g., 2016 HA RfD). As described in Table 6-48 of the EA, derivation of PFOA/PFOS exposure-response functions for the relationship between serum PFOA/PFOS and associated health outcomes in the EPA benefits analysis assumes that there are no threshold serum concentrations below which effects do not occur (USEPA, 2024b). This is appropriate because the EPA's Final Human Health Toxicity Assessments indicate that adverse effects occur in populations exposed to wide range of exposure levels, including exposure levels below 20 ng/kg/day.

One commenter stated that the EPA did not provide data to support the analysis of benefits predicted from the implementation of the Hazard Index MCL. The EPA disagrees with the commenter that the EPA did not provide data to support Hazard Index MCL benefits. As discussed in section XII of the preamble and in Appendix K of USEPA (2024c), the EPA evaluated the impacts of PFNA on birth weight in *quantitative* sensitivity analyses. Because the EPA did not include these estimates in the national quantified benefits analysis, in instances where PFNA is present, the national quantified benefits are likely underestimated. However, these benefits are considered quantitatively as part of this EA in the sensitivity analysis and support the EPA's decision to regulate PFNA. Furthermore, in section XII of the final rule and in Section 6.2 of the EA (USEPA, 2024b), the EPA qualitatively summarized and considered the potential health benefits resulting from reduced exposure to PFAS other than PFOA and PFOS in drinking water (including PFNA, HFPO-DA, PFHxS, and PFBS), as recommended by the EPA's Guidelines for Preparing Economic Analyses and OMB Circular A-4 (USEPA, 2016a; OMB, 2023). These qualitative potential health benefits are based on summaries of a significant body of peer reviewed science. As summarized in the EA, the qualitatively discussed health impacts of these four PFAS are considerable and include cancer, birth weight, endocrine, immune, and hepatic effects; reducing human exposure to them is expected to reduce the incidence of adverse health impacts including cardiovascular, developmental, and immune effects for Hazard Index PFAS. The qualitative benefits discussion of the impacts of the four PFAS which are regulated through the Hazard Index, as well as their co-occurrence in source waters containing PFOA and/or PFOS and additive effects, supports the EPA's decision to regulate them thought the Hazard Index in this rulemaking.

For responses related to comparison between the EPA's PFOA and PFOS toxicity assessments and other Agencies' health assessments, please see response to comment section 4.2.6 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-053384)

ESTIMATES OF THE SOCIAL BENEFITS AND SOCIAL COSTS FROM EPA'S PROPOSED REGULATORY ACTION

Recognizing these flaws, this analysis provides a methodology to overcome many of them. The analysis uses the engineering firm's cost estimates to estimate the treatment costs, EPA's data for the occurrence and monitoring costs of the rule, and EPA's estimates for the economy-wide social costs of the proposal. The analysis uses EPA data to estimate and to value the social costs of greenhouse gas emissions that would be caused by the proposed requirement. As shown in Table ES-1, the social costs are projected to be at least seven times greater than EPA's estimates.

EPA's benefit estimates for PFAS treatment place too much weight on a few possible adverse effects and too little weight on the range of potential adverse effects EPA describes in the supporting documents. Ultimately, EPA's quantified benefit estimates rest on scientific findings that other public health organizations do not support. By failing to account for the possibility that these adverse effects may not exist, EPA overstates the social benefits it quantifies.

Therefore, this analysis' objective is to identify the most comprehensive evaluation of possible biologic changes in response to PFOS exposure. An adverse effect should start with biologic change; if there is little change in response to PFOS exposure at a certain dose, the likelihood of an adverse effect at that dose is greatly diminished. The analysis estimates the social benefits by harnessing recent studies that carry out longstanding practices recommended by the National Academy of Sciences (NAS) to develop hazard assessments that use more of the available scientific information and are more compatible with benefit-cost analysis.

Rather than EPA's approach to quantify a few adverse effects, this analysis considers a wide range of cellular and genomic evidence, animal data, and human epidemiological studies. Based on published studies, the analysis considers 108 diseases that are associated with cellular and genomic responses in in vitro testing. Using the results of Bayesian mathematical evidence integration, the analysis identifies 108 diseases and estimates the probability of these diseases occurring in individuals at different levels of PFOS in drinking water.

Since these studies find that changes in biological activity are likely only to occur at the high end of the modeled drinking water exposure, the analysis develops a bounding estimate of the benefits of reducing PFOS in drinking water. The purpose of the bounding estimate is to establish an upper bound of the possible benefits for PFOS. The bounding estimate assumes conditions that clearly are not realistic and clearly overestimate the likelihood of an adverse effect for several reasons. First, the analysis assumes that a 10 percent genomic or cellular change leads to a person suffering the disease. This outcome is implausible since that change may not be large enough to be significant; since there is an additional 30-fold safety factor

applied to this 10 percent change, and since the body has numerous repair mechanisms that respond when there is abnormal biological changes.

Second, the bounding estimate assumes that the current population's path towards these diseases is halted and is reversed by the drinking water standard. This assumption leads to 90 percent of the total benefits. A more realistic approach would be to assume, as EPA does in the EA, that reducing exposure today causes small changes to the baseline probabilities of contracting a disease. As an illustration, EPA may assume the MCL changes a 60-year old's odds of getting CVD in the future from 23 percent to 22.95 percent; the bounding estimate assumes that all of the exposed 60-year olds' probabilities of contracting CVD from PFOS exposure are eliminated.

Therefore, the bounding estimate shows that, even if all PFOS exposure above any level that shows some biological activity is certain to cause a disease, the benefits are still five times lower than the expected costs. The results of this bounding estimate are shown in Table ES-1. Even with many implausible assumptions to increase the social benefits, the results for PFOS are six times lower than the expected social costs. It is likely that the social benefits are at least ten times lower than this bounding estimate based on the scientific evidence.

Table ES-1: Comparison of Estimated National Annualized Benefits and Costs for EPA's Proposed Rule

[Table ES-1: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: See section 13.3 of the EPA response in this *Response to Comments* document for the EPA's response to comments on the costs of the rule. The EPA disagrees with the commenter's suggested approach to selecting health endpoints and quantifying benefits. As described in sections 4.1.2, 13.4 and 13.8 of the EPA response in this *Response to Comments* document, the EPA relied on the best available science and data to evaluate costs and quantify benefits of the rule and to support the agency's conclusions presented in the Final Toxicity Assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i). The EPA disagrees that other health agencies "do not support" the agency's analysis. Regarding the commenter's comparison to findings from other public health organizations and request for inclusion of additional endpoints, see section 4.2.6 of the EPA response in this *Response to Comments* document.

The EPA disagrees with many of the assumptions in AMWA's benefits modeling exercise and AMWA's conclusions, as AMWA's analysis does not adhere to standard modeling practices and makes assumptions that are not fact based or scientifically valid. Specifically, the EPA disagrees with the commenter's suggestion to use an arbitrary assumption "that reducing exposure today causes small changes to the baseline probabilities of contracting a disease." See the EPA response to comment Doc. #1738, SBC-046013 in section 13.4.5 in this *Response to Comments* document for the EPA's response to AMWA's claim that "changes in biological activity are likely only to occur at the high end of the modeled drinking water exposure." Additionally, the EPA disagrees with the commenter's assumption that a 10 percent genomic or cellular change leads to a person suffering a disease. See section 13.4 of the EPA response in this *Response to Comments*

document for the EPA's response to AMWA's bounding assumptions. The EPA's approach to modeling reductions in health effects resulting only from changes in PFOS exposure under the rule relies on the best available science, as described in section 13.4 of the EPA response in this *Response to Comments* document. Specifically, the EPA determined attributable risk by reviewing existing literature to establish a population attributable fraction (PAF) of adverse health outcomes associated with environmental exposure, as described in Section 6.1.2 of the final rule EA (USEPA, 2024b). The agency then estimated changes in PFOA and PFOS exposure-attributable share of adverse effects incidence associated with promulgation of the rule. This analysis assumes that removal of PFOA and PFOS-related exposure would not alter the distribution of risk factors the exposure does not affect. The EPA also notes that AMWA's statement that benefits from reducing exposure to PFOS in drinking water are six times lower than the expected social costs are based on arbitrary assumptions. As described in section 13.3.3 of the EPA response in this *Response to Comments* document, the EPA disagrees with many of the assumptions made in the AWWA B&V report (also cited by AMWA).

Minnesota Pollution Control Agency (MPCA) (Doc. #1569, SBC-042496)

Section XIII - Health risk reduction and cost analysis (HRRCA)

Topic: Part J, Overall cost-benefit determination:

MPCA comments: Overall, MPCA finds EPA's methods to determine net benefits of enacting the MCLs are reasonable and rigorous to the extent of data availability. MPCA notes the inclusion of a number of non-quantifiable costs and particularly, benefits.

We wish to comment further on two topics:

First topic: Use of the 3% discount rate or less to evaluate net benefits is strongly supported, for the following six reasons, at a minimum:

1. It is reasonable to use a low discount rate in analyses concerned with the health impacts of forever chemicals associated with debilitating diseases including cancer which could carry over to future generations.

2. Several benefits from avoiding these diseases are non-quantifiable and hence not incorporated into the calculation.

3. Benefits from being able to target and remove co-occurring chemicals using the same technology, were also not incorporated into the calculations but are real benefits to water users.

4. While treatment technology costs are high, the bipartisan infrastructure law provides financial aid for public water supplies and includes special provision for small systems.

5. Health impacts associated with contaminated water disproportionately impact environmental justice (EJ) areas. Restricting PFAS will benefit EJ communities by making water safer to consume.

6. PFAS may also have harmful effects on beneficial uses beyond drinking water, such as aquatic life. Less PFAS in drinking water means less PFAS conveyed to, and discharged from, wastewater treatment facilities (assuming PFAS laden residuals from water treatment facilities are not sent to the wastewater facility).

As a point of comparison, the EPA's September 2022 updates to the social cost of carbon has estimates in the range 1.5-2.5% (EPA, 2022).

Second topic: A meta-analytic approach utilized to calculate PFOA and PFOS-attributable disease burdens and related economic costs of medical care and lost productivity for the year 2018 is informative (Obsekov et al, 2022). The costs of legacy PFAS exposures in the US were determined from epidemiological studies and that found significant relationships between 13 types of diseases and PFAS exposure, including low birth weight, childhood obesity, kidney cancer, testicular cancer, hypothyroidism in females, adult obesity, Type 2 diabetes mellitus in females, gestational diabetes, endometriosis, polycystic ovarian syndrome, couple infertility, female breast cancer, and pneumonia in children due to prenatal exposure.

The study calculated the cost for not taking action to control PFOS and PFOA is in the range $5.52 billion-$62.6 billion, significantly higher than EPA's analysis of costs to comply with the proposed MCLs of $772 to 1,205 million (Table 66 of the RFC). The authors consider their findings to provide, "an approximation of the scope of the disease burden and associated costs attributable to exposure to these ubiquitous chemicals." They also consider their estimate conservative as several types of disease outcomes were not included owing to data limitations (e.g. lowered IQ in children from prenatal exposure, prostate cancer in adult men). Moreover, the social costs of PFAS-related disease conditions, such as described by Cordner et al., 2021) were not included.

Another study of impacts from PFAS exposure in Europe identified annual direct healthcare expenditures at 52-84 billion Euros (Goldenman et al., 2019). Using Goldenman's analysis and accounting for population size and exchange rate differences, Cordner et al. (2021) estimates equivalent health-related costs for the US would be $37-59 billion annually.

EPA Response: The commenter's agreement that the "EPA's methods to determine net benefits of enacting the MCLs are reasonable and rigorous to the extent of data availability" provides support for the EPA's benefits analysis. The EPA agrees with the commenter that the "use of the 3% discount rate or less to evaluate net benefits is strongly supported." The EPA also agrees that using a lower discount rate is more appropriate than elevated discount rates: see section 13.2 of the EPA response in this *Response to Comments* document for a detailed discussion of discount rate selection for the agency's HRRCA. Based on other comments, the agency is also providing estimates based on the 2 percent discount rate, consistent with the updated Circular A-4 Guidance (OMB, 2023).

This commenter also stated that, based on a study by Obsekov et al. (2023), the cost for not taking action to control PFOS and PFOA ($5.52 billion-$62.6 billion) is much higher than the EPA's estimates of costs to comply with the proposed MCLs. The EPA agrees that when

considering all quantifiable and nonquantifiable benefits and costs, the potential benefits of enacting the PFAS MCLs are highly likely to exceed compliance costs. The agency notes that although the study by Obsekov et al. (2023) provides useful information on the potential public health burden from exposure to PFAS, the authors' estimates of the total economic burden of PFOA and PFOS -related disease include cost of illness estimates and, for some health endpoints, also the disability-adjusted life year (DALY) lost costs. As stated in the EPA's Guidelines for Preparing Economic Analyses (USEPA, 2016a), "methods that combine information on quality and quantity of life cannot be directly related to willingness-to-pay estimates and thus should not be used for deriving monetary estimates for use in benefit cost analyses". In addition, OMB Circular A-4 Guidance notes that in order to represent a valid measure of individual preferences integrated metrics such as DALY should meet restrictive assumptions (OMB, 2023). Therefore, the EPA is not relying on the estimates of the total economic burden of PFOA and PFOS provided by Obsekov et al. (2023) as quantified benefits. The EPA's benefits estimates rely on cost of illness and willingness to pay information to value the illnesses associated with PFOA and PFOS exposure. As stated in section 13.4 of the EPA response in this *Response to Comments* document, the HRRCA relies on the best available science on health effects that are associated with exposure to the PFAS considered in the rulemaking. The EPA believes there is greater certainty with this approach, even though it produces a lower-end estimate compared to that produced by Obsekov (2023). When considering the nonquantified benefits, the EPA acknowledges that total benefits are substantially higher than those the EPA has been able to quantify in the record for the final rule.

The EPA agrees with the commenter's statements concerning nonquantifiable benefits, funding availability, benefits from the rule for low-income populations and people of color, and other harmful effects from PFAS. While nonquantifiable benefits have been omitted from the quantified health valuation, several significant adverse effects are discussed qualitatively in detail in Section 6.2.4 of the EA (USEPA. 2024b). As PFAS in drinking water are reduced, the EPA anticipates a reduction in these adverse health effects. Also, see section 13.5 and 13.6 in this *Response to Comments* document for the EPA's response to public comments on nonquantifiable benefits. The EPA discusses potential benefits resulting from co-removal of additional contaminants in Section 6.2.6 of the EA. Benefits of co-removal of DBPs are discussed in Section 6.7 of the EA (USEPA, 2024b) and are also discussed in section 13.7 of the EPA response in this *Response to Comments* document. In regard to funding available under the Bipartisan Infrastructure Law, please see Section 9.4 of the EA (USEPA. 2024b) and in section 13.10 of the *Response to Comments* document; please also see section 2.4 of the *Response to Comments* document for further discussion of BIL funding. For additional discussion of the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA. 2024b) and section 14.10 of the *Response to Comments* document. Finally, the EPA acknowledges that this regulation may have important benefits for other species (e.g., pets/companion animals, livestock, wildlife) that may benefit from reduced PFAS exposure, and that these benefits are not quantified. While the EPA recognizes the important environmental and aquatic life benefits associated with removing PFAS, comments on these topics are beyond the scope of this regulatory action. See section 15.1 of the EPA response in this *Response to Comments* document for discussion on the EPA's PFAS

Strategic Roadmap where actions that are part of the EPA's whole-of-agency approach to addressing PFAS are further described.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-053388)

III. ESTIMATES OF THE SOCIAL BENEFITS FROM EPA'S PROPOSED REGULATORY ACTION

EPA posited numerous adverse effects in the MCLG documents for PFOA, PFOS, and the four PFAS that comprise the HI MCL [FN49: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," 6–1.]. However, EPA quantified the social benefits for only three of them, cardiovascular disease (CVD), avoided low birthweight, and avoided cases of renal cell carcinoma (RCC). Moreover, the biological mechanisms for adverse effects in the EA's quantified benefits are not established and the human study data is equivocal. EPA's limited approach raises questions as to the potential existence and the size of social benefits from avoiding the other adverse effects EPA claims could arise from PFAS exposure.

Given the significant social costs if EPA's proposal is promulgated, this analysis sought to evaluate a larger scope of potential health effects. To do so, the analysis employs genomic and cellular studies of human and animal genes to identify how PFOS exposure causes biological changes in cellular function and at the genetic level. If a dose does not alter this biological activity materially, many adverse effect pathways to disease can largely ruled out at levels occurring in drinking water.

The analysis rests on recent, peer-reviewed published studies that use best practices for evidence integration of different lines of toxicological evidence. These toxicology results fit well into benefit-cost analysis.

1. Rationale for the Approach

For over 60 years, toxicology has developed three principal types of evidence – epidemiological studies of human populations, controlled dose experiments in animals, and in vitro testing to measure responses to chemical exposure in cells, genes, and other biological systems. In the last 20 years, the amount and the breadth of in vitro information has soared as researchers have created new, fast, and low-cost techniques to measure cellular and genetic responses [FN50: National Academies of Sciences, Engineering, and Medicine, "Using 21st Century Science to Improve Risk-Related Evaluations" (The National Academies Press, 2017).]. For example, inexpensive, high-throughput transcriptomics data generation platforms allow rapid observations of a constituent's interaction and activation of the full set of human genes. With the generation of this data arose the question: what to do with it and how to interpret it?

How to interpret and to integrate different lines of evidence has always been a challenge in toxicology. Concern arose in the 2000s with the transparency, decision criteria, and reproducibility of EPA's evidence integration in Integrated Risk Information System (IRIS)

hazard assessments, for example [FN51: National Research Council, "Review of EPA's Integrated Risk Information System (IRIS) Process Review of EPA's Integrated Risk Information System (IRIS) Process."]. In a major report, the National Academies of Science (NAS) recommended that EPA develop transparent, reproduceable mathematical approaches to integrate genomic, in vitro mechanistic data, animal experimental data, and data from human observations [FN52: National Research Council, "Review of EPA's Integrated Risk Information System (IRIS) Process Review of EPA's Integrated Risk Information System (IRIS) Process."]. The NAS recommended EPA move toward a formal, mathematical approach to integrate lines of evidence using Bayesian statistics. In its findings, the NAS stated:

Finding: Quantitative approaches to integrating evidence will be increasingly needed by and useful to EPA.

Recommendation: EPA should expand its ability to perform quantitative modeling of evidence integration; in particular, it should develop the capacity to do Bayesian modeling of chemical hazards. That technique could be helpful in modeling assumptions about the relevance of a variety of animal models to each other and to humans, in incorporating mechanistic knowledge to model the relevance of animal models to humans and the relevance of human data for similar but distinct chemicals, and in providing a general framework within which to update scientific knowledge rationally as new data become available [FN53: National Research Council, 105.].

EPA did not follow this recommendation in the EA. EPA continues the practice of picking certain studies for its quantitative assessments while ignoring and not including the data from other high-quality studies. While EPA states that data from animal studies and mechanistic studies are supportive, EPA does not support these claims in a transparent, reproducible manner. For example, for its estimate of the social benefits from the association between PFOA and PFOS exposure and lower birth weights, EPA selects one study for PFOA and used only the data from this study. EPA apparently re-analyzes the data in the selected study for PFOS but apparently did not state if the Agency submitted this reanalysis to independent peer review.

After the 2014 NAS report, researchers continued to develop full human genomic test data and genomic dose-response modeling. The advent of these new tools -- and the information they provide -- has underscored this challenge of how to integrate genomic in vitro evidence into hazard assessments.

The National Academy of Sciences issued a major report on these New Approach Methods (NAM) in 2017 [FN54: National Academies of Sciences, Engineering, and Medicine, "Using 21st Century Science to Improve Risk-Related Evaluations."]. The 2017 report recommended that agencies incorporate NAMs into chemical risk assessments since they could provide substantially more data and insight more quickly than traditional toxicity testing. As the National Toxicology Program (NTP) found, research groups in universities, private institutions, and government agencies expanded their use of NAMs in the peer-reviewed literature. In 2018, the NTP convened experts and published its approach to genomic dose-response modeling. NTP explained the advantages:

NTP's approach to study design focuses on obtaining the best data to determine accurate estimates of biological potency using modeling. The use of a broad array of gene sets such as those curated by MSigDB is to ensure that all known biological signaling processes are covered, therefore ensuring that the most sensitive estimation of biological potency [FN55: National Toxicology Program, "NTP Research Report on National Toxicology Program Approach to Genomic Dose-Response Modeling," April 2018, 4.].

In other words, rather than only toxicology experiments with a limited number of animal studies of potentially unclear biologic mechanisms of action, genomics data can measure changes in all human signaling processes. These genomics experiments can be replicated, can be conducted quickly at different dose levels, and can test the genomes and cells of many different individuals.

However, the NTP identified two major remaining issues: consistent study design of genomic studies and the biological interpretation of the findings [FN56: National Toxicology Program, "NTP Research Report on National Toxicology Program Approach to Genomic Dose-Response Modeling."]. While the NTP guidance (and comparable EPA guidance) provides a standard for study design, the remaining fundamental uncertainty – genes do not fully determine health outcomes – remained. It is essential for benefit-cost analysis that the genetic changes have direct links to adverse effects consumers understand and value. To interpret the genomic data, researchers have turned to in vitro-in vivo (IVIV) studies and modeling to develop mathematical relationships between the results of known animal studies and genomic response and signaling data. The IVIV techniques then link genomic data to measured adverse effects in whole organisms [FN57: Very recent studies find that hazard values developed through genomic analysis are similar to value derived from animal assays. In general, the genomic values are more health-protective than values derived from animal studies.]. Thus, researchers are developing mathematical techniques to link genomic data to animal data. Recent studies are confirming NTP's conclusion that these studies are more sensitive (i.e., more health protective) than results obtained from whole organism studies [FN58: National Toxicology Program, "NTP Research Report on National Toxicology Program Approach to Genomic Dose-Response Modeling," 4.].

Mathematical evidence integration also combines the risk of cancer and the risk of noncancer effects into the same hazard metric. As the NAS stated, Bayesian dose-response methods can be applied to different lines of evidence to create probabilistic estimates of risk for both cancer and noncancer effects. This capability is vital since EPA's current hazard metrics and -study selection by judgement as in this EA – are incompatible with EPA's regulatory analysis requirements.

The mismatch between EPA's current toxicity metrics and benefit-cost analysis is well understood. Over 30 years ago, the NAS called for EPA to adopt probabilistic hazard assessment and to move away from single hazard values such as a reference dose. In its 2009 Science and Decisions report evaluating EPA's risk assessment practices, the NAS concluded: "The end products of noncancer (and nonlinear cancer) assessments in the current paradigm (exposure-effect quotients that qualitatively indicate potential risk—MOEs [Margin of Exposure], RfDs [Reference Doses], and RfCs [Reference Concentrations], Figure 5-1) are inadequate for benefit-cost analyses or for comparative risk analyses." [FN59: National Research Council, "Science and

Decisions: Advancing Risk Assessment" (Washington, DC: National Academies Press, 2009), 133.] The NAS emphasized:

Historically, dose-response assessments at EPA have been conducted differently for cancer and noncancer effects, and the methods have been criticized for not providing the most useful results. Consequently, noncancer effects have been underemphasized, especially in benefit-cost analyses. A consistent approach to risk assessment for cancer and noncancer effects is scientifically feasible and needs to be implemented [FN60: National Research Council, 8.].

The 2009 Science and Decisions report also provided EPA with extensive recommendations concerning uncertainty analysis, value of information analysis, and risk characterization.

Mathematic evidence integration also enables formal uncertainty analysis to be conducted on the hazard assessment. The outputs of Bayesian modeling are probabilities of adverse effects that are related to the dose, allowing estimates of how these probabilities change with a change in dose. These incremental effects fit well into benefit-cost analysis. Benefit-cost analysis rests on estimating the value to society of incremental shifts in resources to different policy outcomes. Probabilistic risk assessment measures provide more information and fit into the incremental analysis framework of benefit-cost analysis.

EPA's benefit-cost analysis for the proposal rests on toxicity relationships that suffer from the same issues raised by the NAS in 2009 and 2014. The EA's benefit estimate selects just three critical effects even though EPA states that PFOS and PFOA are associated with many other effects.

This analysis seeks to consider a greater range of potential biological mechanisms of action for PFOS and to quantify these effects following the NAS recommendations for hazard identification, evidence integration, and presentation of the maximum value of avoiding the probabilities of change through exposure in drinking water.

2. Summary of the Analytical Approach

This analysis attempts to overcome some of the limitations in EPA's approach which relies on only a few studies, evaluates only two possible PFOS adverse effects, and ignores relevant data and studies.

Figure 3 presents an overview of our methodological approach to the benefits analysis. The assessment is performed in the following sequential steps:

1. Concentration. The concentration of PFAS in drinking water is based on occurrence data from EPA's EA.

2. Dose from Drinking Water Exposure. Drinking water consumer patterns are based on EPA's Exposure Factors Handbook (EFH) and take into account age, sex, race, and body weight.

3. Physical Changes and Adverse Effects. The latest toxicological literature presents modeling of how PFOS concentration and dose estimates are likely to result in the probability of physiological changes and, subsequently, adverse effects.

4. Loss of Function and Valued Social Benefits. The analysis takes the loss of function (i.e. disease) from the modeled physical changes and adverse effects from the literature and applies quantification from the World Health Organization (WHO) and willingness-to-pay estimates to estimate total social benefits.

Figure 3: Overview of Benefits Methodological Framework

[Figure 3: see docket ID EPA-HQ-OW-2022-0114-1738]

In summary, this approach has several major advantages over EPA's approach in the EA:

• Includes many more potential adverse effects from PFOS exposure in drinking water than analyzed in the EA;

• Includes potential incremental noncancer and cancer effects into the same hazard metric;

• Develops estimates of the probability of these adverse effects to construct a distribution of the potential population health benefits;

• Assigns values to the expected values of these adverse effects based on internationally-recognized metrics for morbidity and mortality; and,

• Values these effects with a WTP value consistent with Circular A-4 and best practices.

While our approach has significant advantages over EPA's methods, it has limitations. Some limitations are due to fundamental uncertainty; some could be fixed. Due to the limited time available for public comments, this analysis has limitations that could be addressed with additional analysis. Since this information is available in the literature, EPA could construct a more comprehensive and a more robust social benefit estimate using this approach.

EPA Response: The EPA disagrees with the commenter's assertion that the human study data for adverse effects in the EA's quantified benefits are equivocal. For additional detail on the strength of the human epidemiological evidence supporting analyses of RCC, birth weight, and CVD, see sections 4.1.4 and 4.2.1 of the EPA response in this *Response to Comments* document, as well as the EPA response to comment Doc. #1774, SBC-045685, SBC-053211, SBC-053281, SBC-053417, SBC-045682, and SBC-045683. Additionally, while the EPA agrees that the mechanisms by which PFOA and PFOS induce these effects are unclear, mechanistic evidence is generally used to support the relevance of animal effects to humans and provide biological plausibility for evidence integration judgments, but known mechanisms of action are not required for hazard identification or characterization (USEPA, 2022c). See section 4.2.1 of the EPA response in this *Response to Comments* document for more discussion. Additionally, the IRIS handbook is clear in its recommendation that human data are generally preferred for the derivation of toxicity values, compared to laboratory or animal data (USEPA, 2022c). Regarding

the commenter's recommendations regarding evidence integration, see section 4.1.1 and 4.1.3 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter's assertion that the EPA is "picking certain studies for its quantitative assessments while ignoring and not including the data from other high-quality studies." The commenter ignores that for both birth weight and total cholesterol, the two endpoints for which the available literature contained multiple high quality exposure-response studies, the EPA relied on meta-analyses that estimate relationships between PFOA/PFOS exposure and health effects. See EA Sections 6.4 and 6.5 of USEPA (2024b) for the details on studies used for the quantified birth weight and CVD benefits models, respectively. See also section 13.4.2 of the EPA response in this *Response to Comments* document, which clearly describes that the EPA relied on meta-analyses of studies on PFOA/PFOS exposure and birth weight effects. Appendix F of the EA (USEPA, 2024c) presents a discussion of the studies included in the EPA's meta-analysis for PFOA/PFOS and TC relationships and results of sensitivity analysis results of different study inclusion assumptions.

The commenter claims that the EPA did not follow the National Academy of Science (NAS) recommendation that the EPA consider New Approach Methods (NAMs) and expand its modeling capabilities to include Bayesian modeling approaches. The EPA disagrees and notes that while current methods are being developed that use Bayesian Model Averaging in dose-response modeling, these approaches are computationally intensive and have not yet become the norm, nor are they required by the Benchmark Dose Technical Guidance (USEPA, 2012). The EPA also notes the IRIS Handbook (USEPA, 2022c) (which the EPA followed in developing the PFAS toxicity assessments) notes that alternative methodologies (such as read-across and other new approach methods) can be used to supplement other streams of evidence, or in some cases, may be the only available method or evidence (USEPA, 2022c). For PFAS, the large amount of epidemiologic, toxicologic and mechanistic data precluded the need to use alternative methodologies to identify risk.

The commenter notes the NAS recommendation to develop a consistent approach to risk assessment for cancer and noncancer effects is scientifically feasible and needs to be implemented. The EPA agrees, and notes that the agency followed the latest guidance for risk assessment relying on peer-reviewed, published EPA human health risk assessment methodology as well as systematic review best practices (USEPA, 2022c) and the *Guidelines for Carcinogen Risk Assessment* (USEPA, 2005b), as described in section IV of the preamble and sections 4.1.1 and 4.1.2 of the EPA response in this *Response to Comments* document. The risk assessment guidance and best practices serve as the basis for the PFOA and PFOS health effects systematic review methods used to identify, evaluate, and quantify the available data (USEPA, 2021c; USEPA, 2022c).

The commenter asserts that the EPA's benefit-cost analysis for the proposal rests on toxicity relationships that suffer from the same issues raised by the NAS in 2009 and 2014. The EPA disagrees with this assertion and notes in particular that the EPA developed the Toxicity Assessments (USEPA, 2024h; USEPA, 2024i) following the IRIS guidance that underwent NAS review, which was published November 30, 2021 (USEPA, 2022c).

As described in section 4.1.2 of the EPA response in this *Response to Comments* document, the EPA relied on the best available science to support the agency's conclusions presented in the Final Toxicity Assessments for PFOA and PFOS (USEPA, 2024; USEPA, 2024) and to perform its risk analysis.

Regarding the commenter's use of willingness to pay information to estimate total social costs, see section 13.4.4 of the EPA response in this *Response to Comments* document summarizing comments received on benefit valuation and the EPA's use of cost of illness (COI) and willingness to pay information for the final rule. Regarding the commenter's suggestion to include additional potential adverse effects from PFOS exposure, the EPA has carefully considered the strength of the evidence regarding each health endpoint in making including/exclusion determinations. While there is evidence to suggest that PFOS exposure leads to unquantified adverse health outcomes, the EPA elected to include only those endpoints with the strongest evidence supporting their estimation.

Regarding commenter's assumptions on drinking water exposure and the analysis of disease from the modeled literature, see the EPA response to comment Doc. #1738, SBC-046013 in section 13.4.5 in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-047706)

EPA's Quantified Incremental Adverse Effects

While the thousands of pages in the EA, appendices, and supporting information give the impression of substance, the Agency ultimately rests its artifice on a flawed foundation. The benefits estimate suffers both from claiming too much from little evidence and from too little application where the literature provides ample evidence. Some of the specific problems with EPA's approach are listed below.

EPA's analysis rests on an assumption of causality in which "exposure to these PFAS may cause adverse health effects" and "that PFOA and PFOS are likely to cause cancer." [FN16: U.S. Environmental Protection Agency, "PFAS National Primary Drinking Water Regulation Rulemaking," 18638–39.]. However, there is substantial uncertainty as to whether those associations are causal. In this section, we compare EPA's analysis of the existing scientific literature with those of Health Canada (HC), the European Food Safety Agency (EFSA), and the World Health Organization (WHO). Specifically, we review findings and limitations for birthweight, cardiovascular disease (CVD) and cancer. Additional information on the findings, interpretations, and limitations from EPA, HC, WFSA, and WHO are outlined for each adverse effect in Appendix B.

EPA Response: The EPA disagrees with the commenter's assertion that the EA rests on a flawed foundation. As discussed in EA Sections 2.2.5, 6.1.4, 6.3.3, 6.4.2, 6.5.2, and 6.6.2, EA Appendix Sections D.2 and F.1 (USEPA, 2024b; USEPA, 2024c), and the Toxicity Assessments (USEPA, 2024h; USEPA 2024i), the EPA has conducted multiple literature reviews and peer reviews and follows well-established protocols for health risk assessment (e.g., lifetable

methodology) and valuation (e.g., Guidelines for Preparing Economic Analyses, USEPA, 2016a; OMB Circular A-4; OMB, 2023). The EPA is using scientifically valid peer-reviewed risk assessment approaches and the most current literature, and has considered the input of numerous outside reviewers (between the SAB's review, the letter peer reviews, and the journal peer reviews, the EPA notes that dozens of outside peer-reviewers have shared their input on various underlying components of this economic analysis). This is in addition to the numerous internal agency quality reviews conducted of the analyses by many of the leading health experts and economists in the field.

In addition, the EPA notes that it received several comments highlighting differences between the EPA's determination on evidence of certain health effects associated with PFOA and PFOS. Refer to section 4.2.6 of the EPA response in this *Response to Comments* document for details on comparisons to analyses by other health organizations. With respect to the carcinogenicity determination, the EPA followed agency guidelines in making its cancer determinations for PFOA and PFOS (USEPA, 2005b) and the EPA directs the commenter to Section 3.5.5 of the draft and final toxicity assessments (USEPA, 2024h; USEPA, 2024i; USEPA 2023g; USEPA, 2023h), which detail how PFOA and PFOS are *Likely to be Carcinogenic to Humans* according to the *Guidelines for Carcinogen Risk Assessment* (USEPA, 2005b). Please also see section 4.1.4 of the EPA response in this *Response to Comments* document regarding this topic.

The EPA also notes that there is no causality requirement for health effects considered in benefits analysis. Both benefits assessment and toxicity value derivation (e.g., reference dose derivation) require estimates of risk. However, toxicity values are often based on dose levels corresponding to specific response levels near the low end of the observable range of the data (USEPA, 2012) and pose challenges for use in quantified benefits estimation because relying on this information could lead to biased benefits estimates if extrapolated to the general population (USEPA, 2016a). The health outcomes included in the EA are linked to human well-being and monetized using well accepted economic valuation methods. The EPA analysis accounted for potential uncertainty associated with risk and benefit estimates for a better understanding of potential benefits, as described in Section 6.1.2 of the EA (USEPA 2024b). In following the IRIS approach for integrating evidence across human, animal and mechanistic streams, the EPA makes determinations on the strength of evidence for causal relationships, ranging from evidence ***demonstrates, indicates (likely), suggests, is inadequate or there is evidence of no effect.*** The EPA notes that Toxicology Assessments concluded that the overall evidence indicated that PFOA and PFOS exposure was determined ***likely*** to cause cardiovascular (particularly serum lipids) and developmental toxicity in humans under relevant exposure circumstances (USEPA, 2024h; USEPA, 2024i). In addition, there is no requirement or reasonable expectation that a benefits analysis must demonstrate causal relationships; prior EPA rulemakings have included quantified benefits analyses for endpoints that have not been proven to have a causal relationship between pollutant exposure and the associated health outcome (e.g., trihalomethane exposure and associated health effects in the Stage I/Stage II disinfection biproducts rules (DBPRs); USEPA, 2005a; USEPA, 2006).

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046030)

EPA's benefit estimates assume a few possible adverse effects based on scientific findings that other public health organizations do not support. By failing to account for the possibility that these adverse effects may not exist, EPA overstates the social benefits.

EPA Response: The EPA disagrees with the commenter's assertion that the quantified benefits estimation is unsupported, and that the agency overstates benefits. Refer to sections 4.1.4, 4.2.1, 4.2.6, and 13.4 of the EPA response in this *Response to Comments* document for details on the health effects information that the EPA considered for the HRRCA and also for discussion on comparisons of the EPA's toxicity assessments for PFOA and PFOS to assessments performed by other health organizations. Please also see the EPA response to comment Doc. #1738, SBC-047706 in section 13.4 in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045652)

EPA Did Not Follow SDWA Best Practices in Calculating the Benefits of the Proposed Regulations

The SDWA requires EPA to show that the benefits of its proposed regulations justify the costs. EPA did not comply with that requirement in several important respects.

As an initial matter, EPA's analysis of estimated benefits related to its proposed standards for PFOA and PFOS violates the SDWA's requirement that it analyze separately the benefits of each proposed regulatory standard because EPA improperly conflated its benefits analysis for the two separate regulations. See SDWA [sec]1412(b)(3)(C)(i)(I) (stating that EPA "shall" publish and seek public comment on certain considerations including anticipated benefits of regulation at alternative levels for "a maximum contaminant level that is being considered."). For example, EPA's estimated impact on total cholesterol from reducing PFOS is nearly two orders of magnitude less than the reduction in total cholesterol that EPA calculated for PFOA, but EPA combined those levels in its benefits analysis. It did not analyze separately the benefits for PFOA and PFOS individually, as required by the SDWA.

EPA also has not provided enough information in the record to allow the public to understand how EPA conducted its benefits analysis, which precludes meaningful peer review and comment. EPA's benefits analysis is not reproducible or adequately transparent to the public because EPA has not made important inputs and models available for public or peer review.

From the available information, EPA's benefits analysis appears unreliable. EPA purports to distinguish between the benefits of alternative drinking water exposure concentrations of 4.0 ppt, 5.0 ppt, and 10.0 ppt. However, foundational toxicological principles demonstrate that those levels are so similar that there is likely no way to discern changes in benefits between them (and EPA has not provided the information in the record to explain how it purported to do so).

Similarly, EPA did not provide the pharmacokinetics models underlying its estimates of blood serum PFOA and PFOS concentrations on which it based its benefits analysis. See (USEPA 2023a,b,c,d). The serum data estimate is a foundational conclusion supporting EPA's entire benefits analysis. It is the first value input in a sequence that is ultimately used to estimate the health risk reduction benefits for the proposed maximum contaminant level (MCL) and the regulatory alternatives. Without access to the models underpinning the input, the public and scientific experts cannot meaningfully understand and evaluate the scientific validity of EPA's conclusions about the relative benefits of a 4.0 ppt MCL versus a 5.0 ppt or 10.0 ppt alternative.

EPA's benefits analysis also does not consistently take alternative exposure considerations into account and improperly combines estimated benefits for PFOA and PFOS. This results in inflated estimates of the anticipated individual benefit calculation for each proposed regulatory standard and flawed human equivalent internal dose responses that introduce significant uncertainty about EPA's ultimate conclusions.

EPA Response: First, there is nothing in SDWA that requires the EPA to show that the benefits of the rule justify the costs. Rather, the statute requires the Administrator to publish a determination *whether* the benefits of the proposed rule justify or do not justify its costs based on the HRRCA. SDWA Section 1412(b)(4)(C). The EPA did publish such a determination in the proposed rule preamble. For the EPA's response to the commenter's points raised about the costs and benefits of regulatory alternatives, including the EPA's response to the commenter's assertion that "toxicological principles demonstrate that those levels are so similar that there is likely no way to discern changes between them," see the EPA response to comment Doc. #1774, SBC-045689 in section 5.1.3 in this *Response to Comments* document. The EPA disagrees with the commenter's assertion that the agency violated SDWA requirements because the "…EPA improperly conflated its benefits analysis for the two separate regulations." The commenter has misinterpreted the SDWA HRRCA requirements. Section 1412(b)(3)(C)(i) simply states that the EPA must analyze, among other things, the health risk reduction benefits that are likely to occur from treatment to comply with the proposed MCLs and any alternative levels under consideration. It does not require that the analysis be separate for each chemical or MCL in a proposed NPDWR. The PFOA and PFOS standards are not two "separate regulations," as described by the commenter, rather they are two MCLs included in one regulation.

The EPA has completed the HRRCA for the PFAS NPDWR consistent with the statutory requirements under the SDWA. In cases where PFOA and PFOS have the same or related adverse health effects, as is the case for changes in birth weight and changes in cardiovascular disease risk, the EPA appropriately used contaminant specific information on occurrence, pharmacokinetics, dose-response to analyze the benefits from reductions in exposure anticipated from compliance with the rule. The EPA presents quantified benefits according to adverse health effect rather than by contaminant in these cases, as this is an appropriate way to evaluate the total national benefits and costs that are likely to occur as a result of compliance with the rule. The EPA proposed a NPDWR and regulatory options that each included MCLs for both PFOA and PFOS. The EPA had already made a positive regulatory determination for PFOA and PFOS at the time of proposal and therefore did not represent a regulatory option in the EA that included an

individual MCL for PFOA or PFOS that did not include the other. In cases where the EPA determined that the data was available to quantify benefits from one single contaminant only (e.g., PFOA and RCC, PFOS and liver cancer, PFNA and birth weight impacts), the EPA used contaminant-specific information and presents results for that specific regulated contaminant. Furthermore, in the toxicity assessments for the final rule's regulated PFAS, each of the adverse health endpoints from each individual PFAS are discussed at length (see USEPA 2024h; USEPA, 2024i; USEPA, 2024g; USEPA, 2024j; USEPA, 2024k; USEPA, 2024l). Additionally, the EPA has considered the impacts of dose additivity, as described in *Maximum Contaminant Level Goals (MCLGs) for Three Individual Per- and Polyfluoroalkyl Substances (PFAS) and a Mixture of Four PFAS*. The result presented in the EA for the proposed and final rule provides as comprehensive and transparent analysis of the benefits of all parts of the rule as the data allow, which meets the HRRCA requirement for assessment of costs and benefits for "each MCL' in the rule. In short, the EPA has clearly met all of its HRRCA obligations.

The EPA also disagrees with the commenter's assertion of a lack of transparency and materials provided for public review and replication. Copies of cited literature used to define analysis inputs are provided in the rulemaking record, along with commented code and detailed README documents necessary for replication of this analysis. This record was publicly available at proposal. The information provided is more than sufficient for the purpose of this rulemaking and ensures that stakeholders can both review the EPA's work and recreate it as needed. Additionally, see section 13.4.1 of the EPA response in this *Response to Comments* document regarding the relationship between serum PFOS and TC.

The commenter is also incorrect in the assertion that the pharmacokinetics (PK) models underlying blood serum estimates were not provided. The EPA provided a link to the GitHub repository that includes the PK models in Section 6.3.2 of the EA (USEPA, 2024b). Additionally, the EPA described the PK models in Section 4.1.3 of the Final Human Health Toxicity Assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i).

With respect to whether the benefits of this regulation justifies the costs, please see section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits, including the Administrator's determination that the benefits of the rule justify the costs.

3M Company (Doc. #1774, SBC-045695)

1. EPA's failure to clearly analyze the benefits of the PFOA and PFOS proposed standards separately overstates the benefits of the PFOS standard and precludes appropriate analysis of the individual MCLs.

EPA's failure to separately analyze the benefits of the PFOA and PFOS MCLs violated the SDWA directive that EPA analyze "quantifiable and non-quantifiable health risk reduction benefits for which there is a factual basis in the rulemaking record to conclude that such benefits are likely to occur as the result of treatment to comply with each level." [FN102: SDWA

[sec]1412(b)(3)(C)(i)(I).] For example, CVD reduction is a major element of EPA's benefit analysis for PFOA and PFOS. CVD reduction depends on EPA's calculation of the impact of reduction of total cholesterol (TC). There are numerous issues with EPA's calculation of a dose-response relationship between serum PFOS and TC, including that they do not demonstrate what is normally considered a statistically significant relationship between those two factors. Even ignoring those issues, and assuming the accuracy of EPA's analysis, the impact on TC from reducing PFOS is nearly two orders of magnitude less than the reduction in TC that EPA calculated for PFOA. [FN103: EPA stated that "[w]hen using studies reporting linear associations between total cholesterol and serum PFOA or PFOS, EPA estimated a positive increase in TC of 1.57 (95% CI: 0.02, 3.13) mg/dL per ng/mL serum PFOA (p-value=0.048), and of 0.08 (95% CI:-0/01, 0.16) mg/dL per ng/mL serum PFOS (p-value=0.064.)" 88 FR 18709.]

EPA has not provided enough information in the record to allow for replication of the benefit analysis. This lack of transparency with respect to the benefits of the proposed standards prevents meaningful comment on an aspect of the proposed rule with a very significant impact on EPA's analysis of whether the proposed standards meet the SDWA requirements that the benefits outweigh the costs.

EPA Response: The EPA disagrees with the commenter's assertion that SDWA requires separate analysis of PFOA and PFOS. Please see the EPA response to comment Doc. #1774, SBC-045652 in section 13.4 in this *Response to Comments* document for details.

The EPA disagrees with the commenter's statement that the dose-response relationships between PFOS and TC used in the agency's analysis of CVD effects are not statistically significant. See section 13.4.1 of the EPA response in this *Response to Comments* document regarding the relationship between serum PFOS and TC.

The EPA disagrees with the commenter's assertion that the benefits analysis suffers from the fact that the estimated TC slope factor for PFOS is smaller than the slope factor for PFOA. This simply demonstrates that the meta-analysis shows a stronger effect of reduction of PFOA on TC outcomes compared to PFOS.

For comments on transparency and materials provided for replication of the EPA's analyses, see the EPA response to comment Doc. #1774, SBC-045652 in section 13.4 in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1841, SBC-044811)

[The Agency's proposal suffers from the following significant shortcomings –]

• The Agency's analysis inappropriately quantifies benefits from reductions in health effects that have not been associated with PFOA and PFOS exposure or that cannot be solely attributable to the proposal,

[The Agency's proposal suffers from the following significant shortcomings –]

• EPA has not provided data to support its analysis of benefits predicted from the implementation of the HI MCL,

EPA Response: The EPA disagrees with the commenter's assertion that the EPA did not provide data to support benefits analysis from implementation of the Hazard Index MCL. Please see the section 13.4 of the EPA response in this *Response to Comments* document. Furthermore, the EPA conducted extensive literature reviews and conducted analyses discussed in the EA to evaluate quantified and nonquantified benefits for PFHxS, PFNA, HFPO-DA, and PFBS: please see Chapter 6 of USEPA (2024b). In particular, the EPA synthesized evidence of associations between exposure and health effects relying on IRIS assessments (USEPA, 2023i), the most recent ATSDR and National Academies of Science, Engineering and Medicine (NASEM) reports (ATSDR, 2021; NASEM, 2022), and the Toxicity Assessments (USEPA, 2024b; USEPA, 2024b).

The EPA disagrees with the commenter's statement that the EPA's analysis "inappropriately quantified benefits from reductions in health effects that have not been associated with PFOA and PFOS exposure or that cannot be solely attributable to the proposal." The commenter provides no additional information or data explaining why they believe that the EPA quantifies benefits that are not attributable to this regulatory action. The EPA conducted an extensive literature review to identify health effects with evidence of an association with PFOA and PFOS, that are presented in the Final Toxicity Assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i), in order to quantify health benefits from the reduction in PFOA and PFOS exposure due to the regulation. For additional detail on the strength of the human epidemiological evidence supporting analyses of RCC, birth weight, and CVD, see sections 4.1.4 and 4.2.1 of the EPA response in this *Response to Comments* document, as well as the EPA response to comment Doc. #1774, SBC-045685, SBC-053211, SBC-053281, SBC-045682, and SBC-045683. Additionally, the EPA determined attributable risk by reviewing existing literature to establish a population attributable fraction (PAF) of adverse health outcomes associated with environmental exposure, as described in Section 6.1.2 of the final rule EA (USEPA, 2024b). The agency then estimated changes in PFOA and PFOS exposure-attributable share of adverse effects incidence associated with promulgation of the rule. This analysis assumes that removal of PFOA and PFOS-related exposure would not alter the distribution of risk factors the exposure does not affect.

American Chemistry Council (ACC) (Doc. #1841, SBC-044820)

[As outlined in these comments, the Agency's proposal suffers from a number of significant shortcomings, including the following –]

• The Agency's analysis inappropriately quantifies benefits from reductions in health effects that have not been associated with PFOA and PFOS exposure or that cannot be solely attributable to the proposal,

EPA Response: Please refer to the EPA response to comment Doc. #1841, SBC-044811 in section 13.4 in this *Response to Comments* document for a response to the commenter's assertion that benefit attribution is incorrect.

American Chemistry Council (ACC) (Doc. #1711, SBC-044464)

[The Agency's proposal suffers from the following significant shortcomings –]

• The Agency's analysis inappropriately quantifies benefits from reductions in health effects that have not been associated with PFOA and PFOS exposure or that cannot be solely attributable to the proposal,

EPA Response: Please refer to the EPA response to comment Doc. #1841, SBC-044811 in section 13.4 in this *Response to Comments* document for a response to the commenter's assertion that benefit attribution is incorrect.

American Chemistry Council (ACC) (Doc. #1841, SBC-052940)

Finally, we note the Agency's use of county demographic information to substitute for actual demographic information (especially for the smallest water systems). The process that EPA used is described as follows - excerpt (in italics) from the economic analysis:

To determine the number of people expected to benefit from actions under the proposed rule, EPA uses population data from the Safe Drinking Water Information System (SDWIS) 2021 Quarter 4 (Q4) database (U.S. EPA, 2021h). The SDWIS data provide the population served by each PWS in the

U.S. For analyses that rely on age-, sex-, and race/ethnicity-specific populations, EPA uses county-level population proportions based on 2021 estimates from the U.S. Census Bureau (2020a). [FN196: USEPA Economic Analysis, at 2-4.]

This approach will underestimate or overestimate net benefits because water systems (and especially the smallest systems) are unlikely to share aggregate demographic characteristics of their home county. Furthermore, by choosing an approach based on model system types, the Agency masks variability within each model. It is possible that net benefits vary significantly within each model, especially for the smaller systems.

EPA Response: The EPA is using best available information and science to inform its analyses. More precise spatial resolution is not *available.* The EPA notes that the commenter merely critiques the EPA's use of these available data. The commenter does not identify any nationally available data that will improve precision or reduce uncertainties. In short, the commenter does not propose any alternative solutions for the agency to consider. Furthermore, because the EPA models impacts to aggregate populations based on systems triggered into treatment under various scenarios, the EPA relies on national-level demographic data. The impact of this limitation is uncertain, and, as noted by the commenter, the approach taken by the EPA

could either underestimate or overestimate net benefits. However, the EPA describes this uncertainty within Chapter 6 of the EA in Table 6-53 (USEPA, 2024b) and notes that currently, there is no available dataset of demographic information specific to the location of affected population. Furthermore, SDWA recognizes that all scientific analyses have uncertainties: the EPA has listed those that it has identified in a clear and transparent fashion consistent with SDWA Section 1412(b)(3)(B). See section 13.2 of the EPA response in this *Response to Comments* document for discussion and response related to comments received on the model system approach.

13.4.1 Quantified CVD Benefits Estimation

Summary of Major Public Comments and EPA Responses

The EPA received a number of comments on the quantitative analysis of CVD risk reduction. These commenters disagree with the EPA's assessment that cardiovascular benefits are likely to occur as a result of enacting MCLs for PFOA and PFOS. One commenter stated that the associations with total cholesterol (TC) are not biologically significant and criticized the EPA's use of linear models in the CVD meta-analysis, stating that this approach biases the analysis by excluding higher-quality studies. The EPA disagrees with the commenter's statement that associations between PFOA/PFOS and TC are not biologically significant. Such serum lipid changes may or may not result in a concentration considered clinically elevated in a particular individual; however, given the distribution of individual concentrations within the population, small changes in average serum lipid concentrations can result in substantial health impacts at the population level (Gilbert and Weiss, 2006). See sections 4.2.1 and 4.2.2 of this *Response to Comments* document for additional discussion on this topic. The EPA disagrees with the commenter's suggestions that linear assumptions are inappropriate for use in this context. The EPA presents the exposure-response estimates evaluated considering all studies, studies with linear models only, and a variety of sensitivity analyses in Appendix F of the EA (Tables F-2 and F-3, USEPA, 2024c). Meta-analyses of studies reporting linear associations had statistically significant relationships. These relationships are supported by the EPA's review of epidemiological studies in the Final Toxicity Assessments (USEPA, 2024h; USEPA, 2024i) showing positive associations between PFOA/PFOS and TC. The EPA used data from peer-reviewed studies, and the assumption of linear exposure-response function to explain associations between PFAS and serum lipids such as TC which is supported by data from numerous studies, including those used in the meta-analysis. Other studies have explored log-linear or linear-log relationships between PFAS and serum lipids, while acknowledging only "slight improvements" in model fit, especially for serum lipids with least skewed distributions (Steenland et al., 2009).

A couple of commenters stated that the downward trend in decreasing total and low-density lipid cholesterol since the 1970s coupled with the decreasing PFOA and PFOS serum levels suggests that there is a substantial likelihood that the proposed MCLs for PFOA and PFOS are unlikely to result in benefits as great as is reported as part of the proposal. The EPA disagrees with these comments asserting that decreasing trends in cholesterol levels over time indicate that PFAS

exposure is unlikely to contribute to a measurable increase in CVD risk. The EPA relied on recent National Health and Nutrition Examination Study (NHANES) data (2011-2016) to inform baseline cholesterol and blood pressure conditions in the population evaluated under the proposed rule. These data reflect the current population and do not reflect cholesterol conditions in the population between 1970 and 2010. Therefore, the CVD benefits analysis examines how the probability of the current population might benefit from reduced incidence of hard CVD events.

The EPA received a comment stating that the benefits associated with high-density lipoprotein cholesterol (HDLC), often referred to as the 'good cholesterol', are not likely to accrue because the evidence of the relationship between PFAS and the health outcome is not conclusive, and that this endpoint should not have been quantified. The EPA disagrees with the comment: Although the evidence of a relationship between PFAS exposure and HDLC is not conclusive, the SAB recommended that the EPA evaluate how the inclusion of HDLC effects would influence results (USEPA, 2022d). The EPA evaluated how quantified benefits results are affected by the inclusion of HDLC effects in a sensitivity analysis presented in Appendix K of the EA for the final rule (USEPA, 2024c). Additionally, the same commenter and one other commenter challenged the EPA's quantification of PFOS and blood pressure (BP), stating that the EPA's finding that PFOS might have "the potential" to affect blood pressure does not meet the SDWA standard for inclusion in a benefits analysis and that the "rationale for including changes in BP in relation to PFOS is not clear." Another comment identified a study that utilized NHANES data and "did not observe an association" between PFOA and blood pressure. Finally, another commenter mentioned that "Neither the ATSDR nor the National Academy of Sciences (NAS) have found an association between PFOA/PFAS and increased blood pressure." While the EPA is aware of this previous work, in the EPA's own, more recent assessment, the strength of the evidence is determined both by the number but also the quality of studies investigating the relationship. One high confidence study conducted using U.S. general population data from NHANES showed a relationship between PFOS exposure and systolic blood pressure in humans (Liao et al., 2020). In addition, several *medium* and *low* confidence studies provided evidence for an association between PFOS and blood pressure and/or hypertension (Mitro et al., 2020; Bao et al., 2017; Mi et al., 2020; Liu et al., 2018). Because blood pressure is an important component of the Atherosclerotic Cardiovascular Disease (ASCVD) model used to estimate hard CVD event risk, and because epidemiology reports show consistent evidence of an association between PFOS and blood pressure in general adult populations (i.e., the populations evaluated using the ASCVD model), the EPA included the relationship between PFOS exposure and blood pressure in the analysis. The EPA further notes that the Science Advisory Board recommended modeling the impacts of changes in all ASCVD model predictors (including blood pressure and HDLC) for which there is evidence of a likely causal relationship (USEPA, 2022d).

A few commenters questioned the evidence or stated that the evidence supporting a direct association between exposure to PFOA and PFOS and CVD health outcomes is insufficient. One commenter referenced a study finding that no elevated cardiovascular health outcome risk was identified based on PFOA/PFOS-related cholesterol increase. Another commenter wrote that for

"PFOA/PFOS and cholesterol, ATSDR concluded that the evidence is insufficient to determine a cause-and-effect relationship, while the NAS concluded that there is sufficient evidence for the association of PFAS exposure with dyslipidemia (total triglycerides, total cholesterol, and low-density lipoprotein and high-density lipoprotein)." The EPA disagrees with these comments. See sections 4.2.1.3 and 4.2.2.3.2 of the EPA response in this *Response to Comments* document for discussion on the evidence supporting associations between serum lipids and CVD. Additionally, the CVD benefits analysis was reviewed and approved by SAB panelists. Numerous studies have shown consistent associations between PFOA/PFOS exposure and changes in total cholesterol and blood pressure. TC and blood pressure are well-established CVD risk biomarkers, are clearly associated with adverse CVD events, and are important inputs to the ASCVD model that the EPA used to estimate CVD outcomes.

Individual Public Comments

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045921)

A. EPA's Health Risk Reduction and Cost Analysis (HHRCA) is flawed and overestimates benefits

In evaluating benefits of MCLs, there must be a factual basis by which to conclude that such benefits are likely to occur as a result of treatment (emphasis added) [FN179: 42 U.S.C. 300g(b)(3)(C).]. As discussed below, the existing evidence does not support that many of the quantified health effects are likely to occur as a result of treatment. Similarly, while EPA discusses additional non-quantifiable benefits, many of these benefits are "possible" or "potential" benefits, but neither the existing record nor the EPA in this rulemaking has presented information to support these benefits as being "likely."[FN180: See EPA Economic Analysis of the Proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances, 2023, where the first sentence of EPA's benefits analysis chapter states: "This chapter discusses the potential quantified and nonquantifiable benefits to human health resulting from changes in PFAS levels in drinking water due to implementation of the proposed rule, as well as several regulatory alternatives." (emphasis added), at page 6-1.] There is a higher bar for evidence to meet a likely standard, and EPA's speculative and precautionary benefits analysis does not meet this threshold.

1. Benefits assessment for cardiovascular disease (CVD) is not supported by the science

To evaluate CVD, EPA quantifies benefits, for PFOA and PFOS, by evaluating total cholesterol and high-density lipoprotein cholesterol (HDLC). EPA also quantifies benefits related to PFOS and blood pressure. In table 42, in the Federal Register notice, EPA clearly notes that for HDLC the "[e]vidence of the relationship between the PFAS compound and the health outcome is not conclusive."[FN181: 88 Fed. Reg. at 18704 n.5.] Based on EPA's evaluation, it is not likely that these benefits will accrue, and this endpoint should not have been quantified. Similarly, it is not clear why EPA quantifies PFOS and blood pressure. Based on EPA's evaluation of PFOS science, blood pressure is not a prioritized health outcome in this rulemaking, and it was not a

recommended health outcome from the SAB. Additionally, EPA's own evaluation, in summarizing the evidence integration for PFOS and blood pressure, states "While there is some evidence that PFOS exposure might also have the potential to affect blood pressure and other cardiovascular responses in humans given relevant exposure circumstances, the human evidence underlying this possibility is uncertain and without support from animal or mechanistic studies."[FN182: See Public Comment Draft Toxicity Assessment and Proposed Maximum Contaminant Level Goal for Perfluorooctane Sulfonic Acid (PFOS) in in Drinking Water at page 3-175, .regulations.gov/document/EPA-HQ-OW-2022-0114-0034.] EPA's finding that PFOS might have "the potential" to affect blood pressure does not meet SDWA standard for inclusion in a benefits analysis.

EPA also quantifies benefits related to the relationship between PFOA and PFOS and total cholesterol. However, EPA states "EPA recognizes that the epidemiologic literature that provides strong support for an effect of PFOA and PFOS on cholesterol and blood pressure does not provide direct support for an effect of PFOA and PFOS on the risk of CVD."[FN183: 88 Fed. Reg. at 18709.] Thus the quantification of these benefits comes with a great deal of uncertainty. As there is not a direct link between PFOA and PFOS exposure and CVD, EPA links changes in CVD risk biomarkers to changes in CVD risk. Nevertheless, by quantifying benefits that include avoided incidents and avoided deaths due to CVD, EPA is modeling a relationship that is not supported by the epidemiological literature. For PFOS, the estimated increase in total cholesterol, per ng/mL serum PFOS, is not statistically significant,[FN184: Id.] providing even more support for the concerns with the quantification of this health endpoint. Additional recent (2022) science is available to suggest that even if elevated cholesterol levels exist, no PFOA or PFOS-related increase in relevant endpoints (such as stroke, myocardial infarction, or other irreversible measures) occurs in humans, and should properly be considered [FN185: Schillemans T, Donat-Vargas C, Lindh CH, de Faire U, Wolk A, Leander K, et al. (2022) Per- and polyfluoroalkyl substances and risk of myocardial infarction and stroke: a nested case-control study in Sweden. Environ Health Perspect130(3):37007, available at: .niehs.nih.gov/doi/10.1289/EHP9791.].

While the modeling for PFNA is not presented, it appears that EPA nevertheless quantifies the supposed CVD benefits that stem from reductions in PFNA [FN186: See Table 42 in the proposed rule and also Table 6-6 in the Economic Analysis.]. As cholesterol and CVD outcomes are not a critical effect for PFNA, and most epidemiological studies do not show an association between PFNA and LDLC or HDLC,[FN187: See EPA Economic Analysis of the Proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances, 2023, at page 6-23.] these benefits should not be quantified. Additionally, EPA does not discuss the potential for CVD effects from PFHxS and HFPO-DA. [FN188: Id.] As such, when EPA makes broad statements about additional non-quantified benefits, it is imperative that EPA be clear that additional CVD benefits are not expected.

EPA Response: The EPA disagrees with the commenter's assertion that "the existing evidence does not support that many of the quantified health effects are likely to occur as a result of treatment." See sections 4.2.1 and 4.2.2 of the EPA response in this *Response to Comments*

document for the EPA's response to comments claiming that the existing health evidence does not support the EPA's benefits analysis. Additionally, the EPA disagrees with the commenter's statement that the EPA did not present information to support non-quantifiable benefits. See sections 13.5 and 13.6 of the EPA response in this *Response to Comments* document for summary of comments received on nonquantifiable benefits and the EPA's response to those comments.

See section 4.2.1 of the EPA response in this *Response to Comments* document and the Final Toxicity Assessments (USEPA, 2024h; USEPA, 2024i) regarding the rigor of scientific evidence used in identifying quantified noncancer health benefits that are likely to occur as a result of treatment. See section 13.4.1 of the EPA response in this *Response to Comments* document regarding quantification of CVD benefits from reduced exposure to PFOA and PFOS in drinking water and also the EPA's response to the commenter's statements on HDLC and blood pressure modeling components. The commenter incorrectly states, "[b]ased on EPA's evaluation of PFOS science, blood pressure is not a prioritized health outcome in this rulemaking." As described in the Final Toxicity Assessment for PFOS and in section 4.2.1 of the EPA response in this *Response to Comments* document, one of the five prioritized health outcomes in this rulemaking is cardiovascular effects. This health outcome encompasses endpoints including changes in serum lipids (e.g., TC), as well as altered blood pressure.

As described in responses in section 4.2.1 of this *Response to Comments* document, a lack of or limited evidence supporting an association between chemical exposure and a health effect (e.g., increased risk of CVD) does not necessarily mean the association is non-existent, it simply means the agency does not currently have evidence to make definitive conclusions regarding the exposure-response relationship. Additionally, the EPA disagrees that a lack of statistical significance should preclude an endpoint from consideration for quantitative analyses such as those in the HRRCA. The scientific consensus in the epidemiologic and systematic review community is that evidence of an association does not need to rely solely on statistical significance. As stated in the *ORD Staff Handbook for Developing IRIS Assessments* (USEPA, 2022c), consideration of magnitude of the association and biological significance or adversity inform determination of associations.

The commenter incorrectly asserts that the EPA quantified PFNA effects on CVD. As described throughout the EA and section XII of the FRN, the EPA quantified CVD effects for PFOA and PFOS only and does not present quantified benefits for PFNA and CVD in the national benefits assessment. Instead, and as discussed in the section 13.4 of the EPA response in this *Response to Comments* document, the agency presents a quantitative sensitivity analysis for PFNA and birth weight effects in Appendix K of USEPA (2024c). The EPA notes that the best available peer reviewed scientific assessment for PFNA (ATSDR, 2021) provides justification for the EPA's analysis of economic benefits of PFNA exposure reduction and avoided birth weight effects. Furthermore, more recent epidemiological studies that evaluated PFNA and birth weight, including key studies modeled for PFOA and PFOS (Sagiv et al., 2018; Wikström et al., 2020), as well as a recently published meta-analysis of mean birth weight that indicates the birth weight results for PFNA are robust and consistent (Wright et al., 2023).

Lastly, the commenter incorrectly stated that the EPA did not discuss the potential for CVD effects from PFHxS, as the EPA provided a qualitative discussion of cardiovascular benefits for PFHxS in Section 6.2 of the EA (USEPA, 2024b) and also section XII of the FRN. The EPA did not discuss HFPO-DA effects on cardiovascular disease in the qualitative benefits analysis. Table 6-7 of the EA indicates that the EPA HFPO-DA final toxicity assessment did not evaluate associations between HFPO-DA exposure and CVD outcomes (USEPA, 2024b).

American Water Works Association (AWWA) (Doc. #1759, SBC-053061)

4. Comments on the Cardiovascular Disease Risk Reduction Analysis

Previously, the USEPA had proposed using the atherosclerotic cardiovascular disease (ASCVD) model to estimate reductions in CVD risks associated with reductions in exposure to PFOA and PFOS in drinking water. The SAB was generally supportive of the overall approach for estimating reductions in CVD risk; however, the SAB noted that the approach did not mesh with the USEPA's conclusion that there was insufficient evidence of increased CVD risk to inform a candidate RfD. In response to SAB feedback, the USEPA (2023a, 2023c) developed RfDs for total cholesterol (TC) as a precursor to CVD and to further justify its use of the ASCVD model – which uses TC as one of several variables to estimate 10-year risk of CVD events – for quantifying CVD benefits. The quantified health benefits now include the following:

• Number of non-fatal myocardial infarction (MI) cases avoided;

• Number of non-fatal ischemic stroke (IS) cases avoided; and

• Number of CVD deaths avoided.

Under the Proposed Option (MCL of 4 ppt for PFOA and 4 ppt for PFOS and an HI of 1.0 for PFNA, HFPO-DA (GenX chemicals), PFHxS, and PFBS), the USEPA calculated that the following morbidity and mortality are avoided when the Proposed Option is compared to baseline drinking water concentrations: 6,081.0 non-fatal MI cases avoided; 8,870.8 non-fatal IS cases avoided; and 3,584.6 CVD deaths avoided (USEPA 2023e).

In order to calculate the avoided CVD related mortality and mortality, the USEPA used exposure-response functions of serum PFOA and PFOS on TC, and serum PFOS (but not serum PFOA) on systolic blood pressure (BP) to estimate annual changes in TC and BP biomarkers.

4.1 Exposure-response functions for PFOA and PFOS and TC

The USEPA (2023f) conducted a meta-analysis of epidemiological studies of the general population of the associations between certain PFAS and total cholesterol to estimate the exposure-response function. Using these exposure-response functions presumes that further reductions in average PFOA and PFOS concentrations in serum in the general population will result in decreases in serum cholesterol, and that decreases in serum cholesterol will lead to decreases in CVD. In other words, this presumes that serum cholesterol is an intermediate variable on the causal pathway between PFAS exposure and CVDs.

The PFOA-TC exposure-response function developed by USEPA (2023f) is the summary estimate from a meta-analysis of four studies of the general population (Nelson et al. 2010; He et al. 2018; Dong et al. 2019; Fan et al. 2020). [NOTE: The slope factor is 1.57 mg/dL per ng/mL serum PFOA. The number of studies is either four (see p. F-11, Table F-2, and p. F-12, Figure 2, USEPA 2023f) or six (see p. F-10, USEPA 2023f and elsewhere in the documents).] Similarly, the PFOSTC exposure-response function developed by USEPA (2023f) is the summary estimate from a meta-analysis of five studies of the general population (Chateau-Degat et al. 2010, Nelson et al. 2010, He et al. 2018, Dong et al. 2019, Fan et al. 2020), including the same four studies used for the PFOA-TC exposure-response function. Four of these studies were based on cross-sectional analyses serum PFAS and TC from National Health and Nutrition Examination Surveys (NHANES) and included overlapping years. For example:

• Nelson et al. (2010) included NHANES participants from 2003 to 2004; individuals taking cholesterol lowering medication were excluded.

• He et al. (2018) included NHANES participants from 2003-2004 to 2011-2012; individuals taking cholesterol lowering medication were not excluded.

• Dong et al. (2019) included NHANES participants from 2003-2004 to 2013-2014; individuals taking cholesterol lowering medications were excluded.

• Fan et al. (2020) included NHANES participants from 2011-2012 to 2013-2014; individuals taking cholesterol lowering medication were not excluded.

Overall, the USEPA (2023f) identified and included 14 studies in the meta-analysis of exposure-response relationships between PFOA or PFOS and TC. When all 11 studies of PFOA and TC are included in the meta-analysis, the slope factor is 0.003 mg/dL TC per ng/mL in serum PFOA. However, the exposure-response relationship used for the benefits analysis was based only on the summary estimate of the four (PFOA) or five (PFOS) studies that reported linear slope relationships (beta coefficient for a change in TC or HLD-C in mg/dL to increases in serum PFOA or PFOS in ng/mL). These are the studies of the general population and the coefficient (1.57 mg/dL TC per ng/mL serum PFOA) used in the benefits analysis is 500-fold higher than when all 11 studies are included. This means that the estimated benefits will be much greater using the coefficient from the meta-analysis of the four (overlapping) general population studies than from using the coefficient from the 11 studies of PFOA-TC.

In fact, there appears to be a non-linear association between PFOA and TC, which is not accounted for when a linear slope factor is used over a relatively narrow range of PFOA in serum seen in the general population. In an evaluation of serum lipids in participants in the C8 Health Science study, Steenland et al. (2009) reported that the exposure-response function was steeper at concentrations of total cholesterol (TC) below approximately 208 mg/dL. Predicted TC leveled off at around 50 ng/ml of PFOA. By relying on the exposure-response function from four studies (PFOA) or five studies (PFOS) of the general population (with average PFOA and PFOS serum concentrations below 25 ng/ml), the calculated health benefits are greater than would be expected than if the exposure-response function was based on the distribution of serum PFOA

and PFOS seen in occupational populations and studies of communities with drinking water contaminated by PFOA or PFOS. These populations have blood serum concentrations that are 2 to 4 orders of magnitude greater than those in the general population.

4.2 Issues related to use of the ASCVD model

The USEPA assumes that CVD (myocardial infarctions and strokes) can be reduced indirectly by decreasing average serum PFOA and PFOS concentrations further, which would lead to decreased total cholesterol; however, the USEPA has not shown evidence that PFAS exposure (particularly PFOA or PFOS) directly increases the risk of CVD. The USEPA (2023a, 2023c) did not acknowledge that epidemiological studies of PFAS exposures have not observed increased risks of CVD even in studies of populations exposed to the highest concentrations; instead, the USEPA suggested that the results are inconsistent.

The benefits analysis does not directly use PFOA or PFOS concentrations as inputs to the pooled cohort ASCVD model that evaluates the 10-year probability of CVD outcomes (Goff et al. 2014). Instead, the benefits analysis focuses on the exposure-response function between PFOA and PFOS and the precursor endpoint (e.g. total cholesterol) from a meta-analysis of results from epidemiological studies to calculate inputs to the ASCVD model.

Even under the assumption that PFOA or PFOS in serum leads to high total cholesterol, and a shift in the distribution of average cholesterol leads to an increased proportion of individuals with high cholesterol (which potentially affects a large population), there is a lack of evidence that such a shift has occurred based on PFOA and PFOS concentrations in the general population over the past 20 years. As such, there is substantial uncertainty in the population health benefit of reduced TC by further reducing PFOA and PFOS concentrations from the baseline assumptions to 4 ppt each. The USEPA partially acknowledged this uncertainty when it stated:

“The analysis assumes that the CVD risk impact of changes in TC/BP from reductions in serum PFOA/PFOS is the same as the CVD risk impact of changes in these biomarkers due to other reasons such as behavioral changes or medication.” (P. 6-117,6-118, USEPA 2023e).

The ASCVD model uses the following inputs to estimate a 10-year probability of a first hard ASCVD event in adults, 40 to 79 years of age (who are free from ASCVD): age, sex, TC, HDL-C, systolic BP, use of antihypertensive therapy, diabetes, and current smoking (Goff et al. 2014). However, the USEPA (2023e) used changes in TC (in relation to PFOA and PFOS) and changes in blood pressure (BP) (in relation to PFOS, discussed further below), but not changes in high density lipoprotein cholesterol (HDL-C), as inputs to ASCVD model.

Risks of CVD are lower in individuals or populations with higher levels of HDL-C. If PFOA or PFOS are also associated with higher HDL-C, it is plausible that risks of CVD would not be impacted by higher TC (Steenland et al. 2020). In a meta-analysis, the USEPA (2023f) found that, on average, HDL-C increased with PFOA and PFOS, although the summary results of the meta analyses were not statistically significant. Across the documents, the USEPA is not consistent in their conclusions regarding PFOA or PFOS and HDL-C. Separately, the USEPA

made the following conflicting statements regarding the strength of evidence for HDL-C and PFOA:

“Positive associations between PFOA and HDL were also observed in most studies in the general population.” (p. 3-155, USEPA 2023a)

“HDL was not associated with PFOA.” (p. 3-173, USEPA 2023a).

“The available evidence does not support a consistent association between PFOS and reduced HDL.” (p. 3-164, USEPA 2023c).

In contrast, the USEPA presented similarly inconsistent language for effects of PFOS on BP, but included the effect of PFOS on BP in the calculation of the ASCVD model, while excluding the effect of HDL-C on PFOA or PFOS (see next section, Exposure-response function for PFOS and increases in blood pressure for additional information).

The SAB (USEPA SAB 2022a) requested that the USEPA address whether the inclusion of HDL-C would influence the results of the benefits analysis. In response, the USEPA (2023f) conducted a sensitivity analysis of a hypothetical exposure reduction of 1 ppt PFOA and 1 ppt PFOS and found that inclusion of the HDL-C effects (from the meta-analysis) decreases the annualized CVD benefits by 23-25%. Meanwhile, exclusion of the BP effects decreases annualized CVD benefits by approximately 1.8% to 2.2%. In other words, the annualized CVD benefits may be substantially overstated by excluding HDL-C from the model. In any event, the uncertainty associated with the estimated benefits from the proposed MCLs is large. It is not clear that the proposed MCLs will further drive down average PFOA or PFOS in blood serum and therefore if the estimated benefits will materialize.

4.3 Exposure-response function for PFOS and increases in blood pressure

The USEPA (2023e) also justified including changes in BP associated with PFOS as an input into the ASCVD model, and stated that the USEPA (2023c) had concluded “there was overall consistent evidence of an association between PFOS and BP in studies conducted in general adult populations.” (p. 6-15, USEPA 2023e).

Subsequently, the USEPA (2023e) used the exposure-response function between PFOS and increases in blood pressure from a study of NHANES participants, 2003-2012 (Liao et al. 2020). This addition has not been peer-reviewed by the SAB and there is actually inconsistent language regarding the strength of evidence conclusions in the USEPA PFOS Toxicity Assessment (2023c), which also indicated that the evidence of an association between PFOS and BP is uncertain.

Examples of the inconsistency follow here:

“High and medium confidence studies reported positive associations with blood pressure and increased risk of hypertension.” (P. 3-176, USEPA 2023c)

"While there is some evidence that PFOS exposure might also have the potential to affect blood pressure and other cardiovascular responses in humans given relevant exposure circumstances, the human evidence underlying this possibility is uncertain and without support from animal or mechanistic studies." (P. 3-176, USEPA 2023c).

"Results from studies of varying confidence reported mixed results for changes in blood pressure, including DBP and SBP, and risk of hypertension for all study populations. Studies in children (10) reported mostly non-significant associations with blood pressure and/or hypertension, though two studies in adolescents reported significantly increased (1/10) and decreased (1/10) DBP in males. In adults (13), one study reported a significantly increased risk of hypertension (1/13), but associations from other studies did not reach significance (3/13). When stratified by sex, there were mixed results. One study reported a higher risk of hypertension for males (1/13), while another reported higher risk for females (1/13). One study reported an inverse association for DBP (1/13), while others reported positive associations for DBP (6/13), but only three studies reached significance. SBP was significantly increased for all adults (4/13), in females only (2/13), and in males only (1/13). No studies examined blood pressure or hypertension in occupational populations." [USEPA 2023c, p. 3-177]

Overall, the rationale for including changes in BP in relation to PFOS is not clear; the evidence regarding BP effects from PFOS is equivocal, similar to that of changes in HDL-C. Furthermore, to include changes in BP but not include changes in HDL-C in relation to PFOS is inconsistent, especially considering that the sensitivity analysis that included HDL-C effects in the ASCVD model showed a reduction of as much as 25% in the annualized CVD benefits if the USEPA metaanalysis slope factors are used. In contrast, exclusion of BP effects decreases annualized CVD benefits by 1.8%-2.2% if USEPA meta-analysis slope factors are used.

The estimated health benefits do not consider the potential impact of clinical management of CVD risks. That is, clinicians use the ASCVD risk model to evaluate 10-year risk of hard CVD events and inform decisions about risk management, with one of the common methods for modifying CVD risk being the use of cholesterol-lowering medications. At least two scenarios involving the use of cholesterol-lowing medications can result in overestimated CVD risk reductions in relation to PFAS based on the observed association of increased cholesterol with increased PFOA or PFOS:

1. Clinicians recommend that individuals with high cholesterol be administered cholesterollowering medication, with statins typically recommended first. As described in the next section on biological mechanisms, PFAS serum concentrations in individuals who use statins have not been reported to differ from serum concentrations in individuals who do not use of statins. Assuming that statins decrease circulating cholesterol levels but do not effect PFAS serum concentrations (that is, PFAS serum concentrations remain relatively unchanged), the 10-year risk of a hard CVD event will decrease due to medication use but it is unrelated to a decrease in PFAS serum concentrations. The CVD benefits calculated from reductions in PFAS levels using the ASCVD model are overstated.

2. On the other hand, the clinician may prescribe a bile acid sequestrant to lower cholesterol. As described in the next section on biological mechanisms, there is some evidence that use of bile acid sequestrants decreases PFOA serum concentrations as well as circulating cholesterol levels. In this scenario, the CVD health benefits (calculated using the ASCVD model) resulting from medication use are misattributed to decreases in PFOA (or PFOS) serum levels (whether PFAS exposure decreases or not) because the association between PFOA and serum cholesterol is confounded by underlying physiological processes (for example, enterohepatic cycling, which could explain the reported association between bile acids and PFOA and distort the magnitude of the association between PFOA and high cholesterol).

These are theoretical examples for illustrative purposes; however, in the absence of a better understanding of the biological mechanisms that underpin the association between increases in PFOA or PFOS in blood serum in the general population and increases in total cholesterol, the quantified benefits analysis may be less than estimated.

Although the USEPA has added discussion of biological mechanisms that inform the strength of evidence conclusion for increased CVD impacts associated with PFOA and PFOS, the discussion largely focuses on biological mechanisms that inform the decreases with cholesterol seen with PFOA and PFOS at much higher serum concentrations than those reported in the general population on which the RfD is based.

Biological mechanisms for the association between PFOS or PFOA (and other PFAS) and cholesterol has not yet been identified in humans. Some information regarding potential mechanisms, however, may be gleaned from epidemiological analyses of associations between PFAS concentrations and cholesterol among those who take medications to lower cholesterol. For example:

• Statins (HMG-CoA reductase inhibitors) inhibit the synthesis of cholesterol in the liver and increase the removal of low-density lipoprotein cholesterol (LDL-C) that is in the blood. Andersen et al. (2021) analyzed National Health and Nutrition Examination Survey (NHANES) data from 2003 to 2016 (while accounting for NHANES sampling parameters) and reported a 2.9% increase in PFOS concentrations ($p=0.001$) among participants who reported using statins. Statin use was not associated with increased or decreased PFOA concentrations (Andersen et al. 2021). Similarly, Ma and Ducatman (2022) found that statin use was associated with statistically significantly increased PFOS concentrations and borderline significantly increased PFOA concentrations (when compared to non-users) in the C8 Health Study.

• Bile acid sequestrants (cholestyramine) remove bile acids that are made when LDL cholesterol breaks down. Cholestyramine lowers cholesterol by increasing bile acid secretion. Cholestyramine increased fecal elimination of PFOS and PFOA and decreased blood serum concentrations in an individual who self-administered cholestyramine (Genius et al. 2010). In the cross-sectional analysis of NHANES data from 2003-2016, Andersen et al. (2021) reported that use of cholestyramine was associated with a 1.3% reduction in PFOA and a 15.1% reduction in PFOS serum concentrations. Similarly, when compared to non-users, use of cholestyramine was

associated with statistically significant decreases in serum PFAS (and the effect was strongest for PFOS) in the C8 Health Science study (Ducatman et al. 2021).

• Probenicid lowers cholesterol by inhibiting organic ion transporters (OAT). Probenecid helps the kidneys remove uric acid from the blood and is also used in the treatment of gout. Ducatman et al. (2021) compared Probenicid users to non-users and found that use of Probenicid was associated with a small increase in serum PFAS which was not statistically significant for PFOA or PFOS in the C8 Health Study (Ducatman et al. 2021)

• Ezetimibe inhibits the absorption of cholesterol in the small intestine primarily by inhibiting Niemann-Pick C1-like 1 (NPC1L1) protein. Ma and Ducatman (2022) reported that when compared to non-users, ezetimibe was not associated with blood concentrations of PFAS. Ezetimibe use was not associated with PFOA or PFOS serum concentrations in the NHANES analysis, either (Andersen et al. 2021).

Separately, the effects of lifestyle interventions on cholesterol and PFAS blood concentrations are mixed: Morgan et al. (2023) found that lifestyle interventions over 6 months significantly reduced cholesterol; blood concentrations of PFOS and PFOA (as well as other PFAS) decreased significantly as well. After lifestyle interventions, only PFOS and total cholesterol were positively correlated and PFOS was only distributed in albumin lipoprotein fractions. Before the interventions, PFOS was found in both the albumin and non-albumin lipoprotein fractions.

4.4 Effects of other factors that mediate cholesterol levels likely dominate cardiovascular disease risks

Indirect evidence exists that suggests that the MCLs of 4.0 ppt each for PFOA and PFOS are unlikely to result in benefits as great as that reported by the USEPA (2023e) because other risk factors have a considerably larger impact on cholesterol levels. Collectively, this evidence suggests that a population shift in average cholesterol levels by further decreases in serum concentrations of PFOS and PFOA would not be detected. Over the past 20 years, PFOA and PFOS in serum have decreased in the general population. In adults 20 years and older, PFOA in serum decreased from a median of 5.20 ng/mL in 1999-2000 to 1.47 ng/mL in 2017-2018 (CDC 2023b). In adults 20 years and older, PFOS in blood serum decreased from a median of 30.3 ng/mL in 1999-2000 to 4.7 ng/mL in 2017-2018 (CDC 2023b). An examination of cholesterol levels over the past 60 years indicates substantial reductions have occurred, even during the time period when serum concentrations in PFOS and PFOA were likely increasing (before 1999-2000 when use of PFOA and PFOS in industrial applications and consumer products was greatest):

• Since 1960, TC levels have declined across all adult age groups, with the steepest declines seen in the older age groups. For example, average TC decreased from approximately 250 mg/dL in 1960 to approximately 215 mg/dL in adults 60-74 in 19992002 (Carroll et al. 2005). Mean TC in adults aged 20 and older declined to 188 mg/dL in 2017-2018 from 203 mg/dL in 1999-2000, a decrease of 15 mg/dL.

• In adults ages 20 and older, the prevalence of high cholesterol (total cholesterol level of at least 240 mg/dL) was 20% during 1988-1994 (Carroll et al. 2005). Since then, the prevalence of high

cholesterol in adults has continued to decline from 18% during 19992000 to less than 11% in 2017-2018 (Carroll and Fryar 2020, Figure 4 below).

• The prevalence of high LDL-C decreased from 59% in the late 1970s to 27% in 20072010 (Kuklina et al. 2013). This trend was attributed to an increased percentage of adults eating diets low in saturated fats over time (from 25% during the late 1970s to 42% during 1988-1994). The percentage of adults eating diets low in saturated fats remained unchanged from 1988-1994 to 2007-2010 (Kuklina et al. 2013).

• From the late 1980s to 2007-2010, the percentage of adults using cholesterol-lowering medication increased from 5% to 23% (Kuklina et al. 2013).

• [Figure 4: See Docket ID EPA-HQ-OW-2022-0114-1759]

Source of Figure 4: Carroll and Fryar 2020.

With respect to heart disease specifically, the heart disease death rate for men aged 45-64 years in the US declined from 235.7 per 100,000 in 1999 to 183.5 per 100,000 in 2011. It increased to 192.9 per 100,000 in 2018. For women, the heart disease death rate declined from 96.8 per 100,000 in 1999 to 74.9 per 100,000 in 2011, and increased to 80.3 per 100,0000 in 2016 before leveling off (Curtin, 2020). Incidence of CVD has also declined globally over the period from 1990 to 2017 (Amini et al. 2021).

Overall, evidence of consistent decreases in heart disease incidence and mortality rates since 1990 (and earlier) suggests improvements in CVD risk factors and interventions related to diet, physical activity, and cholesterol medications are largely successful and largely drove decreases in CVD incidence and mortality until more recent years. It seems implausible that mean PFOA or PFOS serum concentrations at levels seen in the general public in recent years contribute to increased measurable risks of CVD, given that mean TC concentrations have fallen since the 1960s while PFAS blood concentrations were more likely to be increasing until the late 1990s or 2002. It is unlikely that the benefits of decreased CVD events are detectable with further declines in average blood PFAS serum concentrations.

4.5 Conclusions and Recommendations

• The USEPA should be consistent with its recent decision to include systolic blood pressure (SBP) in the ASCVD analysis related to PFOS (which is inconsistently related to SBP) and include HDL-C in the benefits analysis based on the ASCVD model. The ASCVD model uses HDL-C, and collectively, there is some evidence that PFOA and PFOS are positively correlated with HDL-C concentrations.

• The USEPA should include a more expansive discussion of biological mechanisms for the correlation of PFOA and PFOS concentrations with TC. The mechanisms which explain decreased cholesterol with higher PFOA or PFOS serum concentrations in animals are not likely to explain the small modest increases in cholesterol in relation to small increases in PFAS concentrations in the general population.

• The USEPA should use sensitivity analyses to further explore the potential for confounding by underlying biological processes.

• The USEPA should consider whether the quantified benefits (which are substantial) make sense within the broader context of trends over time for cholesterol levels and heart disease incidence and mortality. Cholesterol levels and heart disease incidence and mortality were decreasing even before PFOA and PFOS concentrations in the blood of the general population began decreasing (since early 2000's).

5. Overall Conclusions/Comments

• The use of a HI based on different target organs or endpoints for estimation of a regulatory value has no support in existing agency guidelines or those of other national and international authoritative bodies. The agency should delay promulgating a HI-based assessment until they have developed the necessary Target Tissue Doses (TTDs), which can readily be derived using the existing ATSDR methodology (ATSDR 2018).

• Available data suggest that further reductions of average PFOA and PFOS concentrations in blood serum are unlikely to result in measurable increases in average birth weight. Data from other areas where PFOS and PFOA concentrations are elevated suggest that increases in average birth weight and decreases in infant mortality are not expected with lower PFOS and PFOA in blood serum (Olsen and Joensen 1985; Olsen et al. 2023) found that that the mean birthweight in the Faroe Islands was higher than other Nordic countries and had increased during 2010–2019 in the Faroe Islands.

• Evidence of consistent decreases in heart disease incidence and mortality rates since 1990 (and earlier) suggests improvements in CVD risk factors and interventions are largely successful. It is unlikely that mean PFOA or PFOS serum concentrations at levels seen in the general public in recent years contribute to increased measurable risks of cardiovascular disease, given that mean TC concentrations have fallen since the 1960s. It is unlikely that the benefits of decreased CVD events are detectable with further declines in average blood serum concentrations.

• Importantly, the quantified health benefits are likely to be overstated. Although epidemiological studies have reported consistent differences in biomarkers of effect (increases in total cholesterol, decreases in antibody response, increases in certain liver enzymes or small decreases in birth weight), there are only inconsistently reported increased risks of adverse health events (e.g. frequency or duration of infections) and there is generally no evidence of increased risks of low birth weight (birth weight < 2500 g) or increased risk of cardiovascular disease, the two adverse health endpoints on which the health benefits are quantified.

• Separately, it is easy to misinterpret and overstate the health benefits potentially associated with decreasing PFOA and PFOS in drinking water by “double-counting” the benefits. As evidenced by the Faroe Islands population, there is likely to be a smaller benefit than estimated (e.g. some Faroe Islands birth cohorts showed decreases in anti-diphtheria and anti-tetanus responses in relation to PFOA and PFOS in birth cohorts that have some of the largest mean birth weights globally). In other words, any quantifiable health benefit for the population would apply to some

combination of endpoints (some small benefits associated with increased birth weight, some small benefits associated with decreased cholesterol) but not the cumulative endpoints (benefits associated with decreased birth weight plus benefits associated with decreased cardiovascular diseases). Because the actual nature of the mechanisms for the observed associations between PFOA and PFOS and the health effects are unknown, there remains substantial uncertainty in the range of the quantified benefits associated with the Proposed Option as well as the alternative regulatory options.

EPA Response: The commenter incorrectly states that the EPA derived RfDs for TC to justify its use of the ASCVD model. As described in section 4.2.1 of the EPA response in this *Response to Comments* document and responses in section 4.2.1.3, the EPA determined in its toxicity assessments for PFOA and PFOS that there was *evidence indicating* an association between PFOA or PFOS and cardiovascular effects in humans (USEPA, 2023g; USEPA, 2023h). In particular, there was consistent evidence of increased serum total cholesterol in adults with increased PFOA and PFOS serum concentrations. The EPA did not derive an RfD to "justify its use of the ASCVD model," but because the data supported quantitative analysis of this endpoint.

Regarding commenter's critique of the exposure-response functions, use of ASCVD model in the analysis, and inclusion of the blood pressure effect in the analysis of reduced CVD risk from the proposed MCLs, please see section 13.4.1 of the EPA response in this *Response to Comments* document. Regarding the commenter's assertion that the association between PFOS and blood pressure is uncertain, see section 13.4.1 of the EPA response in this *Response to Comments* document. Regarding the commenter's assertion that there is uncertainty in the population health benefit of reduced TC by further reducing PFOA and PFOS concentrations to the MCL, see section 13.4.1 of the EPA response in this *Response to Comments* document. The EPA disagrees

with the commenter's assertion that quantified benefits are overestimated due to a failure to account for medication use and other factors such as lifestyle changes that mediate cholesterol levels. The EPA analyzes changes in blood serum PFAS levels resulting from changes in PFAS drinking water concentrations due to the installation of treatment technology. The associated quantified CVD benefits estimates are estimated based on these changes in blood serum levels only and do not reflect changes associated with other factors that mediate cholesterol levels such as lifestyle changes or use of medication. Please note that the baseline data analysis also considers the difference between populations that use statins to reduce TC and populations that do not. The EPA also provided a detailed discussion of uncertainty associated with the use of medication or lifestyle changes in table 6-51 in the EA (USEPA, 2024b). The EPA also notes that merely relying on medication to control cholesterol levels in the general population thereby decreasing PFAS-driven risk of CVD is not a health protective or equitable approach, does not consider costs or affordability to the population, and does not consider potential medication side effects, among many other concerns. The EPA's approach is to prevent increased TC in the first place by preventing chemical exposure and this preventative approach to the rule is reflected in the EPA's benefits analysis.

Regarding the commenter's assertion that the EPA did not consider that studies exposed to high PFAS concentrations reported no increase in CVD risk, see the EPA response to comment Doc. #1713, SBC-045921 in section 13.4.1 in this *Response to Comments* document.

The EPA disagrees with the commenter's characterization of inconsistencies between assessments regarding associations between PFOS and blood pressure in adults. The consistent findings for serum lipids are also supported by evidence of associations with blood pressure in adult populations in *high* and *medium* confidence studies as was summarized in Tables 3-8 and 3-11 of the PFOA and PFOS toxicity assessments, respectively (USEPA, 2024h; USEPA, 2024i). With regard to the commenter's statement that associations between PFOS and blood pressure do not have support from animal or mechanistic studies, the EPA notes that there is no requirement for concurrence between human studies and animal studies. Rather, if there is evidence in humans, even without evidence in animals, then the evidence supports a relationship between exposure and the health effect in humans.

The commenter stated that the EPA was inconsistent in conclusions regarding associations between PFOA or PFOS and HDLC and provided several quotes to support this erroneous assertion. The first quote (p. 3-155, USEPA 2023g) describes results among adults from only the subset of studies included in the 2016 Health Effects Support Document, while the second quote (p. 3-173, USEPA, 2023g) summarizes results among adults from all studies included in the current assessment. The quotes were describing two different subsets of studies and, therefore, were not inconsistent. The EPA additionally notes that the commenter only provided one quote regarding conclusions about associations between PFOS and HDLC and does not show how the EPA was inconsistent by comparing to a second quote. The EPA develops health effects summaries by population (e.g., general adult population, pregnant women, occupational population, children); the quote provided by the commenter pertains to studies of the general adult population, who may show different responses to chemical exposure than other

populations, thus resulting in multiple conclusions regarding the potential for hazard. Please see the evidence integration sections (Section 3.4.3.4) in the PFOA and PFOS Assessments for judgements synthesizing results across populations (USEPA, 2024h; USEPA, 2024i). The EPA therefore evaluated HDLC effects in a sensitivity analysis presented in the EA (see Appendix K; USEPA, 2024c).

The EPA agrees with the commenter's characterization of potential uncertainty associated with the estimated benefits based on the results of the CVD benefits sensitivity analysis. The EPA disagrees with the commenter's assertion that it is unclear whether the proposed MCLs will reduce average PFOA and PFOS in blood serum, as pharmacokinetic models have shown that reductions in PFOA and PFOS in drinking water will result in reduced PFOA and PFOS in blood serum (USEPA, 2024c).

Regarding the commenter's critique of the use of the Hazard Index, see sections 4.3 and 5.2 of the EPA response in this *Response to Comments* document. For additional information on the Hazard Index, see section V.B of the FRN.

The EPA disagrees with the commenter's critique of the EPA's linear assumption for the relationship between PFOA and TC. See section 13.4.1 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's assertion that "reduction in PFOA and PFOS concentrations in blood serum are unlikely to result in measurable increases in average birth weight." The EA clearly indicates that reducing PFOA and PFOS in drinking water will reduce the *risk* of decreased birth weight resulting from PFOA/PFOS exposure (see Section 6.4, USEPA, 2024b). See section 13.4.2 of the EPA response in this *Response to Comments* document.

Regarding the commenter's suggestion that the EPA needs to include a more expansive discussion of biological mechanisms for the correlation of PFOA and PFOS concentrations with TC, the EPA notes that this is not a requirement for quantification of a benefit. The associations identified between exposures to PFOA and PFOS and increases in TC are based on epidemiologic evidence in humans with and without use of cholesterol lowering medications. The EPA points out that the many sensitivity analyses included in the meta-analysis demonstrate one approach to accounting for potential confounding by underlying biological mechanisms. Additionally, the commenter listed citations for epidemiological studies of potential associations between PFAS concentrations and cholesterol levels among patients with high cholesterol who take cholesterol-lowering medications. The commenter suggested that these studies may provide some information on the potential biological mechanisms between PFAS and cholesterol, and the commenter summarized the studies' conclusions; however, the commenter did not explain how these studies inform the mechanistic evidence or support or refute an underlying mechanism of changes in serum lipid levels related to exposure to PFOS or PFOA. The EPA has reviewed these suggestions and determined that, while this information may represent informative epidemiological evidence, it does not provide mechanistic evidence or warrant inclusion in a

mechanistic evidence section (i.e., Section 3.4.3.3 of the Final Toxicity Assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i)).

The EPA disagrees with this commenter's assertion that quantified benefits were "double counted" as evidenced by a comparison to another population with elevated PFAS exposure in the Faroe Islands. The EPA has reviewed the provided sources, and the EPA does not agree that findings from the Faroe Islands inform in any way, as suggested by the commenter, that the quantified benefits apply to only some combination of health points rather than cumulatively. Furthermore, the EPA has diligently considered possible sources of double counting of both costs and benefits throughout the analysis. Upon review, the EPA did not find sufficient evidence provided by this comment to suggest that double counting of quantified benefits occurred. For the endpoints that the EPA modeled in the quantitative national level benefits analysis (i.e., birth weight, CVD, RCC, and bladder cancer), the commenter has provided no data or evidence to support their criticism that the benefits are double counted.

American Water Works Association (AWWA) (Doc. #1759, SBC-045640)

Finally, the benefits analysis includes several assumptions that are not clearly and consistently discussed by the agency. For example, the analysis of CVD risk reduction accounts for impacts to total cholesterol from PFAS exposure but excludes the impacts to HDL-C, which decreases risks of CVD. These analyses, which underpin the rulemaking's HRRCA and affordability analysis, need significant improvements.

EPA Response: The EPA disagrees with the commenter. The EPA has clearly described the key uncertainties and limitations associated with all modeling components. When feasible, the EPA presented the impact (i.e., directionality) of assumptions on the resulting benefit-cost estimates. For detailed explanations of these assumptions and limitations, please refer to the limitations and uncertainties tables in Chapters 5, 6, and 7 of the EA (USEPA, 2024b). Regarding the decision to exclude HDLC effects from the national-level quantified benefits analysis, see the EPA response to comment Doc. #1759, SBC-053061 in section 13.4.1 in this *Response to Comments* document and section 13.4.1 of the EPA response in this *Response to Comments* document. The commenter is incorrect, however, that the EPA did not consider the impacts of HDLC. The EPA conducted CVD sensitivity analyses to explore the impact of inclusion of HDLC effects and exclusion of BP effects from the CVD analysis. Please refer to Appendix K, Section K.3 of the EA for detail (USEPA, 2024c). The EPA found that HDLC effects either increased or decreased CVD benefits based on the slope factors used. Please refer to Appendix K, Section K.3 of the EA for detail (USEPA, 2024c). The EPA considered the information in the HDLC sensitivity analysis, along with all other sensitivity analyses that would impact benefits (some of which would increase benefits and some would decrease benefits), prior to making the determination that the costs are justified by the benefits.

American Water Works Association (AWWA) (Doc. #1759, SBC-045620)

8. Health Risk Reduction Analysis

As required by SDWA, EPA has prepared a health risk reduction analysis for each of the proposal's regulatory options. AWWA contracted with Ramboll Consulting U.S. to assist in reviewing the EPA's approach and to offer detailed recommendations to improve this important work. Ramboll has provided a detailed letter with recommendations, which is included in these comments in Appendix A.

AWWA requests that EPA update its health risk reduction analysis in light of Ramboll's report and the recommendations it contains so as to ensure that the agency is relying on the best available public health information in reaching any regulatory decisions. MCLs are appropriately set at a level where the benefits justify the costs, and without a reliable assessment of both the costs and benefits of the proposal, EPA cannot do so. Based on the information provided in the proposal, the benefits do not justify the costs at the proposed MCL levels and particularly do not justify the costs under EPA's proposed compliance timeline.

Estimating Reductions in Cardiovascular Disease Risks

According to the proposal, increased PFOA and PFOS serum concentrations may lead to an increased risk of cardiovascular disease (CVD), including myocardial infarctions and strokes. To support this analysis EPA relies on an assumption that there is a causal relationship between PFAS exposure and CVD. In particular, this analysis uses exposure-response functions from a meta-analysis that was conducted using data from several epidemiological studies on the general population. In review of this approach, several critical issues have been raised:

• While EPA relies on epidemiological studies of participants from the National Health and Nutrition Examination Surveys (NHANES) to support its meta-analysis of PFAS exposure and CVD risk. These studies did not observe increased risks of CVD in the participants of these studies, including those participants with highest exposures yet EPA characterizes the results of these studies as 'inconsistent'.

• The analysis of CVD risk projects changes to total cholesterol and blood pressure based on PFOA and PFOS exposure but excludes changes to high density lipid cholesterol, which has also been observed. A sensitivity analysis of a hypothetical exposure reduction of 1 ppt PFOA and PFOS, which included the effects of changes to HDL-C, found that annualized CVD risk reduction benefits were decreased by 23 to 25%. By comparison, when changes to blood pressure were excluded the reduction in annualized CVD risk reduction benefits only decreased by 1.8 to 2.3%. This suggests that the benefits analysis, which excludes the impact of PFOA and PFOS on HDL-C, is significantly overestimated.

• Throughout the supporting documentation, the EPA makes contradictory statements about the strength of Associations of PFOA and PFOS on blood pressure and HDL-C. Furthermore, the

inclusion of blood pressure impacts from PFOA and PFOS exposure but not the inclusion of changes to HDL-C is unclear, especially given that these impacts were observed equivocally.

• The biological mechanism for the Association of PFOA and PFOS with cholesterol is not yet identified in humans. In fact, recent work demonstrates that a lifestyle intervention on cholesterol led to a decrease in both the cholesterol and serum PFOA and PFOS concentrations.

• Finally, given the recent downward trend in decreasing total and low-density lipid cholesterol since the 1970s coupled with the decreasing PFOA and PFOS serum levels suggests that there is a substantial likelihood that the proposed MCLs for PFOA and PFOS are unlikely to result in benefits as great as is reported as part of this proposal, given the outsized impact from other risk factors.

Additional details on these and other comments for the EPA's analysis of cardiovascular disease risk reduction are available in Appendix A. Based on the materials made available, it does not appear that EPA's conclusion is fully supported by the evidence or record before the agency.

EPA Response: The EPA disagrees with the commenter's statement that the EPA did not conduct a reliable assessment of both the costs and benefits of the proposal, and the EPA also disagrees with the commenter's claim that MCLs benefits do not justify the costs at the proposed MCL levels. The EPA completed a robust analysis of quantifiable and nonquantifiable benefits and costs and has set the MCLs appropriately taking feasibility into account. Contrary to the commenter's statement, SDWA does not require the EPA to set the MCL at a level at which costs are justified by the benefits. The statute requires that the EPA assess the costs and benefits of the proposed MCLs pursuant to the HRRCA in Section 1412(b)(3)(C) and publish a determination as to whether the costs of the proposed levels are justified by the benefits. SDWA Section 1412(b)(4)(C). Unless the EPA applies an exception, the MCL is set as close as feasible to the MCLG as required under Section 1412(b)(4)(B). As explained in the preamble to the final rule, the EPA confirms that the benefits of the final rule justify the costs. For the EPA's response to comments received on the compliance timeline, see section 12.1 in this *Response to Comments* document.

The EPA disagrees with the commenter's assertion that the literature underpinning quantification of CVD health benefits from PFOA and PFOS concentration reduction is insufficient. Please refer to the section 13.4.1 of the EPA response in this *Response to Comments* document regarding the EPA's determination on evidence of CVD risks associated with PFOA and PFOS exposure, reasons for including HDLC effects in CVD sensitivity analyses only, and the potential effects of decreasing total and low-density lipid cholesterol in the general population on the CVD analyses. The EPA disagrees with the commenter's assertion that the sensitivity analysis results for PFOA/PFOS effects on HDLC suggests that CVD benefits are overestimated. As discussed in Chapter 6.5 of the EA, the relationship between serum PFOA/PFOS and HDLC has a higher degree of uncertainty and therefore, the potential impact of HDLC was evaluated in the sensitivity analysis. Limitations and uncertainties for HDLC effects are described in Chapter 6 of the EA and Appendix F of the EA (USEPA, 2024b and USEPA,

2024c, respectively). The EPA disagrees with the commenter that the EPA makes contradictory statements about the strength of associations between PFOA and PFOS and blood pressure and HDLC. See section 13.4.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1759, SBC-053061 in section 13.4.1 in this *Response to Comments* document for a discussion of other causes of CVD health outcomes, including lifestyle changes.

The EPA disagrees with the commenter's claim that benefits do not justify the costs at the proposed MCL levels. See section 13.8 in this *Response to Comments* document for the EPA's response to comments comparing benefits and costs and the EPA Administrator's benefit-cost determination. As discussed thoroughly throughout the EA and FR but most notably in Chapter 7 of the EA and section XII of the FRN, the EPA Administrator determined at the time of the proposal that both the quantifiable and nonquantifiable benefits of the rule justify the quantifiable and nonquantifiable costs. The economic analysis provides a robust, multi-pronged quantified and nonquantified cost and benefit analysis that substantiates and justifies this determination. Further, for this rulemaking, the Administrator reaffirmed the determination made under the proposed rule that the quantifiable and nonquantifiable benefits justify the quantifiable and nonquantifiable costs for MCLs set as close as feasible to the MCLGs.

As described in the FRN for the final rule, the EPA received comments on the proposed rule regarding the compliance timeline, and some commenters raised concerns with the proposed requirements for initial monitoring and compliance actions. As a result, as described in the Monitoring and Compliance Requirements section (VIII) of the FRN for the final rule and section 12.1 of the EPA response in this *Response to Comments* document, the EPA is exercising its authority under SDWA § 1412(b)(10) to implement a nationwide two-year capital improvement extension to comply with the MCL. Consequently, water systems will have up to the full three years following rule promulgation to plan and conduct monitoring and still have two additional years to complete any actions needed to comply with the MCLs. Additionally, and as described in section 13.3 of the EPA response in this *Response to Comments* document and in the EA for the final rule, the EPA made a number of updates to the costs model to better reflect costs of compliance of the rule and other factors that contribute to the EPA's estimate of total annualized costs, using the best-available peer-reviewed science to inform these estimates.

3M Company (Doc. #1774, SBC-045690)

f. Exposure-Response Relationships Were Improperly Selected

To calculate the health-risk reduction benefits based on serum concentrations, EPA extracts from literature or independently reanalyzes various exposure-response slope factors that are intended to demonstrate a quantitative relationship between a change in serum concentrations and a specific health effect. For both PFOA and PFOS, EPA evaluates the health effects of reductions in birth weight and increases in total cholesterol. EPA also considers increases in renal cell carcinoma risk for PFOA and increases in blood pressure for PFOS. For each endpoint, EPA selects relationships between serum levels and health effects that are not supported by the

underlying studies or are based on uncertain reanalysis of data. These flawed analyses add to the misleading conclusions associated with basing the analysis on inappropriate and indistinguishable regulatory alternatives.

For the endpoints that EPA suggests are associated with cardiovascular disease (e.g., increased cholesterol), EPA also inappropriately derives exposure-response slope factors and ignores their biological relevance. For total cholesterol, EPA conducted its own meta-analysis and only included studies that had linear associations (6 studies for PFOA and 5 studies for PFOS) (USEPA 2023k). This selection criterion biases the results and misrepresents the overall weight of evidence, because other studies that did not show linear associations (6 studies for PFOA and 7 studies for PFOS) were ignored altogether in the calculation of the exposure-response slope factor. Like the birth weight analysis for PFOS, this analysis is not peer reviewed. EPA (USEPA 2023i) also states that it used "untransformed serum PFOA/PFOS," which means that it did not evaluate the relationship using a log scale. The importance of using a log scale is described in Section VII.b above. The associations with total cholesterol also are not biologically significant. For example, EPA derives an exposure-response slope factor for PFOA equal to 0.08 mg/dL per ng/mL, which means that for every 1 ng/mL increase in serum PFOA, total cholesterol increases by 0.08 mg/dL. Based on the demonstration of serum concentrations described in Section VII.d above, the difference in serum concentrations between 4.0 ppt and 10.0 ppt was less than 1 ng/mL. A change of 0.08 mg/dL of total cholesterol is not biologically meaningful, since total cholesterol is typically reported in mg/dL as whole integers (e.g., 175 mg/dL or 200 mg/dL); cholesterol is not measured or reported to the hundredths of mg/dL. Thus, a potential change in total cholesterol going from a drinking water exposure at 4.0 ppt to 10.0 ppt would not likely be measurable. For PFOS, the exposure-response slope factor is 1.57 ng/dL per ng/mL, which also does not represent a biologically significant change in cholesterol, especially over small changes in serum concentrations.

EPA's approach to selection of exposure-response slope factors is scientifically flawed, lacks transparency, and disregards the biological relationship of exposure and effects. EPA should consider and discuss the exposure-response slope factors in the context of biologically relevant effects and obtain peer review for any novel analyses. EPA's analysis egregiously misrepresents any meaningful determination of health risk reduction benefits between the proposed MCL and regulatory alternatives.

g. EPA's Estimate of Decreased Cardiovascular Disease (CVD) Risk is Not Reproducible or Transparent

The estimated CVD risk reduction derived by EPA in the Economic Analysis for the proposed PFOA and PFOS NPDWR is systematically flawed. Issues with the estimated CVD risk reductions stem from deviations from EPA's guidance for study selection and dose-response analysis and are compounded by a lack of transparency and reproducibility in EPA's methods.

i. EPA's study quality evaluation and study selection process are not consistent and are not transparent

EPA used meta-analytic approaches to derive a pooled estimate of the slope of a linear function of exposure-response between serum PFOA and PFOS (ng/dL) and serum total cholesterol (TC) (mg/dL) for use in the Economic Analysis (USEPA 2023c). These pooled slope estimates are developed independently for PFOA and for PFOS. Pooling information across epidemiological literature through use of meta-analysis allows for incorporation of individual-study uncertainty and consideration of the full range of observed exposure-response relationships across epidemiological studies; this allows EPA to use the full body of evidence in lieu of selecting an observed exposure-response slope from one single study. The first step of this process is identification of studies that meet inclusion criteria for the meta-analysis. EPA relied upon the literature review processes from the Agency for Toxic Substances and Disease Registry (ATSDR, 2021) and EPA risk assessments (USEPA 2023a,b). These approaches identified 80 studies on PFAS (see USEPA 2023c, Figure F-1). From those studies, EPA further limited the included studies by the following criteria: the study must 1) be conducted on adults in the general population; 2) quantitatively measure TC and high-density lipoprotein cholesterol (HDLC); 3) evaluate exposure of PFOA and PFOS. Additional exclusion criteria included: 1) pregnant women, infants, or children; 2) reporting of only relative risks or odds ratios for hyperlipidemia or hypercholesterolemia as these measurements of response could not be used. EPA also stated that "studies performed on specific population subsets, such as occupational populations, were not considered for inclusion in the meta-analysis due to the potential for greater levels of exposure to PFOA and PFOS in these populations compared to the general population" (USEPA 2023k, p. F-2). In other words, EPA excluded studies on members of the population expected to have higher-than-average concentrations of PFOA and PFOS in their blood.

In the Economic Analysis, EPA states that "[a]ll studies were evaluated for risk of bias, selective reporting, and sensitivity as applied in developing EPA's Toxicity Assessments and Proposed Maximum Contaminant Level Goals for PFOA and PFOS in Drinking Water (U.S. EPA, 2023a; U.S. EPA, 2023b)" (USEPA 2023c, p. F-8). However as noted in Section V.d.iii, the risk of bias analyses presented by EPA and its systematic review methods lack transparency and consistency in the evaluation of study quality. Despite the lack of transparency and consistency in the process, EPA assigned a determination regarding its confidence in each study (based on EPA IRIS protocol for risk of bias, selective reporting, and sensitivity; see EPA 2023a,b, p. 3-147). However, the study quality ranking was not used as an exclusion criterion for the meta-analysis. Therefore, studies considered as "low confidence" by EPA (based on the study quality evaluation) were not excluded from the pooled analysis.

A total of 23 studies on PFAS and TC and HDLC in the general population were considered for inclusion in the meta-analysis (USEPA 2023c, p. F-2). Of the 23 studies considered for the Economic Analysis by EPA (USEPA 2023c), 14 total studies on adults in general populations met EPA's inclusion criteria. Eleven of the studies evaluated the relationship between serum TC and PFOA and 12 studies evaluated serum TC and PFOS. Each of these 14 studies are described in USEPA 2023c, Table F-1. This includes: 6 studies on serum TC and PFOA/PFOS from NHANES [FN87: Studies based on NHANES are cross-sectional in nature, and therefore have limited utility for purposes of establishing causality (see discussion at the end of this section).

Also see Section V.d.i noting significant concerns regarding studies using uncorrected NHANES data.] that represents the general US population (Dong et al. 2019; Fan et al. 2020; He et al. 2018; Jain 2019; Liu et al. 2018; Nelson et al. 2010); 2 studies from other US populations, including prediabetic adults from a diabetes prevention program (Lin et al. 2019) and a potentially highly exposed population (Steenland et al. 2009); and 6 studies on serum TC and PFOA/PFOS in other countries, including Canada (Fisher et al. 2013), a Canadian Inuit population (Château-Degat et al. 2010), Sweden (Li et al. 2020), Taiwan (Yang et al. 2018; C.Y. Lin et al. 2020) and China (Fu et al. 2014).

EPA does state reasons for exclusion of several additional general population studies that met its initial inclusion criteria (e.g., Eriksen et al. 2013; Fitz-Simon et al. 2013; Huang et al. 2018; Convertino et al. 2018). However, EPA does not clearly explain why other studies on adults in general populations (e.g., Donat-Vargas et al. 2019), clinical trials (e.g., Liu et al. 2020) or highly exposed populations (e.g., Canova et al. 2020; Zare Jeddi et al. 2021) were not considered. Despite being a clinical trial, in which exposure and response are typically known, Convertino et al. (2018) was judged "low confidence" or "uninformative" by EPA due to residual confounding by socioeconomic status (SES) and "lack of information on allocation of participants to treatment levels" (USEPA 2023a, p. C-23, C-44). However, other "low confidence" studies were included in the meta-analyses; in the Economic Analysis, four included studies were designated as "low confidence" due to deficiencies in participant selection, outcome assessment, or confounding domains (Fu et al. 2014; He et al. 2018; Yang et al. 2018; Y. Li et al. 2020). EPA conducted a sensitivity analysis to evaluate the impact of excluding all "low confidence", or higher risk of bias studies (reported in EPA 2023c, Tables F-2 and F-3), however EPA did not conduct sensitivity analyses to evaluate the impact of removing He et al. (2018), a low confidence study, from the "linear models only" pooled estimate or removal of all "low confidence" studies from the US/Canada only models. Inclusion of these low confidence studies may introduce bias into the pooled estimates. Additionally, this sensitivity analysis does not address studies not included in the "all studies" analysis. EPA should demonstrate that the pooled slope estimates are not biased through inclusion and exclusion of specific studies through 1) consistency in application of exclusion criteria; and 2) sensitivity analyses that quantify the impact of inclusion and exclusion of individual studies on the pooled slope estimates. Without additional sensitivity analyses, EPA cannot demonstrate that the pooled effects are not sensitive to (or driven by) one study, lower quality studies, or other specific populations that are not generalizable to the US.

Confidence in the sensitivity analyses that measure the impact of inclusion/exclusion of low confidence studies is further weakened by the lack of transparency and consistency in EPA's determinations of study quality (as noted in Section V.d.iii supra). Many of the studies considered "medium quality" by EPA have critical deficiencies, including inadequate control for confounding or correlated exposures and/or cross-sectional study designs. Without additional sensitivity analyses, including the exclusion of cross-sectional studies and further exclusion of "low confidence" studies, EPA cannot demonstrate that the meta-analyses are not sensitive to inclusion or exclusion of specific studies and improve confidence in the pooled slope estimates

Highly exposed populations include both occupational cohorts and communities that were exposed to elevated levels of PFAS in drinking water. Although EPA states that "studies performed on specific population subsets, such as occupational populations, were not considered for inclusion in the meta-analysis due to the potential for greater levels of exposure to PFOA and PFOS in these populations compared to the general population" (USEPA 2023k, p. F-2), this judgment is not consistently applied. For example, EPA included Steenland et al. (2009) in the meta-analysis despite the fact that "Steenland et al. (2009) retained the results from a study of a highly exposed population in the United States (the C8 Health Project cohort)" (USEPA 2023c, p. F4). Some of the studies not included in the meta-analysis (e.g., Eriksen et al. 2013; Fitz-Simon et al. 2013) are included as key studies in the PFOA (USEPA 2023a, Table A-6) or PFOS (USEPA 2023b, Table A-6) risk assessments. It is unclear why EPA would find those studies appropriate for use in risk assessments but not in derivation of a dose-response curve for its benefits analysis. [FN88: Although information required for incorporation of Erikson et al. (2013) and Fitz-Simon et al. (2013) into the pooled analyses were not available in the publications, EPA did not indicate that it attempted to contact the authors or to re-assess the underlying evidence to incorporate these study populations into the meta-analysis, which is recommended by Cochrane review processes to reduce bias from under-reporting in the primary literature.] Exclusion of studies EPA itself identified as "key" or studies from highly exposed populations create substantial risk of biasing the results of the meta-analysis and limiting generalizability of the findings. These risks can only properly be addressed by EPA through inclusion in the meta-analysis and use of sensitivity analyses to measure the impact of omission.

Occupational exposures were excluded from the pooled analysis (e.g., Olsen et al., 2001, 2003; Olsen et al 2007; Costa et al. 2009). However, the estimated slopes used in the pooled assessment are an estimate of change in TC per ng/mL PFAS exposure, therefore information from these studies would be expected to be informative despite the expected difference in exposure levels. The models used in the meta-analysis are a continuous function of the relationship between exposure and TC outcomes (i.e., straight lines), and so the highly exposed, or occupational, groups should be just an extension of the same dose-response slope.

Further, occupational studies typically represent highly exposed populations and a lack of increased odds of CVD risk in these populations would indicate a potential lack of response in the general population with lower exposures. As noted by EPA (USEPA 2023a, p. 3-174), the occupational studies "suggest no association between PFOA and TC in workers", in part due to a lack of statistically significant associations for the observed increases in serum TC and the reported inverse association between changes in PFOA and serum TC reported by Olsen et al. (2012). EPA states that "[c]ross-sectional occupational studies… reported positive associations between PFOS and increased serum TC…however, the association was not observed in longitudinal analyses," [FN89: A longitudinal study is defined by repeated collections of sampling data in the same individuals over a period of time (typically years). A cohort study is a common example.] which weakens the strength of the causal association as the significant associations were only observed in cross-sectional analyses that cannot establish a temporal relationship [FN90: Temporality is a criterion of the Bradford Hill criteria, an established and

well-accepted list of criteria used to consider causal associations in epidemiology] between exposure and response (USEPA 2023b, p. 3-145). Findings from longitudinal analyses should hold greater weight in the evidence synthesis because they can establish that exposure precedes the observed response. Accordingly, best practice would be to benchmark the slopes of the pooled analyses against these occupational studies to ensure that the proposed exposure-response relationship is coherent across the full body of evidence. Additional sensitivity analyses should also be conducted with inclusion of these occupational populations. For example, EPA conducts a sensitivity analysis excluding "non-US/Canada and high exposure studies" but does not evaluate the pooled results from US/Canada populations including those high-exposure populations. These additional sensitivity analyses are necessary to ensure that the pooled slope used for the economic benefits analysis is representative of the reliable (or high-quality) studies from relevant populations.

EPA's reliance in its benefit analysis on cross-sectional studies is also in contradiction with its statement that "the main considerations specific to evaluating the quality of studies on serum lipids included use of medications, fasting, and potential for reverse causality." (USEPA 2023c, p. F-8). Cross-sectional studies, such as those based on NHANES data, cannot establish temporality and findings may be due to reverse causality. In other words, cross-sectional studies measure exposure and response simultaneously, and therefore cannot establish that the exposure occurred prior to onset of the measured disease or response outcome. When the exposure and response are measured simultaneously, it cannot be demonstrated that the measured exposure is not affected (or caused) by the response. As noted by Dong et al. (2019), "The NHANES data are capable of examining the association but cannot address the issue of causality. Similar to other cross-sectional studies, this study cannot answer whether: 1) exposure to PFASs elevates the cholesterol level; 2) high cholesterol levels allow the storage of PFASs easier; or 3) joint factors simultaneously affect both PFASs and cholesterol". See also, e.g., Andersen et al. (2021); Fragki (2021). Therefore, inclusion of cross-sectional analyses in the meta-analyses is a limitation that must be addressed by EPA.

In summary, EPA does not clearly state the reasoning for inclusion or exclusion of all relevant studies from the meta-analyses. The studies selected for the economic benefits analysis are inconsistent with the studies included in the risk assessment for RfD derivation. This inconsistency limits confidence that that the meta-analyses for CVD risk include all applicable information, which then impacts confidence in the estimated economic benefits.

ii. EPA's dose-response model selection process is not transparent or consistent with generally accepted risk assessment and statistical approaches.

Of the pooled model options presented in EPA's Economic Analysis appendices (USEPA 2023c, Tables F-2 and F-3) EPA selected "linear models only" for use in its CVD risk reduction analysis. This means that EPA chose to include only models that describe a linear relationship (straight line) between exposure and response and excluded studies that fit a linear regression to logarithmically transformed data (i.e., log-linear models). Use of only studies with slope estimates based on linear models, instead of logarithmic or other transformations, limits analyses

to 4 of the 14 studies on serum TC and PFOA and 5 of 15 studies on serum TC and PFOS (USEPA 2023c, Tables F-2 and F-3). In addition, studies considered "low confidence" by EPA are included in the limited numbers of studies included in the "linear models only" analyses. EPA's use of the "linear models only" resulted in the exclusion of higher-quality studies and could bias the analysis. Because of the significant likelihood that the "linear models only" approach omits critical information and biases the results, a proper analysis would require demonstration that the findings from the limited "linear models only" analyses are representative of the body of evidence and are not biased by the study selection criteria.

In other analyses in this rulemaking, EPA has relied on studies using logarithmically transformed data for estimating the slope of the exposure-response and BMD(L) derivation (e.g., Budtz-Jorgensen and Grandjean, 2018). However, EPA states that, for the economic benefits analysis, it "selected the pooled slope estimate based on the studies using linear models to ease interpretability and to reduce bias due to backtransformations of effect estimates with logtransformed outcomes or exposures" (USEPA 2023c, p. 6-55). EPA failed to show that its justification for use of the linear models was based on scientific accuracy; instead, the justification indicates that the selection of models was based on ease of use and not based on best science. Although conversion of non-linear studies into useable linear slope estimates requires mathematical assumptions that impart uncertainties in the backtransformed [FN91: Backtransformation is defined as converting a transformed number (i.e., a log or square root of a measurement) to its untransformed equivalent (i.e., exponentiation or squaring of the log or square root).] estimates, EPA relied upon log-transformed evidence (e.g., Grandjean et al. 2012; Budtz-Jorgensen and Grandjean 2018) in support of derivation of PODs for RfD development and demonstrated a clear willingness to modify and make assumptions from the underlying evidence (see USEPA 2023a,b Appendix E for details of BMD modeling). For example, EPA estimated BMRs from Budtz-Jorgensen and Grandjean (2018) measured as the "log2[tetanus antibody concentration]" (p. USEPA 2023a, p.E-1). This means that EPA had to backtransform the evidence from BudtzJorgensen and Grandjean (2018) in derivation of the RfD. Therefore, the rationale to select the pooled slope estimate based only on linear models "to reduce bias due to backtransformations of effect estimates" is not consistent with approaches used by EPA in its risk assessments in the supporting documents for this Proposed Rule.

In addition, EPA's decision to base the pooled slop estimate only on linear models [FN92: A linear (i.e., straight line) model is equivalent to a linear regression model with the function $y = mx + b$, where y = response; m = slope; x = dose; b = intercept. Non-linear models incorporate other parameters, such as exponential functions, or use transformation (e.g., logarithm) of the dose or response variable to improve description of the observed dose-response. Non-linear models allow for fitting either 1) a linear model to log-transformed dose and/or response data or 2) fitting a curve to the observed data, for which the slope is not constant and may be more steep or more shallow than the rest of the model in the exposure region of interest.] removes a large portion of the complete body of evidence and does not integrate the findings from all studies. Critically, this approach likely biases the pooled estimate toward finding a statistically significant effect through 1) exclusion of higher quality studies; 2) exclusion of additional populations of

interest; and 3) exclusion of non-linear models may better capture the observed dose-response relationship. As evidenced by the sensitivity and other meta-analytic models (e.g., Table F-2 and Figure F-4), inclusion of these additional studies results in a lack of a statistically significant dose-response between PFOA and TC. Meaning, overall, the full body of evidence indicates that there is likely no significant effect between PFOA/PFOS and serum TC. The fact that the "linear models only" analysis is the only pooled analysis of PFOA exposures that identified a statistically significant slope (p-value < 0.05) (see Table F-2) indicates that the "linear models only" analysis is not representative of the full body of evidence. For PFOS and TC, the pooled dose-response using "linear models only" was not statistically significant (p-value > 0.05). Inclusion of additional studies with non-linear models identified a statically significant (p-value < 0.05), albeit shallow, pooled slope estimate for some of the modeled relationships between PFOS and serum TC (Table F-3). The analyses presented in EPA's (2023c) Tables F-2 and F-3 show the meaningful impact that inclusion and exclusion of individual studies has on pooled slope estimates. Therefore, EPA must carefully evaluate its decision to use the "linear models only" slope estimates for the economic analysis and provide additional justification for the use of these models in lieu of models that incorporate more information. This justification is critical due to the differences between the "linear models only" and models with more complete information, both in terms of the magnitude and the significance of the pooled slope estimates.

Further, inclusion of linear-only models assumes that a linear dose-response best explains the observed dose-response relationships between PFAS exposures and serum TC changes. However, EPA has not clearly shown that linear assumptions are appropriate or consistent with underlying toxicological evidence, nor has it provided the information required for peer or public review. Non-linear models incorporate other parameters, such as exponential functions, or use transformation (e.g., logarithm) of the dose or response variable to improve description of the observed dose-response. Use of these non-linear models may allow for improved predictivity of the observed relationship between exposure and response.

Contrary to EPA guidance for dose-response analysis, EPA does not describe relative model fit for each of the included studies or the appropriateness or impact of linear assumptions. As stated by EPA BMDS guidance, "an important criterion for selecting a fitted model is that the model provides an adequate description of the data, especially in the region of the BMR" (USEPA 2012, p. 33). [FN93: See Sections II.a and V.e for further explanation of BMDs and their import] Although EPA is not using a BMD to support this economic assessment, the model fitting criteria prescribed by EPA's BMDS guidance are generally accepted statistical practice. Evaluating the model's ability to predict the observed response (or "model fit") is a critical step in basic regression statistics. EPA's BMDS guidance also recommends visual inspection and plotting of residuals in order to evaluate deviations of the model predictions from the observed response. In selecting models, EPA recommends a stepwise process that 1) assesses the goodness-of-fit; 2) rejects models that do not adequately describe data in the dose-response region of interest; and 3) applies additional "somewhat arbitrary" defaults for model selection (EPA 2012, p. 39-40). Here, EPA has not shown that the linear models fit the observed TC responses from individual studies, nor that they accurately predict responses at exposures relevant to the general population.

Moreover, EPA has not shown that the non-linear or logarithmically transformed models fail to more accurately describe the observed exposure-response. In the absence of causality information among the epidemiological literature, which is the case here, toxicological information could be used to inform on the expected model shape and the appropriateness of assuming linearity. EPA acknowledges this potential issue in its discussion of model limitations and uncertainties (EPA 2021; Table 7) when it states "the derivation of PFOA/PFOS exposure-response functions for the relationship between PFOA/PFOS serum and TC assumes that there are no threshold serum concentrations below which effects do not occur." However, the impact of this uncertainty is described only as "uncertain" and not further addressed by EPA. Therefore, projecting economic impacts based on models that do not clearly demonstrate an exposure-response may overstate the predicted economic benefit.

For PFOA, when looking at the full body of evidence and pooled meta-analytic slope estimates (shown in Table F-2), EPA's pooled slope estimates are only statistically significant when using linear models only. The estimated slopes from the linear models, only, also indicate a steeper (or more potent) dose-response compared to slopes generated from pooled estimates of all studies and all lower risk of bias studies. This inconsistency indicates that the linear models likely are not adequately describing the full body of underlying evidence.

For PFOS, only two models from the studies EPA selected for determining the slope of the dose-response relationship have a statistically significant slope (p-value < 0.05): the serum PFOS and TC model including all lower risk of bias studies and the model excluding Jain et al. 2019 (shown in Table F-3). However, with little or no explanation, EPA changed its criteria for statistical significance (using and alpha value of 0.1 instead of 0.05) to support selection of the "linear models only" estimate that is not statistically significant (p=0.064). As stated by the USEPA, "When including the five studies reporting linear associations, there was a positive increase in TC of 0.08 (95% CI: -0.01, 0.16) mg/dL per ng/mL serum PFOS (p-value=0.064, I2=84%) that was significant at the 0.10 level." (EPA 2023c, p. F-16). As stated in the Economic Analysis, the USEPA noted that "While the association for PFOS and TC is not significant at the 0.05 confidence level, it is significant at the 0.10 confidence level (p = .064)." (EPA 2023c, p. 6-55). No justification was provided for the change in the confidence level used to denote statistical significance. Notably, EPA also did not apply this change in criteria consistently, as evidenced by the statement "When all studies were combined (12 studies, 15 results), EPA observed a borderline statistically significant positive increase in TC of 0.066 (95% CI: -0.001, 0.132) mg/dL per ng/mL serum PFOS (p-value=0.055, I2=100%) (Table F-3, Figure F-8)." (p. F-16) [emphasis added]. The term "borderline statistically significant" is typically used when a study does not achieve statistical significance, but the p-value is close to the pre-determined cutoff. EPA does not explain why a p-value of 0.055 for the "all studies" model was considered "borderline" but the p-value of 0.064 for the "linear models only" is considered statistically significant. This illustrates that EPA is not consistently applying the criteria for statistical significance across models. Although changes in the criteria used for denoting statistical significance may be statistically and scientifically appropriate, these changes are typically made to make the criteria more stringent to adjust for multiple comparisons or reduce the risk of

making a Type I error [FN94: A Type I Error is also called a "false-positive"; it is an error that occurs when a researcher identifies a statistically significant association when there is no true association. Criteria for defining statistical significance traditionally accept a Type I Error rate of 5% (or $p < 0.05$), or 95% confidence in the observed effect.] Any justification to change the criteria from the standard accepted value of a p-value of 0.05 should be done a priori and justified scientifically. EPA has failed to show that the change in p-value criteria to 0.10 was done prior to analyses, is consistently applied, or is supported by the underlying biology.

Based on the reported meta-analyses (Tables F-2 and F-3), it is not clear that there is a statistically significant dose-response relationship between PFOA/PFOS and serum TC when the full body of evidence is considered. Use of information with no significant change in response is not consistent with EPA guidance for dose-response modeling (USEPA 2012). Therefore, based on EPA's own guidance and widely accepted risk assessment practice, the available body of evidence indicates that use of changes in serum TC as the basis for EPA's CVD risk reduction model is not appropriate. Despite the lack of statistically significant slopes in the pooled analyses for PFOA and PFOS when all studies are included, or when only linear models were included for PFOS, EPA justifies its choice for use of serum TC in the CVD risk reduction model by stating "The literature provides sufficient support of a positive association (e.g., Château-Degat et al., 2010; Dong et al., 2019; U.S. EPA, 2023d; U.S. EPA, 2023e). The studies are large with more than 700 and 8,900 participants, respectively (Château-Degat et al., 2010; Dong et al., 2019) and have low risk of bias." (USEPA 2023c, p. 6-55). However, as already described, EPA's literature review lacked guardrails designed to support the reliability of such conclusions. Had EPA followed appropriate systematic review processes, it likely would have found that the overall body of evidence (shown visually in Figures F-4 and F-8) is not clearly supportive of an exposure-response association and the sensitivity analyses (presented in Tables F-2 and F-3) do not support the conclusion of a significant relationship between PFOA or PFOS and serum TC across the pooled body of information. This indicates that the use of serum TC as the basis for the economic benefits analysis may overstate the expected reductions in serum TC with reductions in PFOA/PFOS, thereby also overstating the economic benefits. As a result of these process and analytical failures, EPA has not shown that the pooled dose-response functions are reliable or consistent with the underlying biology. Therefore, any use of these functions to estimate economic benefits from reduced health impacts is uncertain and unreliable.

Additional considerations of model applicability specific to meta-analyses, such as interstudy heterogeneity, must be addressed by EPA. In meta-analyses, the pooled estimate is intended to be derived from a body of comparable studies on similar populations. Inter-study heterogeneity, measured as I2, describes the amount of variability in the response between studies and measures the probability that the pooled estimate contains information from populations that are not similar. This estimate reflects differences in study design, study population, and data analysis, among other study- and population-level differences. Increased inter-study heterogeneity decreases confidence in the generalizability and utility of the pooled estimate. For the analyses presented by EPA (2023c, Tables F-2 and F-3), the measured heterogeneity for the meta-analyses is relatively high (>75%) for most models. EPA does not discuss the impact this high level of

heterogeneity has on its confidence in the meta-analytic models. Heterogeneity could be introduced into these models through differences in underlying population demographics, which is evidenced by the reduction in I2 estimates for PFOA and PFOS when non-US/Canada and high exposure studies are excluded (see Tables F-2 and F-3). EPA uses "the large degree of heterogeneity in the pooled associations when all data were included" to justify use of the meta-analyses using linear models only (EPA 2023c, P. F-16). However, the I2 is not meaningfully lower when comparing the PFOA "linear only" model with those for "all studies" or "all lower risk of bias studies" (I2 range of 87.19 - 89.49; see EPA 2023c, Table F-2). Additionally, the PFOA and PFOS models that "exclude non-US/Canada and high exposure studies" have 1) more included studies, 2) a lower I2 (or less heterogeneity) compared to the linear models only, and 3) are more representative of the US population that EPA is evaluating in its CVD risk reduction models. Based on these considerations, the model that uses only studies from the US/Canada, which do not show a statistically significant dose-response, are likely 1) more statistically appropriate and 2) generalizable to the United States population for whom this economic analysis is based. EPA should provide additional justification to explain its rationale for use of the "linear models only" in lieu of the US/Canada-based population studies.

In summary, EPA did not provide clear or consistent rationales for its selection of the "linear only" meta-analytic models for PFOA and PFOS for use in the CVD risk reduction analysis. Accordingly, the slopes selected for the CVD risk reduction analysis are unreliable and not consistent with EPA guidance.

iii. Dose-response slopes used by EPA for benefits analysis are different from those used in its risk assessment (i.e., RfD derivation).

As discussed in (USEPA 2023a,b), EPA uses the slope estimate from the exposure-response measured by Dong et al. (2019) as a basis for RfD derivation. EPA presents the slopes from Dong et al. (2019) in its sensitivity analyses, but fails to describe why the slope used in RfD derivation is different than that used for estimating the economic benefits. For example, EPA derives a benchmark dose (BMD) and benchmark dose lower limit (BMDL) based on the slopes, or regression coefficients, reported by Dong et al. (2019) (see USEPA 2023a, p. E-297 to E-300; USEPA 2023b, p. E-25 to E-29) and Steenland et al. (2019) (see USEPA 2023a, p. E-301 to E306; USEPA 2023b, p. E- 29 to E-34), and the mean differences in serum TC by quartiles of exposure reported by Lin et al. (2019) (see USEPA 2023a, p. E-306 to E-307; USEPA 2023b, p. E-35 to E-36). Each of these individual studies are included in the meta-analysis. A summary of the derived BMD(L)s is presented in the main text (USEPA 2023a p. 4-33; USEPA 2023b. p. 429) and the appendices for the Proposed MCLGs for PFOA (USEPA 2023a, p. E-308, Table E27) and PFOS (USEPA 2023b, p. E-37, Table E-25). The BMDLs from Dong et al. (2019) and Steenland et al. (2009) are used to derive candidate RfDs for PFOA (USEPA 2023a, p. 4-48) and PFOS (USEPA 2023b, p. 4-43). From the candidate RfDs, EPA chose the value of 3 x10-8 mg/kg/day for PFOA and 1 x 10-7 mg/kg/day for PFOS derived from the BMDLs from Dong et al. (2019) as the basis for considering an RfD for CVD effects (USEPA 2023a, p. 4-52; USEPA 2023b, p. 4-48). Although EPA chose to use the slopes from a single study (Dong et al. 2019) to derive a BMDL and RfD for PFOA and PFOS, EPA used the pooled slope from the meta-

analysis as the basis for the economic analysis. EPA does not provide justification for the lack of consistency in dose-response estimation between the risk assessments and the economic analysis. The difference in methodologies applied by EPA is unexplainable and there is no apparent reason as to why it is appropriate for EPA to use different dose-response slopes between the risk assessments and the economic analysis. As described in Section VII.g, the pooled slopes derived from the meta-analyses could be considered for RfD derivation, however EPA does not describe the meta-analyses in the Proposed MCLG risk assessment documentation. For PFOA, the slope estimates are relatively comparable (i.e., 1.48 mg/dL per ng/mL from Dong et al. 2019 and 1.57 mg/dL per ng/mL from the "linear models only" meta-analysis presented in the economic analysis; Table F-2). However, for PFOS, the slope estimates are drastically different (i.e., 0.40 mg/dL per ng/mL from Dong et al. 2019 and 0.079 mg/dL per ng/mL from the "linear models only" meta-analysis presented in the economic analysis; Table F-3). EPA must explain why Dong et al. (2019) was used as the basis for PFOA and PFOS RfDs, whereas a pooled slope estimate from studies using linear models was employed for estimating the economic benefit of reducing PFOA/PFOS levels to the RfDs.

iv. EPA does not transparently describe how the selected dose-response models inform the economic benefits analysis for CVD risk and fails to illuminate the impact on a benefit reduction analysis for PFOA and PFOS individually.

EPA states that it used the pooled slope estimates for PFOA and PFOS derived from the "linear models only" in order to inform the CVD risk reduction model. However, EPA does not transparently describe in its methods how these pooled slope estimates directly impact the models and estimated CVD risk. Outputs are reported as a pooled estimate of CVD benefits for PFOA and PFOS (see examples in USEPA 2021c, Table 6; USEPA 2023c Table 6-20). However, the estimated impact on serum TC per ng/mL PFOA (estimated at 1.574 mg/dL per ng/mL PFOA) is drastically steeper than that of the impact per ng/mL PFOS (estimated at 0.079 mg/dL per ng/mL PFOS). Even accepting that the dose-response slopes selected by EPA are appropriate, the slope for PFOA is nearly two orders-of-magnitude steeper, compared to PFOS, and therefore should have a larger impact on the estimated economic impact. EPA does not transparently describe its methods for integrating these disparate slope estimates for PFOA and PFOS or provide a description for how PFOA and PFOS exposures mixed to generate a single economic benefit model. The CVD risk reduction model is not described in a way that allows for transparent reproducibility of the approach or evaluation of sensitivity of the model to changes in estimated serum TC responses. It cannot be determined, based on the reported information, whether EPA is accurately accounting for the differences in exposure-response slopes for PFOA and PFOS. Moreover, it is impossible to determine from the record provided by EPA what benefit would be expected from the reduction of PFOA or PFOS alone. Sufficient information should be provided for the model to be independently verified.

Additionally, EPA does not evaluate the sensitivity of the CVD risk reduction model to changes in the estimated slope. As shown in Tables F-2 and F-3 of the Economic Analysis (USEPA 2023c), the estimated slopes for PFOA and PFOS are heavily dependent on the studies included in the meta-analytic models, with ranges changes in serum TC of 0.002 to 1.632 mg/dL per

ng/mL PFOA and 0.0003 to 0.40 mg/dL per ng/mL PFOS. EPA acknowledges in its discussion of modeling limitations and uncertainties (USEPA 2021c; Table 7) that "the derivation of PFOA/PFOS exposure-response functions for the relationship between PFOA/PFOS serum and TC levels assumes that the six studies used in meta-analysis capture the majority of PFOA/PFOS effects on serum TC levels." EPA further states that the included studies "may not represent all possible relationships between PFOA/PFOS and serum TC levels" and describes the impact of this uncertainty as "uncertain." However, EPA does not further address or describe the potential impact of study inclusion or exclusion. EPA neither established that its selection of "linear models only" for meta-analysis was reasonable, nor did it evaluate the impact of other reasonable models (such as the US/Canada-population models) on CVD risk reduction estimates. It is best practice to consider a range of modeling options, especially given the uncertainties attributable to study inclusion and selection. Even if EPA were to select the linear models only, as a conservative estimate assuming a significant dose-response, the 95% CIs for the pooled estimate for PFOA are broad (e.g., 1.57 mg/dL per ng/mL PFOA [95% CI 0.0177, 3.13]) and the 95% lower limit for the pooled estimate for PFOS is negative (i.e. -0.005), indicating a reduction in serum TC (a beneficial effect) with increasing serum PFOS. Therefore, the Economic Analysis may not be appropriately representing the accurate risk/benefit of reduction in PFOA/PFOS exposures. Uncertainties in the underlying slope estimates used as the basis for the economic benefits model translates into uncertainties in the estimated economic benefit for PFOA/PFOS reduction. Because the confidence interval produced by the studies chosen by EPA for PFOS includes both negative and positive slopes in the 95% confidence interval, the interpretation of the economic benefit is uncertain as to whether reductions in PFOS could be beneficial or harmful. Therefore, because of the uncertainties and lack of statistical significance, use of serum TC as the basis for Economic Benefit Analysis is likely not accurate, informative, or appropriate. EPA should provide uncertainty analyses to evaluate the range of impacts on CVD risk based on variations in slope assumptions and show its confidence in the underlying estimate of economic benefit.

In summary, the meta-analysis presented by EPA fails to follow best practice for meta-analyses (e.g. The Cochrane Handbook for Systematic Reviews of Interventions) and does not sufficiently account for underlying uncertainties in the dose-response relationships between serum PFOA/PFOS and serum TC. These uncertainties cannot be evaluated due to the complexity and lack of transparency in EPA's modeling documentation. Additional information regarding the impact of model selection and model uncertainty is needed to provide confidence in EPA's CVD risk reduction model.

EPA Response: The EPA disagrees with the commenter's statement that the "EPA selects relationships between serum levels and health effects that are not supported by the underlying studies." For additional detail on the strength of the evidence supporting analyses of RCC, birth weight, and CVD, see sections 4.1.4 and 4.2.1 of the EPA response in this *Response to Comments* document, as well as the EPA response to comment Doc. #1774, SBC-045685, SBC-053211, SBC-053281, SBC-045682, and SBC-045683.

The EPA disagrees with the commenter that the documentation of the meta-analysis used to develop the exposure-response relationship between PFOA/PFOS and total cholesterol lacks transparency. The limitations and uncertainties of the analysis documented in both the benefits section (Table 6-51 of USEPA, 2024b) and appendices (Appendix F, Section F.4.2; Appendix L, Section L.2.1 of USEPA, 2024c) and all modeling code and results files are provided in the regulatory docket. The EPA notes that the EA and EA appendices for the proposed PFAS NPDWR contain hundreds of pages of information that provides the descriptions and information that commenter claims is lacking. See specifically https://www.regulations.gov/document/EPA-HQ-OW-2022-0114-0028 for the proposed rule EA and https://www.regulations.gov/document/EPA-HQ-OW-2022-0114-0029 for the proposed rule appendices. See also the EPA's response to 3M Company (Doc. #1774, SBC-045652) for comments on transparency and materials provided for replication. The EPA acknowledges that there is a large degree of heterogeneity in the pooled associations and a potential for bias resulting from the back-transformation of effects estimates with log-transformed outcomes. The uncertainty associated with these dose-response factor estimates is thoroughly and transparently characterized in the SafeWater modeling based on estimated confidence intervals reported in Appendix L, Table L-2 of the EA (USEPA, 2024c). See also section 13.9 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's suggestion that study quality was not considered in the meta-analysis. The best practices for conducting meta-analysis would never exclude studies from the analysis based on study quality (such as excluding *low* confidence studies from the database), as the commenter suggests (Higgins et al., 2023). However, the EPA's approach included a sensitivity analysis that did consider only lower risk of bias studies to see the impact of those higher risk of bias studies (Section F.4 of the EA; USEPA, 2024c). Regarding the methods the EPA used to develop the final toxicity assessments for PFOA and PFOS, as well as the results of the systematic review of noncancer effects, please see sections 4.1.1 and 4.2.1, respectively, of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's suggestion that the EPA does not clearly explain why other studies on adults in general populations were excluded. These reasons are transparently presented in Appendix F of the EA (USEPA, 2024c) and include lack of availability of effect estimates that can be used in the meta-analysis and specifically cite the studies that the commenter erroneously claims rationales were not provided for, such as Eriksen et al. (2013), Fitz-Simon et al. (2013), Convertino et al. (2018), and Huang et al. (2018). The EPA also notes that one inclusion criteria for study selection was age of the studied population: 40 to 89 years old, which results in exclusion of studies like Donat-Vargas et al. (2019), Liu et al. (2020), and Canova (2020), which include populations younger than 40 years old. The EPA notes that one study mentioned by the commenter, Zare Jeddi et al. (2021), is a meta-analysis; thus, it would be inappropriate for inclusion in a meta-analysis. Similarly, the EPA provided a clear explanation on why Steenland et al. (2009) was included: the study population is not occupational, but is a highly exposed population in the United States (the C8 Health Project cohort of adults living near a chemical plant).

The EPA conducted nine sensitivity analyses, above and beyond what a typical meta-analysis of this size would report. While the commenter suggests additional analyses that the EPA could have conducted beyond the extensive and robust analyses the EPA has already conducted, this does not invalidate the EPA's confidence in the pooled slope estimate and the direction of the observed association. The EPA is conducting this economic analysis, including all national level benefits and sensitivity analyses, to inform whether the costs of the rule are justified by the benefits. There is both a pressing public interest and a statutory deadline in the EPA finalizing analyses and making timely final decisions. The EPA believes that the additional suggested analyses are unnecessary for purposes of making appropriate and transparent decisions consistent with the SDWA authority and mandate. As discussed above, the EPA has already gone above and beyond what would be considered and included in meta-analyses of this size and scope. Finally, the EPA notes that the analysis excluding non-US/Canada populations and high-exposure populations was specifically requested by the SAB and the EPA prepared it based on the input of this peer-review body.

For discussion related to transparency in the EPA's determination of study quality, please see the EPA response to comment Doc. #1774, SBC-045652 in section 13.4 in this *Response to Comments* document.

The EPA disagrees with the commenter's assertion that lack of increased odds of CVD in occupational studies would indicate potential lack of response in general populations at lower exposures. The EPA presented results from an occupationally exposed population with different exposure patterns than those typically found in the general population, and the lack of association in this high exposure setting does not discredit associations found in other studies. In fact, associations found at lower levels of exposures, such as Shankar et al., (2012) which are representative of the general US population exposure levels, indicate that the general population is at risk.

The EPA disagrees with the commenter's assertion that findings from longitudinal analyses should hold greater weight in the EA. Temporality is not necessarily an issue in instances where the chemical has a long half-life and is not quickly removed from the body. PFAS have half-lives on the orders of years; therefore, cross-sectional exposures are representative of past exposures.. The EPA also disagrees with the commenter that cross-sectional studies provide limited utility for purposes of establishing causality. Based on clinical research literature, the cross-sectional design allows investigators to collect prevalence data and evaluate differences in health outcomes between exposed and unexposed population providing the basis for developing a causal relationship. The EPA also disagrees that the EPA should benchmark the slopes from the pooled analysis against occupational studies. The ASCVD model requirements specifically point to effects in general populations.

The EPA disagrees with the commenter's criticism of the EPA's use of linear-only models as well as the EPA's study selection methods. See section 13.4.1 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's assertion that the rationale to select the pooled slope estimate based only on linear models "to reduce bias due to back transformations of effect estimates" is not consistent with approaches used by the EPA in its risk assessments. The commenter misunderstands the approach used in the Budtz-Jorgensen and Grandjean (2018) data for POD derivation. No back transformation was used to derive the Bone Mineral Destiny (BMD) and Benchmark Dose Level (BMDL) associated with the (Benchmark Reduction) BMR of ½ standard deviation (SD) change in log2(tetanus antibodies concentration) and a BMR of 1 SD change in log2(tetanus antibodies concentration) (see Appendix E of USEPA, 2024j and USEPA, 2024k).

The EPA disagrees with the commenter's assertion that it did not apply criteria for statistical significance consistently across the models. The commenter erroneously suggested that the EPA considered an effect with a p-value of 0.064 significant. The EPA clearly and transparently states that the effect "was significant at the 0.10 level".

The commenter stated that the EPA did not provide justification for using Dong et al. (2019) as the basis for PFOA and PFOS RfDs rather than the pooled slope estimate from the meta-analysis presented in the EA. In the Final Toxicity Assessments for PFOA and PFOS, the EPA notes that the results from meta-analyses were not selected for point of departure (POD) derivation for several reasons. For example, the ASCVD model relied on CVD risk reduction analysis for individuals ages 40-89 whereas the toxicity assessments considered adults of all ages. Another recent meta-analysis was not considered because it combined associations between PFOA and several different serum lipids (i.e., TC, triglyceride, and low-density lipoprotein) across multiple populations (i.e., children, adolescents, pregnant women, and adults), likely resulting in unaddressed confounding by age (Abdullah Soheimi et al., 2021). The EPA notes that reliance on deriving BMDLs based on pooled regression coefficients is not a requirement in the EPA's *Benchmark Dose Technical Guidance* (USEPA, 2012). The EPA also notes that, contrary to what the commenter implies, there is no requirement that the approaches used for quantifying effects used in the economic analysis and the toxicity assessments be identical. In fact, the approaches are consistent across assessments. The economic analysis relied on the rigorous determinations of the toxicity assessments. In addition, the EPA also had to factor in the constraints of, for example, the ASCVD model. The economic analysis also benefits from added flexibility of quantifying outcomes, such as blood pressure, that might not have been considered for POD derivation in the toxicity assessments. Similarly, the economic analysis has the added flexibility of using dose-response approaches (such as a meta-analysis restricted to studies in a certain age-range population) that could not be used for the purposes of RfD derivation in the toxicity assessments. The EPA notes that it provided details on rationales for selection of epidemiology studies for POD derivation in Section 4 of the Toxicity Assessments (USEPA, 2024h and USEPA, 2024i). In accordance with the current *Benchmark Dose Technical Guidance* (USEPA, 2012), the RfD derivation approach relied on study-specific approach rather than a pooled studies approach.

The EPA disagrees with the commenter's argument that benefits analyses for PFOA and PFOS should be considered independently. See the EPA response to comment Doc. #1774, SBC-045652 in section 13.4 in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1841, SBC-052938)

The Association with Cardiovascular Disease is not Sufficiently Strong to Use as a Basis for Quantifying Benefits

According to its estimates, the predicted reduction in CVD risks accounts for nearly one-half of the benefits of the quantifiable benefits of its proposal. [FN180: An expected annualized value of $533M out of $1,232M (43 percent) at a 3% discount rate and $421M out of $908M (46 percent) at a 7% discount. (USEPA Economic Report, at 6-3).] Yet, as discussed above, there is little evidence supporting an association between exposure to PFOA and PFOS and CVD. Moreover, EPA's analysis for PFOS indicates that the association with increased total cholesterol is not statistically significant (at p=0.05 level) or only "borderline statistically significant." [FN181: USEPA Economic Report, at F-16.]

In the draft analysis presented to the SAB in late 2021, EPA concluded that for both PFOA and PFOS the evidence for an association with CVD-related outcomes was limited and inconsistent. [FN182: USEPA Draft PFOA MCLG Approaches 2021, at 191; USEPA Draft PFOS Approaches 2021, at 179.] Consequently, EPA concluded at the time that the evidence was not sufficient to form the basis of an RfD. In its review, the Board summarized the information as follows -

Specifically, with respect to CVD, the assumption is that a shift in cholesterol resulting from PFAS exposure will have the same impact on cardiovascular disease that cholesterol levels based on natural levels or use of cholesterol lowering medications have had. However, the epidemiologic literature that provides strong support for an effect of PFAS on cholesterol does not provide support for an effect of PFAS on the risk of cardiovascular disease. [FN183: USEPA SAB Review, at 102.]

In the background documents for the current proposal, EPA has attempted to justify selection of effects on TC for quantification but has provided no additional information to support the association between PFOA and PFOS exposure and CVD. Although both the Board and EPA have provided additional references, none of the references address exposures to PFOA and PFOS.

Given the significant uncertainty with CVD endpoints, and the negative findings of Schilleman et al. 2022 that came out after the SAB convened, it is not appropriate to include CVD disease as part of EPA's benefits analysis for its proposal.

EPA response: The EPA disagrees with the commenter's assertion that "the association with cardiovascular disease is not sufficiently strong to use as a basis for quantifying benefits." See section 13.4.1 of the EPA response in this *Response to Comments* document for the EPA's response to the commenter's statements on cardiovascular disease.

See section 13.4.1 of the EPA response in this *Response to Comments* document for the EPA's response to comments on the evidence for PFOA and PFOS exposure and CVD outcomes. The EPA disagrees with the commenter's assertion that "there is little evidence supporting an association between exposure to PFOA and PFOS and CVD." High-quality studies have shown consistent associations between PFOA/PFOS exposure and changes in total cholesterol and blood pressure. Total cholesterol and blood pressure are well-established CVD risk biomarkers, are clearly associated with adverse CVD events, and are important inputs to the Pooled Cohort ASCVD model that the EPA used to estimate CVD outcomes. Furthermore, the Science Advisory Board supported the EPA's approach to estimating reductions in CVD risk associated with reduced PFOA and PFOS exposure in drinking water (USEPA, 2022d). The association between PFOA and PFOS exposure and CVD is supported by the consistent associations between PFOA/PFOS exposure and changes in total cholesterol, and the clear record demonstrating that increases in this biomarker increase CVD risk. Please also refer to section 4.2.1 of the EPA response in this *Response to Comments* document, the EPA response to comment Doc. #1713, SBC-045921 in section 13.4.1 in this *Response to Comments* document, and Section 3.4.3.4 of the Final Toxicity Assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i) for detail on the EPA's conclusions regarding evidence supporting an association between exposure to PFOA and PFOS and adverse CVD health outcomes. Further, the EPA disagrees with the commenter's assertion that the meta-analysis of PFOS effects on total cholesterol supports their conclusion that "there is little evidence supporting an association between exposure to PFOA and PFOS and CVD." See section 13.4.1 of the EPA response in this *Response to Comments* document for more information on the relationship between PFOA and PFOS effects on total cholesterol and the discussion of this biomarker's effect on CVD. The commenter suggested that the EPA considered an effect with a p-value greater than 0.05 significant. The EPA clearly, transparently, and appropriately states that such effects estimates are "significant at the 0.10 level" (see Appendix F, USEPA, 2024c). In addition, the EPA notes that statistical significance is not the only criteria for determining the strength of an association based on epidemiologic studies (USEPA, 2022c).

Based on the discussion in this response and throughout the administrative record of this final rulemaking, the EPA disagrees with the commenter's unsupported statement that "given the significant uncertainty associated with CVD endpoints…. it is not appropriate to include CVD disease as part of EPA's benefits analysis for its proposal." Further, the commenter misrepresents the finding from Schillemans et al. (2022). Schillemans et al. (2022) conducted population-based nested case-control study of Swedish adults (n = 1,528) within two cohorts: the Swedish Mammography Cohort-Clinical (SMC-C) and the Cohort of 60-year-old (60YO). Cases were first incident myocardial infarction (n = 345) and stroke (n = 354). In baseline cross-sectional analyses among 631 controls (those individuals without stroke or myocardial infarction), baseline plasma PFOS was associated with increased baseline TC (β per 1-SD-ln- ng/mL PFOS = 0.14, 95 percent CI: 0.06, 0.22), increased LDLC (β = 0.13, 95 percent CI: 0.06, 0.20), increased HDLC (β = 0.05, 95 percent CI: 0.01, 0.07), increased apolipoprotein A1 (β = 0.04, 95 percent CI: 0.02, 0.08), and decreased triglycerides (β = –0.11, 95 percent CI: –0.17, –0.05). In

prospective analyses of the pooled cohorts, there were no significant associations between baseline PFOS and subsequent incidence of myocardial infarction, stroke, or CVD. Thus, this study evaluated associations between PFOS and elevated serum lipids among controls only; therefore, a conclusion about associations between PFOS and elevated CVD risk among individuals with elevated total cholesterol levels cannot be made based on the study findings or data. The EPA has consistently demonstrated that its assumption that increasing total cholesterol increases CVD risk is firmly grounded in the scientific literature; moreover, these conclusions were reviewed and supported by the SAB.

Susan Goldhaber (Doc. #1596, SBC-043003)

May 26, 2023

Michael S. Regan, Administrator Environmental Protection Agency

1200 Pennsylvania Ave., N.W. Washington, D.C. 20460

Re: Docket ID No. EPA-HQ-OW-2022-0114, Comment on Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

Dear Administrator Regan,

As a toxicologist formerly employed at EPA, Office of Drinking Water, (1980-1988), who worked on revising the primary drinking water regulations, I am very familiar with the requirements of the Safe Drinking Water Act and the regulatory process. I am writing because I am very concerned with the underlying science supporting these regulations. I would like to submit the attached comments for your consideration.

Sincerely, Susan B. Goldhaber M.P.H.

SBG Consulting, Inc.

Comments

There are Executive Orders that strongly encourage that the benefits of a major regulation, such as PFAS Drinking Water regulation, exceed the costs. In the Economic Analysis, EPA calculated the economic benefits to the U.S. by avoiding three health outcomes that it attributed to exposure from PFOA and PFOS:

• Developmental effects (reductions in birth weight)

• Cardiovascular effects (increase in total and high-density lipoprotein (HDL) cholesterol resulting in cardiovascular disease including strokes and myocardial infarction)

• Kidney cancer

Cardiovascular Disease

EPA admits in its Economic Analysis that the epidemiologic literature does not provide direct support for the effect of PFOA and PFOS on the risk of cardiovascular disease. This is the same conclusion as the ATSDR that "the available occupational, community, and general population studies have not consistently found increases in the risk of heart disease or stroke that were associated with PFOA levels."

Neither the ATSDR nor the National Academy of Sciences (NAS) have found an association between PFOA/PFAS and increased blood pressure. ATSDR stated that "Most of the available epidemiological studies did not find an association between PFOA and hypertension" https://www.atsdr.cdc.gov/toxprofiles/tp200.pdf and the NAS concluded that the evidence is inadequate or insufficient to make a determination. https://nap.nationalacademies.org/catalog/26156/guidance-on-pfas-exposure-testing-and-clinical-follow-up

Regarding PFOA/PFOS and cholesterol, ATSDR concluded that the evidence is insufficient to determine a cause-and-effect relationship, while the NAS concluded that there is sufficient evidence for the association of PFAS exposure with dyslipidemia (total triglycerides, total cholesterol, and low-density lipoprotein and high-density lipoprotein).

EPA calculated benefits of $421 million to $533 million from calculating the number of deaths avoided due to: cardiovascular disease (fatal and non-fatal myocardial infarction) and ischemic stroke (fatal and not fatal)

3. What is EPA's justification for ignoring the conclusions of the ATSDR and the NAS and the known risk factors for cardiovascular disease, such as obesity, physiological inactivity, tobacco use, and harmful use of alcohol, in its conclusion that PFOA and PFOS are the sole causes of cardiovascular disease?

EPA response: See section 13.4.1 of the EPA response in this *Response to Comments* document for the EPA's response to the commenter's statements that "the epidemiologic literature does not provide direct support for the effect of PFOA and PFOS on the risk of cardiovascular disease." See section 13.4.1 of the EPA response in this *Response to Comments* document for the EPA's response to the commenter's statement comparing the evidence for cholesterol and blood pressure effects in the ATSDR and NAS assessments. Refer to section 4.2.6 of the EPA response in this *Response to Comments* document for details on comparisons to analyses conducted by other health organizations, including ATSDR and NAS. See section 4.2.1 of the EPA response in this *Response to Comments* document, the EPA response to comment Doc. #1713, SBC-045921 in section 13.4.1 in this *Response to Comments* document, and Section 3.4.3.4 of the Final Toxicity Assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i) for detail on the EPA's conclusions regarding evidence supporting an association between exposure to PFOA and PFOS and adverse CVD health outcomes. The EPA disagrees with the commenter's assertion that the EPA attributed all cardiovascular disease to PFOA and PFOS exposure. The agency assessed the quantifiable human health benefits by estimating the share of avoided illnesses that are associated with PFOA and PFOS reductions under the final rule. This

analysis assumes that removal of PFOA and PFOS-related exposure would not alter the distribution of risk factors the exposure does not affect. Additionally, the epidemiology studies considered in the toxicity assessments, which inform the benefits analysis assessment of changes in cholesterol and blood pressure resulting from changes in PFOA/PFOS exposure, controlled for potential confounding factors such as tobacco use, body mass index, and others. Even controlling for these potentially confounding factors, these studies showed associations between PFOA/PFOS and serum lipids.

13.4.2 Quantified Developmental Benefits Estimation

Summary of Major Public Comments and EPA Responses

The EPA received public comments on the benefits analysis for developmental effects. A few commenters claimed that the studies used for developmental modeling did not provide sufficient evidence of an association between PFOA and PFOS exposure and stated that the studies which the EPA used to model the developmental effects relationship did not consider confounders including pregnancy hemodynamics and other chemical and non-chemical stressors, including other PFAS. One commenter stated that the EPA's findings are inconsistent with other regulatory agency findings that small increases in birth weight are associated with maternal exposure to PFOA and PFOS but not increased risk of low birth weight. Other commenters stated that the EPA did not address these concerns and inappropriately used these studies to support quantitative analysis, and one commenter stated that because of the shortcomings of the studies used and the modeling uncertainties, peer review of the developmental effects modeling should be completed.

The EPA disagrees with these comments: the developmental benefits analysis is supported by a wide body of peer reviewed science (Verner et al., 2015; Negri et al., 2017; ATSDR, 2021; Waterfield et al., 2020; USEPA, 2016c; USEPA, 2016d; USEPA, 2024h; USEPA, 2024i). Specifically, decreased birth weight was determined to be a critical effect based on findings in the EPA's health assessments (see USEPA, 2024h; USEPA, 2024i), and low birth weight is linked to a number of health effects that may be a source of economic burden to society in the form of medical costs, infant mortality, parental and caregiver costs, labor market productivity loss, and education costs. Discussion on the EPA's conclusions about associations between PFOA or PFOS and decreased birth weight can be found in section 4.2.1.2 of this *Response to Comments* document. Discussions on why the agency's conclusions may differ from those of other health agencies can be found in section 4.2.6 of this *Response to Comments* document.

Discussion regarding the selection of decreased birth weight as a critical effect, including the selection of specific studies for candidate RfD derivation and the evidence supporting associations between PFOA or PFOS and developmental effects is available in sections 4.2.1.2 and 4.2.2.3.4 of this *Response to Comments* document, as well as Sections 3.4.4 and 4.1 of the final toxicity assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i). In estimating benefits of reducing PFOA and PFOS in drinking water, the agency selected results from Steenland et al. (2018) as the birth weight exposure-response function for PFOA and results from Dzierlenga et al. (2020) as the birth weight exposure-response function for PFOS. The agency

chose the results from these studies because they include the most recent meta-analyses on PFOA- and PFOS-birth weight relationships, and they included a large number of studies, including multiple studies with first trimester samples (seven studies in Steenland et al., 2018 and eight studies in Dzierlenga et al., 2020). To provide insights into the potential effects of sample timing and pregnancy hemodynamics, the EPA also performed a sensitivity analysis considering only first trimester estimates from Steenland et al (2018) for PFOA and Dzierlenga et al. (2020) for PFOS in Section K.4 of the EA appendices (USEPA, 2024c). While reports prior to 2019 found "plausible" or "suggestive" (USEPA, 2016c; ATSDR, 2018) evidence of relationships between PFOA and PFOS and developmental outcomes, the EPA's assessment found clear evidence of an association for PFOA and PFOS in both toxicological and epidemiological studies (USEPA, 2024j; USEPA, 2024k). The agency further disagrees with the commenter's statement that further peer review is needed, as the EPA relies extensively on peer-reviewed studies in its developmental benefits model. Furthermore, the EPA characterizes the uncertainty in the PFOA and PFOS exposure-response functions as described in Appendix L of the EA (USEPA, 2024c). In short, the benefits analysis for developmental effects relies on a wide body of the best available, peer-reviewed science, and the epidemiological evidence provides a reliable basis for quantifying the risks of low birth weight.

A different commenter claimed that the EPA relied on equivocal epidemiological evidence to estimate developmental benefits, stating that the RfDs calculated from animal studies in the EPA's health assessment documents for PFOA and PFOS are significantly higher than those based on human studies used for benefits analysis and that the animal studies represent a more appropriate estimate of the risk of PFOA and PFOS exposure. The EPA disagrees with the commenter that the analysis relies on equivocal epidemiological evidence to estimate benefits. See section 13.4 of the EPA response in this *Response to Comments* document for a detailed explanation of why human data are generally preferred for the derivation of toxicity values, compared to laboratory or animal data. See Section 4.1.6 of the Final Toxicity Assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i) for additional details on the comparison between RfD derivation based on animal studies versus human studies. The systematic literature review and assessment conducted by the EPA concluded that there is moderate evidence for developmental effects based on consistent adverse effects for fetal growth restriction including birth weight measures which are the most accurate endpoint as reported by epidemiological studies (USEPA, 2024h; USEPA, 2024i). One commenter raised concerns about the EPA's reliance on the study (Steenland et al., 2018) that the EPA uses to model PFOA dose response for benefits analysis, stating that the EPA's benefits analysis for PFOA and developmental effects is not supported by the underlying publication. The same commenter questioned the EPA's reliance on the study that is used to model PFOS dose response for benefits analysis (Dzierlenga et al., 2020), stating that the study found that there was no evidence of a relationship at the beginning of pregnancy. The commenter raised that the meta-analysis was not peer reviewed and thus the validity of the EPA's methods should be questioned. The EPA disagrees with these comments, and the use of Steenland et al. (2018) to estimate the impact of PFOA exposure on birth weight effects is supported by findings from more recent toxicity assessments (USEPA, 2024j; USEPA,

2024k). Additionally, Dzierlenga et al. (2020) has been peer reviewed and the authors conducted sensitivity analyses to evaluate sampling bias.

The EPA disagrees with the commenter's criticism of the studies used to assess dose response in developmental benefits analysis. The selected meta-analyses on the relationship between PFOA/PFOS exposure and birth weight produced statistically significant results, are based on recent data, and include a large number of studies in each meta-analysis. In reviewing the analysis in response to comments, the EPA did re-run the analysis from Dzierlenga et al (2020) to remove a duplicated estimate from M.H. Chen et al (2017) in the pooled estimate. Although a formal correction to the Dzierlenga et al (2020) publication was not completed prior to publication of the final PFAS NPDWR, the EPA confirmed with the Dzierlenga et al (2020) authors that the result of that re-analysis was accurate and consistent with the underlying study.

One commenter stated that given the discussion about changes over time in infant mortality, a dataset containing only two years of data is insufficient to build infant mortality regression models. The EPA disagrees that two years of data is insufficient to build regression models relating infant birth weight to infant mortality. The EPA's regression analysis improves upon earlier analyses relating birth weight to infant mortality (Almond et al., 2005; Ma and Finch, 2010) by evaluating two years of recent data. Sample sizes among the Centers for Disease Control and Prevention (CDC) National Center for Health Statistics (NCHS) linked birth/infant death data per year are large (n = approximately 3.8 million infants) and contribute to the overall statistical significance of regression results. As described in Appendix E of the EA (Section E.2, USEPA, 2024c), there has been a notable decline in U.S. infant mortality rates since the analyses reported in Ma and Finch (2010) and Almond et al. (2005). Using recent data from two CDC NCHS linked birth/infant death data cohorts results is a more accurate and conservative characterization of recent infant mortality trends than if the EPA had included older CDC NCHS data.

Individual Public Comments

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-053376)

2. Benefits assessment for developmental impacts is not supported by the science

To evaluate developmental effects, EPA quantifies impacts on birthweight for PFOA, PFOS, PFNA, and PFHxS. In table 42, in the Federal Register notice, EPA clearly notes that for PFHxS the "[e]vidence of the relationship between the PFAS compound and the health outcome is not conclusive."[FN189: 88 Fed. Reg. at 18704 n.5.] Based on EPA's evaluation, it is not likely that these benefits will accrue, and this endpoint should not have been quantified.

As discussed previously in these comments, EPA's justification for relying on birthweight as a critical adverse effect for PFOA and PFOS is also not supported by the body of scientific literature as a whole. The studies upon which EPA relied to justify a relationship did not consider confounding by other chemical and non-chemical stressors, including other PFAS. In addition, for quantification in the benefits analysis, EPA relied on other studies (Negri et al. 2017 and

Seeland et al. 2018 for PFOA and Dzierlenga et al. 2020 for PFOS), which EPA noted as having important uncertainties due to bias from pregnancy hemodynamics [FN190: See Public Comment Draft Toxicity Assessment and Proposed Maximum Contaminant Level Goal for Perfluorooctane Sulfonic Acid (PFOS) in in Drinking Water at page, at page 3-219 and EPA's Economic Analysis of the Proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances, 2023, at page 6-31.]. While EPA acknowledges this uncertainty and the concerns with these studies, it has not addressed the concerns and continued to inappropriately use these studies to support quantitative analysis. As presented in Table 6-50 of EPA's economic analysis, there are significant limitations and uncertainties in the analysis of birthweight benefits [FN191: See EPA Economic Analysis of the Proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances, 2023, at page 6-113 to 6-116.]. While EPA asked the SAB to review the CVD modeling, the developmental effects modeling did not undergo any peer review. Considering the shortcomings of the studies used and the uncertainties in the modeling, peer review of the developmental effects modeling should be done to assess EPA's claimed benefits.

While EPA quantifies benefits related to PFNA and birthweight, it notes that this analysis is not precise, and the confidence intervals for the slope factor include zero, which means that the estimates EPA used were not statistically significant. [FN192: Id. at page 6-31.] In discussing developmental effects of PFNA, EPA states that "mixed results" have been found for birth outcomes, particularly birth weight, and that in general associations between PFAS exposures and adverse pregnancy outcomes have not been seen for PFHxS, and PFNA. [FN193: See EPA Economic Analysis of the Proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances, 2023, at page 6-23.] EPA should not be quantifying these benefits for PFNA or other PFAS. EPA does not provide any discussion of adverse pregnancy outcomes with HFPO-DA in its benefits discussions. As such, when EPA makes broad statements about additional non-quantified benefits, it is imperative that EPA be clear that additional developmental benefits are not expected from other PFAS, including the additional four evaluated in this proposal.

EPA Response: The EPA disagrees with the commenter's statements that the EPA's benefits assessment for developmental impacts is not supported by the science, that is it not likely that developmental benefits will accrue, and that these effects should not have been quantified. The EPA disagrees with the commenter's assertion that the relationship between PFOA and PFOS exposure and adverse birth weight effects is not supported by the literature as a whole. See section 13.4.2 of the EPA response in this *Response to Comments* document for a detailed response to these criticisms of the EPA's developmental benefits analysis. See sections 4.2.1 and 4.2.2 of the EPA response in this *Response to Comments* document regarding the EPA's conclusions about the weight of evidence for developmental effects associated with PFOA or PFOS exposure. Regarding the commenter's discussion of uncertainty due to sample timing/pregnancy hemodynamics, please refer to section 13.4.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1759, SBC-045648 in section 13.4.2 in this *Response to Comments* document.

In addition, the EPA disagrees with the commenter's assertion that the agency should not be quantifying PFNA birth weight benefits or birth weight benefits for other PFAS. As stated in Chapter 6 of the EA (USEPA, 2024b), epidemiological studies support an association between PFNA exposure and developmental effects such as decreases in infant birth weight and birth length, small for gestational age and low birth weight (Lenters et al., 2016; Valvi et al., 2017). The best available peer reviewed scientific assessment for PFNA (ATSDR, 2021) provides justification for the EPA's analysis of potential economic benefits of PFNA exposure reduction and avoided birth weight effects. Furthermore, more recent epidemiological studies that evaluated PFNA and birth weight, including key studies modeled for PFOA and PFOS (Sagiv et al., 2018; Wikström et al., 2020), as well as a recent meta-analysis (Wright et al., 2023) that provides evidence that associations between decreased birth weight and PFNA exposure across the available studies are robust and consistent. Because the PFNA slope factor estimates based on the studies used for sensitivity analysis (Lenters et al., 2016 and Valvi et al., 2017) are not precise, with 95 percent confidence intervals covering wide ranges that include zero (i.e., serum PFNA slope factor estimates used are not statistically significant at 5 percent level), the EPA estimated benefits from reduced PFNA exposure as part of a sensitivity analysis only (see Appendix K of the EA; USEPA, 2024c). Benefits from reduced PFNA exposure were not included in the national-level quantified benefits analysis for the rulemaking. Because PFNA birth weight sensitivity analysis benefits are not included in the national quantified benefits, the EPA has characterized the uncertainty associated with PFNA birth weight benefits by presenting what is effectively a lowest-end estimate of zero PFNA benefits into the national benefits analysis. To inform the reader of the potential higher end estimates, the agency discusses PFNA quantified benefits separately in appendix K of USEPA (2024c). Taking the best available science into account on PFNA birth weight effects, the EPA maintains that the analysis of quantified PFNA benefits from birth weight effects is justified.

Lastly, the EPA disagrees with the commenter's statement that "additional developmental benefits are not expected from other PFAS, including the additional four evaluated in this proposal." The EPA discusses the nonquantifiable developmental benefits for compounds including PFHxS, PFNA, HFPO-DA, and PFBS in Section 6.2.4 of the EA (USEPA, 2024b). However, the EPA notes that the only quantified developmental benefits are for PFOA, PFOS, and PFNA, with PFNA developmental benefits being presented in sensitivity analysis only.

American Water Works Association (AWWA) (Doc. #1759, SBC-045648)

3. Comments on the Birth Weight Risk Reduction Analysis

In the 2021 documents, the USEPA had not quantified benefits of birth weight risk reductions associated with reductions in exposure to PFOA and PFOS in drinking water. The SAB had recommended that the USEPA consider risk reduction analyses for other endpoints, provided a sufficient rationale existed. The quantified health benefits associated with birth weight impacts now include the following, which have not been peer-reviewed by the SAB:

• Increase in birth weight (in millions of grams); and

• Number of birth-weight related deaths avoided.

Under the Proposed Option (MCL of 4 ppt for PFOA and 4.0 ppt for PFOS and an HI of 1.0 for PFNA, HFPO-DA (GenX chemicals), PFHxS, and PFBS), the USEPA calculated an expected increase in birth weight of 209,300,000 grams and 1,232.7 birth-weight related deaths avoided when the Proposed Option was compared to baseline drinking water concentrations.

Previously, after integrating the evidence, the USEPA had been unclear regarding its strength of evidence conclusion that PFOA and PFOS are associated with low birth weight or decreases in birth weight. Nevertheless, the USEPA (2021a, 2021b) had derived candidate RfDs for decreases in birth weight based on epidemiological studies before selecting a critical effect with the lowest point of departure human equivalent dose (which was for vaccine response). The SAB (USEPA 2022a) requested that the "USEPA consider reevaluating its strength of evidence conclusions for some human endpoints, including (but not necessarily limited to) decreased immune response, increased liver enzymes, increased serum lipids (for PFOA) and decreased fetal growth to determine if they are better described as having "likely" or "strong" evidence rather than "suggestive" or "moderate" evidence of an association with exposure to PFOA/PFOS. Such a reevaluation should consider studies included in the 2016 HESD and more recent studies published after the end date of the literature search for the current draft." (emphasis added, p. 23, USEPA 2022a).

Most recently, the USEPA (2023a, 2023c) judged the evidence of an association between PFOA or PFOS and fetal growth restriction as "likely" based on "moderate" evidence in humans (Note: The evidence integration included a review of mechanistic data which had not been reviewed previously by the SAB. There were also new figures that had not been reviewed previously, including the forest plots for low birth weight and small for gestational age, which had been omitted from the USEPA 2021a, 2021b documents). This conclusion of a likely association between PFOA or PFOS and fetal growth restriction based on moderate evidence in humans also allowed for the justification of quantified health benefits from birth weight impacts associated with the Proposed Option (as well as other regulatory options).

3.1 Candidate Reference Dose for Low Birth Weight

For PFOA, the USEPA derived a Reference Dose (RfD) for low birth weight (LBW, defined as birth weight<2500 grams) using a hybrid approach for defining the benchmark response (BMR), where the adverse health effect (LBW) was estimated using the dose that increases the percent of responses falling below the clinical definition of LBW (<2500 g). In 2018, 8.27% of live births fell below 2500 g (CDC 2023a as reported in USEPA 2023b and 2023d). As a result, the USEPA selected a BMR of 5% and the background response of 8.27% to calculate a dose that results in 12.86% of the responses falling within a clinical definition of low birth weight (<2500 g). For the dose-response association, the USEPA (2023a) chose the coefficient for the effect of PFOA on decreased birth weight from Wikstrom et al. (2020) (B -68.0 g per ln-ng/mL, 95% CI -112.0 to 24.0). When re-expressed to ng/mL (which was used to estimate the benchmark dose (BMD) and the lower bound on the BMD (BMDL)), β was -41.0 per ng/mL, 95% CI -67.5 to -14.5 g per ng/mL.

The use of LBW as the critical effect is inconsistent with other regulatory agencies that found small decreases in birth weight in relation to PFOA and PFOS but not increased risk of low birth weight. These include the following examples:

• ATSDR (2021) reported "Small (<20-g or 0.7-ounce decrease in birth weight per 1 ng/mL increase in either PFOA or PFOS blood level) decreases in birth weight (PFOA, PFOS)."

• ATSDR (2021) also reported "most studies found no association between maternal serum PFOA levels and the risk of low birth weight infants (typically defined as <2,500 g) (Chen et al. 2012a; Darrow et al. 2013; Fei et al. 2007, 2008a; Manzano-Salgado et al. 2017a; Savitz et al. 2012b; Stein et al. 2009) or found a decreased risk of low birth weight infants (Nolan et al. 2009; Savitz et al. 2012a). Similarly, most studies found no increases in the risk for small for gestational age (Chen et al. 2012a; Fei et al. 2007, 2008a; Hamm et al. 2010; Lauritzen et al. 2017; Manzano-Salgado et al. 2017a; Savitz et al. 2012b; Wang et al. 2016; Whitworth et al. 2012a)." (p. 465)

• EFSA (2020) reported that PFOA or PFOS exposure was associated with "reduced birth weight." Furthermore, EFSA (2018, 2020) concluded that the decrease in birth weight is small after adjusting for confounders and "the potential longer term consequences of this decrease are unclear."

• EFSA (2020) also stated "As already explained in the previous Opinion on PFOA and PFOS (EFSA CONTAM Panel, 2018), the association with reduced birth weight might at least partly be explained by changes in the physiology during pregnancy, although a recent study seemed to strengthen the causality of the effect (Meng et al., 2018; see also Section 3.3.4.1.1). The remaining decrease in birth weight after adjusting for confounders was not large and the potential longer term consequences of this decrease are unclear. Thus far, there is little evidence for an increase in the proportion of children with low birth weight (< 2,500 g)." (p. 138)

In the hazard assessment, the USEPA (2023a, 2023c) evaluated and integrated evidence for fetal growth restriction by combining epidemiological studies on the risk of LBW (birth weight<2500 grams) with studies on the risk of small for gestational age (SGA, primarily defined in epidemiological studies as birth weight below the 10th percentile for the gestational age). Although these endpoints can be correlated, they are not equivalent endpoints and they should not be evaluated as if they are same. The forest plots (figures 3-54, 3-55, 3-56, and 3-57, USEPA 2023a) are new and were not included in the 2021 draft documents. The USEPA (2023a) concluded that the evidence supports increased risk of LBW and SGA in relation to PFOA:

"Overall, nine of the eleven informative studies reporting main effects for either SGA or LBW or both showed some increased risks with increasing PFOA exposures. The magnitude of the associations was typically from 1.2 to 2.8 with limited evidence of exposure-response relationships among the studies with categorical data. Although the number of studies was fairly small, few discernible patterns across study characteristics or confidence ratings were evident across the SGA or LBW findings. For example, four of the nine studies showing increased odds of either SGA or LBW were based on early sampling biomarkers. Collectively, the majority of

SGA and LBW studies were supportive of an increased risk with increasing PFOA exposures." (p. 3-212, USEPA 2023a).

The tables and figures in the PFOA toxicity assessment (USEPA 2023a) reported that eight studies were informative for a total of nine results (Chu et al. 2020, Wang et al. 2016, Wikström et al. 2020, Lauritzen et al. 2018, Manzano-Salgado et al. 2017, Govarts et al. 2016, Hjermitslev et al. 2020, Meng et al. 2018). Closer inspection showed that the results were not consistent within or between studies. For example:

• Three studies stratified results according to sex. One study found increased risk of LBW in girls, but not boys (Wikström et al. 2020), one study found increased risk of SGA in girls and decreased risk of SGA in boys (Wang et al. 2016), and one study found increased risk of LBW in boys, and decreased risks in girls (Manzano-Salgado et al. 2017). Separately, Manzano-Salgado et al. (2017) also reported increased risk of SGA in boys and decreased risks in girls.

• Lauritzen et al. (2018) stratified by country of birth and reported decreased risk of SGA in Norway (median PFOA concentration, 1.62 ng/mL and median PFOS concentration, 9.74 ng/mL) and increased risk of SGA in Sweden (median PFOA concentration, 2.33 ng/mL and median PFOS concentration 16.4 ng/mL). (The range of PFOA and PFOS was similar among study participants from both countries, suggesting other explanations are likely for the differences in risks).

• Exposure-response results were not consistent within studies where exposures were measured in the general population (at low concentrations of PFOA and PFOS):

o Meng et al. (2018) reported no association between risk of LBW per doubling of PFOA exposure (OR 1.0, 95% CI 0.7–1.5) and slightly increased odds ratios when PFOA exposure was categorized into quartiles and Q2 (OR 1.5, 95% CI 0.8–3.1), Q3 (OR 1.2, 95% CI 0.5–2.5), and Q4 (OR 1.5, 95% CI 0.7–3.3) were compared to Q1.

o Chu et al. (2020) reported a slightly increased OR for LBW of 1.16 per ng/ml increase of PFOA (median concentration 1.54 ng/mL, interquartile range 0.957 to 2.635 ng/mL), but no increased risks when exposure was categorized into quartiles (OR 1.0 for 4th quartile (≥2.64 ng/ml) compared to 1st quartile (≤0.096 ng/ml)).

o Three studies did not show exposure-response relationships or trends when exposure was categorized into quartiles of exposure (Meng et al 2018; Wikström et al. 2020; Chu et al. 2020). Wikström et al. (2020) showed an increased risk only for PFOA>2.30 ng/mL (4th quartile) compared to <1.1 ng/ml (1st quartile). Chu et al. (2020) did not find any increased risk of LBW when exposure was categorized by quartiles of exposure.

o When stratified by maternal sampling in early pregnancy (1st trimester) and maternal sampling in later pregnancy (2nd 3rd trimesters, cord blood, after delivery), there were 4 studies of sampling in early pregnancy (Hjermitslev et al. 2020; Wikström et al. 2020; Meng et al. 2018; Manzano-Salgado et al. 2017) and 4 studies of sampling in late pregnancy (Chu et al. 2020; Govarts et al. 2016; Wang et al. 2016; Lauritzen et al. 2018). Although Wikström et al. (2020)

reported an increased risk of LBW in girls when the highest exposure was compared to the lowest exposure, other studies that sampled early in pregnancy reported decreased risks of LBW (Hjermitslev et al. 2020; Manzano-Salgado et al. 2017).

Importantly, and despite the request by the SAB that the USEPA re-evaluate studies published before and included in the 2016 Health Effects Support Documents (HESD) for PFOA (USEPA 2016a) and PFOS (USEPA 2016b), the USEPA (2023a, 2023c) did not include studies that evaluated risk of LBW or risk of SGA and exposure to PFOA or PFOS that were published prior to 2017 in the overall integration of evidence. Consequently, the USEPA did not consider at least 7 studies that evaluated LBW and did not find an increased risk of low birth weight in relation to PFOA or PFOS (Darrow et al. 2013; Nolan et al. 2009; Savitz et al. 2012a, 2012b; Stein et al. 2009; Chen et al. 2012; Wu et al. 2012). [Note: These studies were summarized in Table D.1.2 in the Appendix to the PFOA Toxicity Assessment (USEPA 2023b) and the study quality evaluation was presented in Figure 3-45 (USEPA 2023a), but these studies were not included in the forest plots (Figures 3-54 and 3-55, USEPA 2023a) or discussed in the integration of evidence]. In contrast, and in response to the request by the SAB (USEPA 2022a), the USEPA (2023a,2023c) had integrated evidence regarding immunotoxicity studies and cholesterol studies that were older and included in the 2016 HESD documents (USEPA 2016a,2016b).

The USEPA concluded in the PFOS toxicity assessment (USEPA 2023c):

“Collectively, the majority (7 of 10) of SGA and LBW studies were supportive of an increased risk with increasing PFOS exposures. The increased odds ranged from 1.19 to 4.14 although evidence of exposure-response relationships was lacking. There was no evidence of differences by study confidence as five of these seven were either high (n=4) or medium (n=1) confidence. There was also no evidence of sample timing differences as the majority of studies with associations were reported in studies based on early sampling periods.” (p. 3-209, USEPA 2023c).

The USEPA (2023c) did not provide references within the above sentence; however, review of tables and figures reported the following studies were high confidence (Chu et al. 2020, ManzanoSalgado et al. 2017, Lauritzen et al. 2018, Wikström et al. 2020) or medium confidence (Govarts et al. 2016; Hjermitslev et al. 2020; Meng et al. 2018) despite the following issues:

• Exposure-response relationships were generally not seen.

• Four studies (Manzano Salgado et al. 2017; Wikström et al. 2020; Meng et al. 2018; Hjermitslev et al. 2020) were based on sampling during early pregnancy while three studies (Lauritzen et al. 2018, Govarts et al. 2016, Chu et al. 2020) were based on sampling late in pregnancy.

The USEPA (2023e) conflates decreases in birth weight with low birth weight in the economic analysis. The USEPA provided a rationale for estimating medical costs associated with changes in infant birth weight and the value of avoiding infant mortality at various birth weights by citing to health effects in relation to low birth weight specifically:

"LBW is linked to a number of health effects that may be a source of economic burden to society in the form of medical costs, infant mortality, parental and caregiver costs, labor market productivity loss, and education costs (Chaikind et al., 1991; J. R. Behrman et al., 2004; R. E. Behrman et al., 2007; Joyce et al., 2012; Kowlessar et al., 2013; Colaizy et al., 2016; Nicoletti et al., 2018; Klein et al., 2018). Recent literature also linked LBW to educational attainment and required remediation to improve student outcomes, childhood disability, and future earnings (Jelenkovic et al., 2018; Temple et al., 2010; Elder et al., 2020; Hines et al., 2020 Chatterji et al., 2014; Dobson et al., 2018)." (USEPA 2023e, p. 6-360)

"Low birth weight (LBW) is an important health outcome affected by PFOA/PFOS exposure because it is a significant factor in survival rates and medical care costs among infants (ATSDR, 2021)." (USEPA 2023e, p. 6-13)

"Epidemiology studies on PFOA supported an increased risk of LBW in infants with PFOA exposures (USEPA, 2023a). Similarly, epidemiology studies on PFOS showed an increased risk of LBW infants with PFOS exposures. Overall, most epidemiology studies evaluating the association between maternal serum PFOA/PFOS and birth weight reported negative relationships (i.e. increased exposure is associated with decreased birth weight)

(Darrow et al., 2013; Verner et al., 2015; Govarts et al., 2016; Negri et al., 2017; Starling et al., 2017; Sagiv et al., 2018; Chu et al., 2020; Dzierlenga et al., 2020; Wikström et al., 2020; Yao et al., 2021). FN30: Recent evidence indicates that relationships between maternal serum PFOA/PFOS and birth weight may be impacted by changes in pregnancy hemodynamics (Sagiv et al., 2018; Steenland et al., 2018)." (USEPA 2023e, 6.13)

When considering the evidence for risk of low birth weight in relation to PFOA and PFOS, the USEPA combines studies of the risk of LBW with studies of the risk of SGA (USEPA 2023a, 2023c).

There is little evidence that the risk of LBW or the risk of SGA is increased (see remarks above).

3.2 Exposure-response functions for PFOA and PFOS and decreases in birth weight used in the Economic Analysis

The USEPA (2023e) Economic Analysis relies on the exposure-response coefficients (slope factors) for decreases in birth weight from the main analyses of a meta-analysis of birth weight effects in relation to PFOA (Steenland et al. 2018) which reported a mean birth weight decrease of 10.5 g per ng/ml (95% CI −16.7, −4.4) and a separate meta-analysis of birth weight effects in relation to PFOS (Dzierlenga et al., 2020) which reported a mean birth weight decrease of 3.0 g per ng/ml (95% CI −4.9, −1.1). [NOTE: An average decrease of 10 grams is equivalent to a decrease of approximately 0.35 ounces]. The biological or clinical significance of such small changes in birth weight is uncertain. The exposure-response function (B -10.5 g birth weight per ng/mL serum) for PFOA used in the economic analysis is also considerably smaller than the coefficient (B -41.0 g per ng/mL, 95% CI −67.5, −14.5 for PFOA) from the study selected for the critical effect and the calculation of the BMD and BMDL (Wikström et al. 2020). For PFOS, the exposure-response function for the economic analysis (B -3.0 g per ng/mL) is slightly smaller

than the coefficient (B 8.4 g per ng/mL, 95% CI −16.0, −0.5) used for deriving the candidate RfD for low birth weight based on Wikström et al. 2020).

Both of these meta-analyses (Steenland et al. 2018; Dzierlenga et al. 2020) conducted specific sensitivity analyses to evaluate bias associated with maternal sampling during late pregnancy compared to maternal sampling during early pregnancy. Both meta-analyses reported that essentially no effect on birth weight was seen when maternal blood is sampled early in pregnancy, while a relatively larger effect on birth weight was seen when maternal blood is sampled late in pregnancy. In general, this suggests that any effect of PFOA or PFOS on birth weight is confounded by the time of sampling (Steenland et al. 2018, 2020; Dzierlenga et al. 2020). In brief, an increased glomerular filtration rate and maternal plasma volume expansion during pregnancy leads to an increased elimination of PFOA and PFOS. Plasma volume expansion and glomerular filtration rate are also related to birth weight. When PFAS in serum is sampled late in pregnancy, the magnitude of the glomerular filtration rate and the plasma volume expansion can distort the association between PFAS and birth weight. Therefore, using the main effect from the meta-analysis (which is essentially an average of birth weight effects reported from early in pregnancy and late in pregnancy) will overestimate the health benefits associated with birth weight risk reductions under the assumption that pregnancy hemodynamics confound the association.

Steenland et al. (2018) found that there was no effect on birth weight after including the C8 Science study in the meta-analysis:

“Our meta-analysis including nine new studies, with an almost equal number of births as prior studies, shows a modest inverse association between maternal or cord PFOA and birthweight, with large heterogeneity across studies. The two studies with exposure above background levels showed no association, and similarly, restriction to studies with blood sampling conducted early in pregnancy or shortly before conception showed little or no association. These findings are consistent with confounding and/or reverse causality being responsible for the inverse association seen in studies with low background exposure levels and blood sampling conducted later in pregnancy, when confounding and/or reverse causality are likely to be more important.”

Overall, there is little evidence that PFOA or PFOS at serum concentrations reported in the general population affect developmental outcomes. The USEPA (2023e) confirmed that there was generally a lack of evidence for exposure-response associations between PFOA and PFOS and other development outcomes:

“Additionally, the magnitude of birth weight changes may be correlated with other developmental outcomes such as preterm birth, gestational duration, fetal loss, birth defects, and developmental delays. As described in Section 6.2, these developmental outcomes have limited epidemiology and toxicology evidence showing associations with PFOA/PFOS exposure and due to this uncertainty, these outcomes were not further assessed.” (p. 6-36).

3.3 Other factors that have affected mean birth weight

The USEPA (2023e) economic analysis calculates that the expected value of birth weight increases, assuming the MCLs are set to 4.0 ppt for PFOA and PFOS plus a hazard index of 1.0 for PFNA, PFBS, PFHxS, and HFPO-DA, is an average increase of 50 grams (1.8 ounces) in mean birth weight. According to US Natality data (CDC 2023a), the mean birth weight in 2018 was 3261.64g and 8.3% of births were low birth weight (<2500 g). If average birth weight were to increase by 50 grams, the mean birth weight would be 3,316.84 g.

During 2003-2018, median PFOS in blood serum decreased substantially by 12 ng/mL, from 14.6 ng/ml in 2003-2004 to 2.6 ng/ml in 2017-2018 (USEPA 2022b) in the population of women aged 16-49 years old (women of childbearing age). During the same years, median PFOA in blood serum also decreased but by a smaller absolute change of 2.1 ng/mL, from 3 ng/mL in 2003-2004 to 0.9 ng/mL in 2017-2018) (USEPA 2022b).

Although the average birth weight in 2003 was 3291.03 grams, which was 30 grams higher than average birth weight in 2018, there were fewer births of low birth weight babies (CDC 2023a). In 2003, 7.9% of births were of low birth weight while in 2018, 8.3% of births were of low birth weight. Together, these data suggest further reductions of PFOA and PFOS concentrations in blood serum are unlikely to result in measurable increases in average birth weight (CDC 2023a).

Tilstra and Masters (2020) reported that average birth weight decreased in the United States since at least 1990. In 1990, average birth weight was 3314.5 grams (approximately 50 grams more than in 2018). However, Tilstra and Masters (2020) provided an analysis that argued that the shift to lower average birth weight is due to changes in obstetric practices (more c-sections and scheduled births). As a result, there are fewer and fewer vaginal births at 40-42 weeks, when babies are heavier; most of these births have shifted to 37-39 weeks because of changes in obstetric practices. This shift has affected the average birth weight.

Data from other areas where PFOS and PFOA are found in the blood serum at similar concentrations to the US also provided evidence that PFOS and PFOA in blood serum at general population levels do not result in decreased birth weight. For example, birth weight in the Faroe Islands (where decreases in antibody response to diphtheria vaccination in relation to increases in PFOA and PFOS form the basis for the RfD for immunotoxicity effects, specifically decreases in vaccine response at age 7 in relation to PFOA or PFOS at age 5) has increased over the past 50 years. For the years 1969-1981, Olsen and Joensen (1985) reported that the average birth weight of liveborn infants delivered in the Faroe Islands was the highest average weight (3,610 g) reported by 33 countries. More recently, Olsen et al. (2023) found that that the mean birthweight in the Faroe Islands was higher than other Nordic countries and had increased during 2010–2019 in the Faroe Islands.

3.4 Conclusions and Recommendations

• When integrating the evidence of birth weight effects and arriving at an evidence stream judgment for humans, the USEPA should consider older studies of LBW in relation to PFOA and PFOS that predated the 2016 HESD (USEPA 2016a, 2016b). Reconsidering these studies likely decreases confidence in the judgment of evidence.

• The USEPA should provide further rationale for using Wikström et al. (2020) as the critical study for the association of decreased birth weight given that it is only one study that sampled PFAS in serum during early pregnancy that showed an association between decreased birth weight and increases in PFAS; other studies that sampled during early pregnancy did not show an association or they showed an attenuated association, which potentially leads to a conclusion that the evidence for an association between PFAS and decreased birth weight is inconsistent after considering potential confounding.

• The USEPA should provide a quantified sensitivity analysis and further discussion of the effects of confounding or reverse causation by pregnancy hemodynamics on the health benefits analysis.

• Available data suggest that further reductions of PFOA and PFOS concentrations in blood serum are unlikely to result in measurable increases in average birth weight. Data from other areas where PFOS and PFOA concentrations are elevated suggest that increases in average birth weight and decreases in infant mortality are likely not expected. For example, PFOS and PFOA in blood serum have been measured in maternal serum in birth cohort studies in the Faroe Islands with mean concentrations similar to that reported in the general population in the US (Grandjean et al. 2012). Studies have reported that the mean birthweight in the Faroe Islands was higher than other Nordic countries and had continued to increase during 2010–2019 in the Faroe Islands (Olsen and Joensen 1985; Olsen et al. 2023). Although there are no published studies of birth weight in relation to PFAS serum concentrations in the Faroe Islands, it is unlikely that small decreases in birth weight in relation to PFAS – should the association exist in this population – have adverse health consequences.

EPA response: Please see section 4.1.3 of the EPA response in this *Response to Comments* document regarding the implementation of the SAB PFAS Review Panel's recommendations in the final toxicity assessments for PFOA and PFOS, including changes that were made (e.g., addition of figures) as a result of this review. Please see section 4.1.2 of the EPA response in this *Response to Comments* document regarding the EPA's use of the best available science, including studies that were considered in the 2016 Health Effects Support Documents (HESDs), in the final toxicity assessments for PFOA and PFOS. The EPA notes that while the evidence profile table for developmental effects in Section 3.4.4 of the draft toxicity assessments for PFOA and PFOS did not previously describe studies considered in the 2016 HESDs, these studies were in fact considered in the evidence integration judgments presented in the draft toxicity assessments. Therefore, the EPA disagrees that incorporation of studies from the HESDs would decrease confidence in the evidence for developmental effects associated with PFOA or PFOS. The EPA has updated the evidence profile tables for all priority health outcomes to explicitly and more clearly describe studies from the 2016 HESDs in the final toxicity assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i).

Please see section 4.2.6 of the EPA response in this *Response to Comments* document regarding why the EPA's conclusions may differ from those of other health agencies. Please see sections 4.2.1 and 4.2.2 of the EPA response in this *Response to Comments* document, the EPA response

to comment Doc. #1774, SBC-053211 in section 4.2.1.2 in this *Response to Comments* document, as well as Sections 3.4.4 and 4.1.1 of the final toxicity assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i) regarding the EPA's rationale for selecting decreased birth weight as a critical effect for RfD derivation, as well as rebuttal to the commenter's claim that decreased birth weight is not a biologically or clinically significant effect.L

The commenter claims that the EPA "derived a Reference Dose (RfD) for low birth weight (LBW, defined as birth weight <2500 grams) using a hybrid approach for defining the benchmark response (BMR), where the adverse health effect (LBW) was estimated using the dose that increases the percent of responses falling below the clinical definition of LBW (<2500 grams)." The commenter fundamentally misunderstands the EPA's RfD derivation and critical effect described in the Toxicity Assessments Sections 4 and Appendices E (USEPA, 2024h; USEPA, 2024i; USEPA, 2024j; USEPA, 2024k). Decreases in birth weight, not LBW, was the critical effect. The term "Low Birth Weight" was incorrectly used in Table 4-8, Table 4-11, and Figure 4-5 (Figure 4-4 in PFOS) in the draft toxicity assessments for PFOA and PFOS and has subsequently been corrected in the final assessments (USEPA, 2024h; USEPA, 2024i). Many of the commenter's subsequent points are predicated on this fundamental misunderstanding of LBW as a critical effect and requirements needed for such a determination, including consistency or lack of dose-response which the commenter points out is lacking for some LBW studies. The EPA agrees that, as described in detail the Toxicity Assessments Sections 3.4.4, "few discernible patterns across study characteristics or confidence ratings were evident across the small gestational age (SGA) or LBW findings." Similarly, the EPA does not claim that there is a clear exposure-response association for PFOA or PFOS exposure and LBW.

The commenter provided a quote on the EPA's conclusions for the association between elevated exposure to PFOS and SGA and LBW. The statements by the commenter are correct; however, the EPA disagrees with the implication that these study results do not support the agency's conclusion of *moderate* evidence for adverse developmental effects. Further discussion of the EPA's consideration of LBW and SGA studies, the selection of Wikström et al. (2020) as the critical study, the consistency of the low birthweight endpoint, and potential for confounding, is provided in the EPA responses to Doc. #1774, SBC-053452 and SBC-053453 in section 4.2.2.3.4 in this *Response to Comments* document. See also responses in section 4.2.1.2 and 4.2.2.3.4 in this *Response to Comments* document.

The EPA agrees with the commenter that fetal growth restriction and low birth weight risk are not equivalent endpoints. As clearly stated in Chapter 6 of the EA (USEPA, 2024b), the EPA considered only studies that related PFOA and PFOS exposure to changes in birth weight. The studies selected for use in the birth weight benefits analysis, Steenland et al., 2018 and Dzierlenga et al., 2020, develop birth weight exposure-response functions for PFOA and PFOS, respectively, and do not conflate birth weight with fetal growth rate.

The EPA disagrees with the commenter's statement that the economic analysis conflates decreases in birth weight with low birth weight. As clearly stated in Chapter 6 of the EA (USEPA, 2024b), the EPA monetized benefits associated with incremental increases in birth

weight resulting from reductions in drinking water PFOA/PFOS levels based on avoided medical costs associated with different birth weight ranges. The estimated incremental medical costs are a continuous function of birth weight over the range from 900 to 4,500 grams. The function does not allow for a discontinuity at the very low birth weight level. The EPA uses CDC data on the state-level distribution of baseline birth weight and the estimated change in birth weight to obtain the simulated cost change for birth weight increases. Based on the baseline birth weight distribution and the estimated increase in birth weight from reduced exposure to PFOA and PFOS, the distribution of birth weight shifts from lower to higher under the post-policy scenario. This shift includes a reduction in the number of LBW infants.

The EPA disagrees with the commenter's assertion that "available data suggest that" reductions of PFOA and PFOS concentrations in blood serum are unlikely to result in measurable increases in average birth weight. The EPA has reviewed the provided sources, and the EPA does not agree that the presented evidence from the Faroe Islands supports the commenter's assertion, or that it is as conclusive as the commenter suggests. Other longitudinal trends occurring simultaneously in the Faroe Island population may explain the increased birth weight trend reported by one study in this population. The EPA review in fact found evidence of associations between PFOA an PFOS and decreased birth weight in a Faroe Island study (Valvi et al., 2017).

Recent evidence indicates that relationships between maternal serum PFOA/PFOS and birth weight may be impacted by changes in pregnancy hemodynamics, however exact patterns are not completely understood (Sagiv et al., 2018; Steenland et al., 2018). While uncertainties remain on the potential impact of pregnancy hemodynamics in later pregnancy due to use of biomonitoring samples from the second and third trimester or post-partum, the evidence for associations between PFOA and PFOS and decreases in birth weight is consistently supported by a large number of *high* and *medium* confidence epidemiology studies and supported by evidence across other measures and fetal growth restriction (see Section 3.4.4.4 of the PFOA and PFOS Toxicity Assessments; USEPA, 2024h; USEPA, 2024i). The EPA acknowledges that this is a possible limitation of the analysis, as described in Section 6.2.2.1.1 of the EA (USEPA, 2024b). See also section 13.4.2 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's assertion that the final report EA incorrectly attributes LBW to PFOA and PFOS when other causes of LBW (e.g., changes in obstetric practices) offer an alternative explanation. This rulemaking only considers the effect on LBW from PFOA and PFOS exposure, and the EPA has in its literature review isolated these effects from other causes of LBW.

American Water Works Association (AWWA) (Doc. #1759, SBC-053055)

Estimating the Reduced Impact of Low Birth Weights

In review of the EPA's approach to estimating the benefits of reducing the incidence of low birth weights resulting from prenatal PFOA and PFOS exposure, it appears that EPA is conflating risk

of low birth weight with differences in mean birth weight. In review of this approach, several critical issues have been raised:

• The use of low birth weight as the critical effect is inconsistent with other regulatory agencies that found small decreases in birth weight but not increased risk of low birth weight in relation to PFOA and PFOS (ATSDR, 2021; EFSA, 2020; EFSA, 2018).

• In deriving the Reference Dose for both PFOA and PFOS, EPA has noted that the derivations for PFOA and PFOS were based on low birth weight (defined as birth weight less than 2,500 grams). However, the exposure-response coefficients used for these efforts were based on decreases in birth weight. In particular, the studies used for these derivations evaluated differences in average birth weight but not risk of low birth weight. EPA's conflation of low birth weight with decreases in birth weight is prevalent in the economic analysis as well. While these endpoints are correlated, they are not equivalent and the should not be evaluated as if they are the same.

• The benefits analysis relies on exposure-response functions based on coefficients for decreases in birth weight from the main analysis of two different meta-analyses for PFOA and PFOS. The critical study that serves as the basis for the PFOA meta-analysis (Steenland et al, 2018) concluded that there was no effect on birth weight when the results of the C8 Science Study were included and noted that the results were consistent with confounding and/or reverse causality. EPA's conclusion is at odds with Steenland et al's own conclusion for their work.

• EPA's characterization of the supporting studies for this health effect is inconsistent with the data that is provided by the studies. In the toxicity assessment for PFOA, EPA concludes that the majority of the studies considered showed supportive evidence of an increased risk of low birth weight with increasing PFOA exposures. However, closer inspection of the studies showed conflicting results. For example, several studies that stratified results by sex provided mixed results on gender-specific impacts. Similarly mixed results were noted for studies that stratified results by country of birth. Furthermore, exposure-response results were not consistent with results from studies where exposures were measured in the general population; in particular, these studies generally reported no Associations or very limited evidence of Associations of PFOA and PFOS with low birth weight.

• While the SAB requested that USEPA reevaluate and consider studies published before the 2016 Health Effects Support Documents for PFOA and PFOS, at least seven studies that were available prior to 2017 were not included (Darrow et al. 2013; Nolan et al. 2009; Savitz et al. 2012a, 2012b; Stein et al. 2009; Chen et al. 2012; Wu et al. 2012). None of these studies found an increased risk of low birth weight in relation to PFOA or PFOS. EPA must include studies that do not support its preferred outcome in its analysis and explain why, in light of these studies, it has still reached its determination.

• The EPA also failed to acknowledge the significance of the results from the sensitivity analysis assessing bias associated with timing of the maternal sampling during late pregnancy versus sampling during early pregnancy. This sensitivity analysis highlighted that there was no effect on

birth weight when maternal blood was sampled early in pregnancy whereas late pregnancy sampling showed a larger effect on birth weight than the meta-analysis. This suggests that the evidence for a conclusion that PFAS exposure is associated with decreased birth weight is inconsistent after considering potential confounding.

Additional details on these and other comments for the EPA's analysis of decreased birth weights are available in Appendix A. Based on the materials made available, it does not appear that EPA's conclusion is supported by the evidence or record before the agency.

EPA Response: Regarding the commenter's suggestion that the literature review of the relationship between PFOA/PFOS exposure and LBW needs to include papers that predated the 2016 HESD and that evidence supporting this relationship is inconsistent with other agencies' findings, see the EPA response to comment Doc. #1759, SBC-045648 in section 13.4.2 in this *Response to Comments* document. Regarding the commenter's assertion that low birth weight and decrease in birth weight are inappropriately conflated, see section 13.4.2 of the EPA response in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-053419)

f. Exposure-Response Relationships Were Improperly Selected

To calculate the health-risk reduction benefits based on serum concentrations, EPA extracts from literature or independently reanalyzes various exposure-response slope factors that are intended to demonstrate a quantitative relationship between a change in serum concentrations and a specific health effect. For both PFOA and PFOS, EPA evaluates the health effects of reductions in birth weight and increases in total cholesterol. EPA also considers increases in renal cell carcinoma risk for PFOA and increases in blood pressure for PFOS. For each endpoint, EPA selects relationships between serum levels and health effects that are not supported by the underlying studies or are based on uncertain reanalysis of data. These flawed analyses add to the misleading conclusions associated with basing the analysis on inappropriate and indistinguishable regulatory alternatives.

For reduced birth weight, EPA uses an exposure-response slope factor of –10.5 g per ng/mL for PFOS from Steenland et al. (2018), which is a random effects meta-analysis based on 24 studies. Contrary to EPA's assessment, however, Steenland et al (2018) concludes, "current human evidence provides only modest support for decreased birth weight with increasing PFOA. Studies with a wide range of exposure, and studies with blood sampled early in pregnancy, showed little or no association of PFOA with birth weight. These are studies in which confounding and reverse causality would be of less importance." (Emphasis added). In other words, EPA relies on an association for an endpoint that is not supported by the underlying publication. For PFOS, EPA conducts its own meta-analysis of data presented in Dzierlenga, Crawford et al. (2020) deriving an exposure-response slope factor of –3.0 g per ng/mL, even though Dzeirlenga et al. (2020) itself found that "when blood was drawn at the very beginning of

pregnancy, there was essential no relation of birth weight to PFOS." This meta-analysis has not been peer reviewed, which calls into question the validity of EPA's reanalysis methods.

EPA's approach to selection of exposure-response slope factors is scientifically flawed, lacks transparency, and disregards the biological relationship of exposure and effects. EPA should consider and discuss the exposure-response slope factors in the context of biologically relevant effects and obtain peer review for any novel analyses. EPA's analysis egregiously misrepresents any meaningful determination of health risk reduction benefits between the proposed MCL and regulatory alternatives.

EPA Response: The EPA disagrees with the commenter's statement that the EPA's selection of relationships between serum levels and health effects are not supported by the science or are based on uncertain reanalysis of data. The commenter references conclusions from Steenland et al (2018) on PFOA and birth weight effects and states that the EPA "relied on an association for an endpoint that is not supported by the underlying publication." The EPA disagrees. For the agency's response to the commenter's arguments, please see section 13.4.2 in this *Response to Comments* document. Additionally, the EPA notes that the studies Steenland et al. (2018) relied on were published prior to 2018. Comprehensive reports published in 2018 or prior found "plausible" or "suggestive" (USEPA, 2016c; ATSDR, 2018) evidence of relationships between PFOA and PFOS and developmental outcomes; however, the EPA's toxicity assessments, which include studies published both before and after 2018, found clear evidence of an association for PFOA and PFOS in both toxicological and epidemiological studies (USEPA, 2024j; USEPA, 2024k). Given the breadth of the studies evaluated for the EPA's toxicity assessment, the EPA disagrees with the commenter that the association between PFOA and birth weight effects is not supported by epidemiology evidence. Please see section 4.2.1 of the EPA response in this *Response to Comments* document for further discussion on the consideration of decreased birth weight as a critical effect.

The commenter's assertion that the Dzierlenga (2020) meta-analysis has not been peer-reviewed is factually incorrect. The study is in fact published in a well know open access peer-reviewed journal Environmental Epidemiology, the official journal of the International Society for Environmental Epidemiology (https://journals.lww.com/environepidem/pages/default.aspx). See section 13.4.2 of the EPA response in this *Response to Comments* document for further discussion on the EPA's use of Dzierlenga (2020) and section 13.4.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1759, SBC-045648 in section 13.4.2 in this *Response to Comments* document for further discussion on sample timing/pregnancy hemodynamics.

The EPA disagrees with the commenter's assertions that the EPA's approach to selecting exposure-response slope factors is scientifically flawed, and that the biological relationship of exposure and effects was disregarded. See section 13.4.2 of the EPA response in this *Response to Comments* document.

The EPA also disagrees with the commenter's assertion that the EPA's analysis lacks transparency. See the EPA response to comment Doc. #1774, SBC-045652 in section 13.4 in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045704)

10. Comments on Effects of Reduced Birth Weight on Infant Mortality (Appendix E, (USEPA 2023b))

(10A) Data Sources

EPA describes a data set with only two years of data. Given the discussion about changes over time in infant mortality described by EPA, a data set with only two years of data is insufficient to build the regression models described in Appendix E. Natural changes over time must also be included in the model. Otherwise, any correlation of birth weight and infant mortality will be erroneous and could easily be due to other time-dependent factors not included in the model.

EPA must make the data set described in E.3.1 available to the public under the EPA's quality assurance and good statistical practice guidelines. It has failed to do so in the supporting documents for the Proposed NPDWRs.

(10B) E.7.1 Mortality Regression Models

Figure E-1 indicates that EPA has built a series of models, generating different model coefficients for various factors that influence birth weight and infant mortality including gender and ethnicity. This approach is inconsistent with scientific best practice. The proper approach is to build a single model with key co-variates like gender and ethnicity included in the single model (Harrell 2016). Otherwise, the model error term (which is the basis for hypothesis testing) is biased and not representative of the entire population included in the data set. EPA could use linear contrast or estimate methods to evaluate differences in gender and ethnicity, but the error term must result from a single model fit.

EPA does not show the significance of each of the regression and logistic model parameters. In other parts of the technical appendices supporting the MCLG, EPA has ignored the fact that many co-variates (e.g., gender or ethnicity) are the variables highly associated with the model response variable, and either PFOS and PFOA are not significant or are minor parameters relative to the key phenotype co-variates. EPA must demonstrate a strong relationship, considering the entire data set and scientifically derived and supported co-variates in the statistical models. As the presentation currently stands, the lack of information provided by EPA negates the ability of the public to evaluate the validity of the models.

EPA must show which co-variates are included in the models generating the odds ratios of Table E-4, including their statistical significance. Otherwise, the validity of the models cannot be examined from a scientific perspective.

EPA Response: The EPA disagrees that two years of data is insufficient to build regression models relating infant birth weight to infant mortality. The peer reviewed analyses that formed the basis of the EPA's updated regression on birth weight and mortality (Almond et al., 2005; Ma and Finch, 2010) used only a single year of CDC NCHS linked birth/infant death data each (Almond et al., 2005 used 1989 data; Ma and Finch (2010) used 2001 data). These papers are highly respected and cited (receiving over 1,000 citations between them) and considered authoritative papers in the field. The analysis performed by the EPA improves upon these seminal analyses by including two years of recent data. Sample sizes among the CDC NCHS linked birth/infant death data per year are large (n = approximately 3.8 million infants) and contribute to the overall statistical significance of regression results. As described in Appendix E (Section E.2), there has been a notable decline in U.S. infant mortality rates since the analyses reported in Ma and Finch (2010) and Almond et al. (2005). The EPA notes that if it were to use the analyses from Ma and Finch (2010) and Almond et al. (2005), the estimated quantified benefits would be significantly higher because of the higher mortality rate among infants in the years of data used for those publications relative to the recent data used in the EPA's infant mortality regressions. Hence, using recent data from two CDC NCHS linked birth/infant death data cohorts results is a more accurate and conservative characterization of recent infant mortality trends than if the EPA had included older CDC NCHS data. Furthermore, like previous studies, the EPA relies on a cross-sectional analysis (rather than a time-series analysis) of the relationship between birth weight and mortality with a carefully selected set of controls for confounding effects. In short, the EPA has clearly and reasonably used best scientific practices and ensured it can produce quantified benefits for low birth weight that are strongly scientifically based, robust, and up to date.

The EPA disagrees with the commenter's assertion that subpopulation-specific regression models do not align with the scientific best practice. In its analysis, the EPA did not simply assume that the relationship between infant mortality and a set of predictors (including birth weight) would be the same in subpopulations defined by race/ethnicity but in fact the EPA evaluated the possible differences. Performing separate regressions is equivalent to including all possible two-way interactions with the race variable and assuming different error distributions for each ethnicity/race. Further, the peer-reviewed analyses upon which the EPA's updated infant birth weight mortality model was based developed separate models for each race/ethnicity. Ma and Finch (2010) investigated whether the strength of predictions of infant mortality varied by race/ethnicity and sex. They found that the models specific to race/ethnicity showed the best goodness-of-fit metrics. Each race/ethnicity-specific model includes covariates for gender and several other variables. Research conducted by the EPA indicates that it is important to model differences in infant mortality by race and ethnicity so that prevention efforts can target risks specific to those populations (Rogers, 1989; Frisbie et al., 1996).

Presentation of the odds ratios in Appendix E (USEPA, 2024c) is consistent with presentation of results in epidemiological literature. Marginal effects are provided additional help with interpretation of the results. The EPA reported the results of regression modeling using both odds ratios and marginal effects that are more informative than just the estimated coefficients. The

EPA also reported the models' fit and the estimated confidence intervals. It is easy enough to include the estimated logistic regression models in Appendix E. However, because the estimated coefficients are in log-odds units, they are often difficult to interpret, so they are often converted into odds ratios in epidemiological literature by taking an exponent of each regression coefficient. The EPA opted for reporting odds ratios via the "logit" command in Stata (StataCorp, 2013).

Information presented in Table E-4 provides information on all covariates included in the model. Table E-4 includes odds ratios for all covariates included in the mortality regression.

The EPA disagrees with the commenter's assertion of a lack of transparency. The dataset described in Appendix Section E.3.1 is available in the docket materials.

American Chemistry Council (ACC) (Doc. #1841, SBC-052939)

The Epidemiological Data are Not Sufficiently Robust to Quantify the Reduction in Developmental Effects

As with RCC, EPA relies on equivocal epidemiological evidence to estimate the benefits of its proposal on developmental effects (i.e., reduced birth weight). While the Agency identified 29 medium and high confidence studies investigating birth weight in humans, it only considered five studies and used only two for its calculation of RfDs. In estimating the benefits of reducing PFOA and PFOS in drinking water EPA relied on two separate meta-analyses. As noted earlier, moreover, the results from the five studies used by the Agency are mixed. In particular, the two studies that EPA relied on for the RfDs report very limited results. Sagiv et al. (2017) did not observe a significant association with maternal serum concentrations of either PFOA or PFOS. While Wikstrom et al. (2019) report an association with PFOA and PFOS concentration in the highest quartile of girls; no association is observed in infant boys.

The human data do not provide a reliable basis for quantifying the risks of lower birth weight, but the findings are supported by the results in laboratory studies. The RfDs calculated from these studies are significantly higher than those based on the epidemiology; they represent a more appropriate estimate of the risk of PFOA and PFOS exposure.

EPA Response: The EPA disagrees with the commenter that the agency's estimation of quantified benefits of its proposal on developmental effects is based "on equivocal epidemiological evidence." For the EPA's response to this comment, including why the EPA believes the epidemiological evidence provides a reliable basis for quantifying the risks of lower birth weight, please see sections 4.2.1 and 4.2.2 in this *Response to Comments* document, the EPA response to comment Doc. #1774, SBC-053212 in section 4.2.2.3.4 in this *Response to Comments* document, as well as Sections 3.4.4 and 4.1.1 of the final toxicity assessments for PFOA and PFOS.

Susan Goldhaber (Doc. #1596, SBC-053416)

May 26, 2023

Michael S. Regan, Administrator Environmental Protection Agency

1200 Pennsylvania Ave., N.W. Washington, D.C. 20460

Re: Docket ID No. EPA-HQ-OW-2022-0114, Comment on Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

Dear Administrator Regan,

As a toxicologist formerly employed at EPA, Office of Drinking Water, (1980-1988), who worked on revising the primary drinking water regulations, I am very familiar with the requirements of the Safe Drinking Water Act and the regulatory process. I am writing because I am very concerned with the underlying science supporting these regulations. I would like to submit the attached comments for your consideration.

Sincerely, Susan B. Goldhaber M.P.H.

SBG Consulting, Inc.

Comments

There are Executive Orders that strongly encourage that the benefits of a major regulation, such as PFAS Drinking Water regulation, exceed the costs. In the Economic Analysis, EPA calculated the economic benefits to the U.S. by avoiding three health outcomes that it attributed to exposure from PFOA and PFOS:

• Developmental effects (reductions in birth weight)

• Cardiovascular effects (increase in total and high-density lipoprotein (HDL) cholesterol resulting in cardiovascular disease including strokes and myocardial infarction)

• Kidney cancer

Reductions in birth weight

ATSDR https://www.atsdr.cdc.gov/toxprofiles/tp200.pdf identified 23 general population studies and three studies of highly exposed populations that did not show an association between PFOA or PFOS and lowered birth weight; 7 studies that reported that higher PFOA/PFOS concentrations in the blood were associated with lower birth weight babies, and two studies that reported the inverse: higher PFOA/PFOS concentrations were associated with higher birth weight babies.

ATSDR concluded, “Evidence is suggestive of an association between serum PFOA and PFOS and small decreases in birth weight: the decrease in birth weight is <20 grams (0.7 ounces) per 1 nanogram/milliliter increase in blood PFOA or PFOS level. “

It has also been suggested that decreased birth weight may be explained by reverse causation, i.e., the higher PFOA concentration is an effect, not a cause in the situation. Since lower birth weight babies have only been noted in studies where PFOA is tested late in the pregnancy (in the 3rd trimester), this could be due decreased kidney filtration rates in some women, which is known to lead to lower birth weight babies. Thus, the lower birth weight babies are due to lower kidney filtration rates, which is associated with higher PFOA levels, but PFOA is not the causative factor.

The primary cause of low birth-weight babies is premature birth and most studies have not found an association between PFOA or PFOS and premature birth. However, EPA calculated a benefit to the U.S. of $139 million to $178 from avoiding low birth weight babies from the proposed regulation.

2. What is the justification for EPA's conclusion that the miniscule decrease in birth weight (less than 1/16th of a pound) due to PFOA/PFOS exposure results in thousands of deaths?

EPA Response: The EPA disagrees with the commenter's assertion that there is insufficient evidence of an association between serum PFOA and PFOS and decreases in birth weight. Please see sections 4.2.1 and 4.2.2 of the EPA response in this *Response to Comments* document, the EPA response to comment Doc. #1774, SBC-053212 in section 4.2.2.3.4 in this *Response to Comments* document, as well as Sections 3.4.4 and 4.1.1 of the final toxicity assessments for PFOA and PFOS regarding the EPA's rationale for conclusions about the associations between PFOA or PFOS and decreased birth weight. Please see section 4.2.6 of the EPA response in this *Response to Comments* document regarding why the EPA's conclusions may differ from those of other health agencies.

The EPA also disagrees with the commenter's speculation that a decrease in birth weight may be due decreased kidney filtration rates in some women and not associated with exposure to PFOA. As the EPA noted in the EA, recent evidence indicates that relationships between maternal serum PFOA/PFOS and birth weight may be impacted by changes in pregnancy hemodynamics, however exact patterns are not completely understood (Sagiv et al., 2018; Steenland et al., 2018). The EPA acknowledges that this is a possible limitation of the analysis, as described in Section 6.2.2.1.1 of the EA (USEPA, 2024b). While uncertainties remain on the potential impact of pregnancy hemodynamics in later pregnancy due to use of biomonitoring samples from the second and third trimester or post-partum, the evidence for associations between PFOA and PFOS and decreases in birth weight is consistently supported by a large number of *high* and *medium* confidence epidemiology studies and supported by evidence across other measures and fetal growth restriction (see Section 3.4.4.4 of the PFOA and PFOS Toxicity Assessments; USEPA, 2024h; USEPA, 2024i).

Additionally, the EPA disagrees with the commenter's assertion that the EPA attributed all developmental effects to PFOA and PFOS exposure. Please see section 13.4.2 of the EPA response in this *Response to Comments* document.

13.4.3 Quantified RCC Benefits Estimation

Summary of Major Public Comments and EPA Responses

The EPA received comments on the benefits analysis for RCC. Two commenters expressed concerns with the EPA's use of Shearer et al. (2021) to estimate RCC risk in benefits analysis and claimed flaws in the study related to outliers in the RCC group and inconsistent evidence of an association across epidemiological studies. One commenter stated that given what they perceive as SAB concerns and uncertainties in the modeling, further peer review is warranted. The EPA disagrees with the comments critical of the agency's use of information from the Shearer et al. (2021) study for purposes of PFOA health assessment and benefits analysis. As noted in Section 3.5.1 of the Final Toxicity Assessment for PFOA (USEPA, 2024h) and 4.1.4 of this response to public comments document, the EPA determined that Shearer et al. (2021) is a *medium* confidence study after conducting study quality evaluation consistent with the Office of Research and Development (ORD) Staff Handbook for Developing IRIS Assessments (USEPA, 2022c). The commenters failed to acknowledge multiple studies further supporting a positive association between PFOA exposure and RCC risk (Bartell et al., 2021; Vieira et al., 2013; Steenland et al., 2022). Critically, the SAB PFAS Review Panel supported the *Likely to Be Carcinogenic to Humans* designation for PFOA in its final report (USEPA, 2022d). The EPA maintains that Shearer et al (2021) has been sufficiently peer reviewed and represents the best available science for purposes of health and benefits assessment in the PFAS NPDWR. For additional information on the use of Shearer et al (2021) in the PFOA health assessment, see section 4.1.4 of the of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1774, SBC-045682 and Doc. #1774, SBC-045683 in section 4.1.4.3 in this *Response to Comments* document.

Individual Public Comments

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-053379)

3. Benefits assessment for cancer is not supported by the science

EPA quantifies the relationship between PFOA exposure and kidney cancer, specifically renal cell carcinoma (RCC). As discussed previously in these comments, and as noted by EPA, the epidemiological evidence does not support a causal association between PFOA and cancer. This concern is compounded by EPA's approach that quantified the benefits of reduced RCC using the Shearer et al. 2021 study, which the SAB expressed concerns about due to an outlier in the RCC group. As presented in Table 6-52 of EPA's economic analysis, there are significant limitations and uncertainties of the analysis of cancer benefits [FN194: Id. at page 6-121.]. While EPA asked the SAB to review the CVD modeling, the cancer benefits modeling did not undergo any peer review. Considering the shortcomings of the study used, the SAB concerns with the study, and the uncertainties in the modeling, peer review is warranted.

EPA Response: The EPA disagrees with the commenter that the "benefits assessment for cancer is not supported by the science." As discussed in detail in section 4.1.2 of the EPA response in this *Response to Comments* document, the EPA reviewed the best available science on cancer effects that stem from exposure to the PFAS considered in the rulemaking. Please see section 4.1.4 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1774, SBC-045682 and Doc. #1774, SBC-045683 in section 4.1.4.3 in this *Response to Comments* document for discussion on epidemiological evidence supporting associations between PFOA and cancer and section 4.2.2 of the EPA response in this *Response to Comments* document regarding the EPA's derivation of cancer slope factors (CSFs) for PFOA. See also responses to comments in section 4.2.2.4. The EPA disagrees with the commenter's criticism of the use of Shearer et al. (2021) in the analysis of RCC quantified benefits. Shearer et al. (2021) studied the relationship between PFOA and RCC in the U.S. general population and found strong evidence of a positive association between exposure to PFOA and RCC in humans. For more discussion on why consideration of this study is appropriate, see section 13.4.3 of the EPA response in this *Response to Comments* document and Section 6.2.2.1.3 of the EA (USEPA, 2024b). Furthermore, the SAB PFAS Review Panel supported the Likely to be Carcinogenic to Humans designation for PFOA in its final report, and after considering the SAB's input, the EPA concurs. The EPA notes that the Shearer et al. (2021) study is peer reviewed and the EPA's RCC cancer benefits modeling logically utilizes and applies this pre-existing available peer-reviewed science. Further peer review of what is merely an application of existing and available peer-reviewed science is unnecessary and unwarranted. See section 13.4.3 of the EPA response in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-053420)

f. Exposure-Response Relationships Were Improperly Selected

To calculate the health-risk reduction benefits based on serum concentrations, EPA extracts from literature or independently reanalyzes various exposure-response slope factors that are intended to demonstrate a quantitative relationship between a change in serum concentrations and a specific health effect. For both PFOA and PFOS, EPA evaluates the health effects of reductions in birth weight and increases in total cholesterol. EPA also considers increases in renal cell carcinoma risk for PFOA and increases in blood pressure for PFOS. For each endpoint, EPA selects relationships between serum levels and health effects that are not supported by the underlying studies or are based on uncertain reanalysis of data. These flawed analyses add to the misleading conclusions associated with basing the analysis on inappropriate and indistinguishable regulatory alternatives.

The exposure-response slope factor of 0.00178 per ng/mL for PFOA and renal cell carcinoma risk is apparently derived from Shearer et al (2021). This publication and its supporting information, however, do not report this value. Shearer et al (2021) instead reports odds ratios, which are not linear associations. EPA should transparently describe how it generated this exposure-response slope factor. Additionally, as described previously (see Section V.c), this study

is fundamentally flawed and did not show consistent dose-response relationships. Thus, deriving an exposure-response slope factor from a study that did not demonstrate a linear dose-response is not scientifically valid. Notably, EPA does not assess risks of cancer from PFOS exposure as part of the benefits analysis. This omission may indicate that there is not enough evidence to support a quantifiable association between PFOS exposure and cancer, which contradicts EPA's conclusions that PFOS is "likely to be carcinogenic."

EPA's approach to selection of exposure-response slope factors is scientifically flawed, lacks transparency, and disregards the biological relationship of exposure and effects. EPA should consider and discuss the exposure-response slope factors in the context of biologically relevant effects and obtain peer review for any novel analyses. EPA's analysis egregiously misrepresents any meaningful determination of health risk reduction benefits between the proposed MCL and regulatory alternatives.

EPA Response: With regard to the commenter's assertion that Shearer et al. (2021) is flawed, see sections 4.1.4, 4.2.2, and 13.4.3 of the EPA response in this *Response to Comments* document, as well as the EPA's response to comment Doc. #1774, SBC-045682 and Doc. #1774, SBC-045683 in section 4.1.4.3 in this *Response to Comments* document and Doc. #1774, SBC-053147 in section 4.2.2.4 in this *Response to Comments* document. The EPA disagrees with the commenter's assertion that the EPA is not being transparent in its description of the exposure-response factor derived from Shearer et al. (2021). The derivation is clearly described in Section E.1.5 and Section 4.2 of the Final Human Health Toxicity Assessment for PFOA (USEPA, 2024h; USEPA, 2024j) and was available in the draft assessment at the time of rule proposal (USEPA, 2023k). These documents include all the information necessary to replicate the exposure-response factor derivation. The EPA also notes that selection of Shearer et al. (2021) as the basis of a candidate CSF for PFOA was peer-reviewed by the SAB and the agency has subsequently addressed all of the SAB's concerns regarding the use of this study in the final assessment.

The EPA acknowledges that the study used to derive a CSF for RCC in the quantified benefits analysis (Shearer et al., 2021) reports odds ratios, and not CSFs. As is a commonly accepted scientific practice, the EPA uses the odds ratios reported in this study to calculate a CSF value using standard CSF calculation procedures. This entails calculating the variance of each odds ratio based on reported 95 percent confidence intervals, weighting each odds ratio based on the range of the PFOA interval, summing the weighted odds ratio interval, and calculating a central-tendency beta value. This central tendency value is multiplied by the lifetime risk of kidney cancer and the proportion of kidney cancers that are renal cell carcinoma subtypes.

The EPA disagrees with the commenter's assertion that deriving an exposure-response slope factor from a study that did not demonstrate a linear dose-response is not scientifically valid. The approach used by the EPA is supported by the *Guidelines for Carcinogenic Risk assessment* (USEPA, 2005b) and it has been applied to previous peer-reviewed assessments, including the Office of Environmental Health Hazard Assessment California Environmental Protection Agency (OEHHA) public health goals for PFOA and arsenic as well as the EPA's CSF calculations for its

2011 trichloroethylene toxicology assessment (OEHHA, 2021; OEHHA, 2004; USEPA, 2011). The use of a linear model in the observable range of the data is often a good general approach for epidemiological data because such data are frequently too limited (i.e., imprecise), and because of the assumption of linear low-dose extrapolation (USEPA, 2005b).

The EPA notes that details of the derivation of the CSF and associated analysis are extensively presented in Appendix E of the PFOA Toxicity Assessment (USEPA 2024j).

Regarding the evidence supporting associations between PFOS and cancer, please see sections 4.1.4 and 4.1.4.2 of the EPA response in this *Response to Comments* document, as well as Section 3.5.5 of the Final Toxicity Assessment for PFOS (USEPA, 2024b). The EPA disagrees with the commenter's assertion that, because the agency did not evaluate benefits of reduced PFOS exposure on incidence of renal cell carcinoma, there is "not enough evidence to support a quantifiable association between PFOS exposure and cancer, which contradicts EPA's conclusions that PFOS is 'likely to be carcinogenic." While the EPA has determined that PFOS is likely to be carcinogenic, the agency did not find consistent evidence of an association between PFOS exposure and RCC, specifically. In fact, as described in section IV of the preamble and in section 4.1.4 of the EPA response in this *Response to Comments* document, Shearer et al. (2021) and other studies on kidney cancer were not the basis of the agency's cancer classification for PFOS. As clearly stated in the EA, evidence of a positive association between PFOS exposure and kidney cancer was inconclusive (USEPA, 2024b, Section 6.2.2.1.3). The literature describing this association was both limited in scope and number of studies. Associations between PFOS exposure and RCC evaluated in Shearer et al. (2021) were not statistically significant after adjusting for other PFAS.

American Chemistry Council (ACC) (Doc. #1841, SBC-052937)

Using of Shearer et al. as the Basis for Quantifying Cancer Risks of PFOA Resulting Overstates EPA's Benefits Calculation

EPA estimates that reductions in PFOA exposure expected with the implementation of the proposed standard will lead to a reduction in the number of cases of kidney cancer (RCC) and the number of RCC-related deaths. The estimates rely on a CSF derived solely from the data reported by Shearer et al. As noted by the SAB, however, "the epidemiological studies have not consistently identified associations between PFOA and RCC; some epidemiological studies support RCC as a critical finding associated with PFOA exposure while others (with several limitations noted) have failed to detect an association between PFOA and RCC." [FN175: USEPA SAB Review, at 39.] In addition to its general concern about the RCC endpoint, the SAB cautions against EPA's use of the Shearer et al. study as the sole basis for its CSF.

Although the human and animal evidence is suggestive of a carcinogenic effect, it is not sufficient to support the conclusion that PFOA is a likely human carcinogen. In its review, the SAB does not oppose the Agency's conclusion but clearly disagrees with the sole use of the Shearer et al. data. In particular, the Board notes –

Eight of the 13 new epidemiologic studies identified in the EPA's systematic review were considered of "medium" overall confidence and the others were considered "low" confidence, whereas the NTP 2020 chronic bioassay in rats is considered a "high" confidence study. However, a CSF was derived for only one of the new medium confidence epidemiologic studies (Shearer et al., 2021), and it is not clear whether any of the other newly identified medium confidence studies support CSF development. The Panel agrees that toxicity values should only be derived from studies with at least "medium" confidence, but the draft document needs to be more transparent as to weighing the strengths and limitations of different studies to support a CSF (including both human and animal studies). [FN176: Ibid, at 40.]

In light of the uncertainty around the RCC results in the epidemiology studies, it is advisable to use the animal bioassay data (i.e., Butenhoff et al., NTP) [FN177: Butenhoff et al. 2012; NTP PFOA Bioassay Technical Report.] as the basis for the CSF. Based on the animal data, the Agency calculates a CSF range of 8.42 to 53.2 per mg/kg/day [FN178: USEPA PFOA MCLG Assessment 2023, at 4-46.] – compared to the value of 0.0293 per nanograms/kg-day for Shearer et al. This 500-fold difference in cancer potency estimates suggests the need for careful consideration prior to using epidemiology as a basis of the CSF. Rather than address the Board's concerns, EPA offers an equivocal evidence supporting possible modes of action for kidney tumors and cites a staff handbook indicating that human data "are generally preferred" for deriving toxicity values. [FN179: Ibid, at 4-59.]

EPA Response: Regarding the commenter's concerns with the EPA's use of Shearer et al. (2021) as the basis of the CSF, see sections 4.1.4, 4.2.2, and 13.4.3 of the EPA response in this *Response to Comments* document, as well as the EPA response to comment Doc. #1774, SBC-045682 and Doc. #1774, SBC-045683 in section 4.1.4.3 in this *Response to Comments* document and SBC-053147 in section 4.2.2.4 in this *Response to Comments* document. The EPA has subsequently addressed all of the SAB's concerns regarding the use of this study, as well as the supporting evidence for associations between PFOA and kidney cancer, and presents rationale for these selections in the Final Toxicity Assessment for PFOA (see Sections 3.5.5 and 4.2) (USEPA, 2024h).

The EPA disagrees with the commenter's assertion that the EPA should consider using animal studies as the basis for the CSF used in the quantified RCC benefits analysis. The EPA disagrees with the commenter's assertion that there is unacceptable uncertainty around RCC results in epidemiology studies; furthermore, the SAB agreed with the EPA's preferential use of epidemiological data for quantitative analyses and stated, "In general, the Panel agrees that it is preferable to base the CSF derivation on human epidemiological data when appropriate human data are available" (USEPA, 2022d). The EPA concluded that appropriate human data are available to quantitatively describe associations between PFOA and kidney cancer. As with data underlying noncancer RfDs, the use of human data eliminates the uncertainties associated with interspecies extrapolation and the toxicokinetic differences between species which are major uncertainties associated with the PFOA animal toxicological studies due to the half-life differences and sex-specific toxicokinetic differences in rodent species. The use of human data

also ensures that the values are based on human-relevant exposure conditions and human-relevant tumor types/sites.

The EPA's *Guidelines for Preparing Economic Analyses* (Chapter 7, USEPA, 2016a) indicates that risk assessors and economists should identify human health endpoints that are economically meaningful and linked to human well-being. The EPA's analysis of RCC benefits relies on the best available science supporting the association of PFOA and RCC in humans. As demonstrated by the estimated numbers of fatal and nonfatal cases avoided under the rule, this endpoint is economically significant.

Susan Goldhaber (Doc. #1596, SBC-053415)

May 26, 2023

Michael S. Regan, Administrator Environmental Protection Agency

1200 Pennsylvania Ave., N.W. Washington, D.C. 20460

Re: Docket ID No. EPA-HQ-OW-2022-0114, Comment on Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

Dear Administrator Regan,

As a toxicologist formerly employed at EPA, Office of Drinking Water, (1980-1988), who worked on revising the primary drinking water regulations, I am very familiar with the requirements of the Safe Drinking Water Act and the regulatory process. I am writing because I am very concerned with the underlying science supporting these regulations. I would like to submit the attached comments for your consideration.

Sincerely, Susan B. Goldhaber M.P.H.

SBG Consulting, Inc.

Comments

There are Executive Orders that strongly encourage that the benefits of a major regulation, such as PFAS Drinking Water regulation, exceed the costs. In the Economic Analysis, EPA calculated the economic benefits to the U.S. by avoiding three health outcomes that it attributed to exposure from PFOA and PFOS:

• Developmental effects (reductions in birth weight)

• Cardiovascular effects (increase in total and high-density lipoprotein (HDL) cholesterol resulting in cardiovascular disease including strokes and myocardial infarction)

• Kidney cancer

Human studies have not shown that PFOA or PFOS cause these health effects.

The available epidemiological studies suggest associations between PFOA/PFOS exposures and developmental and cardiovascular effects; however, cause-and-effect relationships have not been established for these outcomes. https://www.atsdr.cdc.gov/toxprofiles/tp200.pdf

When EPA calculates the economic benefits from avoiding these three health outcomes, they assume that these diseases are solely caused by PFAS exposure. EPA assumes that that the only reason that babies are born with lower-than-average birth weight is due to their mother's exposure to PFAS or that all cardiovascular disease is caused by PFAS exposure, ignoring the myriad of risk factors involved in these diseases. This is a major flaw, both economically and scientifically.

1. What is the basis for EPA's conclusions that PFOA or PFAS cause these adverse health effects when ATSDR and others have stated that cause-and-effect relationships have not been established?

Examining the three health outcomes:

Kidney Cancer

There are studies examining the association between PFOA and PFOS and many different types of cancer, including prostate, testicular, breast, bladder, kidney, colon, and liver. Studies of workers in PFOA/PFOS manufacturing facilities have not reported an increase in all cancer deaths and there is very limited data for an association with the other types of cancer. https://www.atsdr.cdc.gov/toxprofiles/tp200.pdf

According to EPA's Economic Analysis, "Data on the association between PFOA exposure and kidney cancer are limited but suggest a positive association between exposure and increased risk of kidney cancer."

There are three epidemiologic studies that have shown an association between PFOA and an increased risk of kidney cancer, and three studies that did not report an association. EPA based its benefits assessment on the results from a case-control study https://pubmed.ncbi.nlm.nih.gov/32944748/ that showed a positive association between PFOA exposure and kidney cancer in 324 cases and 324 matched controls.

There are several problems with this study: The samples were collected at a single point in time and are not representative of long-term exposure; the cases were more likely than controls to report being obese and to have a higher history of hypertension; and a higher proportion of cases had diminished kidney function compared with controls (but this difference was not statistically significant).

EPA calculated an exposure-response relationship based on this study and used kidney cancer statistics to calculate $217 million to $310 million in economic benefits from number of deaths avoided from this regulation.

4. What is EPA's justification for using a "suggestive" positive association between PFOS and PFOA exposure and kidney cancer to conclude that PFOS and PFOA cause kidney cancer? Why

did EPA use a flawed case-control study to calculate the economic benefits from avoiding kidney cancer and not factor in other risk factors in developing kidney factors in its analysis?

EPA Response: Regarding the commenter's concerns with the EPA's use of Shearer et al. (2021) as the basis for the CSF, see sections 4.1.4, 4.2.2, and 13.4.3 of the EPA response in this *Response to Comments* document, as well as the EPA response to comment Doc. #1774, SBC-045682 and Doc. #1774, SBC-045683 in section 4.1.4.3 in this *Response to Comments* document and Doc. #1774, SBC-053147 in section 4.2.2.4 in this *Response to Comments* document. The Final Toxicity Assessments for PFOA and PFOS present discussion on the weight of evidence for carcinogenicity of these two chemicals, as well as rationale for the EPA's cancer classifications in Section 3.5 (USEPA, 2024h; USEPA, 2024i). The commenter incorrectly states that the EPA concluded that PFOS causes kidney cancer. In fact, as described in section IV of the preamble and in section 4.1.4 of the EPA response in this *Response to Comments* document, Shearer et al. (2021) and other studies on kidney cancer were not the basis of the agency's cancer classification for PFOS.

Regarding the commenter's concern that a cause-and-effect relationship between exposure and outcomes has not been established, the EPA notes that an extensive body of epidemiological studies have shown that increased exposure to PFOA and PFOS is associated with higher risk of the health outcomes considered in the quantified benefits analyses. While research has not established a causal link between exposure to PFOA and PFOS and these outcomes, there is strong evidence of associations between exposure and adverse effects. Demonstrated causality is not necessary to quantify or value benefits, nor to meet the statutory standard of a factual record to conclude that these benefits are likely to occur as a result of treatment to comply with the MCLs, particularly when strong evidence of associations are found. See the EPA response to comment Doc. #1738, SBC-047706 in section 13.4 in this *Response to Comments* document for further discussion. The EPA disagrees with the commenter's assertion that the EPA should consider risk factors other than changes in PFAS exposure resulting from the final rule. Because the study that the EPA relied on for the relationship between PFOA exposure and RCC risk (Shearer et al., 2021) controlled for body mass index, smoking status, history of hypertension, prior sampling freeze-thaw cycles, and calendar year of blood draw, the results of the study provide odds ratios between PFAS exposure and RCC risk only.

The EPA analyzes changes in blood serum PFAS levels as a result of changes in PFAS drinking water concentrations due to the installation of treatment technology. The EPA disagrees with the commenter's assertion that the diseases quantified are assumed to be solely associated from PFAS exposure. The EPA does not make this claim in any of the documentation supporting the rulemaking. The RCC benefits estimates are quantified based on changes in blood serum PFOA levels only and do not reflect changes associated with reduced exposures from other PFAS sources or changes associated with other risk factors. Because of this modeling approach, the EPA does not account for RCC risk factors other than changes in PFAS resulting from this final drinking water rule. The EPA implements in the benefits analysis a maximum population attributable fraction (PAF) limit on total health outcome rates that are likely to result from PFAS exposure. See Section 6.1.2 Uncertainty Characterization in the final rule EA (USEPA, 2024b)

for discussion of the PAF limits. Regarding the commenter's concern with the EPA's use of Shearer et al. (2021) for estimating quantified RCC benefits, see section 13.4.3 of the EPA response in this *Response to Comments* document. Regarding the commenter's concern with the EPA's analysis of birth weight effects in infants due mother's exposure to PFAS, see section 13.4.2 of the EPA response in this *Response to Comments* document.

13.4.4 Valuation

Summary of Major Public Comments and EPA Responses

The EPA received multiple comments discussing the methods used to monetize expected health benefits under the final rule. The EPA followed the EPA's Guidelines for Preparing Economic Analyses and relied on two of the three primary methods, "cost of illness" and "willingness-to-pay," included in the Guidelines and most often used to value morbidity in an environmental context (Analyzing Benefits (Chapter 7); USEPA, 2016a). One commenter stated that COI metrics do not meet the requirements set out by Circular A-4 and other best practices to use consumers' willingness-to-pay (WTP) metrics. The EPA agrees that WTP estimates are conceptually appropriate when estimating benefits because they attempt to capture pain and suffering and other quality-of-life effects in addition to the medical expenditures and opportunity costs caused by adverse health effects. Applicable WTP data, however, are not always available. Circular A-4 clearly states that agencies "should utilize valuation methods that are appropriate for regulatory circumstances" and if WTP data are not available to support monetization the agencies may consider alternative approaches. Although use of COI estimates understates benefits of avoiding adverse health effects, the EPA disagrees that these estimates are misleading. The agency carefully described limitations and the expected magnitude and directional impact uncertainty sources have on the quantified benefits in the EA (see Chapter 7 of USEPA, 2024b).

One commenter noted that using WTP monetization methods is appropriate in some cases when estimating rule benefits. The EPA agrees that, when applicable WTP data are available, these metrics can be used for evaluating benefits. In the EA for the final rule, based on this and other comments, the EPA performed a sensitivity analysis that relied on WTP-based monetization metrics to estimate RCC and bladder cancer benefits. While RCC benefits calculated using WTP-based approaches were, on average, similar to the magnitude of benefits estimated using COI approaches, bladder cancer benefits increased by approximately 20 percent when using WTP-based approaches (see Chapter 6 of USEPA, 2024b and Appendix O of USEPA, 2024c for detailed information). The EPA believes these additional valuation analyses using a second, independent valuation method further support that there are substantial quantified benefits that will result from implementation of this final regulation. This further supports the Administrator's determination that the quantified and nonquantifiable benefits of the rule justify the quantifiable and nonquantifiable costs. One commenter recommended using WTP-based monetization approaches for valuing changes in low birth weight cases. The EPA notes that the analysis implemented in the final rule requires WTP or cost metrics per incremental change in birth weight estimated under the final rule and regulatory options. Such WTP metrics are not available in the economic literature. Therefore, the EPA relied on incremental COI changes per change in

grams of birth weight provided by the EPA's National Center for Environmental Economics (Klein and Lynch, 2018).

One commenter criticized the EPA's use of COI estimates that did not include broader opportunity costs (e.g., opportunity cost of time such as the number of workdays missed) related to low birth weight, cardiovascular disease, and renal cancer risks. They note this "likely results in a significant underestimate of the benefits." The EPA relied on the best available economic information to monetize changes in risks of these endpoints and notes that COI metrics typically only account for avoided medical expenditures. The EPA agrees with the commenter that additional costs (such as opportunity costs) are not captured in the COI estimates used for benefits valuation and that benefits relying on COI information for valuation are likely underestimated as a result.

Individual Public Comments

Earthjustice et al. (Doc. #1808, SBC-046137)

17. Is it possible to incorporate broader opportunity costs into the cost-of-illness (COI) estimates for reduced risks of low birth weight, cardiovascular disease, and renal cancer?

The Agency correctly includes avoided direct expenditures for medical care, as well as broader opportunity costs – namely the opportunity cost of time (e.g., missed work days) – in the COI estimates for reduced risks of bladder cancer. But these broader opportunity costs are not accounted for in the COI estimates for reduced risks of low birthweight, cardiovascular disease, and renal cancer. The COI estimates for these three non-fatal health outcomes only account for avoided medical expenditures. EPA recognizes this shortcoming in various parts of Chapter 6, and points out that these exclusions are due to the lack of available estimates in the literature.

Nonetheless, this omission likely results in a significant underestimate of the benefits. For example, Table 6-43 shows that for bladder cancer (the one non-fatal health outcome where broader opportunity cost estimates are included), the opportunity cost of time beyond medical expenditures makes up 27% to 32% of the total COI estimates for the first year. If a similar proportional scaling is applicable to the other non-fatal health outcomes, then the missing portion of the COI-based benefits for non-fatal cardiovascular disease, renal cancer, and low birthweight cases would be substantial. In the final rule EA, the Agency should consider whether it is possible to incorporate these broader opportunity costs into their COI estimates for these three non-fatal health outcomes.

Even if the inclusion of the broader opportunity costs into these COI estimates is legitimately not possible given the available literature, EPA should still consider a bounding exercise where the available COI estimates for low birth weight, cardiovascular disease, and renal cancer are scaled-up based on the COI estimates for bladder cancer, or perhaps for more similar non-fatal health endpoints where the available literature does provide more comprehensive COI estimates. Such a bounding exercise would require considerable judgement, but at the same time, we know that

assuming the opportunity cost of time associated with these adverse health outcomes is zero (as the EPA currently does) is not correct.

18. Did EPA consider using willingness to pay (WTP) estimates to monetize reductions in non-fatal human health outcomes?

The use of COI estimates to monetize the benefits of reduced risks of non-fatal health outcomes, as EPA does, is standard (EPA 2014), and in my professional experience is generally deemed acceptable for policy analysis. Nonetheless, a theoretically more appropriate approach (when available) is to use estimates of WTP (OMB 2003). For example, WTP estimates better account for "pain and suffering and other quality-of-life effects" (OMB 2023, pg. 48). It is unclear whether such estimates are available in the peer-reviewed literature, but EPA should include a review of the literature and discussion of why available WTP estimates are or are not appropriate to use in the EA.

I would also like to point out that the Organisation for Economic Co-operation and Development (OECD) has implemented stated preference studies that estimate the public's WTP for reductions in the risks of various non-fatal health outcomes that result from reduced exposure to toxic chemicals (OECD, n.d.). Their research includes reductions in the risks of adult asthma, chronic kidney disease, fertility loss, and of particular relevance to the current EA, cases of low birth weight. It is unclear whether the results of the OECD's studies are yet available, but if they are available now or by the time of the final rule EA is being conducted, then the Agency should consider using such estimates (when applicable) in lieu of the current COI estimates.

EPA Response: Regarding the commenter's assertion that opportunity costs should be included in the final rule quantified benefits analysis, see section 13.4.4 of the EPA response in this *Response to Comments* document. The opportunity costs are typically estimated based on lost productivity costs. The lost productivity costs are a function of duration and severity of the primary health effects, potential side effects associated with treating the primary condition, as well as mental health impacts stemming from the disease. Therefore, the opportunity costs could differ significantly between fatal and non-fatal health outcomes, outcomes that require surgical versus non-surgical intervention or more frequent in-patient procedures. Thus, the EPA disagrees with the commenter that a similar proportion of opportunity costs for bladder cancer or other similar non-fatal health endpoints could be generalized to other health outcomes as the proportion of total costs that may be attributed to opportunity costs likely varies considerably.

The commenter noted ongoing OECD Surveys of willingness-to-pay to avoid negative chemicals-related health effects efforts to establish internationally comparable values for WTP to avoid adverse health effects due to chemical exposure for use in policy evaluation. The first round of surveys was implemented in 2022 and included a survey focusing on valuation of Very Low Birth Weight (VLBW). The OECD working paper by Scasny et al. (2023) reports the estimated value per case of VLBW in the U.S. of 1.389 million ($2022) and notes that this value may implicitly include infant mortality. The EPA disagrees with the commenter that

this value can be readily used in place of the COI-based birth weight valuation employed in the final rule EA. The EPA's benefits analysis modeled the impact of PFAS reductions on the entire distribution of birth weights rather than VLBW, which occurs in 1.38 percent of all births (CDC, 2023), and addressed infant birth weight-related mortality over the entire range of the birth weight distribution.

Earthjustice et al. (Doc. #1808, SBC-046113)

Fourth, as noted above, EPA should account for opportunity costs, in addition to avoided medical expenditures, in its final cost-of-illness estimates for non-fatal health effects associated with PFAS exposure. [FN138: Guignet 2023 at 11–12.] As Dr. Guignet explains, "assuming the opportunity cost of time associated with these adverse health outcomes is zero (as the EPA currently does) is not correct" and likely yields a substantial underestimate of the COI-based benefits for reducing non-fatal adverse health effects. [FN139: Id.] While recognizing limitations in the relevant literature, Dr. Guignet has identified multiple approaches for EPA to account for these benefits in the final EA.

EPA Response: Regarding the commenter's assertion that the EPA should account for opportunity costs in its estimates of non-fatal health effects, see section 13.4.4 of the EPA response in this *Response to Comments* document. While the EPA relied on the best available literature to select COI metrics for use in the quantified benefits analysis, the EPA agrees that these metrics have potential limitations. See Section 6.8 of the final EA for a discussion of valuation-based limitations of the final rule analysis.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046011)

Dollar Year

EPA uses 2020 prices as the data source for its projection of costs to 2026. Producer prices have shot up since 2021 due to supply shortages, disruption of trade due to the global pandemic, and financial assistance provide to individuals, businesses, and the economy during the pandemic. EPA chose as the baseline year for its analysis a year that is not representative of current conditions and the likely near-term future when most of the rule's expenditures will be made. Inflation appears to be likely to persist in the near-term. Moreover, the economic policies underway to reduce inflation – raising federal interest rates and reducing the money supply – are increasing the cost of capital, a major input factor into this proposal's costs. By selecting a baseline year for the analysis that had low interest rates and prices and that is not representative of the near-term's economic conditions, EPA is artificially lowering expected compliance costs.

Valuation

EPA uses Value of Statistical Life (VSL) estimates to estimate the economic value of avoided premature deaths [FN47: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," 2–

4.]. EPA approximates VSL growth using a compound annual growth rate of projected values to obtain a VSL suitable for valuation of mortality risk reductions during the period of analysis (2023-2104). As a base value, EPA used a VSL estimate of $4.8 million ($1990, 1990 income year), which is the central tendency of the VSL distribution recommended for EPA's regulatory impact analyses. In the EA, this estimate is adjusted for inflation and income growth. Estimates used in the EA range from $10.7 million in 2023 to $17.7 million in 2104.

As discussed above, EPA did not model the uncertainty in its VSL estimate. More fundamentally, EPA did not include the effect of income growth on other opportunity costs in the rule. If consumers' willingness to pay to avoid mortality risk increases with income, then it is reasonable to assume that consumers' willingness to pay to avoid other economic displacements and adverse effects also increases with income. By including income growth in the valuation of benefits but not costs, EPA biases the results.

EPA used the cost of illness (COI) valuation approach to estimate the economic value of avoided morbidity (non-fatal heart attacks and ischemic strokes, birth weight decrements, and cancers). The COI-based values used in the EA reflect medical care expenditures and opportunity costs associated with condition management and treatment. COI metrics do not meet the requirements set out by Circular A-4 and other best practices to use consumers' willingness-to-pay (WTP) metrics [FN48: U.S. Office of Management and Budget, "Circular A-4: Regulatory Analysis," September 2003.].

In conclusion, EPA's EA for the proposed rule departs from analysis required by Circular A-4. As a result, the EA portrays misleading estimates of the social benefits and the social costs and fails to describe the uncertainty in these estimates.

EPA Response: See the EPA response to comment Doc. #1738, SBC-046007 in section 13.9 in this *Response to Comments* document for the EPA's response to points raised on Value of Statistical Life (VSL) uncertainty. With respect to the commenter's assertion that the agency's analysis artificially lowers expected compliance costs due to the baseline year selected for the analysis not being representative of near-term economic conditions, the EPA notes that the analysis utilized the most recent available price index for both the proposal and final rule. For the proposed rule, the most recently available price index data were from the 2020 dollar-year. The final rule analysis has been updated using a 2022 dollar-year, which are the most up to date data (see sections 13.3.3 and 13.3.4 of the EPA response in this *Response to Comments* document; see the EPA response to comments Doc. #1585, SBC-042777 and Doc. #1623, SBC-052828 in section 13.3.3 in this *Response to Comments* document). Regarding the commenter's notes that the EPA relied on COI instead of WTP metrics, see section 13.4.4 of the EPA response in this *Response to Comments* document. The EPA notes that the EPA's *Guidelines for Preparing Economic Analyses* (Analyzing Benefits (Chapter 7); USEPA, 2016a) include COI as one of the three primary methods most often used to value morbidity in an environmental context.

13.4.5 Other Topics

The EPA received comments on other EA benefit-related topics including the presentation of benefits and costs and the EPA's analysis for Hazard Index PFAS. One commenter raised that the EPA did not provide data to support the analysis of Hazard Index benefits. The commenter compared quantified benefits for the proposed option (PFOA and PFOS MCLs of 4.0 ppt and Hazard Index of 1.0) and Option 1a (PFOA and PFOS MCLs of 4.0 ppt) and incorrectly stated that the EPA claimed benefits for Hazard Index PFAS, specifically PFHxS, PFNA, HFPO-DA, PFBS, without providing health effect potency factors. The EPA clarifies that in the proposed option and for the final rule (PFOA and PFOS MCLs of 4.0 ppt each, PFHxS, PFNA, HFPO-DA, of 10 ppt each and Hazard Index of 1), the quantified benefits represent avoided CVD, BW, RCC, and BC morbidity and mortality from PFOA and PFOS exposure reductions and the quantified costs represent the treatment costs associated with PFOA, PFOS, and PFHxS removal. For Option 1a, quantified benefits represent the same avoided morbidity and mortality health endpoints as the proposed option (and also the final rule), however, only PFOA and PFOS treatment costs are reflected. The additional quantified benefits estimated under the proposed option and also for the final rule (relative to the quantified benefits estimated under Option 1a) are a result of PFOA and PFOS co-removal from PFHxS treatment. Inclusion of the Hazard Index and individual MCLs for PFHxS, PFNA and HFPO-DA will trigger more systems to treat (as shown in Section 4.4.4 of the EA) and provides enhanced public health protection by ensuring reductions of these additional compounds when present above the Hazard Index of 1 or individual MCLs for PFHxS, PFNA and HFPO-DA. The EPA further clarifies that the EPA performed a qualitative benefits analysis for Hazard Index PFAS, consistent with recommendations in the EPA's *Guidelines for Preparing Economic Analyses* to discuss qualitative benefits when quantitative analysis is not possible (Analyzing Benefits (Chapter 7); USEPA, 2016a). Due to data limitations, the EPA was unable to quantify many categories of benefits from avoided adverse effects associated with Hazard Index PFAS; however, PFNA birth weight effects were quantified in a sensitivity analysis and are described in USEPA (2024c). For the final rule, after considering public comment, the EPA completed a sensitivity analysis of costs associated with the Hazard Index MCL and individual MCLs for PFHxS, PFNA and HFPO-DA (see Appendix N of USEPA, 2024c for the presentation of methods and results).

One commenter referenced OMB Circular A-4 to describe that the EPA is required to present undiscounted benefits and costs within the HRRCA. For the final rule, after considering this comment, the EPA generated the undiscounted stream of quantified benefits and costs (see appendix P of USEPA, 2024c). Undiscounted results are now provided for all impacted water systems for all years of the analysis period.

<u>American Chemistry Council (ACC) (Doc. #1841, SBC-044844)</u>

The Economic Analysis Overestimates Quantifiable Benefits of the Proposal

EPA's estimate of the benefits of its proposal relies on the quantification of predicted reductions in the incidence of kidney cancer (despite SAB warnings not to use the cited key study as a basis, as summarized below), cardiovascular disease, and reduced infant body weight associated with reduction of PFOA and PFOS in drinking water. The Agency's estimate also includes a predicted reduction in bladder cancer incidence associated with a reduction of disinfection byproducts (DBPs) – namely trihalomethanes or THMs associated with the implementation of treatment technologies to comply with the proposed MCLs. The Agency also identifies several other health effects that it concludes are nonquantifiable, because of a lack of clear supporting evidence, to support its benefits conclusion. Although the benefits summary includes estimates associated with the proposed HI MCL, the Agency has not provided any details for how those estimates were developed.

The Agency's analysis runs counter to the recommendations of the SAB and/or to the weight of evidence for the endpoints selected for quantification. Moreover, the decision to include predicted benefits from the reduction of DBPs is overly speculative and appears to ignore a robust regulatory process underway with the Water Office. EPA has provided little, if any, information on the benefits expected with the implementation of the HI MCL.

EPA Response: The EPA disagrees with the commenter that the EA overestimates quantifiable benefits of the proposal. For the EPA's response to this comment, see section 13.4 in this *Response to Comments* document. For comments raised related to cardiovascular disease, birth weight, and kidney cancer, see sections 13.4.1, 13.4.2, and 13.4.3, respectively, of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter that the EPA's predicted reductions in the incidence of kidney cancer relies on a study that SAB warned not to use as a basis. SAB cautioned the EPA against using the relationship between *PFOS* and kidney cancer from Shearer et al. (2021) because the findings on this relationship were less definitive than the findings between *PFOA* and kidney cancer from Shearer et al. (2021) (USEPA, 2022d). As described in Section 6.5 of the EA (USEPA, 2024b), the EPA considered only the relationship between PFOA exposure and kidney cancer in its benefits analysis. Regarding the EPA's confidence in associations between PFOA exposure and increased risk of RCC as reported by Shearer et al. (2021) and the kidney cancer evidence base in general, please see section 4.1.4 and 4.2.2.4 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1774, SBC-045682 and Doc. #1774, SBC-045683 in section 4.1.4.3 in this *Response to Comments* document and Doc. #1774, SBC-053147 in section 4.2.2.4 in this *Response to Comments* document.

The EPA disagrees with the commenter's assertion that "[t]he Agency's analysis runs counter to the recommendations of the SAB and/or to the weight of evidence for the endpoints selected for quantification." For the EPA's response to comments regarding the SAB's recommendations on weight of evidence for adverse health effects, see section 4.1.3 in this *Response to Comments* document.

The EPA disagrees with the commenter's statement that "although the benefits summary includes estimates associated with the proposed Hazard Index MCL, the agency has not provided any details for how those estimates were developed." The commenter is incorrect when stating the EPA did not provide information on the benefits expected with implementation of the Hazard Index MCL and that the agency lacks clear supporting evidence to "support its benefits conclusion." The EPA discusses the benefits of PFHxS, PFNA, HFPO-DA and PFBS removal qualitatively and the agency discusses the benefits of PFNA removal in Appendix K of the EA (USEPA, 2024c). Due to data limitations, quantitative national benefits estimates presented in the summary tables of the EA do not include quantified benefits solely associated with removing these regulated PFAS. However, SDWA does not require that all benefits be quantified but rather expressly requires consideration of nonquantifiable benefits. Furthermore, the EPA notes that benefit estimates are increased under the final rule as compared to Option 1a because more systems must apply treatment in order to comply with the Hazard Index. This results in co-removal of PFOA and PFOS, increasing quantified national benefits. Hazard Index benefits are discussed extensively in Chapter 6 of the EA, and they include anticipated reductions of developmental, cardiovascular, immune, hepatic, endocrine, metabolic, reproductive, musculoskeletal, and carcinogenic effects from reduced exposure to PFHxS, HFPO-DA, PFNA, and PFBS; see section 13.4 of the EPA response in this *Response to Comments* document and Chapter 6.2.4 of the EA for additional information on the nonquantifiable impacts of PFHxS, HFPO-DA, PFNA, and PFBS and non-regulated co-occurring PFAS. The EPA disagrees that the benefits from the reduction of DBPs are speculative. Please see section 13.7 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1774, SBC-045705 in section 13.7 in this *Response to Comments* document for further discussion. The commenter is also incorrect that the DBP analysis ignores the robust regulatory process underway at the EPA where the agency is considering updating some of its microbial and DBP regulations. While a separate regulatory process is underway, the DBP reduction benefits from total organic carbon (TOC) co-removal are solely attributable to this PFAS NDPWR. In other words, the DBP co-removal benefits estimated for the final rule will be realized, irrespective of whether the EPA proceeds with proposing and finalizing a separate regulatory action that to update some of the agency's existing microbial and DBP regulations. Furthermore, the benefits of each respective action will not be the same as the rule conditions will differ. The EPA has closely reviewed this DBP co-removal analysis to ensure there is a conservative estimate of benefits; any benefits considered are only those that will be delivered in addition to those already realized under the agency's existing DBP drinking water rules. See section 13.7 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1841, SBC-044845 in section 13.7 in this *Response to Comments* document for further DBP co-removal discussion. Additionally, the other regulatory process referenced by the commenter has not reached the proposal stage. Should that rule be proposed at some point in the future, the EPA will closely evaluate the impacts of the rule to ensure no double counting of benefits, if applicable. Finally, the EPA notes that the same organizational unit within the agency is responsible for both the PFAS and microbial and DBP activities. Hence, organizationally and institutionally, these regulatory efforts will be fully integrated.

American Chemistry Council (ACC) (Doc. #1841, SBC-044847)

Key Information Has Not Been Made Public

According to the Office of Management and Budget's (OMB) Circular A-4, [FN195: Circular A-4 issued on September 17, 2003 provides OMB guidance to Federal agencies on the development of regulatory analysis under Section 6(a)(3)(C) of Executive Order 12866 of September 1993, as amended, the Regulatory Right to Know Act (31 USC 1105 note) and a variety of related authorities. (OMB Circular A-4)] an agency "should include separate schedules of the monetized benefits and costs that show the type and timing of benefits and costs, and express the estimates in this table in constant, undiscounted dollars." Transparency requires that this be done, not just in the aggregate, but for each of the 36 types of model public water systems (PWS) that serve as the foundation for the Agency's analysis.

A search of the rulemaking docket fails to unearth this information. The stream of undiscounted annual benefits and annual costs across PWS model types has not been made available. In addition, the Agency has not provided the variability of benefits and net benefits across PWS model types, which is odd in that the Agency has provided the variability of costs across PWS model types. The missing information, if provided, would allow a reader to identify important regulatory alternatives that could provide more net benefits than those considered in EPA's economic analysis. For example, if EPA estimates negative net benefits for certain types of water systems, it suggests that consideration of a regulatory alternative with higher or positive net benefits than that proposed. This would be true if benefits or net benefits vary widely across public water systems.

EPA Response: As described in section 13.4.5 of the EPA response in this *Response to Comments* document, the EPA has provided the undiscounted stream of benefits and costs for each year of the period of analysis in the HRRCA for the final rule. The EPA notes that SDWA requires the EPA to consider nonquantifiable benefits. Although the undiscounted results are helpful in understanding how quantified benefits and costs are distributed over the period of analysis, considering only the undiscounted results solely to determine net benefits as the commenter suggests would not be compliant with the SDWA because there are many nonquantifiable benefits and costs that are not reflected in the undiscounted results that the EPA considered in determining the total benefits and costs of the action. Additionally, the EPA disagrees with the commenter's recommendation to generate undiscounted results for each PWS strata included in the SafeWater MCBC model; see section 13.2 of the EPA response in this *Response to Comments* document. First, nowhere in executive order 12866 or OMB's Circular A-4 guidance does it state an agency should explicitly list this information at this level of resolution. As a statistical model, the SafeWater MCBC model requires a significant level of computational power. Generating results at the PWS strata resolution is computationally intensive and the length of the tables generated would not be useful to an understanding of the costs and benefits of this action. The EPA has instead focused on generating information that provides the best information at an appropriate scale to inform the agency's decision making; this would not include generating the undiscounted stream of results across 36 different PWS types

as the commenter requests since such information neither helps the agency makes decisions nor helps commenters understand the costs and benefits of the rule. The SafeWater MCBC model instead appropriately focuses on the national level annualized costs and benefits of the rule. In short, generating results at that resolution are not specified under the OMB's Circular A-4 guidance and would have limited utility in determining net benefits due to the nonquantifiable benefits and costs not reflected. The economic analysis for the final PFAS NPDWR is compliant with the SDWA HRRCA requirements, and the suite of information presented in the EA is comprehensive in enabling decisionmakers and the public to understand the estimated impacts of the rulemaking.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043096)

Finally, the benefits analysis includes several assumptions that are not clearly and consistently discussed by the Agency.

EPA Response: The EPA disagrees with the commenter's statement that assumptions are not clearly or consistently discussed in the EA. The EPA has clearly discussed all assumptions and the expected impacts of those assumptions on estimated benefit and costs in the EA. Specifically, please see Section 6.8 in the EA for potential effects of various assumptions on the estimated benefits of the proposed MCLs (i.e., overestimated, underestimated, uncertain) and a summary of limitations inherent in the analysis of benefits (USEPA, 2024b).

American Chemistry Council (ACC) (Doc. #1841, SBC-044846)

EPA Does Not Provide Evidence to Support the Benefits Attributed to the HI MCL

A comparison of the analysis for the Preferred Option to those for Option 1A shows that EPA attributes a small portion of the annual quantifiable benefits of its proposal to implementation of the HI MCL: $2.6 million for birth weight, $8.4 million for CVD, $5 million for RCC, and $820,000 for bladder cancer. [FN192: Estimates are based on the Expected Value at a 3-percent discount rate. (See USEPA Economic Analysis, pages 6-48, 6-68,6-77, and 6-106.) The estimates are slightly less at a 7-percent discount rate.] EPA has not provided potency factors for any of these health effects for the four PFAS included in the HI MCL. The Agency's overview of human and animal evidence, moreover, notes that there is no evidence (or no data) to support an association between any of the four substances and RCC or CVD or between PFBS and birth weight. [FN193: USEPA Economic Analysis, at 6-11, 6-12, 6-14. The overview indicates epidemiology data for PFNA and animal data for HFPO-DA indicating a report of reduced birth weight.]

Had EPA quantified the potential health risks associated with these four substances, moreover, it is still not possible to estimate the benefits of the HI MCL without data on their occurrence in the nation's drinking water. EPA has acknowledged that it does not have nation-wide data on the occurrence of HFPO-DA and that the small number of detections for PFNA and PFBS in the UCMR 3 survey do not provide a sufficient basis for estimating occurrence through modeling.

[FN194: Cadwallader et al. 2021.] While PFHxS was included in the Agency's occurrence modeling, the results suffer from the same shortcomings as those for PFOA and PFOS.

EPA Response: The EPA disagrees with the commenter's suggestion that the EPA does not provide evidence to support benefits attributed to the Hazard Index MCL. See section 13.4 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1774, SBC-045679 in section 13.4.5 in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045679)

b. EPA Has Not Conducted a Benefits Analysis for the HI MCL, in Violation of the SDWA

SDWA [sec]1412(b)(3)(C)(i) requires that EPA "shall" for each alternative MCL considered, publish and seek comment on an analysis of the quantifiable and nonquantifiable health risk reduction benefits and costs of the proposed rule. As described above in Section IV.d, EPA did not consider any alternatives for either the HBWCs or the HI MCL itself, contrary to the SDWA requirements. In addition, EPA failed to conduct any analysis of the benefits or costs of the HIMCL, also in violation of the SDWA. EPA acknowledged in its Proposed Rule that it "has not separately presented changes in quantified costs and benefits" for the "HI approach". 88 FR 18638, 18671. Similarly EPA stated that it "has not separately quantified the benefits and costs for the alternative approach to regulate PFHxS, PFNA, PFBS, and HFPO-DA with individual MCLs instead of the HI." [FN50: Because the individual HBWCs for the HI substances function as individual MCLs (because an exceedance of one HBWC would exceed the HI MCL), establishing individual MCLs for the HI-PFAS is not an "alternative approach" but rather a description of the proposed action.] Id.

Given that the HI MCL can be exceeded by a vanishingly small amount over the nonpeer reviewed HBWCs (for example, 2001 ppt PFBS, where the HBWC is 2000 ppt), and that the HI MCL can be exceeded by a combination of the HI-PFAS all below HBWCs, EPA's failure to engage in SDWA-required analysis of the benefits of the proposed HI MCL leaves the public entirely without information as to the potential benefits and costs of the Proposed Rule. Moreover, any assumption by EPA of a measurable benefit related to the HI MCL is implausible. EPA proposes setting the HI MCL at the same level as the HI MCLG. EPA admits in the Proposed Rule that the MCLG represents "a level at which no known or anticipated adverse effects on the health of persons is expected to occur and which allows for an adequate margin of safety." 87 FR 36848 (March 29, 2023). Similarly, EPA set the PFBS HBWC at the same level as its lifetime health advisory for PFBS. EPA states that its "lifetime health advisories identify levels to protect all people, including sensitive populations and life stages, from adverse health effects resulting from exposure throughout their lives to…PFBS in drinking water." [FN51: See https://www.epa.gov/sdwa/questions-and-answers-drinking-water-health-advisories-pfoa-pfos-genxchemicals-and-pfbs#:~:text=4.-,What%20is%20a%20lifetime%20health%20advisory%3F,or%20PFBS%20in%20drinking%20water.] EPA goes on to state that "the health advisory levels were calculated to offer a margin of

protection against adverse health effects." In other words, EPA's Proposed Rule would set an enforceable standard at levels it concluded is protective against potential risks, with an adequate margin of safety, rather than determining an appropriate regulatory level based on the considerations enumerated in the SDWA.

EPA's failure to prepare any analysis of the benefits or costs of the HI MCL not only violates the SDWA, but also violates the APA's requirement that the Agency engage in notice and comment rulemaking. Without providing the analysis required by the SDWA for the HI MCL, the public is precluded from meaningfully commenting on the potential benefits and costs of the Proposed Rule.

EPA Response: The EPA disagrees with the commenter's statutory analysis; the statute does not require the EPA to propose or analyze a specific number of alternatives. The statute does require that the EPA evaluate those alternatives that it considers, and the EPA has done so here. The commenter incorrectly states that the EPA has not evaluated the benefits or costs of the Hazard Index MCL. The information on benefits and costs of the Hazard Index MCL is discussed in Chapter 6.2.4 of the EA. As a result, the EPA disagrees with the commenter's assertion that the quantified benefits analysis is in violation of SDWA. See section 13.3.2 of the EPA response in this *Response to Comments* document regarding costs associated with the Hazard Index and section 13.4 of the EPA response in this *Response to Comments* document regarding the EPA's benefits assessment for the Hazard Index. The EPA also disagrees with the commenter's assertion that the agency failed to "prepare an analysis of the benefits or costs of the HI MCL" and that the agency violated SDWA and APA requirements. As required by SDWA, the agency considered both the quantifiable and nonquantifiable costs and benefits associated with compliance with the rule, including removal of the PFHxS, PFNA, HFPO-DA, and PFBS. The agency's assessment of quantifiable and nonquantifiable costs and benefits of the Hazard Index were included in the proposed rulemaking for public comment. For additional information, please see section 5.1.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1845, SBC-046056 in section 5.1.3 in this *Response to Comments* document.

The agency also disagrees with the commenter that the EPA did not consider a sufficient range of regulatory alternatives, see section 5.1 of the EPA response in this *Response to Comments* document. As described in Chapter 2.1 of the final rule EA, the EPA presents benefits and costs for the final rule as well as three regulatory alternatives.

The agency received comments on whether establishing traditional MCLGs and MCLs for PFHxS, HFPO-DA, PFNA, and PFBS instead of or in addition to the Hazard Index approach would change public health protection, improve clarity for the rule, or change costs. After considering these comments, in the final rule, the EPA has established individual MCLs for three of these PFAS. Additionally, for the final rule the EPA has separately estimated national level marginal costs associated with the individual MCL for PFHxS if this MCL were to be promulgated in the absence of the Hazard Index; see Chapter 5.1.3 of the EA for details. The EPA has also estimated the marginal costs for the individual PFNA and HFPO-DA MCLs if there

was no Hazard Index in the sensitivity analysis found in Appendix N.4 of the EA. See section XIII of the FRN for further discussion of why the EPA added individual MCLs for HFPO-DA, PFHxS, and PFNA. Furthermore, because the EPA has clarified that the Hazard Index MCL and the MCLs for PFHxS, PFNA, and HFPO-DA are one significant figure instead of two significant figures as proposed, the EPA notes there is a reduction in burden associated with the Hazard Index MCL (even by including the individual MCLs for PFHxS, PFNA, and HFPO-DA) between proposal and final. See discussion in sections 4.3.4 and 5.1.7 of the EPA response in this *Response to Comments* document.

Finally, the commenter's statement that "EPA's Proposed Rule would set an enforceable standard at levels it concluded is protective against potential risks, with an adequate margin of safety, rather than determining an appropriate regulatory level based on the considerations enumerated in the SDWA" is based on a fundamental misunderstanding of the statutory mandate for setting an MCL. As a general matter, the statute requires the EPA to set the MCL "as close to the MCLG as feasible," SDWA Section 1412(b)(4)(B), so the statute itself mandates that the MCL be equivalent to the MCLG – the level that is protective against potential risks with an adequate margin of safety -- if that is feasible.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046013)

Drinking Water Intake/Body Weight Data

Consumption

For water ingestion and daily dose estimation, we use data distributions from EPA's Exposure Factors Handbook [FN68: U.S. Environmental Protection Agency, "Exposure Factors Handbook," 2011, https://www.epa.gov/expobox/about-exposure-factors-handbook.]. EPA revised the water ingestion information in 2019 in the Handbook to include more recent data. The analysis uses the consumers-only, direct and indirect drinking water intake values to construct an intake distribution for the U.S. population.

Figure 6: Probability Distribution of Drinking Water Ingestion Rate [FN69: Figure 4 is a graphical description of data in EPA's Exposure Factors Handbook (EFH).]

[Figure 6: see docket ID EPA-HQ-OW-2022-0114-1738]

Figure 4 shows the probability distribution of direct and indirect public drinking water consumption by age group and other sensitive subgroups.

Population Distribution of PFOS Dose from Drinking Water Consumption

The Drinking Water Dose (DWD) is a translation of the drinking water intake to a dose metric. Values of DWD of PFOS before and after the proposed rule are determined so that they can be compared against the available toxicology information. It is calculated by multiplying a value taken from the drinking water concentration distribution and a value taken from the drinking water intake distributions.

Duration

The analysis assumes people consume drinking water from the same water source for their lifetimes, consistent with EPA's approach.

Human Equivalent Dose (HED) for Different Diseases

The analysis searched the scientific literature to find studies that employed approaches that encompass more potential adverse effects and that analyze this data in an approach consistent with benefit-cost analysis. A paper by Chen et al. that integrated human and animal cellular response data into a probabilistic risk assessment of PFOS is the primary source for the benefit estimate [FN70: Qiran Chen, Wei-Chun Chou, and Zhoumeng Lin, "Integration of Toxicogenomics and Physiologically Based Pharmacokinetic Modeling in Human Health Risk Assessment of Perfluorooctane Sulfonate," Environmental Science & Technology, 2022.].

In the paper, Chen et al extracted toxiogenomic dose-response data and other data from a public repository of in vivo animal and in vitro human high-throughput studies [FN71: Chen, Chou, and Lin, 3624.]. Studies of at least three different doses of PFOS were identified in mice, rats, and human cells. The results were filtered to identify the differentially expressed genes. These genetic responses were enriched by applying a disease ontology approach to cluster the genetic changes into disease pathways.

Applying a Bayesian dose-response model to this genetic data from animal studies and in vitro human cell data, the authors developed benchmark doses (BMDs). The authors selected a ten percent change as the benchmark response, the change significant enough to indicate that the PFOS concentration was altering cellular function. Finally, the authors used a physiological based pharmacokinetic (PBPK) model to convert the BMDs to human equivalent doses (HEDs). Each HED is a probability distribution of cellular response for that disease by dose. The paper and the supporting information contain more detailed information on the author's approach.

The Chen et al. drew on data from different concentrations of PFOS exposure to different cells and from different exposure durations [FN72: Chen, Chou, and Lin, 3267.]. The analysis selected the HEDs from the liver cells and derived from 14 days of exposure since

(1) it yielded the most potential adverse effects;

(2) studies show that the body tends to deposit longer chain PFAS in liver tissue; and,

(3) the HEDs were lower than other results. This selection may overestimate the potential adverse effects and social benefits. Chen et al. identified 108 responses to disease pathways in the 14-day liver tissue results [FN73: Chen, Chou, and Lin, 3626.]. The disease ontology and disease groups are listed in Table 4.

Table 3: Human Equivalent Dose (HED) for Different Diseases (ng/kg-day)

[Table 3: see docket ID EPA-HQ-OW-2022-0114-1738]

These 108 HEDs cover a wide range of possible health effects. For example, the analysis includes 46 different types of cancers and tumor formation.

The authors applied a 30-fold uncertainty factor to the HEDs derived from animal data to reflect animal-human extrapolation and human variability and a 10-fold uncertainty factor to human HEDs to reflect population variability [FN74: Chen, Chou, and Lin, "Integration of Toxicogenomics and Physiologically Based Pharmacokinetic Modeling in Human Health Risk Assessment of Perfluorooctane Sulfonate."]. As an additional safety factor, our analysis applies a uniform 30-fold uncertainty factor to all HEDs and divide the HEDs by this factor.

As shown in Table 4, the analysis groups the 108 HEDs into five disease groups: cancer, immunotoxicity, neurological, cardiovascular disease (CVD), and endocrine response (ER). Each HED is a probability distribution based on dose. Following the practice of fitting a distribution to a series of HED values shown in Figure 4 of Chou and Lin, a distribution is fitted on the HED data extracted the supporting information package of Chen et al. and is done so for each of the five disease types [FN75: Chen, Chou, and Lin; Wei-Chun Chou and Zhoumeng Lin, "Probabilistic Human Health Risk Assessment of Perfluorooctane Sulfonate (PFOS) by Integrating in Vitro, in Vivo Toxicity, and Human Epidemiological Studies Using a Bayesian-Based Dose-Response Assessment Coupled with Physiologically Based Pharmacokinetic (PBPK) Modeling Approach," Environment International, 2020.]

Figure 7: Probability Distributions of HEDs by Disease and Disease Type

[Figure 7: see docket ID EPA-HQ-OW-2022-0114-1738]

Figure 7 plots the probability distribution of the 108 diseases by HED levels. Each disease has a central tendency estimate and a range of probabilities that vary with dose. As with Chou et at., this analysis used a Weibull distribution to fit a curve to the log10(HED) data. Figure 8 is a simplification of Figure 7 since it plots median HED values of the distributions of all 108 diseases aggregated by disease type.

Figure 8: Probability Distribution of Log10(HED) by Disease Type

[Figure 8: see docket ID EPA-HQ-OW-2022-0114-1738]

The analysis then overlays the distributions of the disease probabilities (HEDs) and the drinking water doses (DWDs) for both PFOS and PFOA in Figure 9. Several features become apparent. First, below a dose of 20 ng/kg/day, the probability of all diseases is effectively zero. Second, on the other end of the HED distribution, once the DWD exceeds 52 ng/kg/day, the probability is effectively one – or a certainty that this population would have a disease if the gene and cell response data are perfectly causal. Third, consumers with high end exposures are likely to generate the majority of the benefits. From the DWD curve, 81 percent of the population is expected to be below 20 ng/kg/day. Fourth, at the proposed MCL, there is no expected remaining risk. EPA's proposed action would reduce the expected risk to zero. Finally, reducing the level of current state PFOS MCL to EPA's proposed PFOS MCL is not expected to yield any health benefits.

Figure 9: Probability Distribution of HED by Disease Type for All Ages and Probability of Dose from Drinking Water for the Population

[Figure 9: see docket ID EPA-HQ-OW-2022-0114-1738]

Confidence in the Chen et al work is extended when additional studies are considered. Chou and Lin took a similar approach to Chen et al.'s work and reached similar findings [FN76: Chou and Lin, "Probabilistic Human Health Risk Assessment of Perfluorooctane Sulfonate (PFOS) by Integrating in Vitro, in Vivo Toxicity, and Human Epidemiological Studies Using a Bayesian-Based Dose- Response Assessment Coupled with Physiologically Based Pharmacokinetic (PBPK) Modeling Approach."]. In this study, the researchers gathered data from high-throughput in vitro assays from EPA's ToxCast program, from six controlled dose animal studies, and four human epidemiology studies. The authors selected a range of assays related to the disease groups in Chen et al. As in that study, Chou and Lin considered in vitro data when at least one dose group had a ten percent change in response [FN77: Chou and Lin.]. The authors also applied a Bayesian dose-response model to integrate the human, animal, and in vitro evidence. The authors calculated HEDs for all the studies.

Table 3 of the paper lists the calculated HEDs. Even by applying an uncertainty factor of 30 to the HEDs in Chou and Lin, all of the in vitro and animal studies have estimated PFOS HEDs equal to or greater than those in Chen et al. While the human studies give lower HEDs, the authors explain that the uncertainty over the dose measurement in the epidemiolocal studies, the co-exposure to a mixture of PFAS, and other limitations suggest that the human HEDs are conservative. The Chou and Lin paper complements and reinforces the Chen et al. finding that there is little significant biological activity at doses below 20 ng/kg/day as measured through a wide range of in vitro assays and through animal experimental data.

4. Expected Disease Probabilities from Current Drinking Water Intake

The analysis then randomly samples from the PFOS intake from drinking water and compares the dose to the HED disease group probabilities. This comparison is carried out through several steps.

Calculate the Probability of a Disease Group

As shown in Figure 8, for the same dose, a person could be at risk of contracting a disease in multiple disease groups. Each person is only subject to the risk from a single disease in the analysis. To assign the sample population to a disease group, the area under the curve (AUC) of each disease curve for different HED doses in Figure 5 is estimated. The probability of being in each disease group is equal to the proportion of the area under each cumulative distribution curve (see Figure 7).

Probability of Disease Type

We utilize a Monte Carlo simulation by taking 1,000 random samples from the DWD curves for PFOA and for PFOS in Figure 9 and calculating the AUC for each disease group. If the drinking

water dose is above 20 ng/kg/day, then there is a positive probability of each of the five diseases. Figure 10 below shows the results of this calculation for PFOS.

Figure 10: Probability of Disease Group for All Ages for PFOS

[Figure 10: see docket ID EPA-HQ-OW-2022-0114-1738]

This figure shows both the absolute probability of having a disease and the relative probability of each disease type for a given drinking water dose. In Figure 10, at a dose of approximately 38 ng/kg/day, the probability of having a disease is approximately 50 percent. The colors in the stacked bar at that dose show that this 50 percent risk is the sum of the risks for each of the five disease groups. Once the dose reaches and exceeds 52 ng/kg/day, the estimate is that the probability is certain and the proportions among the disease groups do not change as dose increases.

3. Bounding Estimate of Benefits

Since it appears unlikely that much of the current population exposed to PFOS in public drinking water will garner significant benefits, the analysis creates a bounding estimate of benefits to compare with the social costs. The objective is to map out an extreme upper bound on the possible benefits from the proposed MCLs. The bounding estimate rests on assumptions that overstate the potential benefits:

Causality. The analysis assumes that a probability of disease predicted by the genomic data will in fact occur. Intervening biological repair mechanisms are assumed not to be effective or exist. This assumption clearly overstates the probability and the severity of potential disease from PFOS exposure in drinking water. Due to the many environmental, diet, and random events that perturb the body's functions, the body contains many repair mechanisms. Other studies support that this bounding estimate will overstate the potential benefits substantially:

o In a recent study of PFOA, a HED generated from liver cell cultures was found to predict response levels 40-60 times less than actual responses observed in a human clinical trial with controlled PFOA doses [FN78: Styliani Fragki et al., "New Approach Methodologies: A Quantitative in Vitro to in Vivo Extrapolation

o Case Study with PFASs," Food and Chemical Toxicology 172 (2023).].

o Another study compared 43 chemicals' "safe" dose from both genomics data and traditional toxicity testing. The genomics "safe" value was on average almost 6-fold less than the values derived from controlled animal experiments [FN79: Byron Kuo et al., "Comprehensive Interpretation of in Vitro Micronucleus Test Results for 292 Chemicals: From Hazard Identification to Risk Assessment Application," Archives of Toxicology 96 (2022).].

• A 10 Percent Change in Response Causes Disease. In addition to the causality assumption, the bounding estimate further assumes that the BMD change of a 10 percent response is sufficient to overcome the body's defenses and to cause a disease. In reality, a larger response or disruption could be necessary to cause disease.

• Existing Population will Gain the Full Benefits. The analysis assumes that the population that straddles the rule's effective date will gain all the potential reductions in the probability of adverse effects. In reality, lower future exposure may lessen probabilities of future harm, but not eliminate them. Past exposure may have created an enduring increase in lifetime risk. Since 96 percent of the benefits in this bounding estimate accrue to current members of the population, reducing the existing population's assumed benefits would substantially lower the benefits.

• HEDs with Large Potential Benefits as Surrogates for All HEDs in a Disease Group. Some of the HEDs in the five disease groups have limited occurrence in the U.S. population or have very low adverse health impacts. The analysis transfers the estimated benefit of some of the HEDs with larger benefits to all HEDs with likely small impacts.

Therefore, these assumptions imply that a more realistic estimate of the social benefits is at least 10 times lower than those in this bounding estimate. However, the purpose is to explore whether the social benefits can exceed the costs even with these unrealistic assumptions – and with a more comprehensive consideration of potential benefits.

While the analysis constructed a full uncertainty analysis for the variables with uncertainty, the analysis presents the central tendency estimates for simplicity.

Population Cohorts

The analysis estimates the population that is expected to have a dose from drinking water consumption above 20 ng/kg/day. There are two populations that will benefit from this rule: the population at the time of the rule's effective date and future population that are born in the United States or come to the United States after the rule is effective. The analysis uses the term "new population" as the term for this latter group. The benefit methodology for each group is different.

Existing Population

We apply the following steps to estimate the proportion of the current population that could benefit from the proposed drinking water standard:

Adjust Population to Existing Residents that Consume Public Water in States without Standards

Our analysis assumes that the water systems are in compliance with the rule in 2026. The analysis assumes that the changes eliminate the risk to the 2026 population drinking public water. The present value of the benefits to the current population are assumed to occur over three years, corresponding to roughly the half-life of PFOS. This approach overestimates benefits for several reasons. First, adverse effects from exposure prior to the rule may be irreversible. Second, since the half-life is estimated to be greater than three years, after three years, the average U.S. consumer will still have more than half of their baseline PFOS concentration due to past drinking water consumption. Third, consumers may shift their consumption habits away from public drinking water sources in response to the final rule and in response to lag between public notification and PFAS treatment.

We adjust the population by EPA's proportion of U.S. residents that consumer public water. We further reduce this population to public water consumers in states that are likely not to have a state drinking water standard in place by 2026.

New Population

As stated above, the new population includes people born in the years after the effective date and new residents of the United States. New residences are assumed to have the same age profile and disease incidence as the existing population. The analysis uses Census Department decanal projections for new residents and new births [FN80: U.S. Census Bureau, "2017 National Population Projections Tables: Main Series," 2017, https://www.census.gov/data/tables/2017/demo/popproj/2017-summary-tables.html.]. For births, yearly values are created by assuming a linear relationship between the Census' estimates for each decade from 2020 to 2060. We assume the U.S. will enjoy approximately 1.1 million new residents and 4.1 million new births annually during the study period. For the bounding estimate, the analysis assumes that all newborns grow and live a full life to enjoy the benefits, that there is no emigration, that health care innovations do not reduce the adverse effects from the HED diseases.

The study period includes the annual population additions from 2027 to 2056.

Determine Disease Incidence and Individuals Expected to Suffer Diseases

Estimating the number of avoided cases of diseases from this regulatory action has three steps. First, the existing population and new populations are multiplied by the DWD distribution to determine the number of people expected to have a dose above 20 ng/kg/day from drinking water. This population is broken into unit increments of dose.

Second, for each dose, the corresponding population is divided into one of the five disease groups based on the proportions in Figure 7. Each population in these disease group/dose categories is then multiplied by the probability of having the disease from Figure 6 for that dose.

Finally, this resulting product is multiplied by the percentage of the population incidence of the disease. The analysis assumes that the existing population has consumed PFOS at current levels for some time. Therefore, if the diseases predicted by the HEDs are caused by current PFOS exposure, the current number of cancer cases in the U.S. population include the cases caused by PFOS exposure through drinking water. Therefore, if the genomic data predicts a reduction in the probability of disease, the number of existing U.S. cancer cases will be reduced by this regulatory action. The benefits will be therefore a reduction in the overall population cancer incidence.

The analysis thus requires the incidence in the existing U.S. population of the HEDs. We employ different approaches for each of the five disease groups based on data availability.

Cancer

Data on age-adjusted cancer incidence for specific cancers for the current U.S. population is obtained [FN81: U.S. Census Bureau.]. The analysis uses the major cancers in the HEDs. The analysis did not estimate the risk reduction from rarer cancers such as bone and ocular cancers.

CVD

The analysis gathered specific incidence information on COPD, stroke, fatty liver disease, liver cirrhosis, and acute myocardial infarction (AMI). Some of the HEDs were precursors to these diseases or are captured in the mortality and morbidity estimates for the specific diseases listed. The benefits for COPD are reduced to 30 percent of estimated values since 70 percent of COPD is estimated to be caused by smoking [FN82: World Health Organization, "Chronic Obstructive Pulmonary Disease (COPD)," March 16, 2023, https://www.who.int/news-room/fact-sheets/detail/chronic-obstructive-pulmonary-disease-(copd).]. For the other HEDs in the CVD disease group, the analysis applies a uniform valuation discussed below.

Neurological

The analysis gathers the population incidence rate for Alzheimer's and Parkinson's Disease. The remaining HED represent relatively rare diseases or categories in which Alzheimer's, Parkinson's are the most common specific disease. For the other HEDs in the Neurotologic disease group, the analysis applies a uniform valuation discussed below.

Immunotoxicity and Endocrine Disruption

As with the neurological disease group, the expected values are not likely to be significant in the total bounding estimate. The analysis applies a uniform value for each unique adverse effect in these categories.

Valuation of Disease Cases

The same valuation approach is used for existing and new populations. For each of the five disease groups, information on the burden of the major diseases and of their latency periods is taken from the literature [FN83: Marcia R Weaver et al., "Health Care Spending Effectiveness: Estimates Suggest That Spending Improved US Health from 1996 to 2016," Health Aff (Millwood) 41, no. 7 (2022): 994–1004.]. The analysis calculates a net present value of the value of avoiding the disease in 2023 dollars by placing the value of avoiding the disease in the time of its average latency and then discount the future benefit.

The 108 HEDs span a range of potential effects, some clearly adverse like cancer and some only potentially adverse such as neoplasms. To quantify these adverse effects with the same metric, the analysis uses the disability-adjusted life-year (DALY) methodology. This metric combines the lost value from a disease's reduction in life span and from its reduction in abilities. The WHO employs DALYs as part of its Global Burden of Diseases project to standardize disease burdens across countries [FN84: World Health Organization, "Global Health Estimates: Leading Causes of DALYs," n.d., https://www.who.int/data/gho/data/themes/mortality-and-global-health-

estimates/global-health-estimates-leading-causes-of-dalys.]. To allow comparisons, researchers have measured DALYs for many other diseases that are not part of the WHO project.

This analysis first links any of the HEDs to diseases the WHO valued for the United States in its 2019 Global Disease Burden analysis. The DALY per case of the disease in the United States is estimated by dividing the WHO's DALYs in the United States by the incidence rate of the disease in the United States. For the remainder of the HEDs, the scientific literature is searched to find DALY estimates and incident rates for the United States. Some of the HEDs are precursors and did not have DALY estimates. Others were effects that may lead to the same adverse outcome, such as breast cancer and breast neoplasms. Table 4 shows some of the DALY estimates for the major HED diseases.

Table 4: DALY Estimates for Major HED Diseases

[Table 4: see docket ID EPA-HQ-OW-2022-0114-1738]

Valuation of Each Disease

The Department of Human Health Services' (HHS) economic analysis guidelines use a WTP estimate of approximately $800,000 per DALY [FN85: U.S. Department of Health and Human Services, "Guidelines for Regulatory Impact Analysis," 2016.]. This value is a transformation of the VSL to a life-year metric. This valuation is used in this analysis since it is consistent with Circular A-4's directive to use WTP values to estimate social benefits [FN86: U.S. Office of Management and Budget, "Circular A-4: Regulatory Analysis," September 2003.].

Latency and Commencement of Benefits

The proposed regulation would reduce PFOS exposure in drinking water over time. As in EPA's analysis in the RIA, this analysis must determine the lag between the reduction in PFOS exposure and the change in disease occurrence. We first gather data on the latency between initiation and the manifestation of a disease. The HEDs span diseases with latency periods of a few days to several decades. To standardize each disease with a valuation, we discount the value of the disease to an equivalent current value by its latency period at a seven percent discount rate. For example, if a disease has a DALY loss of $400,000 when it occurs five years in the future, the value today is $285,000 (rounded). For the new population, many diseases are not expected to occur until the person reaches his/her 50s or 60s. Therefore, the valuation of avoiding the adverse effects in the future must be discounted to current dollars.

EPA Response: See section 13.4 in this *Response to Comments* document and also the EPA response to comment Doc. #1738, SBC-053388 in section 13.4 in this *Response to Comments* document for the EPA's response to the commenter's use of a Bayesian dose-response model using animal studies and in vitro human cell data to develop benchmark doses. Regarding the commenter's conclusions resulting from the "bounding exercise" in this and other snippets, see section 13.4 of the EPA response in this *Response to Comments* document. As detailed in section 13.4 of the EPA response in this *Response to Comments* document and in the following response, the EPA disagrees with many of the assumptions that support the bounding exercise,

and therefore disagree with this commenter's overall conclusions that the bounding exercise represents an "extreme upper bound" on the possible benefits from the proposed MCLs. Further, the EPA disagrees with the commenter that "a more likely estimate of the social benefits are more than ten times lower than this bounding estimate."

The EPA disagrees with the commenter's use of the consumers-only drinking water intake values to construct an intake distribution for the U.S. population. The EPA uses a consumption rate of 0.013 L/kg-day, which represents a per capita factor for adults aged 21 and older. Using the consumers-only drinking water intake value (0.016/0.017 L/kg-day for those aged 21 and older, depending on the age range) would overestimate exposure in the general population.

The EPA disagrees with the commenter's suggested approach to determining disease incidence and individuals expected to suffer disease. Please refer to the EPA response to comment Doc. #1738, SBC-053384 in section 13.4 and Doc. #1738, SBC-053388 in section 13.4.5 in this *Response to Comments* document, in particular regarding evidence integration strategy and estimation of disease incidence reductions. Regarding the commenter's estimation of benchmark doses for different diseases, and specifically the application of Chen et. al, see section 13.4 of the EPA response in this *Response to Comments* document.

Regarding the commenter's statement that the bounding estimate rests on assumptions that overstate the potential benefits, see section 13.4 of the EPA response in this *Response to Comments* document.

Regarding the commenter's approach to evaluating population growth, refer to the EPA response to comment Doc. #1808, SBC-046130 in section 13.9 of the EPA response in this *Response to Comments* document. Further, the EPA notes that the bounding exercise uses a study period from 2027 to 2056. The EPA used a longer period of analysis, as discussed in Chapter 2 of the EA (USEPA, 2024b), which allows the agency to capture longer term effects of chronic contaminants such as PFAS.

The EPA also disagrees with the commenter's suggestion to use the disability-adjusted life-year (DALY) methodology to value the potential benefits of enacting the PFAS MCLs. Although other agencies (e.g., the Department of Human Health Services and the World Health Organization) use this methodology for the purpose of their analyses, the goal of their analyses may be different from the EPA's benefit cost analysis. For example, WHO uses DALY to standardize disease burdens across different countries. The EPA's Guidelines for Preparing Economic Analyses (USEPA, 2016a) clearly states that "methods that combine information on quality and quantity of life cannot be directly related to willingness-to-pay estimates and thus should not be used for deriving monetary estimates for use in benefit cost analyses." In addition, OMB Circular A-4 Guidance states that in order for integrated measures such as DALY to represent a valid measure of individual preferences they must t meet some restrictive assumptions (OMB, 2023). Specifically, the guidance states that if data are not available using a more direct monetization approach (e.g., WTP), "Bear in mind, however, that a main drawback of integrated measures of this type is that they must meet some restrictive assumptions to

represent a valid measure of individual preferences. If you use this approach, you should be careful to acknowledge your assumptions and the limitations of your estimates." Therefore, the EPA's benefits estimates using cost of illness and willingness to pay information to value reduction in the number of illness cases associated with from PFOA and PFOS exposure is most appropriate for use in this HRRCA.

The EPA disagrees with the commenter's approach to estimation of the latency and commencement of benefits. The commenter makes unspecified assumptions about the disease latency (i.e., the time between reduction in PFOA exposure and reduction in disease incidence). The commenter also is not transparent about whether the incidence of each evaluated disease is the lifetime incidence or the annual incidence. If the modeled baseline incidence is the annual incidence, then the analysis potentially misses additional benefits from the permanent reduction in PFOS exposure over time. Finally, the commenter's analysis does not address population mortality from other causes over the evaluation time period.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046015)

Valuation of Avoided Disease Cases

Table 5 gives the valuation per case of avoided disease for the major HEDs. Table 5: Valuation of Avoided Disease Cases by Major HEDs

For some of the common immunotox and endocrine disruptor diseases, the net present value benefits are less than $100 million. There are 17 HEDs remaining that are unique diseases. As a bounding estimate, we assign each one an avoided cost present value of $100 million to generate the bounding estimate in Table 5.

Incremental Effect of the Proposed Regulatory Action

As stated above, in this bounding estimate the rulemaking is assumed to eliminate the incremental probability of harm from current PFOS concentrations in drinking water to the existing population and to future populations from 2027 to 2056.

4. Results PFOS

Table 7 gives the results of this bounding exercise. The annualized social benefits for the proposed PFOS drinking water standard are approximately $1.4 billion per year at a seven percent discount rate. This estimate arises from consideration of 108 possible disease states that arise from observed changes in biological function. It would appear that it is implausible that other adverse effects that do not rely on biological function changes could be large enough to exceed this bounding estimate.

As discussed in the next section, this benefit estimate is more than five times less than the estimated social costs. Since a more likely estimate of the social benefits are more than ten times lower than this bounding estimate, the social costs of EPA’s proposed regulatory action exceed the potential social benefits by a large margin.

Table 6: NPV of Estimated Annualized Benefits ($ M)

[Table 6: see docket ID EPA-HQ-OW-2022-0114-1738]

PFOA

As the occurrence data and EPA's population estimates show, there is extensive overlap between the populations that would benefit from a PFOS standard and a PFOA standard. There does not appear to be comparable studies to Chen et al. and Chou and Lin in the literature for PFOA. In EPA's MCLG documents, EPA finds that PFOA and PFOS share many of the same adverse effects at roughly the same dose levels. The estimated occurrence in drinking water is roughly the same as shown in Figure 4.

Even doubling or trebling the benefits from the PFOS bounding estimate to account for the social benefits of PFOA, however, does give benefits close to the social costs.

Table 7: NPV of Estimated Annualized Benefits ($ M)

[Table 7: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: The EPA disagrees with the commenter's suggested approach and the commenter's assumptions in the bounding exercise. Please refer to the EPA response to comment Doc. #1738, SBC-053384 in section 13.4 of this *Response to Comments* document, as well as the section 13.4 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter's assertion that the social benefits of the rule are "more than five times less" than social costs. As detailed in section 13.4 of the EPA response in this *Response to Comments* document, the EPA disagrees with many of the assumptions used in the commenter's bounding exercise and disagrees that the results represent an "extreme upper bound" of the benefits of the rule. Regarding this commenter's estimates of the costs of the final rule, the EPA also disagrees with many of the commenter's approaches and overall conclusions; see sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document for more information. Therefore, the EPA disagrees with this commenter that the social benefits of the rule are less than the social costs. As detailed in the EA, the EPA anticipates significant additional nonquantifiable benefits as a result of the final rule and has reaffirmed the agency's determination at proposal that the quantifiable and nonquantifiable benefits of the rule justify it quantifiable and nonquantifiable costs; see section 13.8 of the EPA response in this *Response to Comments* document for further discussion.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044681)

VII. EPA's estimate of public health benefits appears to be significantly overstated and must be revised and republished.

EPA has ignored the lack of any documented health impacts from areas around the country where there have been acute impacts, for example, groundwater contamination in the Parkersburg/Vienna, West Virginia area. Another example is Wilmington, North Carolina where a

Chemours/DuPont facility discharged what we believe was wastewater containing millions of parts per trillion of a variety of PFAS chemicals, likely for decades. During an online Town Hall meeting regarding PFAS-related issues we believe that North Carolina's health agency represented that they were not aware of any PFAS-related health clusters. We believe it is imperative that EPA address how these real-world human health impacts (or lack thereof) were considered in the development of its ultra-low proposed MCLs.

In particular, EPA must identify whether there are any health clusters due to elevated PFAS impacts in communities that have been documented to date.

We know based upon the testing performed so far by water systems, the States and federal government, that people have been exposed to levels of PFOA/PFOS for years and decades that are orders of magnitude higher than EPA's proposed MCLs. However, EPA fails to identify any health clusters as a result of these "hot spot" exposures. We believe that lack of actual health impacts in these circumstances compels EPA to reconsider the level of its proposed MCLs.

If we are wrong about there being no documented health clusters tied to PFAS contamination, EPA should expand on such data to help justify the $1.3 billion in annual public health benefits that EPA asserts.

EPA Response: The EPA disagrees with the commenter's assertion that benefits are overestimated. An extensive systematic literature review uncovered compelling evidence that was carefully assessed for study quality and validity, as discussed in the toxicology assessments for PFOS and PFOA and section IV of the preamble (USEPA, 2024h; USEPA, 2024i). Contrary to commenters claim, the lack of reported cancer clusters or other "health clusters" does not undermine this economic analysis or any analysis done to support the rulemaking. Rather, the EPA's action is based on the best available science and data collected by the best available methods; the EPA's action is necessarily based on the information available, not the information not available. See SDWA 1412(b)(3)(C). Please refer to sections 4.1.4, 4.2.1, 13.4, 13.4.1, 13.4.2, and 13.4.3 of the EPA response in this *Response to Comments* document for detail on the EPA's determination on evidence of certain health effects associated with PFOA and PFOS.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044659)

VII. EPA's estimate of public health benefits appears to be significantly overstated and must be revised and republished.

EPA has ignored the lack of any documented health impacts from areas around the country where there have been acute impacts, for example, groundwater contamination in the Parkersburg/Vienna, West Virginia area. Another example is Wilmington, North Carolina where a Chemours/DuPont facility discharged what we believe was wastewater containing millions of parts per trillion of a variety of PFAS chemicals, likely for decades. During an online Town Hall meeting regarding PFAS-related issues we believe that North Carolina's health agency represented that they were not aware of any PFAS-related health clusters. We believe it is

imperative that EPA address how these real-world human health impacts (or lack thereof) were considered in the development of its ultra-low proposed MCLs.

In particular, EPA must identify whether there are any health clusters due to elevated PFAS impacts in communities that have been documented to date.

We know based upon the testing performed so far by water systems, the States and federal government, that people have been exposed to levels of PFOA/PFOS for years and decades that are orders of magnitude higher than EPA's proposed MCLs. EPA Response: Please see the EPA response to comment Doc. #1816, SBC-044681 in section 13.4.5 in this *Response to Comments* document.

Brian Hackman (Doc. #1539, SBC-042908)

Given that USEPA's approach to the health advisory limits would say most all American's have a lifetime exposure that says any improvement in drinking water will have little effect, USEPA is attempting to make a rule that, in essence, can not show any benefit until all PFAS is removed from human presence and the next generation of that generation is free of any vectors to exposure. The Agency is setting itself up to chase a ghost that it can not win against nor fight because of its impossible dream at such low concentrations.

EPA Response: The EPA disagrees with the commenter's interpretation of the health advisories and assessment that benefits from reducing PFOS and PFOA exposure may not be realized. As demonstrated at length in the EPA's economic analysis, any reduction in exposure to regulated PFAS, including PFOA and PFOS, is expected to reduce risks for persons alive today and is anticipated to produce significant health benefits at a national scale. The benefits estimation relies on an extensive literature review to identify existing research on the adverse health effects brought by PFOA and PFOS exposure and potential benefits of reducing exposure to PFAS. Please see Chapter 6 of the EA for details on the EPA's approach to estimating benefits of the proposed MCLs (USEPA, 2024b). Furthermore, the EPA notes that treating to the MCLs in this final rule are feasible and that the rules regulatory requirements are not an "impossible dream". See section V of the preamble for today's rule for discussion about treatment feasibility for the final rule's regulated PFAS.

Brian Hackman (Doc. #1539, SBC-042903)

Also, USEPA has not explained how it will achieve and monitor the $1.06 billion in healthcare savings represented by implementing treatment across the United States. USEPA has not demonstrated in areas where PFAS treatment has been implemented any cost reductions using data collected by the CDC (Centers for Disease Control) to show a reduction in related health impacts as a result of cleaner water. Having such large datasets as 10,000 or more populations would be beneficial and necessary to demonstrate the benefit used to justify the proposed health improvement benefit. Otherwise, it is a struggle to see that USEPA is conducting a $1 billion money grab out of the medical community revenues without some impact on medical jobs and infrastructure used to sustain healthcare. The $1 billion health benefit becomes a significant challenge to achieve especially when the USEPA recognizes that only 20 percent of environmental exposure is being achieve through this regulation alone. Is USEPA saying and really missing out on the ability to achieve $4 billion in healthcare reduction costs by not regulating the other 80 percent of exposure vectors?

EPA Response: Regarding the commenter's point that the EPA has not demonstrated that PFAS treatment already implemented is reducing health effects, the EPA's action is based on the statutorily-mandated best available science and data collected by best available methods, SDWA Section 1412(b)(3), so is necessarily based on information available, not information that is not available. The EPA disagrees with the commenter's suggestion that the EPA has failed to explain how healthcare savings are achieved. Please see Chapter 6 of the EA for details on the EPA's approach to estimating the avoided medical cost and the value of avoiding premature mortality resulting from the proposed MCLs (USEPA, 2024b). The EPA also disagrees with the commenter that avoided cost of illness resulting from reduced exposure to PFOA and PFAS would have adverse impacts on medical jobs and infrastructure. The American Hospital Association reports a significant shortage of physicians, nurses, and other medical professionals in the healthcare system (AHA, 2021). Therefore, reduction in adverse health effects associated with the implementation of the proposed MCLs is likely to alleviate existing pressure on medical professionals and, as a result, benefit the healthcare system. The EPA acknowledges that the proposed MCLs address only a fraction of environmental exposure, and as described in the EA and FR, the EPA is addressing PFAS contamination in the U.S. across all media types with both voluntary and regulatory actions. The commenter is incorrectly interpreting the relative source contribution (RSC) and is directed to section 4.2.5 of the EPA response in this *Response to Comments* document for discussion regarding RSC derivation and exposure sources. The benefits analysis provides a maximum population attributable fraction (PAF) limit on total health outcome rates that could be attributed to PFAS exposure. See Section 6.1.2 Uncertainty Characterization in the final rule EA (USEPA, 2024b) for discussion of the PAF limits. Section 5.3.2 of the EA describes the estimation of administrative monitoring costs (USEPA, 2024b).

Dixon Tucker (Doc. #2797, SBC-046229)

With the very detailed sampling protocol required for sampling PFOS/PFOA in water, it begs the question of how much exposure can be reduced through regulation of PFOS/PFOA in water.

EPA Response: The EPA expects there will be a reduction in human exposure to regulated PFAS through implementation of this final rule. The EPA has estimated the reduced exposure to the regulated PFAS that will occur as a result of the final rule by characterizing the baseline (exposure in the absence of the PFAS NPDWR) and the populations served by water systems that are expected to exceed the final MCLs. For more information see Chapter 4 of the EA. For the EPA's response to comments regarding monitoring and compliance requirements of the rule, see section 8 in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045691)

IX. THE SDWA REQUIRES A COST-BENEFIT ANALYSIS FOR EACH MCL

The SDWA was amended in 1996 to specifically require cost-benefit analysis as part of the regulatory process. Id. [sec] 300g-1(b)(3)(C), (4)(C). For each drinking water standard and each alternative standard being considered by EPA, [sec] 1412(b)(3)(C)(i) provides that EPA must publish and seek public comment on an analysis of the health risk reduction benefits and costs associated with the proposed MCL. Id. [sec] 300g-1(b)(3)(C)(i). The purpose of the cost-benefit analyses is to determine whether the benefits of the MCL justify, or do not justify, the costs of the proposed regulation.

EPA failed to determine whether the benefits of the HI-MCL justify the costs of the proposed regulation as it did not quantify benefits for any health point for PFHxS (USEPA 2023i). Because there is no quantitative benefit analysis for the HI portion of the rule, there cannot be a cost-benefit analysis for that portion of the rule. This violates the SDWA.

EPA Response: The EPA disagrees with the commenter's assertion that the EPA "failed to determine whether the benefits of the HI-MCL justify the costs" and that the EPA's analysis "violates the SDWA." The EPA completed a benefits analysis for the Hazard Index contaminants (specifically PFHxS, PFNA, HFPO-DA, and PFBS) consistent with the requirements under the SDWA. The commenter incorrectly states that the "EPA failed to determine whether the benefits of the HI-MCL justify the costs" because the EPA "did not quantify benefits for any health point for PFHxS." The EPA clarifies to the commenter that the agency estimated PFHxS treatment costs in the national quantitative analysis and also quantified the costs associated with PFNA, HFPO-DA, and PFBS treatment in Appendix N.3 and N.4 of the EA (USEPA, 2024c). The commenter has misinterpreted the statute and the EPA clarifies to the commenter that the SDWA allows for both quantifiable and nonquantifiable benefits analysis for MCLs. In the case of this rulemaking, the EPA completed a robust nonquantifiable benefits analysis for Hazard Index contaminants, specifically PFHxS, PFNA, HFPO-DA, and PFBS. The nonquantifiable benefits analysis describes the many adverse health effects associated with these PFAS and is described

in detail within section 6.2 of the EA (USEPA, 2024bb) and section XII of the FRN for the final rule. Specifically, and as described in the EA and the FRN, the qualitatively discussed health impacts of these four PFAS are considerable and include cancer, birth weight, endocrine, immune, and hepatic effects; reducing human exposure to them is expected to reduce the incidence of adverse health impacts including cardiovascular, developmental, and immune effects. Additionally, the EPA completed a quantitative sensitivity analysis of birth weight benefits associated with PFNA exposure reductions, which is described in Appendix K of the EA (USEPA, 2024c). Under the proposed PFAS NPDWR, the agency fully considered the costs and benefits of the action, including the quantifiable and nonquantifiable benefits and costs, and the EPA Administrator determined that the benefits of the rule justified the costs. For the final rule, the EPA is reaffirming the Administrator's determination made at proposal that the quantified and nonquantifiable benefits of the rule justify its quantified and nonquantifiable costs (88 FR 18638).

13.5 Nonquantifiable Benefits of PFOA and PFOS Exposure Reduction

Summary of Major Public Comments and EPA Responses

The EPA received comments concerning the nonquantifiable benefits of PFOA and PFOS exposure reduction. One commenter claimed that the EPA's nonquantified benefits are not supported by the science. The commenter asserted that the "EPA makes overly conservative decisions to protect against what is portrayed to be an array of affects from additional PFAS not directly addressed by the proposal" and that "for the large majority of health endpoints discussed, EPA has not provided a factual basis by which to conclude that such benefits are likely to occur when EPA decreases the levels of PFAS in drinking water." The commenter was critical of the EPA's consideration of nonquantifiable benefits associated with PFOA and PFOS such as nonquantifiable benefits associated with reductions in several health effects (including hepatic and endocrine effects) where the EPA characterized the evidence as inconsistent. For hepatic effects, the EPA's toxicity assessments determined that exposure to PFOA/PFOS causes hepatic toxicity in humans. However, the EPA did not quantify benefits for hepatic effects because although there will be benefits delivered by reducing PFOA and PFOS in drinking water, there is a lack of adequate data available to accurately quantify those benefits. Further information on health effects related to PFAS exposures is provided in the health assessments within the EPA's final toxicity assessment documents (USEPA, 2024h; USEPA, 2024i). The EPA disagrees with the commenter's assertion that the agency has not provided a factual basis for the benefits that are likely to occur as a result of the rule. The EPA has provided sufficient factual basis for the quantifiable and nonquantifiable health endpoints discussed in the HRRCA and has evaluated the best available science in support of the HRRCA, as required under the SDWA. The EPA has reviewed and cited to hundreds of peer reviewed studies that discuss a wide variety of health effects caused by PFAS: many of those studies document the exact non-quantifiable health effects for which the commenter claims there is no factual evidence.

The EPA further disagrees with the commenter's assertion that claims about non-quantifiable benefits are not supported by the EPA's own benefits analysis. The EPA has noted that quantified benefits were evaluated for some health outcomes for which the toxicity assessments found that evidence indicates an association with PFOS or PFOA (USEPA, 2024h; USEPA, 2024i). This does not preclude the EPA from assessing non-quantified benefits for which evidence of an association was determined to be suggestive (e.g., endocrine effects), and in fact, SDWA is explicit that the EPA must consider non-quantifiable and quantifiable benefits from regulating a given contaminant. SDWA Section 1412(b)(3)(C). While the EPA acknowledges that the evidence of adverse health effects can sometimes be more limited for other PFAS, this is the exact reason why the EPA did not quantify those benefits and instead characterizes them in a nonquantifiable fashion, consistent with the scientific literature. The EPA notes that the PFOA and PFOS toxicity assessments summarize the available health effects literature, of which there are thousands of health effects studies. Evidence on health effects associated with PFAS exposure is supportive of the EPA's conclusions on nonquantified benefits. Additionally, the body of evidence for a wide range of adverse health effects from PFAS is growing, demonstrated most recently by a study from the peer reviewed literature (Jones et al., 2023), which shows evidence of associations between some PFAS and childhood acute lymphoblastic leukemia. In short, the EPA believes the commenter is incorrect and that, as demonstrated by the substantial body of scientific literature documenting a wide variety of adverse health effects from exposure to a wide variety of PFAS, the EPA has appropriately considered the nonquantifiable benefits as outlined in Sections VIII of the preamble for this rule and Section 6.2.4 of the EA.

One commenter stated that the (HRRCA underestimates significant health and environmental benefits of the proposed drinking water regulations. The commenter noted that impacts on immune system dysfunction and on women's breast cancer risk and lactation duration are "not properly accounted for in the HRRCA." The EPA agrees with the commenter that the quantified benefits associated with the PFAS NPDWR are underestimated; however, the EPA notes that the agency has considered numerous adverse health endpoints in its nonquantifiable benefits analyses. In the FRN and also the economic analysis for the final PFAS NPDWR, the EPA describes the unquantified adverse health effects that are associated with exposure to the PFAS included in the regulation and also PFAS that are anticipated to be co-removed as a function of treatment. In summary, the EPA anticipates significant additional benefits that cannot be quantified will result from avoided developmental, cardiovascular, liver, immune, endocrine, metabolic, reproductive, musculoskeletal, and carcinogenic effects as a result of reductions in the levels of the regulated PFAS and other co-removed contaminants. For detailed information on unquantified benefits, please refer to section XII of the FRN and also Chapter 6 of the EA for the final rule (USEPA 2024bb).

Another commenter described several adverse health effects associated with PFAS exposure that the EPA did not quantify. The commenter stated that PFAS exposure is associated with a wide range of adverse health effects including reproductive, developmental, cancer, and other effects. The commenter urged the EPA to expand upon its quantification and, where supported, monetization of the Proposed Rule's benefits. The commenter further claimed that when

measuring the Proposed Rule's benefits, the EPA ignored or improperly dismissed evidence of the connection between PFAS and liver disease, impaired mammary gland development and reduced lactation duration, and immune system suppression and increased susceptibility to infectious disease, and thus failed to measure all of the benefits attributable to the Proposed Rule's reduction in PFAS exposures. The commenter also stated that the EPA should reconsider its omission of reduced testicular cancer incidence from its assessment of the Proposed Rule's benefits. This commenter raised that the EPA incorrectly omitted the opportunity cost of time in valuing non-fatal illnesses, which "likely results in a significant underestimate of the benefits" and recommended that the EPA use willingness to pay information to account for the opportunity cost of time when literature was available to do so. Lastly, the commenter stated that the EPA should consider illustrative analyses or a "break-even" analysis to provide further insight on the potential magnitude of qualitatively discussed benefits.

In response to the commenter's request for the EPA to quantify additional benefits, the EPA reevaluated whether there were additional benefits the agency could quantify. Based on this reevaluation, the agency determined that it could prepare a quantitative estimate of liver cancer benefits associated with reduced exposure to PFOS for the final rule based on animal toxicity data. See Appendix O in the Economic Analysis for a discussion of liver cancer benefits analysis methodology and results. The EPA disagrees with the commenter's assertion that the EPA "ignored or improperly dismissed evidence of the connection between PFAS and liver disease, impaired mammary gland development and reduced lactation duration, and immune system suppression and increased susceptibility to infectious disease." The EPA did consider the connection between PFAS and liver disease in its nonquantifiable benefits analysis, and the nonquantifiable benefits analysis helps inform the Administrator's determination that the costs of the PFAS NPDWR are justified by the benefits.

The EPA disagrees with the commenter's assertion that the EPA ignored or improperly dismissed evidence of the connection between PFAS and immune system suppression and increased susceptibility to infectious disease. The EPA did consider the connection between PFAS and immune system suppression in its nonquantifiable benefits analysis. The EPA clearly stated that immune effects had indicative evidence of associations with exposure to PFOA and PFOS. Additionally, the EPA identified studies that observed the potential for adverse COVID-19 impacts in persons with elevated PFAS exposure. These studies suggested immunosuppressive effects of PFAS and/or increased COVID-19 respiratory toxicity due to PFAS exposure, as described in Sections 6.2.2 and 6.2.3 of the EA (USEPA, 2024b). Although these studies provide a suggestion of possible associations, the body of evidence does not permit any conclusions about the relationship between COVID-19 infection, severity, or mortality, and exposures to PFAS.

With respect to the portion of the comment asserting that the EPA ignored PFAS effects on liver disease, the EPA determined that the evidence indicates that PFOA and PFOS exposures are likely to cause hepatotoxicity in humans under relevant exposure circumstances and epidemiological studies show consistent evidence of a positive association with alanine

aminotransferase (ALT) in adults. However, while increased ALT is considered an adverse effect, ALT can be one of several contributors to a variety of diseases, including liver disease, and it is difficult to therefore quantify the relationship between this biomarker and a disease that can be monetized.

In conclusion, the EPA disagrees with the commenter's statement that additional health endpoints were not adequately considered in the analysis. The EPA did consider a wide variety of adverse health effects as part of its nonquantifiable benefits analysis, and the agency quantified benefits where the agency deemed there was sufficient information or purpose to do so. To quantify benefits, the EPA systematically assessed each endpoint with evidence of an association in humans to select endpoints with robust links to adverse human health outcomes and minimize duplication of health impact estimates. The EPA also prioritized endpoints for quantification based on whether the expected magnitude of the impact would meaningfully inform policy decisions, which is consistent with OMB guidance stating that "analytic priority should be given to those additional benefits, costs, and transfers that are important enough to potentially change the rank ordering of the main alternatives in the analysis" (OMB, 2003). For some endpoints such as testicular cancer, the magnitude of the potential benefits was not expected to influence policy decisions materially (see Section 6.2.2.2 of the main EA).

The EPA disagrees with the commenter's statement that additional break-even analyses should have been implemented for endpoints that lack evidence of association in humans but have valuation information readily available. The majority of the endpoints in the qualitative benefit group were non-specific as disease biomarkers, or the relationship between these endpoints and human disease states was complex (e.g., vitamin D levels, hemoglobin levels, uric acid levels, body weight); these endpoints do not have readily available valuation information and, thus, are not candidates for a break-even analysis. A few other endpoints in this group were more directly linked to human disease states (e.g., gestational hypertension/preeclampsia, thyroid hormone disruption) and, therefore, more amenable to valuation, however, these endpoints were not prioritized because information produced by these analyses would not have meaningfully informed policy decisions relative to the health endpoints that have already been quantified, and this prioritization is consistent with OMB Circular A-4 guidance (OMB, 2003; OMB, 2023).

Individual Public Comments

Minnesota Center for Environmental Advocacy et al. (Doc. #1707, SBC-045726)

1. The Benefits of Imposing the Proposed MCLs are Immense

When EPA Commissioner Reagan determined in the proposed NPDWR that the benefits of the Proposed Rule outweighed the costs, the Agency pointed to a diverse set of data to support that finding. Commenters write to remind the Agency that behind the numbers are real people whose stories with PFAS are riddled with expensive doctor visits, missed time from work, and lives lost or forever changed.

Calculating the financial benefit from preventing just one PFAS-related health impact is an inexact science. Actuarial tables, workers' compensation benefit charts, and insurance adjusters endeavor to pin a dollar amount of each year of life cut short from what is expected or how much a limb is worth. But these blunt instruments are unable to put a value on the laughter, hugs, or milestones that go missing when someone dies early. This rough science lacks compassion and fails to reflect that the true cost of cancer and other PFAS-related aliments is borne by family, friends, and the greater community who watches while individuals are ravaged by rare and debilitating diseases.

For these reasons, the Strande's estimated $50,000 annual outlay for Amara's treatment does not include the anguish, grief, and pain shared by Amara's loved ones. And how do you put a price on JD's difficulty forming new memories? How much value do we assign the ability to recall life's most beautiful moments, or remember details about a work assignment or a school project? And how do we account for the collective anxiety of tens of thousands of East Metro residents who are uncertain if the tap water in the homes, schools, and places of work is slowly killing them?

The true value of EPA's Proposed Rule is communities with bright futures, with graduating classes of high school students not decimated by abnormally high cancer rates, and with individuals who will have the opportunity to live full, productive lives. EPA must remember the real benefits behind enacting the Proposed Rule, benefits that are measured not in dollars and cents but in memories, laughs, and years with loved ones not clouded by cancer.

EPA Response: The EPA agrees with the commenter that the PFAS NPDWR will result in substantial, lasting human health benefits. See section 13.5 of the EPA response in this *Response to Comments* document. The EPA further notes that the quantified benefits analysis associated with PFAS exposure reductions is limited to health effects with exposure response information and economic data to monetize the impacts, and quantified benefits are likely underestimated as a result. The information available to effectively value lost opportunity and productivity as a result of avoided morbidity and mortality for health effects quantified in this NPWDR is limited, and as such, the quantified benefits estimated for the NPDWR are likely underestimated. Based on this and other comments, for the final rule, the EPA included a sensitivity analysis for bladder and kidney cancer exposure reductions where willingness to pay information was used for valuation, which accounts for lost productivity and opportunity costs (see Appendix O in USEPA, 2024c). In addition to the valuation limitations for quantified health effects, there are also many adverse health effects associated with PFAS exposure that the EPA was unable to quantify for this NPDWR, which also results in underestimated quantified benefits. Considering both quantified and nonquantifiable costs and benefits, the EPA has reaffirmed that the benefits associated with the rulemaking justify the costs.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045923)

5. EPA claims of non-quantified benefits are not supported by the science

For PFOA, PFOS, PFNA, PFBS, PFHxS, and HFPO-DA, EPA makes repeated claims about non-quantifiable benefits. These claims are not supported by EPA's own benefits analysis. For instance, while EPA purports that there are non-quantified benefits to the hepatic system from decreasing PFOS exposure, in discussing ALT levels, EPA notes that "[s]tudy results showed inconsistent evidence on whether the observed changes led to changes in specific liver disease"[FN202: See EPA Economic Analysis of the Proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances, 2023, at page 6-18.]. EPA refers to the ALT endpoint, which it determined was a critical effect for the RfD, as a "non-specific biomarker."[FN203: Id. at 6-21.] When discussing endocrine effects, EPA states: "[e]pidemiology studies reported inconsistent evidence regarding associations between PFOA and PFOS exposure and general endocrine outcomes, such as thyroid disease, hypothyroidism, and hypothyroxinemia."[FN204: Id. at 6-19.] Regarding musculoskeletal effects EPA states: "[s]ome studies found that PFOA/PFOS exposure was linked to osteoarthritis, in particular among women under 50 years of age (ATSDR, 2021). However, other reviews reported mixed findings on the effects of PFOS exposure including decreased risk of osteoarthritis, increased risk for some demographic subgroups, or no association (ATSDR, 2021)."[FN205: Id. at 6-20.]

When discussing the non-quantified effects of other PFAS, the data are even more limited. For instance, while EPA mentions inconsistent evidence on associations between PFNA with cardiovascular effects, EPA also notes that for "[o]ther PFAS for which lipid outcomes were examined in toxicology or epidemiology studies observed limited to no evidence of associations. Studies have examined possible associations between various PFAS and blood pressure in humans or heart histopathology in animals. However, studies did not find suggestive or likely evidence for any PFAS in this summary except for PFOS."[FN206: Id. at 6-23.] Throughout the proposed rule, EPA makes overly conservative decisions to protect against what is portrayed to be an array of affects from additional PFAS not directly addressed by the proposal. However, the scientific information in EPA's benefits analysis, when held to the scientific requirements of SDWA, does not support this approach. For the large majority of health endpoints discussed, EPA has not provided a factual basis by which to conclude that such benefits are likely to occur when EPA decreases the levels of PFAS in drinking water.

EPA Response: The EPA disagrees with the commenter's assertion that the agency has not provided a factual basis for the benefits that are likely to occur as a result of the rule. Please see section 13.5 of the EPA response in this *Response to Comments* document. The EPA has provided sufficient factual basis for the quantifiable and non-quantifiable health endpoints discussed in the HRRCA and the record is based on an evaluation of the best available science in support of the HRRCA, as required under the SDWA.

The EPA disagrees with the commenter's assertion that claims about non-quantifiable benefits are not supported by the EPA's own benefits analysis. The EPA has noted that quantified benefits were evaluated for some health outcomes for which the toxicity assessments found that evidence indicates an association with PFOS or PFOA (USEPA, 2024h; USEPA, 2024i). This does not preclude the EPA from assessing non-quantified benefits for which evidence of an association was determined to be suggestive, as was the case for endocrine or musculoskeletal effects. For

ALT, the EPA has indeed concluded that the available evidence supports selection of increased ALT as a critical effect for candidate RfD derivation. Changes in ALT associated with PFOS or PFOA can be clinically relevant, a position supported by the SAB PFAS Review Panel in their final report (USEPA, 2022d; pg. 28). As previous research on lead exposure has found, although small changes in an outcome (e.g., ALT) at the individual level may or may not reach a level considered clinically significant, such small changes can result in substantial health impacts at the population level (Gilbert and Weiss, 2006). Rationale supporting the agency's selection of increased ALT as a critical effect is presented in section 4.2.1.5 and 4.2.2.3.3 of this *Response to Comments* document, as well as in Sections 3.4.1.4 and 4.1.1 of the Final Toxicity Assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i).

There is sufficient evidence in the record for this action demonstrating the rule will result in significant nonquantifiable benefits for other PFAS. In addition to the evidence of health impacts of other PFAS discussed in the EA for this final rule, new evidence on the impacts of other PFAS, especially on the impact of PFAS on CVD is emerging and supportive of the EPA's conclusions on nonquantified benefits: a recent meta-analysis reports that PFAS exposure might be associated with moderate overall effect on CVD, including hypertension (Abdullah Soheimi et al., 2021). The EPA also notes that the PFHxS IRIS assessment determined that the evidence suggests cardiometabolic effects in humans. The PFNA IRIS Assessment is currently under development, and is informed by many of the same studies from the PFHxS assessment and the PFOA/PFOS toxicity assessments. See section 13.5 of the EPA response in this *Response to Comments* document and Chapter 6.2.4 of the economic analysis of nonquantifiable benefits for more discussion about nonquantifiable benefits. Additionally, the EPA notes that the administrative record for this action contains hundreds of scientific sources which clearly highlight adverse health effects associated with multiple PFAS. See the section 13.6 of the EPA response in this *Response to Comments* document for further information on comments received on nonquantifiable benefits for other PFAS.

<u>PFAS Project Lab (Doc. #1786, SBC-044718)</u>

The Health Risk Reduction and Cost Analysis (HRRCA) underestimates significant health and environmental benefits of the proposed drinking water regulations

We agree with EPA's own economic analysis that there "are significant nonquantifiable sources of benefits that were not captured in the quantified benefits." The includes numerous health benefits and medical savings beyond the very limited ones quantified in the analysis. For example, impacts on immune system dysfunction and on women's breast cancer risk and lactation duration, are just some risks that are not properly accounted for in the HRRCA.

EPA Response: Please see section 13.5 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046110)

In addition to maintaining or expanding upon these robust features of the Draft EA, there are several ways that EPA can and should strengthen the EA. These are outlined in detail in Dr. Guignet's analysis, and we highlight several key recommendations here:

First, EPA should utilize the best available scientific and economic information to quantify and/or monetize additional benefits of the rule in the final EA. In the Proposed Rule, EPA correctly determined that:

PFAS exposure is associated with a wide range of adverse health effects including reproductive effects such as decreased fertility; increased high blood pressure in pregnant women; developmental effects or delays in children, including low birth weight, accelerated puberty, bone variations, or behavioral changes; increased risk of some cancers, including prostate, kidney, and testicular cancers; reduced ability of the body's immune system to fight infections, including reduced vaccine response; interference with the body's natural hormones; and increased cholesterol levels and/or risk of obesity. [FN117: Proposed Rule, 88 Fed. Reg. at 18,725.]

Yet EPA quantified only "three PFOA- and PFOS-related health endpoints in [the economic] analysis," while recognizing that the rule is "expected to produce substantial benefits that have not been quantified." [FN118: Id.]

We urge EPA to expand upon its quantification and, where supported, monetization of the Proposed Rule's benefits. As explained by Dr. Guignet, EPA's economic analysis guidance dictates that the agency

should try to get as far as possible in first identifying all key benefit and cost categories. The next step (when possible) is to then quantify the projected change in each benefit and cost outcome that is expected to result from the policy option, relative to the baseline. Quantifying in this case means to measure the change in terms of some quantitative metric, such as the number of lives saved, number of cases prevented, etc. The final step is to monetize the quantified change, meaning that a dollar value is assigned. [FN119: Guignet 2023 at 9.]

Here, consistent with recently proposed revisions to OMB's Circular A4, EPA should assess and disclose the expected magnitude of benefits that EPA recognized but did not quantify. [FN120: Id. at 10.] This would enable some quantification of additional benefits, even if fully monetizing a benefit category is not possible. In addition, where quantification is not possible, EPA should utilize available monetary cost-of-illness or willingness to pay estimates to illustrate the potential magnitude of benefits discussed qualitatively. [FN121: Id.]

In addition, as summarized in the accompanying analysis by Drs. Anna Reade and Katherine Pelch, the best available science supports EPA's consideration, and potential quantification and monetization, of additional regulatory benefits. [Fn122: See generally Reade and Pelch 2023.] When measuring the Proposed Rule's benefits, EPA ignored or improperly dismissed evidence of the connection between PFAS and liver disease, impaired mammary gland development and

reduced lactation duration, and immune system suppression and increased susceptibility to infectious disease. EPA thus failed to measure all of the benefits attributable to the Proposed Rule's reduction in PFAS exposures. At a minimum, EPA should assess these benefits qualitatively and it should utilize the analysis provided by Drs. Reade and Pelch to attempt to quantify and, where possible, monetize these benefits as well. [FN123: Id.; Guignet 2023 at 10.]

EPA should also reconsider its omission of reduced testicular cancer incidence from its assessment of the Proposed Rule's benefits. To justify that omission, EPA asserts in the Draft EA that "testicular cancer is rarely fatal which implies low expected economic value of reducing this risk because Value of Statistical Life is the driver of the economic benefits evaluated in the EA." [FN124: Draft EA at 6-21– 6-22.] But that assertion is not well supported. While the Draft EA relies on the Value of Statistical Life metric "[t]o estimate the economic value of avoided premature deaths" associated with the rule, it utilizes the cost of illness (COI) valuation approach "[t]o estimate the economic value of avoided morbidity (i.e., non-fatal heart attacks and ischemic strokes, birth weight decrements, and cancers)," with the COI values "reflect[ing] medical care expenditures and opportunity costs associated with managing/treating the condition." [FN125: Id. at 2-4.] EPA has not explained why COI-based valuation of avoided non-fatal testicular cancer cases is not justified. EPA also has not provided a reasoned basis to dismiss as "implie[dly] low" the expected economic value of reducing testicular cancer risks associated with PFOA exposure because EPA has not attempted to estimate the economic value of reducing this risk. [FN126: Id. at 6-21.] Moreover, as explained by Dr. Guignet, the COI values EPA did employ to evaluate the benefits of reducing other non-fatal health effects incorrectly omit the opportunity cost of time, which, as elaborated below, "likely results in a significant underestimate of the benefits." [FN127: Guignet 2023 at 12.] For this reason too, EPA's speculation that the economic value of avoided testicular cancer cases would be "low" is unsupported. In the final EA, EPA should estimate the economic value of reduced testicular cancer cases associated with the Proposed Rule. [FN128: Peer-reviewed literature is available to support the monetization of avoided testicular cancer cases. See, e.g., Michael Aberger et al., Testicular Self-Examination and Testicular Cancer: A Cost Utility Analysis, 3 Cancer Med. 1629 (2014), https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4298389/.] In doing so, EPA should utilize COI estimates that properly account for the opportunity cost of time in addition to avoided medical expenses or use willingness-to- pay estimates where supported by the literature. [FN129: Guignet 2023 at 12.]

EPA Response: In response to this and other comments requesting that the EPA quantify additional benefits, the EPA identified information in the administrative record of this action that allowed the EPA to prepare a quantitative estimate of liver cancer benefits associated with reduced exposure to PFOS for the final rule. See Appendix O in the Economic Analysis for a discussion of liver cancer benefits analysis methodology and results (USEPA, 2024c).

The EPA disagrees with the commenter's assertion that the EPA "ignored or improperly dismissed evidence of the connection between PFAS and liver disease, impaired mammary gland development and reduced lactation duration, and immune system suppression and increased susceptibility to infectious disease." Regarding the agency's consideration of impaired mammary

gland development, please see the EPA response to comment Doc. #1784, SBC-045800 in section 4.2.1.6 in this *Response to Comments* document.

The EPA disagrees with the commenter's assertion that the EPA ignored or improperly dismissed evidence of the connection between PFAS and immune system suppression and increased susceptibility to infectious disease. As discussed in the section 13.5 of the EPA response in this *Response to Comments* document, the EPA clearly stated that immune effects had indicative evidence of associations with exposure to PFOA and PFOS. However, the EPA did not identify the necessary information to connect the measured biomarker responses (i.e., decrease in antibodies) to a disease that could be valued in the economic analysis. It is difficult to quantitate the relationship between altered immune responses, such as decreases in antibody production, and frequency or severity of disease in inherently diverse human populations.

The EPA determined that the evidence indicates that PFOA and PFOS exposures are likely to cause hepatotoxicity in humans under relevant exposure circumstances. In human studies, there is consistent evidence of a positive association with ALT in adults. Associations for other hepatic outcomes were less consistent, including for functional outcomes such as liver disease. Elevated liver serum biomarkers are frequently an indication of liver injury, though not as specific as structural or functional analyses such as histology findings and liver disease. The EPA agrees that there is evidence from animal studies that PFAS exposure causes liver toxicity across animal species. However, there is also literature that supports that steatosis, non-alcoholic fatty liver disease , and alcoholic liver disease can be common causes of mild elevations in liver enzyme levels (Oh, 2017; Giannini, 2005; Kwo, 2017).

In regard to quantifying additional health endpoints in the benefits analysis, the EPA systematically assessed each endpoint with evidence of an association in humans to select endpoints with robust links to adverse human health outcomes and minimize duplication of health impact estimates. The EPA also prioritized endpoints for quantification based on whether the expected magnitude of the impact would meaningfully inform policy decisions, which is consistent with OMB guidance stating that "analytic priority should be given to those additional benefits, costs, and transfers that are important enough to potentially change the rank ordering of the main alternatives in the analysis" (OMB, 2003). As a result, the EPA quantified impacts for total cholesterol, blood pressure, and high-density lipoprotein cholesterol as part of cardiovascular disease impacts, birth weight, renal cell carcinoma, and liver cancer because these endpoints met the EPA's criteria for quantification. For endpoints like small for gestational age, there was an overlap with birth weight, and low-density lipoprotein cholesterol overlapped with total cholesterol and high-density lipoprotein cholesterol, so these were not separately quantified. Several unquantified endpoints were non-specific as disease biomarkers or the relationship between the biomarker and disease outcomes was complex. For instance, while linked to fatty liver disease, ALT levels can be affected by medication use (e.g., Tylenol and statins) and conditions such as hepatitis (A, B, C), heart failure, obesity, and drinking alcohol. Further, the relationship between leptin and diabetes is complex, with some evidence of the protective effects of leptin for non-obese individuals and research on leptin therapy for diabetic persons (Schmidt et al., 2006). Finally, for some endpoints, the magnitude of the potential benefits was not

expected to influence policy decisions materially. For example, based on the epidemiological information and relative magnitude of the PFOA slope factors for testicular cancer and RCC, the EPA expects that avoided testicular cancer cases would represent 14 percent of RCC cases and an even smaller share of avoided cancer deaths because of high survival rates for testicular cancer (ACS, 2023). See section 13.5 of the EPA response in this *Response to Comments* document and EA Section 6.2.3 for further discussion.

Re: PFAS National Primary Drinking Water Regulation Rulemaking, Docket No. EPA–HQ–OW–2022–0114

Dear Assistant Administrator Fox:

While EPA's proposed National Primary Drinking Water Standards acknowledge a broad range of adverse health effects from PFAS exposures, EPA has not fully accounted for those effects, or the corresponding benefits of the proposed regulation, in its analysis of the rule's economic impacts. [FN1: Preliminary Regulatory Determination and Proposed Rule, PFAS National Primary Drinking Water Regulation Rulemaking, 88 Fed. Reg. 18,638 (Mar. 29, 2023) (the "Proposed Rule"). The six PFAS covered by the Proposed Rule are perfluorooctanoic acid ("PFOA"), perfluorooctane sulfonic acid ("PFOS"), perfluorohexane sulfonic acid ("PFHxS"), hexafluoropropylene oxide dimer acid and its ammonium salt ("GenX"), perfluorononanoic acid ("PFNA"), and perfluorobutane sulfonic acid ("PFBS") (collectively, the "Six PFAS").] This document summarizes several of the health effects that EPA failed to quantify and provides resources and information that EPA should use to estimate additional benefits of the proposed drinking water standards.

Together, we have extensive experience reviewing the health and toxicological effects associated with PFAS exposure. As co-leads on the development of the PFAS-Tox Database, we have reviewed over 1,000 studies that evaluate the health impact of PFAS exposure. [FN2: Katherine E. Pelch, Anna Reade, Carol F. Kwiatkowski, Francheska M. Merced-Nieves, Haleigh Cavalier,

Kim Schultz, Taylor Wolffe, and Julia Varshavsky, The PFAS-Tox Database: A Systematic Evidence Map of Health Studies on 29 per- and Polyfluoroalkyl Substances, Environment International 167 (September 1, 2022): 107408, https://doi.org/10.1016/j.envint.2022.107408; Katherine E. Pelch, Anna Reade, Taylor A. M. Wolffe, and Carol F. Kwiatkowski, PFAS Health Effects Database: Protocol for a Systematic Evidence Map, Environment International 130 (September 1, 2019): 104851, https://doi.org/10.1016/j.envint.2019.05.045; Katherine E. Pelch and Carol F. Olson, Comments to New York State Governor Hochul and New York State Commissioner Bassett on the Need to Establish Comprehensive, and Health Protective, Drinking Water Standards for PFAS, September 9, 2022; Anna Reade and Katherine E. Pelch, Technical Comments Re: Advance Notice on the Regulation of Perfluoroalkyl, Polyfluoroalkyl Substances (PFAS) as a Class, November 16, 2022, https://www.nrdc.org/sites/default/files/pfas-class-technical-comments-20201116.pdf; Erika Schreder and Katherine E. Pelch, Comments on Washington Department of Health's Draft Recommended State Action Levels for per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water: Approach, Methods and Supporting Information (Chapter 246-290 WAC) January 2020.] These activities inform our additional comments regarding EPA's proposed National Primary Drinking Water Standards, specifically identifying health effects that should have been better incorporated into the economic benefits analysis.

I. Lactation duration [FN5: We acknowledge helpful technical support and feedback from Dr. Megan Romano in the development of this section.]

EPA has not fully considered the impact of PFAS exposure on mammary gland development and function, and specifically on lactation duration. Given the importance of breastfeeding and its association with many other health impacts, this is a major oversight. Breastfeeding is associated with short- and long-term health benefits for both mother and child, but <30% of mothers in the U.S. continue any breastfeeding until the American Academy of Pediatrics (AAP) recommended 12 months. [FN6: Arthur I. Eidelman, Richard J. Schanler, Margreete Johnston, Susan Landers, Larry Noble, Kinga Szucs, and Laura Viehmann, Breastfeeding and the Use of Human Milk, Pediatrics 12, no. 3 (March 2012): e827–41, https://doi.org/10.1542/peds.2011-3552; CDC, Results: Breastfeeding Rates, Centers for Disease Control and Prevention, April 4, 2023, https://www.cdc.gov/breastfeeding/data/nis_data/results.html.] The benefits of human milk for children are well described, with health benefits extending into adulthood. [FN7: Stanley Ip, Mei Chung, Gowri Raman, Priscilla Chew, Nombulelo Magula, Deirdre DeVine, Thomas Trikalinos, and Joseph Lau, Breastfeeding and Maternal and Infant Health Outcomes in Developed

Countries, Evidence Report/Technology Assessment, no. 153 (April 2007): 1–186, https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4781366/.] Potential health benefits of lactation for the mother are often described with the "reset" hypothesis, whereby the adverse cardiometabolic changes during gestation (insulin resistance, hyperlipidemia, and visceral fat of pregnancy) are ameliorated by breastfeeding. In contrast, without breastfeeding, these metabolic changes persist. [FN8: Alison M. Stuebe and Janet W. Rich-Edwards, The Reset Hypothesis: Lactation and Maternal Metabolism, American Journal of Perinatology 26, no. 1 (January 2009): 81–88, https://doi.org/10.1055/s-0028-1103034.] Meta-analyses with over 200,000 women confirmed relationships between breastfeeding for 12 months and protection against common adverse cardiometabolic health outcomes, including a 30% risk reduction for diabetes and a 13% risk reduction for hypertension. [FN9: Rabel Misbah Rameez, Divyajot Sadana, Simrat Kaur, Taha Ahmed, Jay Patel, Muhammad Shahzeb Khan, Sarah Misbah, Marian T. Simonson, Haris Riaz, and Haitham M. Ahmed, Association of Maternal Lactation With Diabetes and Hypertension: A Systematic Review and Meta-Analysis, JAMA Network Open 2, no. 10 (October 16, 2019): e1913401, https://doi.org/10.1001/jamanetworkopen.2019.13401.]

Importantly, shortened duration of breastfeeding has been associated with PFAS exposure in human studies. Six human studies, published between 2010 and 2022 were recently reviewed and evaluated in a meta-analysis. [FN10: Amalie Timmermann, Oyemwenosa N. Avenbuan, Megan E. Romano, Joseph M. Braun, Janne S. Tolstrup, Laura N. Vandenberg, and Suzanne E. Fenton, Per- and Polyfluoroalkyl Substances and Breastfeeding as a Vulnerable Function: A Systematic Review of Epidemiological Studies, Toxics 11, no. 4 (April 2023): 325, https://doi.org/10.3390/toxics11040325.] Four of the five included studies reported shortened total duration of breastfeeding with higher PFOS and PFOA exposure. The human epidemiological findings are consistent with findings from experimental animal studies. Despite these consistencies and the importance of breastfeeding duration on maternal and infant health, EPA failed to adequately review and consider shortened lactation duration in the 2023 Draft Toxicity Assessment and Proposed Maximum Contaminant Level Goal for Perfluorooctanoic Acid (PFOA) in Drinking Water. In that document, EPA reviewed the animal evidence for impacts on mammary gland development and function but did not evaluate the corresponding epidemiological evidence. [FN11: US EPA, Public Comment Draft Toxicity Assessment and Proposed Maximum Contaminant Level Goal for Perfluorooctanoic Acid (PFOA) in Drinking Water, Office of Water, March 14, 2023, https://www.epa.gov/system/files/documents/2023-03/MAIN_Proposed%20MCLG%20for%20PFOA%20in%20Drinking%20Water_3.9.23_For%20Proposal.pdf.]

The 2023 Draft Toxicity Assessment and Proposed Maximum Contaminant Level Goal for Perfluorooctanoic Acid (PFOA) in Drinking Water cites but does not thoroughly discuss two of the epidemiological studies that are included in the recent meta-analysis on breastfeeding (Timmerman et al. 2017 and Romano et al. 2016) [FN12: Clara Amalie Gade Timmermann, Esben Budtz-Jørgensen, Maria Skaalum Petersen, Pál Weihe, Ulrike Steuerwald, Flemming Nielsen, Tina Kold Jensen, and Philippe Grandjean, Shorter Duration of Breastfeeding at Elevated Exposures to Perfluoroalkyl Substances, Reproductive Toxicology, Developmental

Origins of Disease, 68 (March 1, 2017): 164–70, https://doi.org/10.1016/j.reprotox.2016.07.010; Megan E. Romano, Yingying Xu, Antonia M. Calafat, Kimberly Yolton, Aimin Chen, Glenys M. Webster, Melissa N. Eliot, Cynthia R. Howard, Bruce P. Lanphear, and Joseph M. Braun, Maternal Serum Perfluoroalkyl Substances during Pregnancy and Duration of Breastfeeding, Environmental Research 149 (August 1, 2016): 239–46, https://doi.org/10.1016/j.envres.2016.04.034.], and fails to cite or discuss the four additional studies, including those published before the review cut-off date (Fei et al., 2010, Nielsen et al., 2022, Rosen et al., 2018, and Timmerman et al., 2021). [FN13: Chunyuan Fei, Joseph K. McLaughlin, Loren Lipworth, and Jørn Olsen, Maternal Concentrations of Perfluorooctanesulfonate (PFOS) and Perfluorooctanoate (PFOA) and Duration of Breastfeeding, Scandinavian Journal of Work, Environment & Health 36, no. 5 (September 2010): 413–21, https://doi.org/10.5271/sjweh.2908;Christel Nielsen, Ying Li, Magdalena Lewandowski, Tony Fletcher, and Kristina Jakobsson, Breastfeeding Initiation and Duration after High Exposure to Perfluoroalkyl Substances through Contaminated Drinking Water: A Cohort Study from Ronneby, Sweden, Environmental Research 207 (May 1, 2022): 112206, https://doi.org/10.1016/j.envres.2021.112206; Emma M. Rosen, Anne Lise Brantsæter, Rachel Carroll, Line S. Haug, Alison B. Singer, Shanshan Zhao, and Kelly K. Ferguson, Maternal Plasma Concentrations of Per- and Polyfluoroalkyl Substances and Breastfeeding Duration in the Norwegian Mother and Child Cohort, Environmental Epidemiology (Philadelphia, Pa.) 2, no. 3 (September 2018): e027, https://doi.org/10.1097/EE9.0000000000000027; Clara Amalie Gade Timmermann, Marianne Skovsager Andersen, Esben Budtz-Jørgensen, Henriette Boye, Flemming Nielsen, Richard Christian Jensen, Signe Bruun, Steffen Husby, Philippe Grandjean, and Tina Kold Jensen, Pregnancy Exposure to Perfluoroalkyl Substances and Associations With Prolactin Concentrations and Breastfeeding in the Odense Child Cohort, The Journal of Clinical Endocrinology and Metabolism 107, no. 2 (September 13, 2021): e631–42, https://doi.org/10.1210/clinem/dgab638.] None of the epidemiological studies are cited or discussed in the 2016 Drinking Water Health Advisory for Perfluorooctanoic Acid (PFOA). [FN14: US EPA, Drinking Water Health Advisory for Perfluorooctanoic Acid (PFOA), May 2016, https://www.epa.gov/sites/production/files/2016-05/documents/pfoa_health_advisory_final- plain.pdf.] Though the animal literature is discussed in the document, the 2016 Drinking Water Health Advisory for PFOA did not consider any candidate reference doses (RfDs) based on mammary gland effects.

Perhaps EPA's failure to adequately consider mammary gland and lactational effects in the 2023 toxicity assessment is, in part, a result of mammary gland impacts being improperly diminished in earlier documents. Evidence for this can be seen in the conclusions EPA makes in the 2023 toxicity assessment. In the 2023 Draft Toxicity Assessment and Proposed Maximum Contaminant Level Goal for Perfluorooctanoic Acid (PFOA) in Drinking Water document EPA states, "no differences in response to a lactation challenge were seen in PFOA-exposed CD-1 mouse dams with delayed mammary gland development, and no significant effects on body weight gain were seen in pups nursing from dams with less fully developed mammary glands (White, 2011, 1276150)." [FN15: US EPA, Public Comment Draft Toxicity Assessment and

Proposed Maximum Contaminant Level Goal for Perfluorooctanoic Acid (PFOA) in Drinking Water, Office of Water, March 14, 2023, https://www.epa.gov/system/files/documents/2023-03/MAIN_Proposed%20MCLG%20for%20PFOA%20in%20Drinking%20Water_3.9.23_For%20Proposal.pdf.] Similarly, ATSDR stated "… the mammary gland effect did not result in an adverse effect on lactational support at maternal doses as high as 1 mg/kg/day, based on normal growth and survival in F2 pups (White et al. 2011). Given that milk production was adequate to support growth, the biological significance of the delayed development of the mammary gland observed at very low doses is uncertain and was not considered a suitable basis for the MRL." [FN16: ATSDR, Toxicological Profile for Perfluoroalkyls, May 2021, https://www.atsdr.cdc.gov/toxprofiles/tp200.pdf.]

However, these summaries simplify the complex behaviors that are observed during lactation between a mother (dam) and offspring (pup). The lactation challenge in White et al. 2011 only evaluated the amount of milk passed from the dam to the pups in a single nursing event; it did not account for compensatory behaviors that may have been present in the pups. [FN17: Sally S. White, Jason P. Stanko, Kayoko Kato, Antonia M. Calafat, Erin P. Hines, and Suzanne E. Fenton, Gestational and Chronic Low-Dose PFOA Exposures and Mammary Gland Growth and Differentiation in Three Generations of CD-1 Mice, Environmental Health Perspectives 119, no. 8 (August 2011): 1070–76, https://ehp.niehs.nih.gov/doi/epdf/10.1289/ehp.1002741.] The study authors added this additional context, stating "[t]hese data suggest that nursing behavior of the neonates may have changed (i.e., increased number of nursing events per day or longer nursing per event) to compensate for the decreased potential in milk production by the F1 dam, but we did not evaluate these end points in this study." [FN18: Id.] We previously submitted comments to ATSDR highlighting the agency's misinterpretation of the study by White et al. (2011), pointing out that "an estimated 3-6 million mothers each year are unable to produce milk or have difficulty breastfeeding. The cause of this remains unclear, however, exposure to toxic environmental chemicals are one candidate explanation for the inability to initiate and/or sustain breastfeeding." [FN19: Anna Reade, Comments on ATSDR Toxicological Profile on Perfluoroalkyls 2018 Draft," September 6, 2018, https://www.nrdc.org/sites/default/files/comments-on-atsdr-toxicological- profile-on-perfluoroalkyls-2018-draft_2018-08-21.pdf.]

Importantly, a 2009 workshop of experts in mammary gland biology and risk assessment came to the consensus that changes in mammary gland growth and differentiation, including changes in developmental timing, are a relevant human health concern. [FN20: Ruthann A. Rudel, Suzanne E. Fenton, Janet M. Ackerman, Susan Y. Euling, and Susan L. Makris, Environmental Exposures and Mammary Gland Development: State of the Science, Public Health Implications, and Research Recommendations, Environmental Health Perspectives 119, no. 8 (August 2011): 1053–61, https://doi.org/10.1289/ehp.1002864.] Altered mammary gland development may lead to difficulty in breastfeeding and/or an increase in susceptibility to breast cancer later in life.

Although Michigan and New Jersey did not directly base their risk assessments for PFOA on mammary gland effects or changes in lactation duration, they did address the increased risk for

this effect through their application of uncertainty factors. Michigan stated that mammary gland effects may not be considered adverse, but that they could be representative of endocrine (hormone) effects at doses below Michigan's selected point of departure. [FN21: Jamie C. DeWitt, Kevin Cox, and David A. Savitz, Health Based Drinking Water Value Recommendations for PFAS in Michigan, June 27, 2019, https://www.michigan.gov/-/media/Project/Websites/PFAS-Response/Reports/2019-Health-Based-Drinking-Water-Value-Recommendations-PFAS-MI.pdf?rev=1779be946a5c41439f1db4f3eeaec4ec.] Michigan therefore applied an additional uncertainty factor for database limitations regarding endocrine effects. [FN22: Id.]

New Jersey stated that the mammary gland effect is "the most sensitive systemic endpoint for PFOA with data appropriate for dose-response modeling. It is a well-established toxicological effect of PFOA that is considered to be adverse and relevant to humans for the purposes of risk assessment." [FN23: New Jersey Drinking Water Quality Institute, Health-Based Maximum Contaminant Level Support Document: Perfluorooctanoic Acid (PFOA), February 15, 2017, https://www.nj.gov/dep/watersupply/pdf/pfoa-appendixa.pdf.] However, New Jersey also concluded that because altered mammary gland development had yet to be used as the basis for a risk assessment it would not select it as the critical effect, but did apply an uncertainty factor to protect for this more sensitive effect. [FN24: Note that Texas has used altered mammary gland development in its PFAS risk assessment prior to NJ Drinking Water Quality Institute's comments. The report was formerly available from the Texas Commission on Environmental Quality (TCEQ) at https://www.tceq.texas.gov/assets/public/implementation/tox/evaluations/pfcs.pdf, but an update is now available: TCEQ, Per- and Poly-Fluoroalkyl Substances (PFAS), February 14, 2023, https://www.tceq.texas.gov/downloads/toxicology/pfc/pfcs.pdf.]

In finalizing the toxicity assessment and economic analysis, EPA should reconsider the effects of PFOA on mammary gland development and function, with specific attention to impacts on lactation duration. EPA could then quantify the number of people who may be impacted by the proposed regulation. For example, using data available from the meta-analysis by Timmerman et al. (2023), an attributable risk for shortened lactational duration could be calculated as follows:

AR = Io (RR-1) [FN25: Noel S. Weiss and Thomas D. Koepsell, eds, Epidemiologic Methods: Studying the Occurrence of Illness. Second edition. Oxford University Press, 2014, https://academic.oup.com/book/24995.]

• where RR is the relative risk of the outcome of interest - In our case stopping any breastfeeding before 6 months. In this example we will use the data from Romano et al., 2016 [FN26: Megan E. Romano, Yingying Xu, Antonia M. Calafat, Kimberly Yolton, Aimin Chen, Glenys M. Webster, Melissa N. Eliot, Cynthia R. Howard, Bruce P. Lanphear, and Joseph M. Braun, Maternal Serum Perfluoroalkyl Substances during Pregnancy and Duration of Breastfeeding, Environmental Research 149 (August 1, 2016): 239–46, https://doi.org/10.1016/j.envres.2016.04.034.]

• where Io is the disease incidence in the unexposed - Here we estimate this based on data from the National Immunization Survey, which suggests that the prevalence of children who were breastfed at 6 months in the U.S. was 55.8% for 2019. [FN27: CDC, Results: Breastfeeding Rates, Centers for Disease Control and Prevention, April 4, 2023. https://www.cdc.gov/breastfeeding/data/nis_data/results.html.]

• This means that 44.2% of children are not breastfed at 6 months, which can be used as an estimate of cumulative incidence. [FN28: Ideally the cumulative incidence is based on the disease incidence in an unexposed population. However, with PFAS, the general population is not a truly unexposed population. Therefore, the cumulative incidence, and consequently the attributable risk, may be overestimated. Therefore, an alternative analysis with a more conservative assumption of the cumulative incidence is also provided.]

Calculation Inputs:

[Table: See Docket ID EPA-HQ-OW-2022-0114-1808]

*These RRs were statistically significant in the original paper, so there is more confidence in the precision of these estimates. The others were borderline significant, so though they are still reasonable, they are also possibly less precise.

Given the calculation inputs provided above, the attributable risk for stopping breastfeeding by 6 months can be calculated for those with the highest serum PFAS level in pregnancy (i.e., in the 4th quartile in the HOME Study) compared to those the lowest serum PFAS exposure (1st quartile in the HOME study). The HOME Study is the Health Outcomes and Measures of the Environment study) which was used in Romano et al., 2016.

The resulting attributable risks are:

o ARPFOA= 18 per 100 mothers

o ARPFOs= 11 per 100 mothers

o ARPFHxS= 9 per 100 mothers

o ARPFNA= 5 per 100 mothers

In other words, 18 additional mothers (per 100 mothers) stopped breastfeeding before 6 months of age in the highly exposed PFOA group versus the lowest exposed PFOA group.

More conservatively, one could assume that the incidence of stopping breastfeeding among truly unexposed women is ¼ that of the general population (11.05%). If that is the case, then the attributable risks are as follows.

o ARPFOA= 5 per 100 mothers

o ARPFOs= 3 per 100 mothers

o ARPFHxS= 2 per 100 mothers

o ARPFNA= 1 per 100 mothers

Monetization of the impact of shortened lactation duration is also possible. [FN29: Dylan D. Walters, Linh T H Phan, and Roger Mathisen, The Cost of Not Breastfeeding: Global Results from a New Tool, Health Policy and Planning 34, no. 6 (July 2019): 407–17, https://doi.org/10.1093/heapol/czz050.] An online tool that estimates the cost of not breastfeeding suggests that in the US there is an additional $28 million in healthcare system treatment costs when children are not breastfed due to increased maternal and child infections, and additional costs due to cognitive losses and the need for households to purchase breastmilk substitutes. [FN30: Alive & Thrive, In the USA, Breastfeeding Impacts Families, Communities, and the Economy, 2022, https://www.aliveandthrive.org/en/country-stat/usa.]

II. Immunotoxicity

In its explanation of why immune effects were not selected for economic analysis, EPA states:

"While immune effects had indicative evidence of associations with exposure to PFOA and PFOS, EPA did not identify the necessary information to connect the measured biomarker responses (i.e., decrease in antibodies) to a clinical effect that could be valued in the economic analysis." [FN31: US EPA, Draft for Public Comment: Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation, March 14, 2023, https://www.epa.gov/system/files/documents/2023-03/Proposed%20PFAS%20NPDWR%20EA_final_03_09_2023_0.pdf.]

While it is difficult to quantitate the relationship between altered immune responses, such as decreases in antibody production, and frequency or severity of disease in inherently diverse human populations, these "subclinical" effects are associated with increased disease risk and economic cost and are therefore important to address. Small shifts within the range of normal clinical values can still have devastating population-level impacts. Specifically, the cellular and humoral immune response to vaccination is thought to be a sensitive indicator of immunosuppression. [FN32: Ronald Glaser, Gary R. Pearson, Robert H. Bonneau, Brian A. Esterling, Cathie Atkinson, and Janice K. Kiecolt-Glaser, Stress and the Memory T-Cell Response to the Epstein-Barr Virus in Healthy Medical Students, Health Psychology 12, no. 6 (1993): 435–42, https://doi.org/10.1037/0278-6133.12.6.435.] In a literature review from 2018 the authors conclude that, "[t]aken together, we find that results of epidemiological studies, supported by findings from toxicological studies, provide strong evidence that humans exposed to PFOA and PFOS are at risk for immunosuppression." [FN33: Jamie C. DeWitt, Sarah J. Blossom, and Laurel A. Schaider, Exposure to Per-Fluoroalkyl and Polyfluoroalkyl Substances Leads to Immunotoxicity: Epidemiological and Toxicological Evidence, Journal of Exposure Science & Environmental Epidemiology 29, no. 2 (March 2019): 148–56, https://doi.org/10.1038/s41370-018-0097-y.] In a more recent review, authors find that, "there is ample evidence illustrating PFAS affect multiple aspects of the immune system, which supports the overall conclusion that not only PFOA and PFOS, but also other members of the PFAS family alter immune functions in humans." [FN34: Veronika Ehrlich, Wieneke Bil, Rob

Vandebriel, Berit Granum, Mirjam Luijten, Birgitte Lindeman, Philippe Grandjean, et al, Consideration of Pathways for Immunotoxicity of Per- and Polyfluoroalkyl Substances (PFAS), Environmental Health 22, no. 1 (February 22, 2023): 19, https://doi.org/10.1186/s12940-022-00958-5.] They go on to confirm that the "most reported immunotoxic effect in humans is immunosuppression, reflected by reduced vaccine antibody levels and increased risk of common infectious diseases." [FN35: Id.]

Importantly, immunosuppression has been defined by experts as "a reduced ability of the immune system to respond to a challenge from a level considered normal, regardless of whether clinical disease results." [FN36: Jamie C. DeWitt, Dori R. Germolec, Robert W. Luebke, and Victor J. Johnson. Associating Changes in the Immune System with Clinical Diseases for Interpretation in Risk Assessment, Current Protocols in Toxicology 67 (February 1, 2016): 18.1.1-18.1.22, https://doi.org/10.1002/0471140856.tx1801s67.] However, there are clinical consequences of mild-to-moderate chronic immunosuppression, including an increase in the incidence of infectious diseases. Even small changes in infectious disease frequency can have major social and economic impacts, particularly on vulnerable populations. The elderly experience age-related declines in immune function and factors that contribute to immunosuppression in this population can increase the risk of morbidity and mortality. Adults 65 and older make up approximately 90% of the total pneumonia and influenza-related deaths in the U.S. [FN37: C. P. Mouton, O. V. Bazaldua, B. Pierce, and D. V. Espino, Common Infections in Older Adults, Health Care Food & Nutrition Focus 18, no. 3 (November 2001): 1, 3–7.] Furthermore, vaccines are less effective in the elderly. [FN38: Richard Aspinall, Giuseppe Del Giudice, Rita B. Effros, Beatrix Grubeck-Loebenstein, and Suryaprakash Sambhara, Challenges for Vaccination in the Elderly, Immunity & Ageing: I & A 4 (December 11, 2007): 9, https://doi.org/10.1186/1742-4933-4-9.] The young are particularly susceptible to infectious agents that require adult-level immune responses. For example, the ability to produce antibodies develops slowly, with infants (1-3 months old) starting off with approximately 30% of adult antibody levels and children (12- 16 years old) still only producing around 70% of adult levels. [FN39: E. R Stiehm and H. H. Fudenberg, Serum Levels of Immune Globulins in Health and Disease: A Survey Pediatrics 37, no. 5 (May 1966): 715–27.] Agents that induce immunosuppression can exacerbate the inherent deficits in infants' and children's immature and still developing immune systems. [FN40: Jamie C. DeWitt, Dori R. Germolec, Robert W. Luebke, and Victor J. Johnson, Associating Changes in the Immune System with Clinical Diseases for Interpretation in Risk Assessment, Current Protocols in Toxicology 67 (February 1, 2016): 18.1.1-18.1.22, https://doi.org/10.1002/0471140856.tx1801s67.]

In a recent epidemiology study, authors looked directly at the link between PFAS exposure and persistent infections. [FN41: Catherine M. Bulka, Vennela Avula, and Rebecca C. Fry, Associations of Exposure to Perfluoroalkyl Substances Individually and in Mixtures with Persistent Infections: Recent Findings from NHANES 1999–2016, Environmental Pollution 275 (April 15, 2021): 116619, https://doi.org/10.1016/j.envpol.2021.116619.] They found that, "[e]ach PFAS was individually associated with significantly higher pathogen burdens and the most pronounced associations were observed in adolescents [e.g., among adolescents, a doubling

of PFOS was associated with 30% (95% CI: 25–36%) higher pathogen burden]. Quantile g-computation revealed PFAS mixtures as a whole were also associated with higher pathogen burdens. Taken together, these results suggest PFAS exposure may increase susceptibility to and foster the clustering of persistent infections, particularly among adolescents." [FN42: Id.]

Impacts associated with mortality and morbidity from common pathogens (such as influenza and pneumonia) have been studied and estimated. These can serve as a basis for beginning to quantitate and even monetize the benefit of reducing the risk of immunotoxicity associated with PFAS exposure as these common pathogens are more likely to increase mortality and morbidity in those who are mildly to moderately immunosuppressed, i.e., the young, the elderly, and those with toxicant-induced PFAS immunosuppression. Relevant data includes:

Quantitative data on morbidity [FN43: M. Heron, Deaths: Leading causes for 2010, National Vital Statistics Reports. 2013; 62.]

• In 2010, influenza and pneumonia together were ranked the ninth leading cause of death in the U.S. for all ages.

• For infant deaths in 2010, influenza was ranked 46th and pneumonia was ranked 47th.

• For the elderly population, chronic lower respiratory disease was ranked 3rd and influenza-pneumonia was ranked 7th in leading causes of death in 2004.

Cost estimates

• Total cost of influenza and pneumonia was estimated to be $40.2 billion in the U.S. [FN44: American Lung Association, Influenza and pneumonia: State of lung disease in diverse communities, 2010.]

• Ear infections (otitis media) is the most common indication for antibiotic use and outpatient visits in children – $2.88 billion in added annual health care expense in the U.S. [FN45: Sameer Ahmed, Nina L. Shapiro, and Niel Bhattacharyya, Incremental Health Care Utilization and Costs for Acute Otitis Media in Children, The Laryngoscope 124 (2014): 301–5, https://doi.org/10.1002/lary.24190.]

• Annual cost of treating RSV for children under 5 in 2000 was $652 million [FN46: L. Clark Paramore, Vincent Ciuryla, Gabrielle Ciesla, and Larry Liu, Economic Impact of Respiratory Syncytial Virus-Related Illness in the US, PharmacoEconomics 22, no. 5 (April 1, 2004): 275–84, https://doi.org/10.2165/00019053-200422050-00001.]

Taken together, the data support the identification of protecting against immune system effects, particularly immunosuppression, as a key benefit resulting from the proposed MCLs. The data also suggests that EPA has sufficient information to quantify this benefit. Examples include the number of infection-related deaths avoided, the number of infectious disease cases avoided, and the increased proportion of the population with successful responses to immunization. Finally, there is information detailing some of the costs related to common infectious diseases that can be used to monetize some of these benefits. In finalizing the economic analysis EPA should

quantitate and monetize, where possible, the health benefits of reduced PFAS-related immunotoxicity that the proposed MCLs will provide.

III. Liver disease

We disagree with EPA's conclusions that the hepatic effects that have been observed are modest and unquantifiable. The reality is that the experimental literature and human literature are substantial, mutually reinforcing, consistent, and point to a problem of PFAS hepatotoxicity. [FN47: Elizabeth Costello, Sarah Rock, Nikos Stratakis, Sandrah P. Eckel, Douglas I. Walker, Damaskini Valvi, Dora Cserbik, et al, Exposure to Per- and Polyfluoroalkyl Substances and Markers of Liver Injury: A Systematic Review and Meta-Analysis, Environmental Health Perspectives 130, no. 4 (April 27, 2022): 046001, https://doi.org/10.1289/EHP10092.] Few findings in environmental health are as consistent as the experimental and epidemiological evidence that PFAS, notably but not limited to PFOA and PFOS, are associated with liver damage. [FN48: Id.]

Across species and toxicological studies, PFAS exposure causes increased ALT (alanine aminotransferase) levels and liver steatosis (fat accumulation), which is the starting point for NAFLD (nonalcoholic fatty liver disease). Yet, EPA has argued that 1) the connection from increased ALT to liver disease is lacking and 2) that the changes in ALT after PFAS exposure is modest (implying lacks importance).

1) Connecting increased ALT to liver disease:

Specifically, with respect to connecting increases in ALT to liver disease, EPA states, "Elevated ALT levels could be one of several contributors to the non-alcoholic fatty liver disease. Additionally, high ALT levels can be associated with alcohol consumption, heart failure, hepatitis (A, B, and C), medication use (e.g., Tylenol and statins), and obesity (Mayo Clinic, 2022) and this wide range of associations makes it difficult to model economic benefits of non- specific ALT level changes in response to reduced exposures." [FN49: US EPA, Draft for Public Comment: Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation, March 14, 2023, https://www.epa.gov/system/files/documents/2023-03/Proposed%20PFAS%20NPDWR%20EA_final_03_09_2023_0.pdf.] Most health effects are associated with more than one risk factor. This does not mean that quantifying the benefit of reducing one of these multiple risk factors is not possible.

Multiple studies show that PFAS exposure causes liver toxicity and fatty liver disease across animal species, without known species exceptions so far. There is no reason to expect humans to be the exception. Evaluating environmental contributors to NAFLD in cross-sectional studies is difficult due to how and when the disease is diagnosed. NAFLD is seldom diagnosed in early stages in clinical practice and may not be coded as among the comorbidities for other diagnoses. Therefore, cross- sectional studies that have relied on medical record review (ICD-code verified) of NAFLD are likely to suffer from outcome misclassification. However newer studies, not reliant on ICD-code verification, but rather on imaging of livers, have linked PFAS exposure

with deleterious effects on fatty liver findings. [FN50: Xinchen Wang, Xiaoqian Jin, Hancheng Li, Xianyu Zhang, Xi Chen, Kuan Lu, and Chenliang Chu, Effects of Various Interventions on Non-Alcoholic Fatty Liver Disease (NAFLD): A Systematic Review and Network Meta-Analysis, Frontiers in Pharmacology 14 (2023), https://www.frontiersin.org/articles/10.3389/fphar.2023.1180016.] In a biopsy-proven cohort of 105 patients with NAFLD, PFAS were found to be adversely associated with liver fat content, lipid metabolism, and bile acid metabolism. [FN51: Partho Sen, Sami Qadri, Panu K. Luukkonen, Oddny Ragnarsdottir, Aidan McGlinchey, Sirkku Jäntti, Anne Juuti, et al., Exposure to Environmental Contaminants Is Associated with Altered Hepatic Lipid Metabolism in Non-Alcoholic Fatty Liver Disease, Journal of Hepatology 76, no. 2 (February 1, 2022): 283–93, https://doi.org/10.1016/j.jhep.2021.09.039.]

2) Addressing the biological significance of "modest" changes in ALT

EPA states that the effects of PFAS exposure on observed ALT levels are modest, but fails to recognize that more recently, professional societies have recommended more appropriate, physiologically-based cutoffs for what is considered a normal or abnormal ALT level based on the important societal need to address the NAFLD epidemic. [FN52: Naga, Chalasani, Zobair Younossi, Joel E. Lavine, Michael Charlton, Kenneth Cusi, Mary Rinella, Stephen A. Harrison, Elizabeth M. Brunt, and Arun J. Sanyal, The Diagnosis and Management of Nonalcoholic Fatty Liver Disease: Practice Guidance from the American Association for the Study of Liver Diseases, Hepatology 67, no. 1 (January 2018): 328, https://doi.org/10.1002/hep.29367; Jin Hwa Park, Jun Choi, Dae Won Jun, Sung Won Han, Yee Hui Yeo, and Mindie H Nguyen, Low Alanine Aminotransferase Cut-Off for Predicting Liver Outcomes; A Nationwide Population-Based Longitudinal Cohort Study, Journal of Clinical Medicine 8, no. 9 (September 11, 2019): 1445, https://www.mdpi.com/2077-0383/8/9/1445.]

A large epidemiological study of more than 30,000 participants in a community with PFOA exposures ranging from national background levels to very high levels of contamination, concluded participants in the fifth quintile had 16% increased odds of having above-normal ALT (95% CI: odds ratio: 1.02, 1.33%). [FN53: Lyndsey A. Darrow, Alyx C. Groth, Andrea Winquist, Hyeong-Moo Shin, Scott M. Bartell, and Kyle Steenland, Modeled Perfluorooctanoic Acid (PFOA) Exposure and Liver Function in a Mid-Ohio Valley Community, Environmental Health Perspectives 124, no. 8 (August 2016): 1227–33, https://doi.org/10.1289/ehp.1510391.] There is a near monotonic increase in ALT with increasing PFOA, with the dose-response beginning at what are considered to be "background" levels of population exposure.

A reanalysis of the above data was performed using the updated physiologically-based cutoffs for ALT as recommended by the medical liver disease societies. [FN54: Alan Ducatman, Youran Tan, Brian Nadeau, and Kyle Steenland, Perfluorooctanoic Acid (PFOA) Exposure and Abnormal Alanine Aminotransferase: Using Clinical Consensus Cutoffs Compared to Statistical Cutoffs for Abnormal Values, Toxics 11, no. 5 (May 2023): 449, https://doi.org/10.3390/toxics11050449.] This reanalysis showed an increased association of PFOA to abnormal ALT and emphasized the near monotonic increases in ALT with increasing

dose. For example, males in the 5th quintile of measured PFOA were 35% more likely and females 20% more likely to have abnormal ALT, with mean continuous increases of 9% per quintile for men and 4% for women. [FN55: Id.]

Independent of PFAS, populations with higher biomarkers of liver distress such as ALT have worse outcomes for morbidity and mortality. [FN56: Paul Y. Kwo, Stanley M. Cohen, and Joseph K. Lim, ACG Clinical Guideline: Evaluation of Abnormal Liver Chemistries, American Journal of Gastroenterology 112, no. 1 (January 2017): 18–35, https://journals.lww.com/ajg/Fulltext/2017/01000/ACG_Clinical_Guideline_Evaluation_of_Abnormal.13.aspx; Naga Chalasani, Zobair Younossi, Joel E. Lavine, Michael Charlton, Kenneth Cusi, Mary Rinella, Stephen A. Harrison, Elizabeth M. Brunt, and Arun J. Sanyal, The Diagnosis and Management of Nonalcoholic Fatty Liver Disease: Practice Guidance from the American Association for the Study of Liver Diseases, Hepatology 67, no. 1 (January 2018): 328, https://doi.org/10.1002/hep.29367.]

In finalizing the economic analysis EPA should reconsider the conclusions drawn regarding the literature exploring ALT and NAFLD in relationship to PFAS exposure and attempt to quantitate the number of people who would benefit from reduced risk of liver effects from the proposed MCLs. EPA should also attempt to monetize the health benefit from reduced NAFLD cases, as there are studies available that provide estimates of the economic burden associated with NAFLD.

For example, one study from 2016 estimated that in the U.S., "over 64 million people are projected to have NAFLD, with annual direct medical costs of about [$103.3] billion ($1,613 per patient)" but that the "burden is significantly higher when societal costs are included." [FN57: Zobair M. Younossi, Deirdre Blissett, Robert Blissett, Linda Henry, Maria Stepanova, Youssef Younossi, Andrei Racila, Sharon Hunt, and Rachel Beckerman, The Economic and Clinical Burden of Nonalcoholic Fatty Liver Disease in the United States and Europe, Hepatology 64, no. 5 (2016): 1577–86, https://doi.org/10.1002/hep.28785.] The study estimated societal costs to be $188.9 billion, yielding a total cost of $292.2 billion. These cost estimates account for drugs, healthcare, and changes in quality of life, but they under-value other indirect costs such as lost productivity and federal benefits for disability. They also underestimate even the pharmaceutical costs, as they rely on formal diagnoses and it is clear that NAFLD treatment, hospitalization, and indirect costs can precede the diagnosis and treatment. [FN58: Myriam Alexander, A. Katrina Loomis, Jolyon Fairburn-Beech, Johan van der Lei, Talita Duarte-Salles, Daniel Prieto-Alhambra, David Ansell, et al., Real-World Data Reveal a Diagnostic Gap in Non-Alcoholic Fatty Liver Disease, BMC Medicine 16, no. 1 (August 13, 2018): 130. https://doi.org/10.1186/s12916-018-1103-x.] Despite these limitations, EPA can still use this information to begin to monetize the benefit of reduced NAFLD cases from the proposed MCLs.

***

EPA failed to quantify several of the health effects associated with PFAS exposure. We have provided resources and information that EPA should use to estimate the proposed drinking water

standards' additional benefits of protecting against PFAS-associated effects on mammary gland development, the liver and immune system.

Sincerely,

Anna Reade, PhD

Senior Scientist

EPA Response: The EPA acknowledges commenters' submission of additional health information that they deem could result in additional quantified benefits. Please see section 13.5 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1808, SBC-046110 in section 13.5 in this *Response to Comments* document for discussion about liver effects, ALT, lactation duration, and immunotoxicity. Please see the EPA response to comment Doc. #1784, SBC-045800 in section 4.2.1.6 in this *Response to Comments* document regarding mammary gland development and lactation duration. The EPA has characterized some hepatic effects, developmental impacts, and immunotoxicity effects in the nonquantifiable benefits analysis. The EPA notes that the information submitted by the commenters further supports the EPA's conclusions in the nonquantifiable benefits discussion, as well as the EPA's conclusions in the Final Toxicity Assessments for PFOA and PFOS: that the PFAS regulated by the final rule adversely impact a wide variety of health endpoints and that the benefits of reducing these regulated PFAS from drinking water are substantial.

Regarding ALT, the EPA considered the new evidence provided by Ducatman et al. (2023) and referenced by this commenter in the Final Toxicity Assessments for PFOA and PFOS. When considering BMRs for the effect of increased ALT, the EPA selected the adverse effect level of ALT for liver disease to be C = 42 IU/L for males and C = 30 IU/L for females based on the sex-specific upper reference limits found in Valenti et al. (2021). These are slightly lower and more health protective than the cutoff values used in the original study (45 IU/L for men and 34 IU/L for women). These cutoffs are also slightly higher than the American College of Gastroenterology cutoffs, which considers that "true healthy normal ALT level ranges from 29 to 33 IU/L for males, 19 to 25 IU/L for females" (Kwo et al., 2017). The limits from Valenti et al. (2021) are the most up-to-date clinical consensus cutoffs which update the American Association for the Study of Liver Diseases journal Clinical Liver Disease recommended values of 30 IU/L for males, and 19 IU/L for females (Kasarala and Tillmann, 2016; Ducatman et al., 2023). Valenti et al. (2021) determined the updated values using the same approach at the same center as those presented in Ducatman et al. (2023) but used an updated standardized method.

Earthjustice et al. (Doc. #1808, SBC-046133)

12. Any environmental benefits anticipated to result from the proposed regulatory action should be included in the EA.

The quantified and qualitative benefits identified in the EA focus solely on human health. Given the persistence of PFAS pollutants, PFAS that are left untreated by a PWS in the baseline likely would be passed through the entire system and eventually released back into the environment. If this is the case, then the proposed MCLs would reduce the concentrations of PFAS in the public water before it is eventually discharged into the environment, and thus reduce any adverse impacts to ecosystem services and other environmental endpoints. EPA should consult with environmental risk assessors and ecotoxicologists, but if reasonable, then such benefits at the very least deserve a qualitative discussion and consideration in the EA.

13. EPA should reconsider whether additional health benefits can be quantified and/or monetized.

As described in comment #6, EPA went to impressive lengths to identify and qualitatively discuss potential health benefits that it asserted could not be quantitatively estimated. However, in developing the final rule EA, EPA should consider whether there is adequate information to support quantification and/or monetization of additional benefits. As per EPA's (2014) own economic guidelines, analysts should try to get as far as possible in first identifying all key benefit and cost categories. The next step (when possible) is to then quantify the projected change in each benefit and cost outcome that is expected to result from the policy option, relative to the baseline. Quantifying in this case means to measure the change in terms of some quantitative metric, such as the number of lives saved, number of cases prevented, etc. The final step is to monetize the quantified change, meaning that a dollar value is assigned. EPA spent significant effort in monetizing benefits when possible, and then qualitatively identifying and discussing other benefits, but the Agency should consider whether there is adequate information to at least quantify additional benefit categories in the final EA.

As suggested by OMB's recently proposed revisions to Circular A4 (OMB 2023), EPA should consider highlighting the expected magnitude of some of the qualitatively discussed benefits. For example, quantified estimates of the number of individuals potentially exposed, and/or that are susceptible to the increased risks and that would therefore benefit from the proposed regulatory options, would provide further insight and aid the qualitative discussion. In other words, perhaps the quantification step can be taken to some degree for some benefit categories, even if fully monetizing a benefit category is not possible.

Additionally, there may be health outcomes where quantification is not possible, but perhaps monetary cost-of-illness (COI) or willingness to pay (WTP) estimates exist. In such cases, as suggested by the Agency's own economic guidelines (EPA 2014), EPA should consider illustrative analyses or perhaps even a full-blown "break-even" analysis, to provide further insight to the potential magnitude of the qualitatively discussed benefits and plausibility that

those unquantified benefits may further result in positive net benefits. Such analyses are recommended in cases where unquantified benefits could be meaningful (OMB 2003, 2023).

Finally, EPA should thoroughly evaluate information submitted during the public comment period for the proposed rule and assess whether additional health benefits can be identified, quantified, and ideally monetized in the EA for the final rule. For example, the comments submitted by Earthjustice and the Natural Resource Defense Council (NRDC) include estimates of lactation duration effects attributable to increased exposures to PFOA, PFOS, PFHxS, and PFNA. Impacts of PFAS exposure on breastfeeding, and the resulting impacts to infant and maternal health are not currently discussed in the EA. At the very least, this is a benefit category that deserves qualitative discussion, and as the commenters' analysis suggests, perhaps quantification and even monetization of these benefits is possible. As another example, on page 6-21 of the EA, EPA states that hepatic effects were not quantified or monetized because PFAS exposure could not be linked to a health endpoint (i.e., an increased incidence of disease). However, more recent studies discussed in the comments submitted by Earthjustice and NRDC may allow for quantification, and perhaps even monetization of this important benefit category.

EPA Response: Please see the EPA's previous response to Earthjustice et al. (Doc. #1808, SBC-046110) and section 13.5 of the EPA response in this *Response to Comments* document addressing quantification of benefits related to hepatic, breastfeeding and lactation effects. Please see section 13.5 of the EPA response in this *Response to Comments* document for the EPA's response to the comment recommending further quantification using break-even analysis and using a willingness-to-pay valuation methodology.

13.6 Nonquantifiable Benefits of Removal of PFAS Included in the Proposed Regulation and Co-removed PFAS

Summary of Major Public Comments and EPA Responses

The EPA received comments on the nonquantifiable benefits of other PFAS included in the regulation and co-removed PFAS. One commenter claimed that the EPA's HRRCA lacked analysis for the benefits and costs of addressing Hazard Index chemicals. A different commenter stated that the EPA did not provide data to support its analysis of benefits predicted from the implementation of the Hazard Index MCL. The EPA disagrees with these comments. The comprehensive qualitative benefits analysis that the EPA provided in Section 6.2 of the EA (USEPA, 2024b) and section XII of the FRN, summarizes the best available information on health effects associated with exposure to Hazard Index chemicals and also other PFAS chemicals not included in the regulation that may be co-removed. The nonquantifiable benefits analysis is consistent with the requirement under the SDWA that the EPA analyze the "quantifiable and nonquantifiable health risk reduction benefits" (see USC 300g-1(b)(C)(i)).

One commenter stated that the HRRCA "likely omits or underestimates significant health and environmental benefits to PFAS limits in drinking water." The commenter requested that the EPA emphasize how the current benefits are likely much greater than what the EPA has quantified and

pointed to other health endpoints including immune toxicity and mammary gland effects as additional benefit categories. Additionally, the commenter discussed additional benefits anticipated including those resulting from reduced exposure to co-occurring contaminants and improved environmental quality. The EPA agrees with the commenter that benefits of the rule are likely underestimated and that additional benefits are likely to occur as a result of the final NPDWR. In the EA for the final rule and also in the FRN for this action, the EPA has provided a comprehensive discussion on quantifiable and nonquantifiable benefits and has clearly described that the quantified benefits are likely underestimated.

Individual Public Comments

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043061)

EPA's lack of analysis for the benefits and costs of addressing PFHxS, PFNA, HFPO-DA, and PFBS is concerning and conflicts with the intention of SDWA to require that new regulations undergo such an analysis.

EPA Response: The EPA disagrees with the commenter that the EPA lacks analysis for the benefits and costs of Hazard Index compounds, and that the EPA's analysis conflicts with the intention of the SDWA. The EPA has completed the HRRCA for the PFAS NPDWR consistent with the SDWA 1412(b)(3)(C) statutory requirements. The statute states that the EPA is required to analyze quantifiable and non-quantifiable health risk reduction benefits associated with each MCL. Due to data limitations, the EPA discusses the benefits of PFHxS, PFNA, HFPO-DA, and PFBS removal qualitatively. Further, as discussed in Chapter 6.2 and Appendix K of the EA, the EPA quantified benefits associated with PFNA effects on birth weight in sensitivity analyses. Additionally, the EPA notes that the agency has quantified some of the incremental benefits associated with PFHxS in the primary analysis, as shown in the increased quantified benefits estimates of the proposed rule compared to option 1a. These benefits stem from the additional reduction in PFOA and PFOS that is estimated to occur as a result of including PFHxS in the regulation. See also sections 13.3.2 and 13.6 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1774, SBC-045679 and Doc. #1845, SBC-046056 in sections 13.4.5 and 5.1.3, respectively, in this *Response to Comments* document. Regarding the EPA's evaluation of costs associated with PFHxS, PFNA, HFPO-DA and PFBS, see section 13.3.2 of the EPA response in this *Response to Comments* document.

Silent Spring Institute (Doc. #1784, SBC-045803)

4. The Health Risk Reduction and Cost Analysis (HRRCA) likely omits or underestimates significant health and environmental benefits to PFAS limits in drinking water.

In its own analysis, EPA acknowledged that "[t]here are significant nonquantifiable sources of benefits that were not captured in the quantified benefits." The current analysis monetized health benefits associated with medical savings from improving cardiovascular health, preventing low infant birth weight, reducing kidney cancer incidence, and avoiding health effects associated

with disinfection byproducts. EPA has also qualitatively described benefits associated with preventing negative health effects associated with hazard index PFAS compounds, other health effects associated with PFOA and PFOS that could not be monetized (e.g., immune system dysfunction), and health effects associated with unregulated PFAS.

We acknowledge EPA's significant effort and the challenges and limitations of economic cost-benefit analyses. We agree with EPA's expectation that the proposed rule will result in additional nonquantifiable benefits not included in the HRRCA. However, we recognize that a more comprehensive assessment is challenging, and we do not support any delay that might result from trying to monetize additional possible benefits. To weigh the benefits appropriately, EPA should emphasize how the current HRRCA underestimates this rule's benefits and the accrued benefits of adopting this rule are likely much greater than what EPA has quantified. These benefits include:

• Benefits from other health improvements. Subclinical effects (e.g., ALT levels) were overlooked, and critical health endpoints, including immune toxicity, were not reflected in the economic analysis. Another critical endpoint undervalued in the economic analysis was PFAS impacts on the mammary gland despite evidence of deleterious effects. Mammary gland impacts have consequence for breastfeeding/infant nutrition and future breast cancer risk.[REF2: Kay JE, Cardona B, Rudel RA, et al. Chemical Effects on Breast Development, Function, and Cancer Risk: Existing Knowledge and New Opportunities. Curr Environ Health Rep. 2022;9(4):535-562.; REF18: Rudel RA, Fenton SE, Ackerman JM, Euling SY, Makris SL. Environmental exposures and mammary gland development: State of the science, public health implications, and research recommendations. Environ Health Perspect. 2011;119(8):1053-1061.] Some of these effects occur among sensitive subpopulations, like pregnant women and infants.

• Benefits from reduced exposure to contaminants that co-occur with the six PFAS in this rule. Those co-occurring contaminants include other PFAS, regulated contaminants other than disinfection byproducts, and unregulated contaminants.

• Improved environmental quality. [REF29: Cordner A, Goldenman G, Birnbaum LS, et al. The True Cost of PFAS and the Benefits of Acting Now. Environ Sci Technol. 2021;55(14):9630-9633.] Although the focus of the HRRCA is on human health benefits resulting from drinking water standards, the economic analysis altogether omits the socioenvironmental value of PFAS removal on the environment. The current rule may result in more source water protection and downstream reductions of PFAS at wastewater treatment plants and natural waters. As a result, reductions of PFAS in drinking water may also result in lowered PFAS in wildlife, including certain fish, which itself can be a major source of PFAS exposures.

• Lowered costs borne by state agencies and residents from implementing a state-by-state approach of PFAS regulations.[REF29: Cordner A, Goldenman G, Birnbaum LS, et al. The True Cost of PFAS and the Benefits of Acting Now. Environ Sci Technol. 2021;55(14):9630-9633.]

EPA Response: See section 13.6 of the EPA response in this *Response to Comments* document. Please see section 13.5 of the EPA response in this *Response to Comments* document

and the EPA response to comment Doc. #1808, SBC-046110 in section 13.5 in this *Response to Comments* document and Doc. #1784, SBC-045800 in section 4.2.1.6 in this *Response to Comments* document for discussion about quantification for ALT and mammary gland effects. See the quantitative benefits analysis for DBP exposure reduction resulting from installation of PFAS treatment (Chapter 6 of USEPA, 2024b and also section XII of the FRN) where the EPA qualitatively discussed the benefits resulting from removal of other contaminants including microbial contaminants and SOCs. See Chapter 4 of the EA for discussion on state regulations and the EPA's approach for adjusting PFAS occurrence information for states with promulgated PFAS regulations.

While potential environmental improvements are beyond the scope of this rulemaking, the EPA is fully committed to reduce PFAS pollution through policies that safeguard communities, protect the environment, and hold polluters accountable. For additional information on the EPA's PFAS actions, see the EPA PFAS Strategic Roadmap.

American Chemistry Council (ACC) (Doc. #1841, SBC-044821)

[As outlined in these comments, the Agency's proposal suffers from a number of significant shortcomings, including the following –]

• EPA has not provided data to support its analysis of benefits predicted from the implementation of the HI MCL,

EPA Response: See sections 13.3.2 and 13.4 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1774, SBC-045679 and Doc. #1845, SBC-046056 in sections 13.4.5 and 5.1.3, respectively, in this *Response to Comments* document.

13.7 Benefits Resulting from Disinfection By-Product Co-Removal

Summary of Major Public Comments and EPA Responses

The EPA received comments on uncertainties associated with bladder cancer reductions. One commenter incorrectly stated that the "EPA does not recognize the uncertainty that there is not always direct correlation between THM4 levels and TOC in all public water systems". In response, the EPA notes that the trihalomethanes (THM) concentrations in this co-removal analysis were not calculated based on TOC reduction. TOC was used to bin systems in the universe of PWSs using the fourth Six Year Review (SYR4) database and PFAS occurrence model with the THM4 reduction calculated from the formation potential experiments before and after GAC treatment in the DBP ICR database. This dataset is the best available data to determine THM4 reduction based on TOC removal using GAC treatment. Another commenter stated that the causal link of DBPs and bladder cancer has not been established. The EPA notes that an extensive body of epidemiological studies have shown that increased exposure to chlorinated DBPs is associated with higher risk of bladder cancer and other adverse health outcomes (Cantor et al., 1998; Freeman et al., 2017). Weisman et al. (2022) found that

approximately 8,000 of the 79,000 annual bladder cancer cases in the U.S. were potentially attributable to chlorinated DBPs in drinking water systems. While research has not established a causal link between THM4 and bladder cancer, there is strong evidence that there is a correlation between THM4 and bladder cancer.

One commenter stated that the DBP co-removal benefit analysis did not meet the standards required by SDWA for estimating benefits since it was not reviewed by the SAB. The commenter is incorrect. SDWA 1412(e) directs the EPA to request comments from the Science Advisory Board prior to proposing an MCLG and NPDWR. The EPA sought and received comment from the SAB prior to proposing this NPDWR (see USEPA, 2022d). The statute does not dictate the precise level of scientific questions for which the EPA must seek comments from the SAB. The EPA sought SAB comment on the four most significant areas that informed derivation of the MCLGs for all six PFAS regulated by this action and for other parts of the benefits analysis that informed the overall development of the NPDWR. It is neither required nor feasible for the EPA to seek the SAB's input on every potential scientific question that may come about as part of a rulemaking as there are hundreds or thousands of such questions in any given rulemaking. The EPA did seek additional peer review of its DBP co-removal benefit analysis prior to its inclusion in the economic analysis for which it received overwhelmingly favorable comments from reviewers (see USEPA, 2023j). Furthermore, this rule is based on the EPA's consideration of a wide body of existing peer-reviewed science on this subject (e.g., Regli et al., 2015; Weisman et al., 2022). In short, the EPA has used peer reviewed science and sought further peer review to support its DBP co-removal analysis, and as part of the supporting material for the rule proposal, the EPA included the comments from the expert peer reviewers as well as how each comment was addressed or the rationale for why it was not changed. Please see "Response to Letter of Peer Review for DBP Co-benefits" (USEPA, 2023j) for discussion of that peer review and the EPA's responses to peer reviewed comments.

Another commenter claimed that the EPA improperly quantified benefits of co-removed substances rather than co-occurring substances. The EPA disagrees with these assertions since the analysis of DBP co-removal is focused on co-occurring contaminants. As demonstrated elsewhere in the record for this action, PFAS commonly co-occur with each other. Additionally, in waters where disinfection is required, TOC (i.e., a DBP precursor) and PFAS may co-occur. The DBP co-removal benefits analysis relied on DBP formation potential experiments that highlighted the changes to TOC with and without GAC treatment. Furthermore, as discussed above, the methodology to estimate THM4 reductions was externally peer reviewed by three experts in GAC treatment for PFAS removal and DBP formation potential.

A few commenters stated that the EPA already had initiatives to reduce THMs in drinking water and suggested that reduction of bladder cancer cases is better addressed through existing DBP rules. While the EPA agrees that there are existing DBP regulations to reduce DBP exposure and risks, this rule will provide additional health risk reduction benefits associated with enhanced DBP reduction. The EPA has considered those co-removal benefits as part of the economic analysis. The EPA notes that it is required under the SDWA 1412(b)(3)(C)(i)(II) to assess

quantifiable and nonquantifiable health risk reduction benefits for which there is a factual basis in the rulemaking record to conclude that such benefits are likely to occur from reductions in co-occurring contaminants that may be attributed solely to compliance with the maximum contaminant level, excluding benefits resulting from compliance with other proposed or promulgated regulations. DBP reductions presented in the EPA's HRRCA are anticipated to result solely from the PFAS NPDWR. As required under the SDWA, any quantifiable and nonquantifiable benefits from future actions concerning DBPs in drinking water will be addressed at the time of those actions and are independent from benefits stemming as a result of the PFAS rulemaking. A couple of commenters supported the EPA's analysis of DBP benefits but recommended that the EPA also consider other co-removed contaminants. The EPA agrees with the commenters that multiple co-occurring contaminants will be removed as a result of this rulemaking. Furthermore, the EPA acknowledges in the EA that additional co-removal benefits would be realized due to treatment for PFAS. While, with the exception of DBPs co-removed, the EPA has not quantified other co-removal benefits at this time, the agency included discussion of non-quantifiable benefits for multiple other PFAS and for other contaminants.

Individual Public Comments

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044948)

10. The Department acknowledges the large contribution of benefit that reductions in bladder cancer, due to disinfection byproduct (DBP) precursor removal, has on the total benefit of the proposed rulemaking. However, there are many uncertainties associated with this benefit that do not appear to be addressed in Table 6-53: Limitations and Uncertainties in the Analysis of DBP Quantified Benefits, including:

- This benefit assumes total organic carbon (TOC) reduction due to reverse osmosis (RO), GAC installation, or presence of ion exchange resins that can concurrently remove TOC and PFAS compounds. This proposal also does not recognize emerging treatment technologies such as natural and engineered clays that will have limited TOC reduction benefit, although EPA acknowledges that GAC or RO may not be the selected treatment alternative.
- According to Table 6-53 of the Economic Analysis "EPA uses relationships between TOC levels and changes in THM4 levels among GAC-treating systems from the 1998 DBP ICR..." Although the Department recognizes the importance of TOC precursor removal as a DBP reduction strategy, the EPA does not recognize the uncertainty that there is not always direct correlation between THM4 levels and TOC in all public water systems. (Consonery et. al, 2004)
- In New York State, most PFAS impacted public water systems have groundwater sources and disinfection byproduct levels are negligible. Of the 551 public water supplies New York State expects may exceed one or more proposed MCLs 12% are surface water or groundwater under the direct influence (GWUDI) of surface water and 88% are

groundwater systems. As indicated in 6.7.1.2 Baseline Information on DBP Precursors and Trihalomethane Formation, "the [TOC] levels in Ground Water plants tended to be lower compared to concentrations in Surface Water plants"

- Of the 12% of public water systems that are surface water or GWUDI systems, approximately 21% have at some time exceeded a THM4 or haloacetic acid (HAA5) MCL. This represents 2.7% of the total number of public water systems expected to exceed a PFAS MCL.

The Department supports rulemaking based on sound science that provides meaningful reduction of all cancers. According to the New York State Department of Health, approximately 5,400 New Yorkers are diagnosed with bladder cancer each year [FN1: https://www.health.ny.gov/statistics/cancer/registry/abouts/bladder.htm]. However, we suggest that reduction of bladder cancers is best addressed by TOC removal benchmarks through the existing practice of treatment technique regulations for disinfection byproducts as well as distribution system controls, rather than indirectly through PFAS MCLs that do not include a treatment optimization component with no mechanism to monitor performance.

EPA Response: There are many treatment technologies available for PFAS removal from drinking water with varying levels of effectiveness. For the rule, the EPA has identified GAC, PFAS-selective IX, RO, and NF as BATs. However, water systems are not required to use BATs to meet the rule. More details on the ramifications of such a choice may be found in the summary of major comments for section 10 of the EPA response in this *Response to Comments* document which also contains information on alternative treatment technologies. The EPA has not quantified their costs, evaluated co-removal, or considered benefits of technologies not selected as BATs.

The EPA agrees with the commenter that there is not always a direct correlation between THM4 levels and TOC in public water systems. The THMs were not calculated based on the TOC reduction. The TOC was used to bin systems and THM reduction was calculated from formation potential before and after GAC treatment. This dataset is the best available data to determine THM4 reduction based on TOC reduction using GAC treatment. Because we are not estimating THM4 from TOC, this reduces the uncertainty in correlation estimates. Even though systems may be in compliance with the current MDBP regulations, they may still achieve a reduction in THM4 that is a quantifiable benefit for bladder cancer reduction. The EPA characterized THM4 levels and TOC in public water systems using the best available data on the occurrence of these compounds. (Please see Table 6-29 in the economic analysis titled “Data Sources and How the Information Derived from each Source is Used in the DBP Co-Removal Analysis”). Further, the EPA estimated TOC percent removal in both surface water and ground water systems using a logistic equation model. The methodology for estimating DBP reductions was externally peer reviewed by three experts in GAC treatment for PFAS removal and DBP formation potential. The external peer reviewers supported the EPA’s approach and edits based on their recommendations for clarity and completeness are reflected in the following analysis and discussion.

The EPA agrees that reducing bladder cancer cases attributable to DBP drinking water exposure can be addressed by existing DBP-focused regulations and distribution system controls. However, as required by the SDWA, the EPA has reviewed the science concerning removal of co-occurring compounds and based on the available information anticipates that DBPs will be reduced under the PFAS rulemaking as a result of PFAS treatment installation. Therefore, as required under the SDWA, the EPA assessed the benefits of avoided bladder cancer morbidity and mortality.

See also section 13.7 of the EPA response in this *Response to Comments* document regarding uncertainty inherent in the relationship between THM4 levels and TOC in public water systems.

While the EPA acknowledges that New York state groundwater systems may have lower TOC than their surface water systems, the model for TOC removal and THM4 reduction was based on the best available national dataset that are representative on a national level but may not be identical on a local or state level.

For the DBP co-removal analysis, the EPA assigned TOC values at the system level based on Ground Water or Surface Water distributions. Because the TOC levels for all systems is not available, the EPA used TOC data provided by states in response to the fourth Six-Year Review to derive TOC probability distributions for influent into a PFAS treatment process; one distribution for Ground Water systems and another for Surface Water systems. The EPA randomly assigned values from these distributions to each Ground Water or Surface Water system, respectively. The actual TOC values may be higher or lower than the assigned values. The EPA notes that for systems using GAC for PFAS removal the corresponding impact would be under-stating or over-stating costs.

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044353)

4. Page 18732, Column 1, Section XV—Statutory and Executive Order Reviews

a. NHDES Comment - The proposal estimates the economic cost associated with implementation and the projected health benefit. More than half of the projected health benefit associated with adopting the proposed PFAS MCLs is associated with coincidently reducing disinfection by-products (DBPs) when treating for PFAS which are already regulated through the DBP rules and associated MCLs. NHDES believes a more complex analysis needs to be completed whereby EPA completes an assessment to optimize human health protection and economic costs by considering alternative MCLs for DBPs in tandem with alternative MCLs for PFAS. Without further consideration of DBPs, communities impacted by DBPs without the presence of PFAS will not realize the same benefit/level of public health protection as those with PFAS levels above the proposed MCLs.

EPA Response: The EPA disagrees with the commenter. The EPA's analysis of health benefits associated with DBP exposure reductions is independent of DBP MCLs because the regulatory action is for PFAS contaminants only. The EPA is advancing public health protection from DBPs by considering revisions to the DBPRs in a separate process. Specifically, the DBP

regulations were listed as candidates for revision based on the Third Six Year Review findings and the EPA is currently evaluating potential changes to the DBP regulations. Any potential changes to the DBP rules will be evaluated separately from the PFAS NPDWR under those actions. Based on the SDWA requirements, the HRRCA for potential DBP rules would take into account simultaneous compliance benefits that may be relevant for systems subject to both PFAS and DBP NPDWRs. The EPA further notes that the commenter is incorrect in stating that half the rule's benefits are attributable to DBP reductions. DBP reductions are anticipated to produce approximately 23 percent of the rule's quantified benefits. While the EPA anticipates there may be some nonquantifiable benefits from reduction of unregulated DBPs, the agency has focused the majority of its nonquantifiable benefits analysis on benefits attributable to regulated and unregulated PFAS.

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044335)

Second, NHDES believes the suggested benefits for treatment for PFAS are misleading, since more than half of the projected health benefit associated with adopting the proposed PFAS MCLs is associated with coincidently reducing disinfection by-products (DBPs) when treating for PFAS. As disinfection by-products are already regulated through the DBP rules and associated MCLs we feel those regulations are the correct path to realize and attribute those benefits.

EPA Response: The EPA disagrees with the commenter, as the benefits quantified for reduced DBP exposure under the PFAS NPDWR are independent of public health benefits stemming from the DBP rules and the DBP MCLs. Specifically, DBP benefits quantified under this rulemaking are a result of reduced DBP exposure from installation of PFAS treatment technologies. The EPA notes that the body of evidence for health effects associated with DBPs shows that additional DBP removal can further reduce bladder cancer risk. See the EPA response to comment Doc. #1690, SBC-044353 in section 13.7 in this *Response to Comments* document for discussion of the percentage of quantified rule benefits attributable to DBP reduction.

See also section 13.7 of the EPA response in this *Response to Comments* document for additional detail on the body of evidence for health effects for DBPs.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045922)

4. Benefits assessment for bladder cancer is not supported by the science

A significant portion of the benefits that EPA is claiming for this rulemaking come from co-benefits that would stem from reductions in disinfection byproduct (DBP) formation that EPA predicts are likely to occur due to compliance with the MCLs in the proposed rule. These benefits do not flow directly from reductions in PFAS but are due to the identification of GAC as a possible treatment technology [FN195: The proposed rule identifies GAC as a treatment technology but does not compel its use. Other approaches, including use of an alternative source of water supply, are available. 88 Fed. Reg. at 18,684.]. Use of GAC would decrease the levels of other contaminants, specifically trihalomethanes. EPA quantifies benefits of avoided bladder

cancer cases and avoided bladder cancer-related deaths. The significant problem with this approach is that a causal link between DBP and bladder cancer has not been established [FN196: See EPA Economic Analysis of the Proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances, 2023, at page 6-109 to 6-110.]. While EPA cites Weisman et al. 2022 to support estimates of DBP-attributable bladder cancer, Weissman's overall conclusion calls into question the specific approach EPA is using by questioning the utility of using the four regulated trihalomethanes (THM4) as a surrogate for DBP mixtures [FN197: See: Weisman, R.J., Heinrich, A., Letkiewicz, F., Messner, M., Studer, K., Wang, L., and Regli, S. 2022. Estimating National Exposures and Potential Bladder Cancer Cases Associated with Chlorination DBPs in US Drinking Water. Environmental Health Perspectives,130(8):087002. https://doi.org/10.1289/EHP9985, which states: "Despite the increased weight of evidence established in recent years toward inferring a causal relationship between DBP exposure and bladder cancer, more work is needed to understand the possible mechanisms involved in that relationship, clarify different sources of uncertainty, and address the utility of THM4 as a surrogate measure of risk from the most relevant DBP mixtures of toxicological interest."]. Weisman et al. 2022 states "[w]e also identified several uncertainties that may affect the results from this study, primarily related to the use of THM4 as a surrogate measure for DBPs relevant to bladder cancer."[FN198: Id. at results section.] This paper also notes limitations related to the lack of a good animal model for THM-associated bladder cancer as well as the lack of an established mode of action.

The approach EPA is taking to estimate these benefits is not only highly uncertain but also complex and raises many questions. For instance, in the 2006 DBP rule, EPA includes a lag period in the modelling to account for when the reduction in exposure begins and when the full benefit might be realized [FN199: 71 Fed. Reg. 444 (Jan. 4, 2006).]. However, the modeling in this proposed rule does not include a lag period for either the bladder cancers or the kidney cancers. While EPA acknowledges that they did not include a cessation lag, they simply note that this likely leads to an overestimate in benefits, and no effort is made to account for this overestimate [FN200: See EPA Economic Analysis of the Proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances, 2023, at page 6-127.]. EPA must explain why the modeling in this rule is not consistent with the approaches taken in the DBP rulemaking.

EPA realized its approach was complex and quietly, without any public input or awareness, had three anonymous peer reviewers respond to specific charge questions regarding EPA's approach through the use of a letter review [FN201: See EPA Response to Letter of Peer Review for Disinfectant Byproduct Reduction as a Result of Granular Activated Carbon Treatment for PFOA and PFOS in Drinking Water: Benefits Analysis Related to Bladder Cancer. 2023 EPA–815–B23–001.]. EPA does not disclose the expertise of these anonymous reviewers, nor does EPA explain why this modeling and approach was not presented to the SAB. SAB review, which includes opportunity for transparency and public comment and is far more robust than a letter review, as discussed earlier in these comments, is warranted for influential scientific information

that supports rulemaking. This novel and uncertain analysis does not meet the standards required by SDWA for estimating benefits.

EPA Response: The EPA disagrees with the comment. While research has not established a causal link between THM4 and bladder cancer, there is strong evidence that there is a correlation between THM4 and bladder cancer. THM4 may not be the causative agent but there is a well-established association: Epidemiological studies have shown that increased exposure to chlorinated DBPs is associated with higher risk of bladder cancer and other adverse health outcomes (Cantor et al., 1998; Freeman et al., 2017). Weisman et al. (2022) found that approximately 8,000 of the 79,000 annual bladder cancer cases in the U.S. were potentially attributable to chlorinated DBPs in drinking water systems.

The EPA's approach to using THM4 as a surrogate for the suite of chlorinated DBPs is consistent with the approach used in numerous epidemiological studies to estimate the co-occurrence and co-removal of specific genotoxic or cytotoxic DBPs.

The EPA's modeling approach for kidney and bladder cancer differs significantly from the approaches used in the Stage 2 Disinfection and Disinfection Byproducts Rule (D/DBPR). The Stage 2 D/DBPR did not consider cumulative exposures and prospective cohorts. While the EPA did not model the transitional dynamics in relative annual risk of bladder cancer following the THM4 exposure reduction, the EPA considered age-specific cohort cumulative exposures to THM4. Therefore, while drinking water THM4 concentrations are assumed to be reduced upon compliance with the rulemaking, the changes in cumulative average exposure are much more gradual. The EPA has not identified any studies on bladder cancer-specific risk cessation lag. The Stage 2 D/DBPR analysis relied on cancer risk cessation lag studies focused on smoking and arsenic exposure when modeling bladder cancer cessation lag. Additionally, Regli et al. (2015) did not include pertinent information on cessation lag. For this rule, a cross-sectional analysis quantifying the relationship between lifetime cancer risk and lifetime average exposure was used.

The DBP rulemaking approach also does not provide information on kidney cancer-specific risk cessation lag. However, The EPA evaluates gradual declines in PFAS blood serum concentrations resulting from the proposed rulemaking by implementing ORD's pharmacokinetic model. Gradual changes in PFAS blood serum combined with age-dependent data on baseline kidney cancer incidence result in modeling that considers gradual changes in kidney cancer incidence over the period of analysis.

The studies estimating the link between serum PFOA and RCC are not dynamic, and hence do not provide insights into whether RCC incidence may respond gradually to changes in serum PFOA. See also section 13.4.3 of the EPA response in this *Response to Comments* document, RCC Benefits Estimation.

The EPA disagrees with the commenter's assertion that the peer review completed does not meet the requirements of the SDWA. As discussed in section 13.7 of the EPA response in this *Response to Comments* document and part 12 of the preamble, the EPA must not take every

question to the SAB. The EPA's methodology to estimate DBP reductions was externally peer reviewed by three experts in GAC treatment for PFAS removal and DBP formation potential. This peer review was fully consistent with the EPA's peer review policy, utilized three highly respected independent drinking water treatment experts. See the *EPA Response to Letter of Peer Review for Disinfectant Byproduct Reduction as a Result of Granular Activated Carbon Treatment for PFOA and PFOS in Drinking Water: Benefits Analysis Related to Bladder Cancer* (USEPA, 2023j) for more information as to how the EPA conducted this letter peer reviews. As part of the supporting material for the rule proposal, the EPA included the comments from the three expert peer reviewers as well as how each comment was addressed or the rationale for why it was not changed. The EPA has met all peer review requirements for this DBP analysis and the rulemaking overall.

3M Company (Doc. #1774, SBC-045705)

11. Comments on Figure 6-10 Overview of Analysis of Co-Removal Benefits ((U.S, 2023a))

In a decision tree like that seen in Figure 6-10, each step of the decision analysis is comprised of models with uncertain predictions, decisions based on subjective judgement, value-based judgements, and uncertain cost estimates and cost expectations. This graphic represents the decision process EPA has both implicitly and explicitly used to generate the MCL. At issue is the level of uncertainty a multi-branched decision analysis actually represents. In practice, EPA has not identified nor quantified the measurable uncertainty in each step of the decision process used by EPA. EPA must provide the public with an honest estimate of the degree to which the MCGL will result in a benefit to human health, including the actual costs which the public must incur for these indeterminate benefits. A rigorous uncertainty analysis of the Figure 6-10 decision tree will result is such a large uncertainty in the total value of reduced bladder cancer, that any positive benefit will not be quantifiable.

EPA Response: The EPA disagrees with this comment that such a large uncertainty would result from the bladder cancer, that the agency cannot quantify benefits. A conservative approach to the THM4 reduction estimates was chosen and the limitations and uncertainties associated with the analysis were also detailed at length in the rule proposal. See also sections 13.2, , 13.8, , and 13.9, of the EPA response in this *Response to Comments* document. Furthermore, to ensure the methodology and analyses were scientifically robust, the estimation of THM4 reduction due to GAC and PWS universe estimation based on TOC occurrence in the SYR4 database was peer reviewed. Other elements that fed into the analysis were also peer reviewed: specifically, the PFAS occurrence model (Cadwallader et al., 2022) and the bladder cancer slope factor (Regli et al., 2015; Weisman et al., 2022). In short, the DBP co-removal benefits analysis is based on peer-reviewed, best available science, fully consistent with the statutory requirements of the SDWA.

3M Company (Doc. #1774, SBC-045694)

b. EPA Improperly Inflated the Purported Benefits of the Rule

i. EPA improperly quantified benefits of co-removed substances rather than co-occurring substances

EPA quantified benefits of a co-removed substance (THM4) (USEPA 2023i, p. 6-108). This is inappropriate as it artificially inflates the benefits of the MCL. The SDWA contemplates quantifying benefits from co-occurring substances but not quantifying the benefits of all co-removed substances. [FN101: See SDWA [sec]1412(b)(3)(C).] If EPA were to weigh the benefits of all co-removed substances as a result of treatment, every NPDWR would have its benefits inflated because any treatment technique will remove more than the targeted substance. For example, THM4 is not a PFAS and EPA did not make a determination that it is a co-occurring substance. EPA's inclusion of the purported benefits of THM4's removal in the cost-benefit analysis violates the SDWA's clear direction on considerations to be included in that analysis.

EPA Response: See section 13.7 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046111)

Second, while it is appropriate for EPA to consider co-benefits when estimating the health benefits of the Proposed Rule, [FN130: Id. at 5.] EPA's analysis of co-benefits is incomplete. The Draft EA considers only reduced bladder cancer risks from co-removal of disinfection byproducts associated with PFAS drinking water technology, [FN131: Proposed Rule, 88 Fed. Reg. at 18,721.] ignoring the benefits that will arise from co- removal of additional synthetic organic contaminants, including additional PFAS that are not directly regulated by the Proposed Rule.

EPA Response: The EPA describes in the EA that additional non-quantifiable co-removal benefits would be realized due to treatment for PFAS (USEPA, 2024b). These are non-quantifiable due to lack of occurrence and health data on a national scale. See also section 13.7 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046128)

5. The inclusion of co-benefits (or ancillary benefits) in benefit-cost analyses is well- grounded in economic theory.

Roughly 14% to 18% of the estimated quantified benefits of the PFAS NPDWS are due to reduced bladder cancer risks, which in the current context is a co-benefit or ancillary benefit – i.e., a benefit that results from a regulatory action but that is not the direct intent of that action (OMB 2003). More specifically, the proposed PFAS NPDWS is anticipated to also reduce disinfection byproducts, and in turn reduce the risks of bladder cancer associated with exposure to those byproducts. The inclusion of such benefits in benefit-cost analysis is directed under the Safe Drinking Water Act (SDWA) and is well-grounded in economic theory (EPA 2014, OMB 2003).

EPA Response: The EPA agrees with the commenter that inclusion of co-benefits in benefit-cost analysis is well-grounded in economic theory and directed under SDWA.

American Chemistry Council (ACC) (Doc. #1841, SBC-044845)

The Projected Benefits of a Reduction in Disinfection Byproducts Cannot be Attributed Solely to Compliance with the Proposed MCLs

EPA's estimate of benefits also includes a reduction in bladder cancer as a result of the decrease in the formation of THM expected to result from the removal of total organic carbon (TOC) achieved through treatment of source water required by the proposal. As EPA notes in its analysis, TOC levels are lower in groundwater sources which represent more than three-quarters of the systems EPA estimates will be impacted by the proposal. [FN184: USEPA. Disinfectant Byproduct Reduction as a Result of Granular Activated Carbon Treatment for PFOA and PFOS in Drinking Water: Benefits Analysis Related to Bladder Cancer. EPA-815-P23-002. Office of Water (2023). (USEPA DBP Benefits Analysis)] In addition, one of the two most likely options for treatment for PFAS (ion exchange or IX) is only marginally effective for removal of TOC. [FN185: EPA's Economic Analysis estimates that 75 to 95 percent of systems will select granular activated carbon or IX as a compliance option (USEPA Economic Analysis, at 5-12.) The Economic Analysis also notes that IX is not expected to remove a substantial amount of DBP precursors.]

PWSs are required to achieve a certain percentage of TOC removal as part of the Stage 1 and Stage 2 Disinfectants and Disinfection Byproducts (DBP) Rules. The Stage 2 DBP Rule promulgated MCLs for total THMs and haloacetic acids as well as monitoring, reporting, and public notification requirements. The rule lists granular activated carbon (GAC) – the most likely treatment approach identified by EPA for PFAS removal - as a best available technology (BAT) for removal of THM. As a result of the monitoring and reporting requirements, EPA has collected a large amount of information on TOC and DBP levels.

According to its latest enforcement policy, EPA has identified non-compliance with the Stage 2 DBP Rule and other drinking water standards as a priority initiative for 2024-27. [FN186: 88 Fed. Reg. 2093 (January 12, 2023).] EPA also held two public meetings in October 2020 to consider revisions in the DBP Rules [FN187: 85 Fed. Reg. 61680 (September 30, 2020).] and the Agency has tasked its National Drinking Water Advisory Council to develop recommendations for revisions to these and other Rules. [FN188: https://www.epa.gov/ndwac.]

These ongoing, and long-standing activities by both PWSs and the Agency to monitor and reduce THM levels belie EPA's contention that the benefits predicted to occur from reductions in THMs "may be attributed solely to compliance with the maximum contaminant level" as required by Section 1412(b)(3)(C)(i) of the Safe Drinking Water Act (SDWA). EPA has several initiatives underway to reduce THM levels in drinking water and the Agency has not attempted to separate reductions achieved through those actions compared to the current proposal.

EPA's analysis moreover notes that removal of TOC by GAC is dependent on a large number of factors, including the amount and type of TOC, other water quality characteristics, pretreatment processes, and the type of GAC used and the operation practices. [FN189: USEPA. Technologies and Costs Document for the Final Long Term 2 Enhanced Surface Water Treatment Rule and Final Stage 2 Disinfectants and Disinfection Byproducts Rule. EPA 815-R-05-013. Office of Water (2005). (USEPA Stage 2 DBP Rule Technologies Document)] Despite the significant amount information collected on THM levels and GAC systems, EPA notes "the lack of available data to directly inform THM4 from PFAS adsorption studies." [FN190: USEPA Economic Analysis, at 6-89.] In fact, the Agency identified only seven systems to use as a basis for its analysis. While the analysis shows a decrease in THM4 levels after the installation of GAC in the four surface water systems, two of the three ground water systems showed increased THM4 formation after the installation of GAC. [FN191: USEPA DBP Benefits Analysis, at 25.] The Agency offers several possible explanations for why this levels may have increased, but fails to offer empirical evidence to support the quantification of benefits for THM reduction from the proposal.

EPA Response: The EPA disagrees with the commenter, as the benefits quantified under this PFAS NPDWR are in fact solely attributable to the PFAS MCLs. The PFAS NPDWR requires installation of treatment technologies for PFAS removal that have the added benefit of reducing TOC, which is a precursor to DBP formation. As a result of the PFAS NPDWR, TOC is expected to be reduced upon the installation of PFAS treatment technology installations, and DBPs and bladder cancer morbidity and mortality will be reduced as a result. The benefits quantified for reduced DBP exposure under the PFAS NPDWR are independent of public health benefits stemming from the DBP rules and the DBP MCLs, and existing and future DBP regulations do not take away from this DBP co-benefit from the PFAS rule.

While the current DBP rules are effective, the EPA considered cost and risk/risk trade off with microbes in the development of those regulations and there are still residual risks, even if a system is in full compliance with the MCLs. The PFAS NPDWR reduces those risks beyond those from the DBP rule alone. Additionally, the DBP regulations, the benefits of which are separate from the benefits quantified under the PFAS NPDWR, were listed as candidates for revision based on the Third Six Year Review findings and the EPA is currently evaluating potential changes to the DBP regulations. Any potential changes to the DBP rules will be evaluated separately from the PFAS NPDWR under those actions.

For the THM4 changes based on SYR4 comparison, the EPA specifically looked at systems that installed GAC for PFAS removal and reported THM4 concentrations. While the levels of THMs will fluctuate over time in any system, there is empirical evidence from the DBP ICR Treatment Study Database that GAC treatment removes TOC (a DBP precursor) and that THM4 concentrations decrease after GAC treatment based on DBP formation potential experiments.

The EPA's analysis assumed that systems implementing IX do not accrue benefits associated with bladder cancer risk reductions, which was highlighted as an "underestimate of benefits" in characterizing the exposed population. Systems using IX for PFAS removal will also benefit

from some TOC removal, but the removal will be limited in comparison to GAC treatment because PFAS-selective IX can show preferential removal of PFAS over organic matter (de Abreu Domingos et al., 2018).

See section 13.7 of the EPA response in this *Response to Comments* document for further discussion of the EPA's DBP co-removal benefits analysis.

13.8 Comparison of Costs and Benefits

Summary of Major Public Comments and EPA Responses

Many commenters agreed with the Administrator's determination that the benefits of the rule justify its costs. Specifically, commenters asserted that the EPA's estimation of the net benefits of enacting the MCLs is reasonable, stating that "even if the costs are very substantial, the benefits associated with the anticipated drinking water improvements justify such expenditures" (Doc. #1687, SBC-044448). Commenters also stated that it is likely that "the analysis understates the benefits" (Doc. #1808, SBC-046094) of the rule, particularly given the "significant unquantified risk reduction benefits and co-benefits" (Doc. #1846, SBC-045833) that are anticipated to result from the rule.

In response to these comments, the EPA agrees that its quantified benefits likely significantly understate the benefits of the rule due to the large share of nonquantifiable benefits that are expected to be realized as avoided adverse health effects, in addition to the benefits that the EPA has quantified. The EPA anticipates additional benefits associated with developmental, cardiovascular, liver, immune, endocrine, metabolic, reproductive, musculoskeletal, and carcinogenic effects beyond those benefits associated with decreased PFOA and PFOS that the EPA has quantified. In response to commenters urging the EPA to quantify additional health endpoints associated with PFAS exposure, the EPA has developed a quantitative sensitivity analysis of PFOS effects and liver cancer, further strengthening the justification for this determination. Due to occurrence, health effects, and/or economic data limitations, the EPA is unable to quantitatively assess additional benefits of the rule.

Conversely, several commenters stated that the EPA has failed to demonstrate that the benefits of the rule justify its costs. Specifically, commenters disagreed with this determination because the EPA's analysis "significantly underestimates the costs of its proposed MCLs…and overestimates its benefits" (Doc. #1841, SBC-044848). Commenters asserted that the EPA needs to update its EA to more accurately reflect the true costs of compliance of the rule to make the determination that the rule's costs are justified by its benefits.

After considering public comments, the EPA has made a number of adjustments to the cost model and collectively these changes have increased the agency's estimated annualized total costs. The EPA made many of these changes as recommended by commenters that increased both unit cost estimates (the capital, operation and maintenance costs at a system level associated with the final rule) as well as the national costs, as detailed in section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA has used the best available peer reviewed

science to inform the cost estimates, including treatment costs, of the final PFAS NPDWR. For more information on the EPA's responses to comments on the rule costs, see Sections XII.A.2-XII.A.4 of the preamble for this action. The EPA disagrees with commenters that the EPA has overstated the benefits. As discussed in section XII.A.1 of the preamble for this action, the EPA has used the best available peer reviewed science to quantify the benefits of the rule, and as discussed above, the agency believes the quantified benefits likely significantly understate the benefits of the rule.

A few commenters urged the EPA to consider whether the benefits of finalizing the rule at regulatory alternative MCLs (e.g., 5.0 or 10.0 ng/L) would better justify the costs of the rule. The EPA disagrees with commenters that suggested the benefits better justify the costs of PFOA and PFOS standards at 5.0 or 10.0 ng/L. These commenters pointed to the quantified net benefits of the regulatory alternatives and noted that net benefits are positive at 3 and 7 percent discount rates for a standard of 10.0 ng/L for PFOA and PFOS. The commenters' sole reliance on the quantified costs and benefits of the rule to support their argument is incorrect, as SDWA requires the agency to consider both the quantifiable and nonquantifiable impacts of the rule in the determination. Under SDWA 1412(b)(4)(B), the EPA is required to set an MCL as close as feasible to the MCLG, taking costs into consideration. In other words, SDWA does not mandate that the EPA establish MCLs at levels where the quantified benefits exceed the quantified costs. This was many commenters' justification for the recommendation to promulgate a standard of 10.0 ppt each for PFOA and PFOS in lieu of the proposed rule, and the EPA therefore disagrees that quantified costs and benefits can or should be the sole determinant of an MCL value. The Administrator's assessment that the benefits of the proposed rule justified its costs was based on the totality of the evidence, specifically the quantified and nonquantifiable benefits, which are anticipated to be substantial, as well as the quantified and nonquantifiable costs. SDWA is clear that the EPA should not limit its evaluation and determination to solely quantifiable costs and benefits.

At the time of the EPA's proposal, it had issued a final regulatory determination for PFOA and PFOS. The MCLs for PFOA and PFOS in the proposed rule and final rule are both 4.0 ng/L. EPA's proposal included preliminary regulatory determinations for PFHxS, PFNA, HFPO-DA, and/or PFBS and mixtures and addressed them all through the Hazard Index MCL. The proposal defined a mixture as containing one or more of the four PFAS and therefore covered each contaminant individually if only one of the four PFAS occurred. The Hazard Index as proposed ensures that the level of exposure to an individual PFAS remains below that which could impact human health because the exposure for that measured PFAS is divided by its corresponding HBWC. The EPA proposed HBWCs of 9.0 ng/L for PFHxS; 10.0 ng/L for HFPO-DA; 10.0 ng/L for PFNA; and 2000.0 ng/L for PFBS. The EPA considered and took comment on establishing individual MCLGs and MCLs in lieu of or in addition to the Hazard Index approach for mixtures of PFHxS, PFNA, HFPO-DA, and/or PFBS. The final rule includes individual MCLs for PFHxS, PFNA, and HFPO-DA as well the Hazard Index MCL for mixtures of PFHxS, PFNA, HFPO-DA and PFBS concurrent with final regulatory determinations for these contaminants. The EPA is finalizing a mixture MCL at 1 and individual MCLs for HFPO-DA MCL of 10 ng/L; PFHxS

MCL of 10 ng/L; and PFNA MCL of 10 ng/L. As detailed in section XIV of the preamble for the final rule, each MCL is independent of the others and can be implemented on its own.

The EPA's economic analysis uses contaminant specific information to estimate treatment costs (e.g. contaminant specific occurrence and removal efficiencies for various treatment technologies, accounting for co-occurrence of other PFAS and other water quality conditions) and quantified benefits (e.g. contaminant specific pharmacokinetic, dose-response, and health outcome valuation information) to evaluate the impact of each regulated PFAS based on its individual facts and circumstances. Where evidence supported that PFOA and PFOS had the same adverse health effects and there was sufficient data to quantify those impacts (i.e. birthweight impacts, CVD) the EPA analyzed these impacts separately and presents the combined quantified benefits of reduced exposure to both contaminants. Where a single contaminant had sufficient evidence and data to quantify an adverse health effect (i.e. PFOA and Renal Cell Carcinoma (RCC)), and this adverse impact could not be quantified in other regulated contaminants, the EPA presented contaminant specific benefits associated with reduced exposure.

With respect to treatment costs, there are significant estimated cost efficiencies when co-removal of the regulated PFAS is correctly characterized. The cost of each individual PFAS MCL would be overestimated without considering the sunk capital expense and economies of scale associated with the co-treatment of PFOA and PFOS in addition to the other regulated PFAS. For example, as demonstrated in Chapter 5.1.3 of the EA, the majority of systems where PFHxS is expected to exceed its individual MCL are also expected to exceed the PFOA and PFOS MCLs. Therefore, estimating the national costs of solely treating for PFHxS to below its MCL, absent the PFOA and PFOS MCLs, would substantially overestimate the actual expected national costs associated with the PFHxS MCL and not be representative of the conditions the EPA expects when the rule is implemented. This is also the case for the Hazard Index MCL, the PFNA MCL and the HFPO-DA MCL.

In order to delve into the Administrator's determination that the benefits of the rule justify its costs one must consider the regulatory scenarios that were used to build out the EA analysis of costs and benefits for the proposed and final rule. These EA analyses were designed in light of the fact that the EPA had already made a regulatory determination for PFOA and PFOS at the time of proposal, the recognition that PFAS frequently cooccur and treatment costs will frequently not be attributable solely to a single PFAS, and the practical recognition that public water systems would be designing treatment for all PFAS addressed by the rule rather than designing treatment to comply with any single individual MCL.

The EA starts with the base MCL grouping of PFOA and PFOS. These two MCLs and their contaminant co-occurrence are always considered together in the impact analysis. This is a reasonable assumption, as EPA had already made a final regulatory determination for PFOA and PFOS at the time of proposal, so any examination of the impacts of the other MCLs should assume that PFOA and PFOS MCLs are also in effect. EPA has considered the costs and benefits of the PFOA and PFOS MCLs at 4.0 ng/L each (known as option 1a in the EA) and under that

regulatory alternative, the quantified benefits exceed the quantified costs (see tables ES-1 and ES-2 of the EA for more information). Additionally, the EPA anticipates additional benefits from reduced exposure to PFOA and PFOS due to the final rule associated with developmental, cardiovascular, liver, immune, endocrine, metabolic, reproductive, musculoskeletal, and carcinogenic effects beyond those benefits that the EPA has quantified (see Chapter 6.2.2 of the EA for more information). The nonquantifiable costs of the PFOA and PFOS MCLs are the same as those of the final rule (see Chapter 5.3.1 and 5.7 of the EA), with the exception of the nonquantifiable costs associated with the Hazard Index MCL and the MCLs for PFHxS, PFNA and HFPO-DA. In the case of the PFOA and PFOS MCLs, the EPA has determined that the quantifiable and nonquantifiable benefits of the rule justify the quantifiable and nonquantifiable costs.

When considering the incremental costs and benefits of the Hazard Index MCL and the individual MCLs for PFNA, PFHxS, and HFPO-DA, the EPA assumed that the PFOA and PFOS MCLs were also in effect. In the case of PFHxS, the EPA has considered the incremental national impact associated with the PFHxS MCL and Hazard Index MCL exceedances where PFHxS is present above its HBWC while one or more other Hazard Index PFAS are also present in that same mixture, under the assumption that the PFOA and PFOS MCLs are also in effect (see Chapter 5.1.3 of the EA). The quantified national primary analysis costs and benefits represent the impact of the three MCLs and EPA also considered non-quantified costs and benefits in making a positive determination for this MCL grouping. In the case of PFNA and HFPO-DA, the EPA considered the cost of each these MCLs in addition to the PFOA and PFOS MCLs. Specifically, the EPA has considered the national impact associated with the PFNA MCL, under the assumption that the PFOA and PFOS MCLs are also in effect. The EPA performed the same analysis for the HFPO-DA MCL (See Appendix N.4). These estimates also represent the marginal costs of Hazard Index MCL exceedances where PFNA or HFPO-DA are present above their respective HBWCs while one or more other Hazard Index PFAS are also present in the same mixture. Finally, the EPA has considered the incremental national impact of the Hazard Index based on occurrence information for PFHxS, PFNA, HFPO-DA and PFBS and the individual MCLs for PFHxS, PFNA, and HFPO-DA together, assuming the PFOA and PFOS MCLs are in effect (See Appendix N.3). The final positive determination, considering quantifiable and nonquantifiable benefits and costs, extends to this inclusive grouping as well as any combination of these MCLs when the PFOA and PFOS MCLs are in effect. The PFOA and PFOS MCLs account for the large majority of the costs of the final rule, and as detailed in Appendix N.3, the Hazard Index and individual MCLs for PFHxS, PFNA, and HFPO-DA are expected to increase costs nationally by approximately 5 percent. Combinations of fewer than all of these MCLs would therefore increase costs nationally by less than 5 percent. However, as discussed in detail in Chapter 6.2 of the EA, the EPA anticipates considerable nonquantifiable benefits from developmental, cardiovascular, immune, hepatic, endocrine, metabolic, reproductive, musculoskeletal, and carcinogenic effects associated with the Hazard Index MCL, PFHxS MCL, PFNA MCL, and HFPO-DA MCL. Therefore, the EPA anticipates significant benefits as a result of the Hazard Index and individual MCLs, as well as any combination of them, in addition to the benefits resulting from the PFOA and PFOS MCLs.

In sum, the EPA's determination at proposal and reaffirmation that the benefits of the final rule justify the costs takes into account that the large majority of the costs of compliance result from the PFOA and PFOS MCLs, the associated significant benefits from these MCLs, and the fact that the costs from the other MCLs (including various combinations) result in less than 5 percent of the total costs but contribute significant benefits. The EPA's reaffirmed determination for the final rule extends to each of the various MCLs in this final rule.

As discussed in section 13.2 of the EPA response in this *Response to Comments* document and in section XII.J of the FRN for this action, in addition to estimating the benefits and costs of the rule at both a 3 percent and 7 percent discount rate, in compliance with OMB guidance in effect at the time of rule proposal, the EPA has also estimated expected value costs and benefits using a 2 percent discount rate. At a 2 percent discount rate, estimated quantified annualized costs are $1,548.64 million and estimated quantified annualized benefits are $1,549.40; when considering the stochastic nature of SafeWater MCBC, the modeled quantified net benefits are nearly at parity. To further explore how the relationship between costs and benefits is impacted by relatively small methodological changes the EPA assessed how the use of willingness to pay information (more closely related to opportunity cost), instead of cost of illness information, for non-fatal RCC and bladder cancer illnesses, affects total net benefits at a 2 percent discount rate. In this case the estimated expected quantified annualized costs are $1,548.64 million and the estimated expected quantified annualized benefits increase to $1,632.34 million, giving $83.7 million in expected annualized net benefits. While quantified results are not the sole consideration in the Administrator's determination, net negative mean results of a small magnitude at the 2 percent discount rate with a significant probability that net benefits are greater than zero, and positive net benefits under a valuation sensitivity analysis, further support the Administrator's determination that the benefits of the rule justify its costs.

Although the modeled quantified net benefits are nearly at parity at the 2 percent discount rate, and mean net quantified benefits are negative at the 3 and 7 percent discount rates for the final rule, based on the EPA's consideration of the full record, specifically the quantified and nonquantifiable benefits, which are anticipated to be substantial, as well as the quantified and nonquantifiable costs, the benefits of the final rule justify its costs.

Other commenters incorrectly stated that SDWA requires the EPA to set an MCL at a level "... that maximizes health risk reduction benefits at a cost that is justified by the benefits" (Doc. #1713, SBC-045920; Doc. #1761, SBC-047717 and SBC-046080). This test is found in Section 1412(b)(6)(A) of SDWA and applies only when the Administrator determines based on the HRRCA that the benefits of a proposed MCL developed in accordance with paragraph (4) (i.e., an MCL as close as feasible to the MCLG) would not justify the costs of complying with the level. In the case of the proposed PFAS NPDWR, the Administrator determined that the benefits justify the costs for MCLs set as close as feasible to the MCLGs. For more information on the EPA's response to comments on the regulatory alternative MCLs considered in this rulemaking, see section V of the final rule preamble.

For the final rule, considering both quantifiable and nonquantifiable costs and benefits of the rule, the EPA is reaffirming the Administrator's determination made at proposal that the quantified and nonquantifiable benefits of the rule justify its costs.

Individual Public Comments

Brian Hackman (Doc. #1539, SBC-042888)

The current USEPA proposal for PFAS (polyfluoroalkyl substances) chemicals does not consider the actual risks, if any to the population, to have establish its $1.06 billion per year health care cost savings to implement the about $800 million per year costs for water treatment to reduce PFAS. While not much of surprise, Agency's taking an activist role in establishing new regulations, contrary to the recent West Virginia vs. USEPA Supreme Court ruling, have found that their cost estimates are no where near reality. For example, the recent Inflation Reduction Act, following review by the Office of Management and Budget (OMB) found that legislators had misappropriated the cost liabilities of their legislation by approximately 3 times that of the negotiated liability during rulemaking.

The lack of Office of Management and Budget (OMB) input prior to this proposal demonstrates an inherent lack of wisdom and failure to account for real costs that are meant to be discovered before Rulemaking. I would encourage the Director of the USEPA to pick up any tab for costs not included in this proposal should he continue to put his stamp on the proposed MCL and HI's.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. The EPA disagrees with the commenter's assertion that the EPA did not consider OMB input prior to the rule proposal. As directed under Executive Order 12866, the proposed regulatory action, including the EA, was submitted to OMB for review as part of interagency review before the proposed rulemaking was published. OMB and other federal government agencies and departments engaged in the interagency review process reviewed the proposed EA and the EPA incorporated reviewer comments into the proposed and final rule.

Water & Health Advisory Council (Doc. #1590, SBC-042790)

Overall, the U.S. EPA has not demonstrated that the financial burden that will be placed on municipalities and their community members associated with the proposed PFAS drinking water regulations is justified by a meaningful protection of public health. Science is still evolving, with critical research ongoing. An overly conservative and not scientifically supported interpretation of the science can have negative public health consequences by not only diverting resources away from known public health drinking water issues (e.g. arsenic, lead or microbial contaminants in water, failing infrastructure, raised water utility costs), but also by the unnecessary stigma and stress that is put on a community identified as living with contaminated drinking water.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. The EPA disagrees with the commenter's suggestion that the EPA has applied "overly conservative and not scientifically supported interpretation of the science" in informing its economic estimates for this action. The EPA has used the best available peer reviewed science to inform estimation of costs and benefits of the rule, including synthesis of health studies ranked based on study quality and significance and peer review of analyses used to develop and evaluate the benefits and costs of the regulation. For the EPA's responses to comments related to estimation of costs and benefits for the final rule, please see sections 13.3 and 13.4, respectively, in this *Response to Comments* document. In response to the commenter's statement that this action will be "diverting resources away from known public health drinking water issues", the EPA disagrees with the suggestion that PFAS is not a known public health drinking water issue; to the contrary, as explained in the preamble to the final rule, PFAS is a very significant health concern for many water systems and reductions in PFAS levels will provide many benefits across the nation. Moreover, there may be an opportunity for many communities to utilize BIL (P.L. 177-58) funding to provide financial assistance for addressing emerging contaminants, with specific allocations for emerging contaminants, including PFAS. For responses to comments regarding funding available through BIL, please see section 2.4 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043633)

BWWB is committed to providing reliable, equitable, cost-effective delivery of high-quality water and services while protecting public health and environmental resources for current and future generations. We acknowledge that the regulation of PFAS is important to address public health risks, however we strongly believe that the option selected by EPA for the proposed PFAS Rule is likely to incur costs and customer hardship well in excess of the identified benefits calculated by USEPA. The proposed Rule is simply not cost justifiable. BWWB's internal analysis (by our staff and expert advisors), suggests that full compliance with the proposed regulation could result in over 40% of our customer base (more than 300,000 Alabamans) spending more than 2% of their income on water bills alone. We submit these comments to bring your attention to the enormous financial burden and practical challenges that utilities and local communities would face under the proposed PFAS Rule.

If you have any questions, please reach out to me at michael.johnson@bwwb.org. Thank you for your consideration.

Sincerely,

Michael Johnson, MBA, CPA x

General Manager

Attachment 1 – Detailed Technical Comments on the Proposed PFAS National Primary Drinking Water Regulation, elaborates on the ideas summarized in this letter. The detailed technical comments highlight potential shortcomings of the proposed rule and are organized into five main

sections: 1) Cost Benefit Analysis, 2) Affordability, 3) Utility Impacts, Treatability, and 5) Regulatory Unreasonableness and Continued Uncertainty. Attachment 1 has several supporting appendices provided with it, for reference.

• Appendix A: Comparison of Total Capital Cost and O&M Cost between EPA's Cost Model and Arcadis Case Studies

• Appendix B: Rate Impacts of BWWB's Ongoing and Emerging Compliance and Infrastructure Needs (Excluding the PFAS Rule)

• Appendix C: Combined Impact on BWWB's Capital and O&M Budgets and Rates (Including the proposed PFAS Rule)

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. The EPA agrees that regulating PFAS is important in addressing public health risks. For discussion of the EPA's estimation of costs of the final rule, please see section 13.3.1 of the EPA response in this *Response to Comments* document for responses to comments on primacy agency costs, section 13.3.3 of the EPA response in this *Response to Comments* document for responses to comments on water system treatment costs, section 13.3.4 of the EPA response in this *Response to Comments* document for responses to comment on water system monitoring costs, section 13.3.5 of the EPA response in this *Response to Comments* document for responses to comments on water system administrative costs, and section 13.3.6 of the EPA response in this *Response to Comments* document for responses to comments on water system non-treatment costs, respectively. For discussion of the EPA's affordability analysis, please see section 13.10 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1602, SBC-043640 in section 13.10 in this *Response to Comments* document. For responses to comments on funding available through BIL, please see section 2.4 of the EPA response in this *Response to Comments* document.

Arlington County Virginia (Doc. #1603, SBC-043011)

Economic Analysis

As required by law, the EPA has developed an Economic Analysis of the proposed regulation. Our understanding of the Economic Analysis raises several concerns that bring into question the justification for the proposed rule.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document.

Arlington County Virginia (Doc. #1603, SBC-043012)

First, we interpret the published Cost/Benefit analysis as demonstrating an ambiguous case for the rule as proposed.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document.

Illinois Farm Bureau (IFB) (Doc. #1630, SBC-043134)

Of utmost importance is the accuracy of the cost/benefit analysis when setting the drinking water MCL for PFOA and PFOS at the very low level of 4ppt. We fear that the costs will far outweigh the benefits and that rural farming communities and/or underserved and underprivileged areas will be hit hardest.

EPA Response: In response to the commenter's assertion that "the costs will far outweigh the benefits," please see section 13.8 of the EPA response in this *Response to Comments* document. In response to the commenter's concern regarding impacts to "rural farming communities and/or underserved and underprivileged areas", in the EPA's EJ analysis for the final rule, the agency examined the distribution of costs across demographic groups and across multiple water system size categories. When examining costs anticipated to result from the rule, the EPA found that cost differences across demographic groups were small, with no clear unidirectional trend in cost differences based on demographic group. Additionally, the agency found that incremental household costs to all race/ethnicity and income groups generally decrease as system size increases, which is expected due to economies of scale. For further discussion of the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA, 2024b) and section 14.10 of the EPA response in this *Response to Comments* document. To alleviate potential cost disparities identified by the EPA's analysis, there may be an opportunity for many communities to utilize BIL (P.L. 117-58) funding to provide financial assistance for addressing emerging contaminants. BIL funding has specific allocations for both disadvantaged and/or small communities and emerging contaminants, including PFAS. For responses to comments regarding BIL funding, please see section 2.4 of the *Response to Comments* document.

In the EPA's small system affordability analysis, the EPA analyzed the household level cost impacts of the final rule on small system size categories and determined the rule is affordable for small systems. While the EPA did not separately present the impacts of the final rule on rural communities, many rural communities are served by small systems. For more information, see the EPA's affordability analysis in Chapter 9 of the EA (USEPA, 2024b).

Superfund Settlements Project (SSP) and RCRA Corrective Action Project (RCAP) (Doc. #1631, SBC-043439)

Third, beyond the failure to consider contaminated site costs, EPA's cost analysis underestimates costs and overestimates benefits. The costs outweigh the benefits.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. In addition, regarding the commenter's assertion regarding the EPA's "failure to consider contaminated site costs," see the

EPA response to comment Doc. #1631, SBC-043430 in section 13.8 in this *Response to Comments* document.

Superfund Settlements Project (SSP) and RCRA Corrective Action Project (RCAP) (Doc. #1631, SBC-043430)

EPA underestimates costs, failing to consider, among other things, significant costs that will be incurred in connection with remediation of contaminated sites. EPA, in turn, overestimates benefits

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document. With respect to the commenter's assertion that the EPA has failed to consider "significant costs that will be incurred in connection with remediation of contaminated sites", this action solely applies to public water systems and the HRRCA required by SDWA expressly excludes costs resulting from compliance with other proposed or promulgated regulations in developing an NPDWR (SDWA 1412(b)(3)(C)(i)(III)).

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044303)

The Safe Drinking Water Act requires consideration of the costs and benefits, but in the case of PFAS, the lack of occurrence data limits EPAs ability to develop a legitimate benefit/cost analysis.

There is significant uncertainty regarding the health risks at the proposed MCL levels for all six PFAS. These levels are significantly lower than any state has proposed for PFAS chemicals, which would seem to indicate that even states highly concerned with PFAS contamination have arrived at different conclusions than EPA with regard to the benefit/cost analysis. Analysis fundamental to the 1996 amendments to the SDWA requires a detailed risk and cost assessment, and best available peer-reviewed science, when developing standards.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. In response to the commenter's assertion that "there is significant uncertainty regarding the health risks at the proposed MCL levels" and comparison of state PFAS MCLs to the MCLs promulgated under this action, the PFAS NPDWR is informed by regulatory development requirements under SDWA and includes the EPA's analysis of the best available and most recent peer-reviewed science. In contrast to commenter's assertion, the EPA has conducted detailed cost and benefit assessments and risk analyses (see e.g., the EA and EA Appendices (USEPA, 2024b; USEPA, 2024c), the Final Human Health Toxicity Assessments for PFOA and PFOS (USEPA, 2024h; USEPA, 2024i), and the Final Maximum Contaminant Level Goals for PFOA and PFOS (USEPA, 2024l)).

With respect to the commenter's assertion that "even states highly concerned with PFAS contamination have arrived at different conclusions than EPA with regard to the benefit/cost analysis," the commenter provides no detail or references to support this statement. While no

specific references were given, potential differences in conclusions between the EPA and states could arise from differences in number entities included in the analyses, baseline levels of PFAS contamination, estimation of health risk reduction benefits, and the estimation of costs. The EPA has compiled and synthesized the best available and peer-reviewed science on PFAS occurrence, health effects, and the best available technology to achieve reductions in PFAS in drinking water and the EPA's benefit-cost analysis for this action relies on the best available peer-reviewed information. Additionally, the Administrator determined at proposal that the benefits of the rule justify its costs. For additional discussion on international and state drinking water standards and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. For further discussion of PFAS adverse health effects, please see sections II.B, III.B, and IV of the preamble for this action.

Additionally, the EPA disagrees with the commenter's assertion that the agency's "lack of occurrence data limits the EPA's ability to develop a legitimate benefit/cost analysis". As discussed in section 6 of the EPA response in this *Response to Comments* document, the agency has sufficiently robust occurrence information to inform its decisions The EPA's cost analysis uses modeled entry point concentration estimates from the peer-reviewed Bayesian hierarchical Markov chain Monte Carlo (MCMC) occurrence model which employs a statistically robust framework (see Section 4.4 of the EA; USEPA, 2024b). These modeled occurrence estimates are informed by the best available data, which is the UCMR 3 data and a robust quantity of more recently available state monitoring data. Additionally, the EPA notes that the model uses these data to estimate occurrence at levels below the MCLs employed by UCMR 3. For the EPA's responses to comments on the occurrence analysis for the final rule, please see section 6 in this *Response to Comments* document.

Alabama Water and Wastewater Institute (AWWI) (Doc. #1700, SBC-043510)

• AWWI believes that the economic analysis prepared by USEPA to support the regulatory process grossly underestimates the economic impacts to customers based on the projected occurrence of PFAS compounds. USEPA notes that the estimates of PFAS occurrence used in the cost benefit modeling were fitted with data from Unregulated Contaminant Monitoring Rule ("UCMR)3, which used a higher MRL for PFAS detection. A new minimum reporting limit (MRL) of 4 parts per trillion is being utilized under the current UCMR 5. Thus, AWWI believes more systems and the rate payers of those systems will be impacted economically both in terms of capital expenditures and long-term operations and maintenance costs. AWWI recommends that the cost-benefit analysis be re-evaluated based on a sensitivity analysis for greater PFAS occurrence, not just the previously performed sensitivity analysis for various MCLs for PFOA and PFOS.

Thank you for your consideration of the AWWl's comments submitted in regard to the proposed PFAS national primary drinking water standards. AWWI's member utilities remain committed to providing high quality, safe potable water to its customers. Thus, we appreciate the opportunity

to submit our comments on these new proposed PFAS national drinking water regulation of behalf of our member utilities in the State of Alabama.

Sincerely,

Chad Hare

Chairman

Alabama Water and Wastewater Institute, Inc.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. The EPA disagrees with the commenter's suggestion that the agency "grossly underestimates the economic impacts to customers based on the projected occurrence of PFAS compounds" for PFOA and PFOS; please see the EPA response to comment Doc. #1684, SBC-044303 in section 13.8 in this *Response to Comments* document. Regarding UCMR 5, please see section 6.8 of the EPA response in this *Response to Comments* document. Additionally, the EPA also notes that occurrence uncertainty is already captured in the model, therefore the sensitivity analysis suggested by the commenter is not necessary.

Minnesota Center for Environmental Advocacy et al. (Doc. #1707, SBC-045725)

C. The Benefits to Human Health Far Outweigh the Costs of Compliance

The SDWA mandates EPA to conduct a HRRCA to support its proposed MCLs: "At the time the Administrator proposes a national primary drinking water regulation under this paragraph, the Administrator shall publish a determination as to whether the benefits of the maximum contaminant level justify, or do not justify, the costs." [FN42: 42 U.S.C. § 300g-1(b)(4)(C).] The Commenters agree with EPA Administrator's overall conclusion that the benefits of the proposed MCLs justify the costs. We write to express our assertion that 1) the benefits of saving Amara, Senator Xiong, JD, Ben, their families, and myriad others from the harms of PFAS are immense, and 2) the costs of compliance will be reduced significantly by innovation and other advancements in treatment technology that will be spurred on by the need for the nation's public water suppliers to get into compliance.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. The EPA agrees with the commenter that costs of compliance may be reduced by advancements in treatment technologies in the future.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045920)

VI. Proposed Benefits of Complying with the Proposed MCLs Do Not Justify the Costs

While the MCLG is set solely based on health risk reduction, SDWA requires EPA to engage in cost-benefit balancing in setting the level of the MCLs and also requires that EPA follow a science-based process. If EPA determines that the benefits of a MCL would not justify the costs of complying with the level, EPA may, after notice and opportunity for public comment, promulgate a MCL for the contaminant that maximizes health risk reduction benefits at a cost that is justified by the benefits [FN177: 42 U.S.C. 300g-1(b)(6)(A).]. Even at the grossly underestimated costs, as described in the section above, the benefits of EPA's proposal to regulate PFOA and PFOS at a MCL of 4 ppt and to regulate PFNA, PFBS, PFHxS, and HFPO-DA at a Hazard Index of 1 do not justify the costs. As discussed below, EPA's quantified benefits analysis is not grounded in science and overestimates benefits, and EPA's non-quantified analysis does not meet the statutory standard of SDWA [FN178: 42 U.S.C. 300g-1(a)(3)(A).].

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045924)

B. In light of the costs, the stated benefits do not justify the cost of the proposed MCLs

As previously discussed, EPA has significantly underestimated the costs of this proposal. As discussed in this section, EPA has also overestimated both the quantified and non-quantified benefits. These comments do not address many other shortcomings, uncertainties, and limitations in EPA's analysis. For instance, EPA notes that 13-33% of the U.S. population consumes bottled water as their primary drinking water source, yet EPA did not take this into account in the modelling [FN207: Id. at 6-108.]. EPA also could have modelled costs and benefits at 20 ppt- 40 ppt where there is more certainty in the occurrence data. Yet EPA chose not to present these analyses, not even as an alternative analysis. It is also important to note that for some of the costs and benefits analyses, EPA modified approaches in published studies to derive its estimates. In most cases, EPA did not have these revised approaches peer reviewed [FN208: Only the CVD modelling was reviewed by the SAB.]. This is inconsistent with SDWA approach that requires the HHRCA to rely on the best available science.

EPA must set the MCL at a level where the benefits justify the costs. EPA has an obligation to protect public health while relying on the best available science and while also ensuring that the cost of the standard is achievable. Considering the uncertainties and the lack of evidence supporting that effects are "likely," coupled with the significant costs of this rule, including the significant costs to individual households,[FN209: Id. at 9-29, where table 9-14 shows costs to individual households ranging from $57 to $1,153 annually. See also AWWA analysis on household costs available at: https://www.awwa.org/AWWA-Articles/awwa-statement-on-proposed-pfas-drinking-water-standards.] EPA should adjust the MCL upward to a more optimal, and more affordable balance. As EPA conducts more robust scientific assessments that are appropriately reviewed by the SAB and decreases the levels of uncertainty in the underlying science, including in the occurrence data, it should then modify the MCL as appropriate.

Based on the information presented in the Proposed Rule, the purported benefits do not justify the costs at the proposed MCL levels.

EPA Response: In response to the commenter's concern that the EPA did not rely on the best available science and incorrect assertion that the benefits of the rule do not justify the costs, see section 13.8 of the EPA response in this *Response to Comments* document. Despite the commenter's repeated unsupported assertions, as discussed throughout this *Response to Comments* document, the EPA has used best available science, which includes relying on hundreds of peer reviewed studies to inform its analyses and conclusions. Many of the analytical frameworks themselves have undergone further peer review. While the commenter disagrees with the conclusions that the EPA has drawn from these analyses, that does not invalidate the thoroughness or robustness of the EPA's analyses or the fact that the agency used best available science consistent with commonly accepted scientific practices and SDWA requirements.

In response to the commenter's recommendation to model costs and benefits at MCLs of 20 ppt and 40 ppt, the EPA disagrees with this recommendation because the agency selected thresholds in the EA that were potential regulatory alternatives under the proposed rule. Selecting regulatory alternative PFOA and PFOS MCLs of 20 or 40 ppt would not meet the SDWA criterion to establish MCLs as close to the MCLGs as feasible, taking costs into consideration. For responses to comments on the EPA's MCLs and regulatory alternatives, see section 5.1.3 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's statement that "EPA must set the MCL at a level where the benefits justify the costs" as that is incorrect. The EPA must set the MCL as close as is feasible to the MCLG as specified under SDWA Section 1412(b)(4)(B). In response to the commenter's incorrect assertion that the EPA's analysis was "inconsistent with SDWA approach that requires the HHRCA to rely on the best available science", the EPA disagrees. The commenter provides no detail or supporting information to support the claim that the EPA modified approaches in published studies to derive its estimates. As stated above, the EPA use the best available, peer-reviewed science pursuant to SDWA Section 1412(b)(3)(A)(i).

In response to the commenter's reference to cost estimates submitted by other commenters, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. For further discussion, see section 13.3.3 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's assertion that the agency has overestimated the quantified and non-quantified benefits. For the quantified benefits analysis, the EPA relied on peer-reviewed literature and synthesis of multiple high-quality studies to evaluate the effects of PFAS exposure on human health. Using this information, the EPA relied on the best available data on baseline health incidence, dose-response, life tables, medical costs, and the value of a statistical life to evaluate potential benefits of reduced incidence of adverse health effects and death. As described in section 13.8 of the EPA response in this *Response to Comments* document, limitations on health effects and/or economic information prevented the EPA from evaluating additional benefits of the rule, including those for health impacts shown to have associations

with PFAS exposure. Contrary to the commenter's assertion, the EPA expects that benefits are underestimated.

Finally, in response to the commenter's note about bottled water consumption, the EPA's benefit-cost analysis does not account for populations that consume bottled water as their primary drinking water source due to data limitations that did not allow for modeling at the national scale; the effect on the EPA's benefits estimates is uncertain. As explained in Chapter 6 of the EA, as the benefits models do not consider these populations, this could result in an overestimate of avoided cases of health effects and associated benefits (USEPA, 2024b). However, bottled water consumers can also be community water system (CWS) consumers and may still be exposed to PFAS by using water for other consumptive uses (e.g., cooking) and therefore would benefit from PFAS removal (USFDA, 2022; Aquafina, 2022). The benefits may also be underestimated because those using bottled water as a primary drinking water source may switch to a CWS supply as a result of the final rule.

Environmental Working Group (EWG) (Doc. #1721, SBC-045411)

The benefits are of the proposed rule are underestimated and outweigh the costs.

The proposed rule correctly finds that the benefits of limiting PFAS in drinking water far outweigh the costs. In 2022, leading experts quantified the estimated disease burden and related economic costs due to legacy PFAS exposure at $5.52 billion to $62.6 billion in annual costs. [FN43: Vladislav Obsekov, Linda G. Kahn, & Leonardo Trasande, Leveraging Systematic Reviews to Explore Disease Burden and Costs of Per- and Polyfluoroalkyl Substance Exposures in the United States, J. OF EXPOSURE & HEALTH (2022), https://link.springer.com/article/10.1007/s12403-022-00496-y.] Reducing PFAS in drinking water to the proposed MCL levels will dramatically reduce exposures, improving health outcomes, reducing medical and other economic costs, and lowering risks for PFAS-associated diseases.

The proposal rule is accompanied by a thorough economic assessment detailing the quantified and non-quantified benefits of the rule, as required by SDWA. [FN44: 42 U.S.C. [sec] 300g-1(b)(3)(C)-(b)(4).] While EWG supports the conclusions in the economic assessment, there are also several ways that the assessment could be expanded or strengthened. The assessment by Dr. Peter Guignet, Ph.D., appended to the comments submitted by Earthjustice et al. includes several recommendations for strengthening the analysis. [FN45: See Earthjustice et al., supra note 7.] Dr. Guignet suggests monetizing several additional health benefits, including quantifying benefits from additional health endpoints and from PFAS other than PFOA and PFOS; assessing and estimating the number of individuals exposed and who would benefit; and quantifying the benefits of reduced hepatic effects and reduced disruption of mammary gland development and associated effects on lactation. Dr. Guignet also suggests quantifying additional co-benefits in addition to the reduction in bladder cancer from co-removal of disinfection byproducts, including the health benefits from removing additional contaminants, including PFAS not covered by the proposed rule. Dr. Guignet also recommends lowering the discount rate and accounting for

opportunity costs in its final cost-of-illness estimates for low birthweight, cardiovascular disease, and renal cancer. [FN46: Id. at 16-20.]

EPA Response: These comments provide additional support for the conclusions of the agency's economic analysis for this action. The EPA agrees with the commenter that the quantified benefits of the rulemaking are likely underestimated, and that the rulemaking will likely result in additional quantified benefits beyond the health endpoints described in the economic analysis. As described in section 13.8 of the EPA response in this *Response to Comments* document, limitations of occurrence, health effect, and economic data availability prevented the EPA from considering additional quantified benefit categories in its national benefit-cost analysis, including co-benefits.

In response to the commenter's suggestion that benefits be evaluated using a lower discount rate, see sections 13.2 and 13.8 of the EPA response in this *Response to Comments* document for the EPA's responses to comments on discount rates.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046031)

We conduct a benefit-cost analysis to produce more accurate estimates. We rely on established NAS recommendations to develop hazard assessments based on recent available scientific information. Rather than EPA's approach to quantify a few adverse effects, this analysis considers a wide range of possible cellular and genomic evidence, animal data, and human epidemiological studies. Since these studies find that biological activity is likely only to occur at the high end of the modeled drinking water exposure, we develop a bounding estimate of the benefits of reducing PFOS in drinking water.

The results of this bounding estimates are shown in Table 32. We show that, whereas EPA estimated, at a seven percent discount rate, the annualized costs and benefits of the proposed rule to be $1,205 M and $908 M, respectively, we estimate them to be $7,500 M and $1,200 M, respectively. Thus, even with many assumptions to increase the social benefits, the results for PFOS are six times lower than the expected social costs. Even if these benefits are doubled to account for reductions in PFOA exposure, the social benefits are well below the social costs.

Table 32: Comparison of Estimated National Annualized Benefits and Costs for EPA's Proposed Rule ($ M) [FN136: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," 1–1.]

[Table 32: see docket ID EPA-HQ-OW-2022-0114-1738]

[FN137: Even if these benefits are doubled to $2,400 M/year to account for reductions in PFOA exposure, the social benefits would still be well below the social costs.]

These social costs will fall heavily on rural and low-income households. Despite EPA's claims, recently-enacted federal support for water utilities is insufficient to pay for even the capital costs of the proposal's requirements. As a result, ratepayers may pay a significant portion of the

rulemaking until other resources are secured. Ratepayer may pay hundreds of dollars per household.

EPA Response: In response to the commenter's assertion that benefits are underestimated, see sections 13.4 and 13.8 of the EPA response in this *Response to Comments* document.

In response to the commenter's comparison of their cost estimates to those prepared by the agency, the EPA notes that it disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. See section 13.3.3 of the EPA response in this *Response to Comments* document.

In response to the commenter's assertion that the social costs will fall heavily on rural and low-income households, please see the EPA response to comment Doc. #1630, SBC-043134 in section 13.8 in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046006)

CONCLUSIONS

Even if the benefits from the bounding estimate were doubled to account for PFOA and the other four PFAS, the benefits would still be below the costs. The social costs of EPA's proposal exceed the social benefits.

[Table of Acronyms: see docket ID EPA-HQ-OW-2022-0114-1738]

I. INTRODUCTION

1. Overview of EPA's Proposed Rulemaking and Economic Analysis Notice of Proposed Rulemaking

(NPRM)

On March 29, 2023, the Environmental Protection Agency (EPA) published a Notice of Proposed Rulemaking (NPRM) in the Federal Register to propose a National Primary Drinking Water Regulation (NPDWR), Maximum Contaminant Level Goals (MCLGs), and Maximum Contaminant Levels (MCLs) for several per- and polyfluoroalkyl substances (PFAS) [FN1: U.S. Environmental Protection Agency, "PFAS National Primary Drinking Water Regulation Rulemaking," Federal Register, no. 88 FR 18638 (March 2023).] The NPDWR are legally enforceable standards that require treatment in public water systems (PWSs) to ensure certain contaminants do not exceed specified levels in drinking water. The level is set by the enforceable MCL, which is the highest level of a contaminant that is allowed in drinking water. An MCLG is the non-enforceable level of a contaminant in drinking water under which there is no expected risk to human health. EPA issued a request for public comment on the following:

• The determination to set individual MCLs of four parts per trillion (ppt) or nanograms per liter (ng/L) for perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS). EPA seeks comment on its evaluation of feasibility, treatment capabilities at CWSs, and costs;

• The preliminary determination to regulate four additional PFAS, including: perfluorohexane sulfonic acid (PFHxS), hexafluoropropylene oxide dimer acid (HFPO– DA) and its ammonium salt (also known as a GenX chemicals), perfluorononanoic acid (PFNA), perfluorobutane sulfonic acid (PFBS). EPA seeks comment on its evaluation of health information and occurrence data;

• The determination to set a MCL through a Hazard Index (HI) approach set at a unitless one for any mixture of one or more of the four additional PFAS (PFHxS, HFPO-DA, PFNA, and PFBS). EPA seeks comment on its HI approach;

• EPA's methodology used to estimate national costs for the proposed rule; and,

• EPA's approach to estimate the health impacts of exposure to PFAS covered by the proposed rule. EPA seeks comment on its assumptions and the magnitude of risks avoided by the proposed regulatory actions.

Economic Analysis (EA)

EPA is required to conduct an economic analysis (EA) for the proposed NPDWR in compliance with Executive Order (EO) 12866 and SDWA's requirements for a Health Risk Reduction and Cost Analysis (HRRCA) [FN2: "P.L. 104-182: The Safe Drinking Water Act" (1996).]. In its EA,

EPA provides its assessment of quantified and nonquantifiable health risk reduction benefits and compliance costs, including:

• Health risk reduction benefits for which there is a factual basis in the rulemaking record to conclude that such benefits are likely to occur as the result of compliance with each treatment level;

• Benefits likely to occur from co-occurring contaminants reductions that may be attributed solely to compliance with the MCL;

• Costs likely to occur solely due to compliance with the MCL, including monitoring, treatment, and other costs;

• Incremental costs and benefits associated with each alternative MCL considered;

• Effects of the contaminant on the general population, including sub-population groups likely to be at greater risk of adverse health effects due to exposure to contaminants in drinking water;

• Any increased health risk that may occur as a result of compliance, including co- benefits and co-occurring contaminant risks; and,

• Other relevant factors, including the quality and extent of the information and uncertainties in the analysis.

EPA evaluated the benefits associated with several rule options, including its preferred option. The EA presents quantified health benefits from avoided cases of illnesses and deaths expected from reductions in PFAS exposures resulting from the NPRM. Quantified economic benefits are estimated as avoided morbidity and mortality due to cardiovascular disease (CVD), avoided low birthweight, and avoided cases of renal cell carcinoma (RCC).

In EPA's EA, the costs of the proposed NPDWR are the expenses incurred by PWS to monitor for PFAS, to notify consumers, to adopt treatment technologies, and to conduct subsequent record-keeping and monitoring requirements. EPA also includes the costs associated with primacy agency implementation. The EA estimates the number of water systems that must procure treatment technologies and incur administrative costs to comply with the rule. EPA's estimated annualized benefits are summarized in Table 1 and range between $908 million (M) to $1,233 M at seven percent and three percent discount rates, respectively. EPA estimates the annualized costs over 82 years between $772 M to $1,205 M at three and seven percent discount rates, respectively.

Table 1: EPA's Estimated National Annualized Benefits and Costs for the Proposed NPDWR

[Table 1: see docket ID EPA-HQ-OW-2022-0114-1738]

2. Outline of the Report

The analysis spans six sections. This section provides an overview of EPA's proposed rule and its supporting EA. Section II discusses best practices in benefit-cost analyses and evaluates EPA's

EA against these best practices. The section identifies fundamental limitations in EPA's framework and methodology, analytical gaps that it is obligated under government directives to include in its estimates, and other implications from its assumptions.

Section III presents an alternative analysis of the social benefits of EPA's proposed rule. The section contains the methodological framework, data, and assumed values. The analysis provides a discussion of the results and limitations. Similarly, Section IV presents the social cost analysis by first outlining the approach and data sources and then by providing results for each component of the analysis. Section V provides a focused discussion on the economic impacts of EPA's rules on household income. The concluding section, Section VI, compares these estimates with EPA's estimates.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits.

Del-Co Water Company, Inc. (Doc. #1744, SBC-043615)

I. General Comments

Del-Co is confident in offering expertise and opinions as they relate to the real impact that new drinking water standards will have on our operations and related services. However, we are less confident commenting on the complex toxicological principles, risk assessments, uncertainty factors, and epidemiologic research. That said, we do question whether a reduction in our known PFOA concentrations of 4 – 5 ppt to less than 4.0 ppt is the best use of our resources and the best method to improve public health. In the current situation wherein PWSs are subject to increased costs in replacing lead service lines, upgrading cybersecurity, replacing aging infrastructure, and assuring sustainable water supplies, we question if dedicating $8 – $110 million dollars to upgrade/expand/retrofit our existing treatment plants provides the most meaningful reduction in public health risk to our customers.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. The EPA disagrees with the commenter's suggestion that this action is not "the best use of our resources and the best method to improve public health" as the Administrator has determined that the benefits of reducing PFAS in drinking water through this regulatory action justify the costs. For the quantified benefits analysis, the EPA relied on peer-reviewed literature and synthesis of multiple high-quality studies to evaluate the effects of PFAS exposure on human health. The Administrator's assessment that the benefits of the proposed rule justified its costs was based on the comprehensive scientific and cost and benefit assessment information in the record for this rulemaking, and specifically the data relating to, and analysis of, the quantified and nonquantifiable benefits, which are anticipated to be substantial, as well as the quantified and nonquantifiable costs.

PFAS Regulatory Coalition (Doc. #1761, SBC-047717)

4. EPA's cost/benefit analysis relies too heavily on nonquantifiable costs and benefits.

EPA presents its evaluation of costs and benefits of MCLs at different MCL values and at both 3% and 7% discount rates, in Tables 66 through 69 of the Proposal. These tables show uneven net benefits, with only PFOA and PFOS MCLs set at 10 ppt projected to have positive next net benefits at both discount rates. Nevertheless, EPA proposes 4 ppt for each compound and concludes its cost/benefit analysis by stating: "To fully weigh the costs and benefits of the action the Agency considered the totality of the monetized values, the potential impacts of the unquantified uncertainties described above, and the nonquantifiable costs and benefits. The Administrator has determined that the benefits of this proposed regulation justify the costs." 88 Fed. Reg. 18729. The only way that EPA could reach this conclusion is if the unquantified uncertainties and the nonquantifiable costs and benefits were given more weight than the quantified values.

Given the concerns about costs that the Coalition has discussed above, EPA should conduct a new cost/benefit analysis. Considering the Agency's underestimation of costs, EPA has not met the Safe Drinking Water Act requirement that an MCL be set at a level that "maximizes health risk reduction benefits at a cost that is justified by the benefits." SDWA Section 1412(b)(6).

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document. First, the commenter is incorrect that SDWA requires that an MCL be set at a level that ""maximizes health risk reduction benefits at a cost that is justified by the benefits.' SDWA Section 1412(b)(6)." To the contrary, SDWA requires that the MCL be set as close to the MCLG as is feasible as specified under Section 1412(b)(4)(B). Section 1412(b)(6) only applies to those situations where the Administrator has determined that the costs of a proposed rule would not justify the benefits and has decided to exercise their authority to set an alternative level; those circumstances do not apply here where the Administrator found that the costs of the rule do justify the benefits. Furthermore, as required under SDWA, the EPA considered both nonquantifiable and quantifiable costs and benefits in its EA for the final rule. As such, the agency did consider nonquantifiable costs and benefits: see Tables 5-22, 6-48, and 7-6 of the EA for an overview of nonquantifiable costs and benefits (USEPA, 2024bb). See Section 5.1.3 of the EA for an overview of quantified costs and Section 6.1.3 of the EA for an overview of quantified benefits (USEPA, 2024bb). The commenter's statement that "the only way EPA could reach this conclusion is if unquantified costs and benefits were given more weight" is not based on or consistent with the record in this rulemaking, including the EPA's extensive quantified analyses. While it is true that the EPA considered the nonquantifiable costs and substantial nonquantifiable benefits in its determination, as required under SDWA, the agency has demonstrated that the rule will produce substantial quantified benefits as well and has not given more weight to either quantified or nonquantified benefits.

PFAS Regulatory Coalition (Doc. #1761, SBC-046080)

F. The Proposal fails to propose MCLs at levels where costs are justified by the benefits, as required under statute.

The Safe Drinking Water Act requires that an MCL be set at a level that "maximizes health risk reduction benefits at a cost that is justified by the benefits." SDWA Section 1412(b)(6). The Proposal fails to meet this statutory requirement for several reasons, including that. EPA seriously underestimates the costs of the Proposal. Other organizations, including AWWA and the US Chamber of Commerce, have already submitted cost estimates to EPA and OMB, and each independently shows that EPA's cost estimates are much too low. Below, the Coalition outlines additional cost/benefit issues that need to be considered and addressed by the Agency.

EPA Response: First, the commenter is incorrect that SDWA requires that an MCL be set at a level that ""maximizes health risk reduction benefits at a cost that is justified by the benefits.' SDWA Section 1412(b)(6)." To the contrary, SDWA requires that the MCL be set as close to the MCLG as is feasible as specified under Section 1412(b)(4)(B). Section 1412(b)(6) only applies to those situations where the Administrator has determined that the costs of a proposed rule would not justify the benefits and has decided to exercise their authority to set an alternative level; those circumstances do not apply here where the Administrator found that the costs of the rule do justify the benefits. See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. In response to the commenter's note about cost estimates prepared by other organizations, the EPA notes that it disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. See section 13.3.3 of the EPA response in this *Response to Comments* document. See the EPA response to comment Doc. #1537, SBC-042649 in section 13.3.3 in this *Response to Comments* document regarding the US Chamber of Commerce's comments related to costs.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043878)

Benefit and Cost Analyses

EPA developed a comprehensive framework for evaluating the costs and benefits of regulating the six contaminants addressed in this rulemaking. However, given data limitations, the agency's quantitative analysis was limited primarily to PFOA and PFOS, and, to a more limited extent, PFHxS. EPN commends EPA for quantifying benefits from multiple health effects, including reductions in heart attacks and strokes, developmental impacts to fetuses and infants, kidney cancer cases resulting from control of PFOA and PFOS, and reductions in bladder cancer cases from disinfection byproducts as co-benefits. We also commend EPA for describing all the significant health effects they were unable to quantify, as well as clarifying the sources of uncertainty in their analysis. We note that EPA did a more comprehensive quantification of costs, leaving only two types of costs unquantified for PFOA, PFOS and PFHxS (hazardous waste disposal of treatment media and POUs not in compliance). The end result is that EPA estimates

the expected value of net annual incremental benefits to be $461M using a 3% discount rate and -$297M using a 7% discount rate. Consideration of all the unquantified benefits would likely result in positive benefits under the 7% discount rate, but the appearance of negative benefits is concerning.

EPA used the 3% and 7% discount rates because those are the default rates recommended by OMB in Circular A-4 which guides federal agencies' regulatory analyses. On April 6, 2023, OMB released an updated Circular A-4 for public comment. OMB is now recommending that the default discount rate should instead be 1.7% based on analyses of the inflation-adjusted average interest rate of federal securities over the past 30 years on a pre-tax basis. OMB further states that using a higher discount rate to account for risk would be inappropriate when evaluating regulations that reduce risk. Accounting for this risk reduction would be akin to using a lower, not higher, discount rate. EPN recommends that EPA redo their benefit and cost analyses using the 1.7% discount rate which will undoubtedly indicate even greater net annual incremental benefits than the 3% rate and further bolster the justification for these PFAS drinking water standards. In the final rule, EPA should quote this new OMB guidance and eliminate the 7% discount rate analyses, even if the new guidance has not yet been finalized.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. This comment provides additional support for the EPA's evaluation of costs and benefits. In response to the commenter's suggestion that benefits be evaluated using a lower discount rate, based on this and other comments, the EPA has included analyses using a 2 percent discount rate. Please see sections 13.2 and 13.8 of the EPA response in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045693)

a. EPA Did Not Account for the Fact that Costs Incurred are "Solely the Result of the" NPDWR, but Purported Benefits are Not.

EPA's analysis of the benefits of the proposed MCLs does not comply with SDWA [sec]1412(b)(3)(C)(i)(I)'s requirement to analyze "[q]uantifiable and nonquantifiable health risk reduction benefits for which there is a factual basis in the rulemaking record to conclude that such benefits are likely to occur as the result of treatment to comply with each level." And while the costs of the Proposed Rule are "solely as a result of compliance" with the Rule, the purported benefits are not. [FN96: SDWA [sec]1412(b)(3)(C)(i)(I)]

The first step in assessing the benefits of the Proposed Rule is to analyze the baseline conditions of the population in the United States. Average blood levels of PFOA and PFOS in the U.S. population have decreased by more than 70% and 85% respectively since 2000. [FN97: See https://www.atsdr.cdc.gov/pfas/health-effects/us-population.html] Moreover, based on the latest NHANES biomonitoring data from the 2017-2018 timeframe, average blood levels of PFAS such as PFHxS and PFNA also decreased significantly during that time. [FN98: The CDC stopped analyzing for PFBS since 2014 as part of its NHANES monitoring program because of

the lack of detection in general population blood.] In short, the baseline conditions of PFOA and PFOS exposure and blood serum levels, as well as PFAS subject to the HI, have decreased significantly in the past two decades, and there is no evidence indicating they will not continue to do so in the absence of the Proposed Rule. [FN99: See Biomonitoring Data Tables for Environmental Chemicals | CDC] The SDWA requires that EPA demonstrate the incremental decrease in illness or morbidity is meaningful and associated with the NPDWR itself, not other actions such as decreased exposure through voluntary cessation of manufacturing or use. [FN100: See SDWA [sec]1412(b)(3)(C)(i)(I).]

The SDWA requires EPA to evaluate how the small fraction of any purported benefit of reduced PFOA and PFOS exposure would result from EPA establishing a NPDWR as opposed to the myriad other factors already greatly reducing exposure over time. Under the SDWA, EPA must also show that the small incremental reduction in exposure is meaningful or even measurable in terms of benefit as compared to reductions from other means. Unless EPA can demonstrate an incremental benefit based solely on a NPDWR that outweighs the associated cost, which in fact would derive from the NPDWR, then the proposed NPDWR does not comply with the mandates of the SDWA.

EPA Response: The EPA disagrees with the commenter's assertion that the benefits analyzed in the EPA's economic analysis supporting the NPDWR are the result of actions other than the NPDWR itself. The EPA analyzes changes in blood serum PFAS levels as a result of changes in PFAS drinking water concentrations due to the installation of treatment technology. The associated benefits estimates are estimated based on these drinking water treatment-driven changes in blood serum levels only and do not reflect changes associated with reduced exposures from other PFAS sources. See the EPA response to comment Doc. #1841, SBC-044811 in section 13.4 in this *Response to Comments* document where the EPA describes the steps that were taken to determine the risk reduction benefits solely attributable to the PFAS NPDWR. See also the EPA response to comment Doc. #1841, SBC-044844 in section 13.4.5 in this *Response to Comments* document where the EPA describes how the benefits from other agency actions, including benefits from actions related to the microbial and disinfection byproduct rules, were not considered in this rulemaking.

Uttara Jhaveri (Doc. #1778, SBC-045450)

The benefits of monitoring, compliance and technological changes need to be highlighted, considering the $1.2 billion annual cost savings based on the public health benefits [FN31: Jen Christensen, EPA proposes first standards to make drinking water safer from 'forever chemicals,' CNN, Mar. 15, 2023, https://www.cnn.com/2023/03/14/health/epa-pfas-standards-wellness/index.html.] to push the rulemaking to stakeholders and the public.

EPA Response: The EPA agrees with the commenter that the public health benefits of the rule are significant. See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043799)

Federal Funding and Assistance. The 4ppt MCL limit is based on application of weak evidence of cause and effect. This level is below detection limits of current instrumentation and methodology, rendering this limit impracticable for compliance. The level should be based on a thorough analysis of the cost and benefit and the practicality of implementation, such as availability of adequate instrumentation and reliable analytical methods.

EPA Response: In response to the commenter's assertion that "the 4ppt MCL limit is based on application of weak evidence of cause and effect", the EPA disagrees. Please see the agency's Maximum Contaminant Level Goals for PFOA and PFOS (USEPA, 2024ll) for discussion of the science underlying the derivation of MCLGs for the final rule. Additionally, the commenter is incorrect in their assertion that "this level is below detection limits of current instrumentation and methodology": the 4.0 ppt MCLs for PFOA and PFOS are not below practical quantitation limits or detection limits and thus not impracticable for compliance. For responses to comments regarding the feasibility of the EPA's PFAS MCLs promulgated under this action, see section 5 of the EPA response in this *Response to Comments* document.

Bailey Smith (Doc. #1787, SBC-045815)

To the extent that challengers to the rule think that these MCLs will be costly to attain,[FN49: See e.g., Hampton et al., supra note 10; Tanaka et al., supra note 21.] the benefits (saving families from preventable illnesses) far outweigh the costs.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document.

Peggy Kurtz (Doc. #1799, SBC-046042)

Strong EPA regulations will also send a strong signal to the chemical industry to invest in safe alternatives now.

The argument that will be raised against the new EPA standards is the cost of filtration. But the costs are far outweighed by the costs of healthcare due to the impacts of PFAS. Ultimately, it is the chemical industry that should bear these costs. The shocking fact is that manufacturers knew about the health impacts many decades ago- and they continued to push these chemicals out, regardless.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046104)

Moreover, as described below, EPA's benefit-cost analyses found that these systems are cost-effective, with health benefits exceeding treatment costs in many circumstances.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046129)

6. EPA provides a balanced and detailed qualitative accounting of the benefits and costs that could not be quantified.

Ideally, all benefits and costs of a regulatory action would be quantified and monetized, but analysts are often limited by the available information, as well as resource constraints when conducting an EA. EPA prioritizes the quantification of benefits, for example, based on the contaminants and endpoints (i.e., adverse health outcomes) where (i) the weight of evidence linking the contaminant to key biomarkers is strongest, (ii) it is possible to link the contaminant or related biomarkers to a health endpoint (e.g., cardiovascular disease) that can be monetized (i.e., valued in dollar terms based on available economic literature and practices), and (iii) the endpoint does not overlap with another benefit category. Based on my professional experience, the first two criteria are standard practice when prioritizing analytical efforts given the practical constraints in conducting empirical analyses. The third criterion helps EPA avoid "double counting." As stated in EPA's Guidelines for Preparing Economic Analyses, when estimating the effects separately for each health endpoint "it is important to avoid double counting benefits across effects as much as possible" (EPA, 2014, pg. 7-3). Additionally, given limited resources, EPA prioritizes quantification of benefits and costs that are anticipated to be the largest. In my professional experience, prioritizing in this manner is sometimes necessary, and it is an appropriate way to prioritize given the objective of providing the best and most comprehensive information possible to inform the regulatory development process.

It is important to emphasize that the lack of quantification does not imply that any unquantified benefits and costs are not relevant. Following standard practice (EPA 2014, OMB 2003), EPA goes to great lengths to detail benefits and costs that could not be quantified, but that are still relevant for the EA and the ultimate determination of whether the benefits of the proposed PFAS NPDWS exceed the costs. A systematic summary is provided in Table 7-5 in Chapter 7, and further details are discussed in Chapters 5 and 6. Based on my own professional experience, the qualitative discussion in this EA is more rigorous than others I have reviewed. The Agency goes into a lot more detail, combs the literature more thoroughly, and touches on a larger number of potential health endpoints.

Although the net benefits for the central estimates of the proposed regulatory option are negative in some scenarios (e.g., under an assumed 7% discount rate), the Agency lays out convincing evidence that the net benefits are likely positive. The net benefits are positive under an assumed 3% discount rate (see Table 7-1), and the qualitative evidence and sheer number of unquantified benefit endpoints suggest that the benefits likely do exceed the costs. Furthermore, although consideration of alternative 3% and 7% discount rates is currently the standard practice for EAs of federal regulations (OMB 2003), the lower 3% discount rate may be more appropriate in this context. See comment #15 below for details.

In any case, the reliance of the key conclusions of this EA on qualitatively discussed health benefits is not atypical. A review by Petrolia et al. (2021) of EAs for all major EPA rules from 2008 to 2019 revealed that of the 43 analyses that included non-fatal health outcomes, nine (21%) only included unquantified health benefits (see Figure 2 in Petrolia et al. 2021); and additional qualitative health benefits were included in the other EAs that did quantify at least one health endpoint. In OMB's recently proposed revised guidance for economic analysis, it is emphasized that:

"relying on materially incomplete monetized BCA [net benefits] does not offer an adequate summary of evidence intended to inform determination of the most beneficial alternative, and such reliance could even be misleading. You [(analysts)] should exercise professional judgement in identifying the importance of non-quantified factors and assess as best you can how they might change the ranking of alternatives based on estimated net benefits" (OMB 2023, pg. 5).

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document. This comment provides support for the agency's evaluation of costs and benefits.

Earthjustice et al. (Doc. #1808, SBC-046108)

III. EPA Should Take Steps to Strengthen the Economic Analysis Supporting the Proposed Rule

As required by the SDWA, EPA's Proposed Rule is supported by a draft Economic Analysis ("Draft EA") that assesses the proposal's "[q]uantifiable and nonquantifiable health risk reduction benefits," its "[q]uantifiable and nonquantifiable costs," the incremental costs and benefits of the alternative MCLs considered, the effects of the Six PFAS on the general population and greater-risk subpopulations, any increased health risks associated with compliance with the Proposed Rule, and other relevant factors such as uncertainties in the analysis. [FN100: 42 U.S.C. § 300g-1(b)(3)(C)(i); see EPA, Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (EPA Doc. No. EPA- 822-P-23-001) (Draft for Public Comment) (Mar. 2023).] As described in the accompanying expert review of EPA's Draft EA by Dennis Guignet, Ph.D., many features of the Draft EA are exceptionally thorough and transparent, [FN101: Memorandum from Dennis Guignet, Ph.D., to Earthjustice, Re. Review of the Economic Analysis for the Proposed PFAS NPDWR (May 26, 2023) ("Guignet 2023") (Attached as Exhibit B).] and the Draft EA provides ample justification for EPA's conclusion that the Proposed Rule's quantified and unquantified benefits justify its costs. [FN102: See Proposed Rule, 88 Fed. Reg. at 18,689, 18,727–29. At the same time, we stress that EPA has the authority to set the MCL "as close to the [MCLG] as feasible, even if [EPA] determines that the benefits of the MCL at this level do not justify the costs." S. Rep. No. 104-169 at 33.] Further, as discussed in the accompanying expert review by Elin Betanzo, EPA's treatment cost estimates are robust and, if anything, may overstate actual costs. [FN103: Elin Betanzo, Safe Water Engineering, Analysis of the USEPA Proposed PFAS National Primary Drinking Water Regulation Treatment Costs and Comparison to the AWWA National PFAS Cost Model Report (May 30, 2023) ("Betanzo 2023") (Attached as Exhibit C).]

Nevertheless, there are important steps EPA can and should take to strengthen the EA to better support the proposed drinking water standards.

At the outset, we encourage EPA to maintain, and consider expanding upon, several key methodological strengths of the Draft EA. [FN104: See Guignet 2023 at 2–7.] The Draft EA is predicated on a detailed, data- driven Monte Carlo simulation model that supports comprehensive sensitivity analyses, which evaluate the impact of specific variables on estimates of the Proposed Rule's net benefits. As described by Dr. Guignet, this is the most thorough approach to account for multiple sources of uncertainty in the economic analysis simultaneously. [FN105: Id. at 2–3.] The Draft EA accounts appropriately for existing state-level drinking water standards when estimating the costs and benefits attributable to the Proposed Rule. [FN106: Id. at 5.] In addition, the EA relies appropriately on unquantified health benefits (though, as discussed below, the record supports quantification of additional health benefits). [FN107: Id. at 6–7.] EPA's reliance on unquantified health benefits is consistent with the agency's standard practice, [FN108: Id.] and is expressly required by the SDWA, which mandates that EPA's health risk reduction and cost analysis account for all "[q]uantifiable and nonquantifiable health risk reduction benefits for which there is a factual basis in the rulemaking record to conclude that such benefits are likely to occur" due to compliance with the MCL. [FN109: 42 U.S.C. § 300g-1(b)(3)(C)(i)(I)–(II).] Congress "require[d] [EPA] to determine whether the benefits of a [drinking water] standard 'justify' (rather than 'exceed' or 'outweigh') the costs to reflect the nonquantifiable nature of some of the benefits and costs that may be considered. [EPA] is not required to demonstrate that the dollar value of the benefits are greater (or lesser) than the dollar value of the costs," and "[a]ll costs and benefits, both quantifiable and nonquantifiable, must be considered when making determinations under this authority." [FN110: S. Rep. No. 104-169 at 33. Moreover, Congress recognized the inherent difficulty and subjectivity in fully quantifying the economic benefits of rules, so the SDWA authorizes EPA to establish an MCL at a feasible level even if the agency cannot formally determine that MCL is justified by the economic costs. Id. We note that, for example, there are often equity considerations, as there are with PFAS, whereby certain populations, often low-income communities and communities of color, bear disproportionate burdens from exposure to environmental contaminants. See Jahred M. Liddie et al., Sociodemographic Factors Are Associated with the Abundance of PFAS Sources and Detection in U.S. Community Water Systems, Env't Sci. Tech. (2023), https://pubs.acs.org/doi/pdf/10.1021/acs.est.2c07255. Such equity considerations often are not reflected in economic analyses but are valid considerations under the SDWA.]

EPA Response: These comments support the agency's evaluation of costs and benefits. For discussion on the EPA's comparison of costs and benefits, please see section 13.8 of the EPA response in this *Response to Comments* document. For responses to comments on the EPA's PFAS MCLs and regulatory alternatives, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

With respect to the commenter's mention of "equity considerations", the EPA has conducted an environmental justice analysis for this action, as directed by Executive Order 14096. As the commenter suggests, the EPA's EJ analysis demonstrates that communities of color are

anticipated to experience elevated baseline PFAS drinking water exposures compared to the entire sample population included in the analysis. However, the EPA believes that this action is likely to reduce existing disproportionate and adverse effects on people of color, low-income populations, and/or Indigenous peoples. Based on this comment, the EPA has added Liddie et al. (2023) to the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in in Section 8.2 of the EA (USEPA, 2024b). For more information on the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA, 2024b) and section 14.10 of the EPA response in this *Response to Comments* document.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045777)

• Based on EPA's own cost-benefit analysis, it is suggested that, if EPA moves forward with a final PFAS rule, only Option 1c(10 ppt MCL for both PFOA and PFOS) is likely to meet the Agency's criteria that the rule must provide a net benefit.

DC Water appreciates the opportunity to comment on EPA's proposed PFAS National Primary Drinking Water Regulations. Please let me know if we can provide any additional information or share our utility operating expertise to inform improvements to the proposed rule with the goal of ensuring its successful implementation.

Sincerely,

Chief Operating Officer, EVP

C: David L. Gadis, CEO and General Manager

Marc Battle, Chief Legal Officer and EVP, Government and Legal Affairs

EPA Response: The EPA disagrees with the commenter's assertion that the rule must provide a net benefit; rather, SDWA specifies that when proposing an NPDWR, the Administrator shall publish a determination as to whether the benefits of the MCL justify, or do not justify, the costs based on the analysis conducted under paragraph 1412(b)(3)C), which is based on the entire rulemaking record, including quantified and nonquantifiable costs and benefits. For further discussion of the EPA's comparison of costs and benefits, see section 13.8 of the EPA response in this *Response to Comments* document.

Citizens Energy Group (Doc. #1838, SBC-044857)

Citizens also urges EPA to make efforts to balance reasonable risk mitigation with practical affordability realities for utility customers.

EPA Response: For discussion on the EPA's comparison of costs and benefits of the final rule, please see section 13.8 of the EPA response in this *Response to Comments* document. For responses to comments on the EPA's PFAS MCLs and regulatory alternatives, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of

feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis, please see the response in section 5.1.2 of the EPA response in this *Response to Comments* document (for laboratory considerations) and section 5.1.4 of the EPA response in this *Response to Comments* document (for treatment considerations).

For information on the agency's small system affordability analysis conducted for the final rule, please see EPA response to comment Doc. #1630, SBC-043134 in section 13.8 in this *Response to Comments* document, section 13.10 of the EPA response in this *Response to Comments* document, and the EPA's affordability analysis in Chapter 9 of the EA (USEPA, 2024b).

American Chemistry Council (ACC) (Doc. #1841, SBC-044848)

EPA Cannot Determine that the Benefits of the Proposal Justify the Costs

Section 1421(b)(4)(C) requires that the Administrator determine "whether the benefits of the [MCL] justify, or do not justify, the costs" based on the Agency's health risk reduction and cost analysis. As detailed above, the Agency's analysis significantly underestimates the costs of its proposed MCLs for PFOA and PFOS and overestimates its benefits. For the proposed HI MCL for the four other PFAS, EPA fails to conduct an appropriate benefit and cost analysis as required by Section 1421(b)(3) of the Act. Without such a determination, the Agency cannot promulgate the regulation as proposed in the absence of a determination that the substances present an "urgent threat to public health." [FN197: 42 U.S.C. Section 300g-1(b)(1)(D)] The Administrator cannot reach such an urgent threat determination, based on the information presented.

EPA's estimates of the cost of complying the proposed MCLs for PFOA and PFOS are significantly at odds with the estimate from AWWA. Although both rely on extrapolation from the UCMR 3 data, AWWA's analysis includes nearly twice as many PWSs and a far larger number of smaller systems. The impact of the proposal on smaller systems is a particular weakness of the Agency's analysis – given their large numbers and limited resources and the considerable and unexplained disparity in EPA's estimate of the percentage of affected systems (5.3 percent for small systems vs 23.9. percent for large ones).

EPA's analysis of costs for an HI MCL for the four other PFAS is equally unsupportable, as the Agency does not have a basis for estimating the number of additional water systems potentially impacted for three of the four systems. Estimates for the fourth substance, PFHxS, suffer from the same limitations as PFOA and PFOS.

In accessing benefits, EPA has inappropriately quantified benefits for reductions in PFOA and PFOS for health effects for which the available data are not sufficient to support such a determination. As described above, the epidemiology data do not provide evidence for an association with CVD and the use of an association with increases in total cholesterol is inappropriate. The assumption that reductions in bladder cancer cases and fatalities resulting from the lowering of THM levels is not well supported by the empirical data. In light of multiple ongoing activities on DBPs, moreover, EPA has not attempted to identify the benefits that can be

"attributed solely" to this proposal. Further, it is not clear that separating benefits likely to be achieved from this proposal versus the larger Agency effort is even possible.

In quantifying benefits for improvements in birth weight and cancer incidence, EPA relies on epidemiological data despite conflicting results and a lack of clear evidence. In the case of RCC, the estimates of benefits are based solely on the study by Shearer et al. despite the clear recommendation from SAB not to do so. EPA's analysis of birth weight impact is confused – relying on equivocal results from two studies as a basis for the RfD, but a meta-analysis of multiple studies many of which are not evaluated in EPA's analysis and some of which are considered low confidence by the Agency – for quantifying the estimated benefits.

The Agency has provided little to no evidence to support the projected benefits associated with the HI MCL. Combined with the unscientific basis of the Hazard Index, the Agency's determination for a "meaningful opportunity for health risk reduction" lacks substantiation.

Considering the AWWA analysis for PFOA and PFOS alone, the cost of the proposed MCLs far exceed the Agency's estimates of benefits by a large margin ($5.2 billion versus $900 million to $1.2 billion). Factoring in the concerns about the Agency's analysis of the benefits, the disparity is likely to be even greater.

EPA Response: The EPA disagrees with the commenter's assertion that the "EPA cannot determine that the benefits of the proposal justify the costs." See section 13.8 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1759, SBC-045620 in section 13.4.1 in this *Response to Comments* document, where the EPA Administrator's benefit-cost determination, and the factors considered in making that determination, are discussed in detail.

The EPA disagrees with the commenter's assertion that the "agency's analysis significantly underestimates the costs of its proposed MCLs for PFOA and PFOS and overestimates the benefits." See section 13.4 of the EPA response in this *Response to Comments* document for the EPA's response to comments claiming that the agency overestimated benefits. See section 13.3 of the EPA response in this *Response to Comments* document for the EPA's response to comments claiming that the agency underestimated costs.

The EPA disagrees with the commenter that the EPA failed to conduct "an appropriate benefit and cost analysis" for the Hazard Index MCLs and that the EPA's analysis of costs to comply with the Hazard Index MCL is "unsupportable." See section 13.3.2 of the EPA response in this *Response to Comments* document regarding the evaluation of costs associated with the Hazard Index and individual MCLs for PFHxS, PFNA and HFPO-DA and section 13.4 of the EPA response in this *Response to Comments* document regarding the EPA's benefits assessment for Hazard Index PFAS. The EPA also disagrees with the commenter's assertion that the EPA has provided "little to no evidence to support the projected benefits associated with the HI MCL" as the agency has qualitatively summarized the potential health benefits resulting from reduced exposure to PFHxS, HFPO-DA, PFNA, and PFBS, in addition to other PFAS anticipated to be co-removed, in Section 6.2.4 of the EA (USEPA, 2024b).

The EPA disagrees with the commenter's assertion that the EPA "cannot promulgate the regulation as proposed in the absence of a determination that the substances present an "urgent threat to public health". This condition in SDWA solely applies to the promulgation of interim MCLs where the EPA has not completed the HRRCA or made the determination whether the proposal's costs are justified by the benefits. As discussed extensively in the preamble and this *Response to Comments* document, the EPA has completed a HRRCA consistent with SDWA requirements and the Administrator has determined that the benefits of this rule justify the costs.

With respect to the commenter's assertion that the EPA's estimates are "significantly at odds with the estimate from AWWA", the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs; see section 13.3.3 of the EPA response in this *Response to Comments* document for further discussion.

The EPA disagrees with the commenter's assertion that the "EPA has inappropriately quantified benefits for reductions in PFOA and PFOS for health effects for which the available data are not sufficient to support such a determination." See section 13.4 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's method for estimating quantified benefits. See section 13.4.1 of the EPA response in this *Response to Comments* document for responses to comments on CVD benefits estimation and for the EPA's response to comments concerning the association between PFAS exposure and CVD. See section 13.4.2 of the EPA response in this *Response to Comments* document for responses to comments on developmental benefits estimation and the EPA's responses to comments on the studies used for estimating developmental benefits. See section 13.4.3 of the EPA response in this *Response to Comments* document for responses to comments on RCC benefits estimation and the EPA's responses to comments on using Shearer et al (2021) for benefits estimation. See section 13.7 of the EPA response in this *Response to Comments* document for responses to comments on DBP co-removal benefits estimation. The EPA disagrees with the commenter's statement that "EPA has not attempted to identify the benefits that can be "solely attributed" to this proposal." See the EPA response to comment Doc. #1841, SBC-044811 in section 13.4 in this *Response to Comments* document where the EPA describes the steps that were taken to determine the risk reduction benefits solely attributable to the PFAS NPDWR. See the EPA response to comment Doc. #1841, SBC-044844 in section 13.4.5 in this *Response to Comments* document where the EPA describes how the benefits from other agency actions, including benefits from actions related to the microbial and disinfection byproduct rules, were not considered in this rulemaking.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045833)

C. The proposed NPDWRs are cost-justified, especially considering the significant unquantified benefits of the regulation and the availability of federal funding for drinking water projects.

Commenters support the Administrator's determination that the proposed rule's benefits justify its costs given (1) the significant unquantified risk reduction benefits and co-benefits that would accrue from this regulation, (2) the availability of federal funds for PFAS projects through the

Bipartisan Infrastructure Law (BIL) that was not accounted for in the economic analysis, and (3) the proper use of a consumption-based discount rate for the quantified portion of the analysis.

The SDWA requires EPA to analyze costs and benefits as part of the rule proposal process. [FN30: 42 U.S.C. § 300g-1(b)(3)(C).] This analysis must include consideration of non-quantifiable benefits. [FN31: 42 U.S.C. §§ 300g-1(b)(3)(C)(i)(I)-(II).] The Administrator must publish a determination as to whether the proposed rule's benefits justify its costs. [FN32: 42 U.S.C. § 300g-1(b)(4)(C).] EPA's rigorous analysis concludes that the quantifiable benefits of the proposed rule are greater than the quantifiable costs at a 3 percent discount rate, but not at a 7 percent discount rate. [FN33: 88 Fed. Reg. 18638, 18724.] Critics may seize on this statement in the cost-benefit analysis to argue the rule's costs do not justify its benefits. However, such a commentary is myopic and one-sided because it fails to (1) account for the significant non-quantifiable benefits of the proposed rule and (2) acknowledge that the costs are overestimated because a 7 percent discount rate is not appropriate for this type of regulation, and existing streams of federal funding are in place to defray compliance costs.

First, EPA should not give less consideration to unquantified benefits in favor of more easily quantifiable costs. The agency properly "provided substantial detail on the benefits of the rule, and the reason why quantification was not possible," [FN34: Nicopure Labs, LLC v. Food & Drug Admin., 266 F. Supp. 3d 360, 406 (D.D.C. 2017) (noting that agencies are not required to quantify benefits "in any particular way when compared to the costs" and are allowed to engage in qualitative analysis).] concluding that the unquantified benefits associated with this rulemaking would be significant. These benefits include the health effects of reduced exposure to PFOA and PFOS, the HI PFAS compounds, and other PFAS not regulated by this rule beyond the three health endpoints analyzed by EPA. Given the range of other health effects that PFAS compounds are associated with—including multiple types of cancer—the unquantified benefits of the rule, if quantified, would render the rule unambiguously cost-benefit justified. However, the Agency has provided enough detail in its qualitative analysis to support its determination the overall benefits of the proposed regulation outweigh its costs irrespective of the discount rate used, and, therefore, has fulfilled its mandate under the SDWA.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2047, SBC-046221)

The cost to implement the regulation of any and all PFAS removal to below 50 PPT is not offset by the proven health savings. Do not enact any federal PFAS regulations

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2322, SBC-046306)

The TTHM rule of 80 ppb and 60 ppb was supposed to save lives from cancer and the cancer rates have not dropped at all from this costly regulation. No value for the cost, just wasting consumers money like paying someone to dig a hole in your front yard and then fill it back in again. No provable health savings have been achieved. It will be the same with the PFAS regulations. Nothing measurable will be achieved and a great waste of time and money. This is the plan of the bureaucratic unelected federal government, destroy the wealth in the United States by every means possible. Using borrowed federal money to achieve these treatment goals and devalue the dollar further was never the intent of the safe drinking water act amendment. This rule should be dropped.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. In response to the commenter's assertion that this action will be a "great waste of time and money" and that "this rule should be dropped", the EPA notes that once fully implemented, the final rule is anticipated to prevent thousands of deaths and reduce tens of thousands of serious PFAS-attributable illnesses and, as explained in section 13.8 of the EPA response in this *Response to Comments* document, the Administrator has determined that the benefits of reducing PFAS in drinking water through this regulatory action justify the costs.

Arlington County Virginia (Doc. #1603, SBC-043018)

To summarize, it appears to us that the costs (both capital and operating) assumed in the EPA's economic analysis appear to be off by a factor of 2 to 3. We believe that the EPA's assumptions about number of utilities affected are also too conservative, and that the proposed regulation will exceed the market capacity resulting in unpredictable, but extraordinary, inflation in this sector. Finally, even with the EPA's most favorable assumptions, the cost-benefit analysis can best be characterized as ambivalent.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. See sections 13.3 and 13.3.3 of the EPA response in this *Response to Comments* document for the EPA's responses to comments on the EPA's method for estimating costs and treatment costs, respectively. See sections 6.5 and 6.8 of the EPA response in this *Response to Comments* document for the EPA's response to comments on the number of water systems estimated to be impacted by the final rule. The EPA disagrees with the commenter that the "cost-benefit analysis can best be characterized as ambivalent;" as the Administrator has determined that the total quantifiable and nonquantifiable benefits justify the quantifiable and nonquantifiable costs of the rule.

Arlington County Virginia (Doc. #1603, SBC-043007)

3. The Economic Analysis underestimates actual costs, and even as presented does not provide convincing justification of this proposed rule making

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. See section 13.3 of the EPA response in this *Response to Comments* document for the EPA's responses to comments on the EPA's method for estimating costs.

Arlington County Virginia (Doc. #1603, SBC-043015)

1. The Cost-Benefit analysis of the proposed rule utilized two different discount values (3% and 7%) and ran Monte Carlo simulations to capture the wide range of uncertainties in both the Costs and Benefits of the proposed rule. The Cost Benefit analysis then presented 6 different scenarios (5th, 50th, and 95th percentile at the 3% and 7% discount rates). Remarkably, 3 of the 6 scenarios presented indicate a net cost of the rule as proposed.

EPA Response: See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. Additionally, the EPA notes that 5th and 95th percentile results represent uncertainty in the central estimates of the analyses, not different scenarios.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045469)

Comprehensive Approach to Controlling PFAS – As NGWA expressed with eight other water associations in our joint letter to the Administrator on June 3, 2020, a comprehensive approach is needed to address PFAS affecting public health and the environment. The steps identified in that letter include:

• conducting the necessary technical and economic analyses to support proposed SDWA maximum contaminant levels for PFOA and PFOS,

EPA Response: The EPA has conducted a HRRCA for the proposed and final rule consistent with the requirements of SDWA. See section 13.8 of the EPA response in this *Response to Comments* document for discussion of the EPA's comparison of costs and benefits. The EPA has also conducted significant technical analyses related to occurrence, treatment, and health effects, among other things. See sections 3, 4, 5, 6, 7, 8, and 10 of the EPA response in this *Response to Comments* document.

13.9 Quantified Uncertainties in the Economic Analysis

Summary of Major Public Comments and EPA Responses

One commenter, who represented part of a larger group of commenters, supported the EPA's assessment of uncertainty in its economic analysis, stating that "the entire EA is centered on a detailed, data-driven Monte Carlo simulation model that has been calibrated based on existing federal and state data." The commenter further asserts that Monte Carlo simulations, such as those used by the agency in producing its economic estimates for this action, are "a common and defensible approach to account for uncertainty…and are the most thorough way to

simultaneously account for numerous sources of uncertainty in economic analysis." The EPA agrees with these comments which provide additional support for the agency's assessment of uncertainty in its economic analysis.

One commenter claimed that the EPA failed to follow federal requirements for regulatory analysis, including those of OMB Circular A-4, by not considering all of the opportunity costs and by not conducting a formal uncertainty analysis. The EPA disagrees with this commenter's assertion that the agency's methodology is inconsistent with the OMB Circular A-4's suggested methodologies for regulatory analysis. The EPA completed a formal uncertainty analysis consistent with all requirements for uncertainty analysis, including numerous sensitivity analyses for the proposed and final rule, which builds upon the comprehensive uncertainty analysis that was completed and adds further explanation to how differences in the underlying modeling assumptions impact benefit and cost results. See Sections 5.1.2 and 6.1.2 of the EA, where quantified uncertainties in the costs and benefits analyses, respectively, are listed and discussed at length.

Specifically, this commenter claims that the EPA is required to conduct a "full formal uncertainty analysis" under Circular A-4; however, the commenter is incorrect for two reasons. Under OMB Circular A-4 (2023), for major rules involving annual economic effects of $1 billion or more, agencies "*should, when feasible and appropriate,* present a formal quantitative analysis of the relevant uncertainties about benefits and costs" (emphasis added). The guidance states "When feasible, you *should* use appropriate statistical techniques to determine a probability distribution of the relevant outcomes" (emphasis added). The first reason the commenter is incorrect is because the EPA did provide a comprehensive uncertainty analysis in the PFAS NPDWR EA (see USEPA, 2024b and section XII of the FRN for this action). Moreover, the EPA assessed all major sources of uncertainty in the EA using both quantitative and qualitative approaches, which is consistent with the OMB Circular A-4 guidance suggesting that important uncertainties be analyzed and presented. Specifically, the EPA assessed all significant sources of uncertainty and described the impact of those uncertainties on the resulting benefit-cost estimates. For some key sources of uncertainty, including model inputs for health effect exposure response slope factors, baseline entry point PFAS concentrations, and compliance technology unit costs, the EPA quantitatively assessed uncertainty by evaluating the distribution of values for those inputs. Throughout the economic analysis, resulting benefit and cost estimates are presented using mean (or "expected value") 5th, and 95th percentile results to characterize these key sources of uncertainty, which is consistent with OMB and EPA guidance (OMB Circular A-4 2003, 2023; USEPA, 2016a). See Sections 5.1.2 and 6.1.2 in USEPA, 2024b and section XII in the FRN for this action for further discussion. The second reason the commenter is incorrect is even if the EPA did not complete this uncertainty analysis (which as discussed above, the EPA did conduct), the EPA is not *required* to conduct this analysis. When used in a document such as the OMB A-4 Circular, "should" is used to give advice or suggestions and it is suggestive rather than mandatory. "Should" leaves discretion for an entity (the EPA in this case) to determine whether to follow the delivered recommendation. Hence, even if the EPA had failed to conduct this analysis, which it did not, it is not required to do so.

It is impossible for all sources of uncertainty to have been included in the agency's quantitative uncertainty analysis due to data limitations. For those unquantified sources of uncertainty, the EPA summarized the expected magnitude and directional impact each uncertainty source has on the quantified benefits and costs (see Chapter 7 of USEPA, 2024b and section XII of the FRN for this action). Further, the EPA included numerous sensitivity analyses assessing the impacts from changes in assumptions, which are described in detail within the economic analysis appendices (see USEPA, 2024c). This approach to assess key sources of uncertainty quantitatively and qualitatively in the economic modeling is compliant with all requirements for uncertainty analysis and is effective in describing the impacts of uncertain data inputs across the benefit cost modeling. Specifically, the 2003 Circular A-4 guidance states that agencies should "disclose qualitatively the main uncertainties in each important input to the calculation of benefits and costs" and use "numerical sensitivity analysis to examine how the results of your analysis vary with plausible changes in assumptions, choices of input data, and alternative analytical approaches." Further, under the updated OMB Circular A-4 released in 2023, the guidance states that "both qualitative and quantitative assessments of uncertainty can provide useful information."

The updated OMB Circular A-4 (2023) states that "the treatment of uncertainty should be guided by the same principles of full disclosure and transparency that apply to other elements of your regulatory analysis. Your analysis should be credible, objective, realistic, and scientifically balanced." The EPA went to great lengths to follow all of the circular's recommendations for uncertainty analysis and thoroughly assess each key source of uncertainty and describe the impact of uncertainty sources. Therefore, even if the EPA were *required* to follow these recommendations, which it is not, the commenter's assertions that the EPA failed to complete a comprehensive uncertainty analysis for the PFAS NPDWR are unfounded.

As discussed above, the EPA notes that the agency is unable to evaluate the impacts of all limitations quantitatively due to the inherent differences across uncertainty sources. Specifically, it is not possible to merge qualitative and quantitative metrics across data sources to inform quantitative estimates, as the commenter suggests.

Regarding the commenter's assertion that social benefits are overestimated, the EPA disagrees. In the quantitative benefits analyses (for cardiovascular disease, birth weight, and cancer) the EPA used cost of illness information to value non-fatal cases of illness. Cost of illness information represents direct medical costs and does not include additional social costs associated with illnesses including lost opportunity and productivity costs. As such, contrary to the commenter's assertion, the social benefits of the PFAS NPDWR are actually significantly underestimated as the agency has included no additional costs associated with lost opportunity or productivity. As is demonstrated in numerous studies and situations, opportunity costs of lost work or caring for a sick family member or child, pain and suffering associated with the sickness or loss of a loved one, long-term loss of income associated with loss of a partner, among many other things, these social costs are substantial and important. Therefore, since none of these or other potential social benefits are quantified in this regulation, the commenter's assertion that social benefits are

overestimated is demonstrably incorrect. Regarding the commenter's assertion that not incorporating opportunity costs into the economic analysis results in an underestimate of social costs, the EPA disagrees. The commenter correctly points out that when conducting an economic analysis of a proposed regulation, it is important to consider the opportunity costs imposed upon society by the regulation. The EPA also agrees that using only direct compliance costs as a measure of opportunity costs can lead to an underestimate of costs, but not in the case of this PFAS NPDWR. In a competitive market where demand for goods is price sensitive (i.e., elastic demand elasticity), the increased cost of production associated with a regulation would cause suppliers to reduce the amount of product they are willing to sell at a given price (i.e., upward shift in the supply curve) and this would result in an increase in the equilibrium price for the good in the market. Facing this higher price, consumers would choose to purchase less of the product. In this case, both consumers and producers incur a welfare loss (e.g., a decrease in consumer and producer surplus, respectively). The sum of the decrease in consumer and producer surplus is the opportunity cost of the regulation. However, water supply is not a competitive market; it is almost exclusively a regulated monopoly. In addition, potable water has a highly inelastic demand -- customers' consumption of water does not change much when the price of water changes (Metaxas and Charalambous, 2005). Because they are regulated monopolies, water suppliers can pass the increased cost of production resulting from the regulation to their customers through an increase in price. Furthermore, consumers are unlikely to decrease the quantity of water consumed due to the higher price. In this case, there will be a change in the price of water -- equal to the increase in production costs due to the regulation -- but little change in the quantity of water produced and consumed. In addition, since water utilities can fully recover costs through rate adjustments, alternative investment opportunities are not crowded out. Therefore, the direct cost of compliance, as estimated by the EPA, is a sound estimate of the opportunity costs of the proposed and final PFAS NPDWR.

One commenter recommended that the EPA use an economy-wide model to analyze the impacts of the PFAS NPDWR. The EPA agrees that economy-wide models can be a valuable tool in assessing the social costs of some environmental regulations, depending on the context. The EPA's SAB has recommended that the EPA build capacity in computable general equilibrium (CGE) models, a type of economy-wide model, as a complement to the agency's current suite of tools for analysis (SAB, 2017). Consistent with recommendations made by the SAB, the EPA has developed (Marten et al., 2023) and peer reviewed (SAB, 2020) a CGE model, called SAGE, to aid in the evaluation of the social costs and cost incidence of regulations, as appropriate.

While the theory and inherent model structure, including key underlying assumptions and model parameterization, have been through rigorous peer review, applying SAGE to specific regulatory contexts requires the EPA to determine when and how the tool can best be leveraged to gain insights. The SAB (2017) noted that there is "no hard and fast rule" for deciding when an economy-wide modeling approach will add value beyond other tools typically utilized by the EPA to quantify costs, though they suggest several relevant factors, including strong cross-price effects between markets, pre-existing distortions present in those markets, and impacts that are not small relative to the precision of the model. Further, the SAB noted inherent difficulties in

leveraging CGE models to evaluate some types of rules. For instance, the SAB noted that "finding an appropriate way to represent a narrowly targeted regulation in a high-level economy-wide model can … be a very difficult challenge." Likewise, "the more spatially, sectorally, and/or temporally detailed the regulation, the more challenging it is to represent in a modeling framework."

Marten et al. (2019), a paper referenced by the commenter, finds that social costs for generic, illustrative single sector environmental regulation scenarios range widely, and may be 6 percent to 33 percent larger than engineering-based compliance expenditures depending on the regulated sector and input composition of compliance. The paper also notes that how the specific details of the individual regulation are modeled can significantly affect the social costs (e.g., which sources are subject to the rule and the general design of the regulation), and "therefore generalizations about the bias of engineering cost estimates (beyond the direction of the bias) are unlikely to be robust." Marten et al. (2019) also notes that in water and other utilities sectors the percentage difference between general equilibrium (GE) and engineering costs is relatively low.

There are additional considerations that are equally important when considering whether a CGE model will add value, on net, beyond the set of tools already being leveraged to estimate costs. For example, care must be given when preparing engineering costs to be used as an input in an economy-wide model to avoid double counting taxes and transfers, translate capital costs to a consistent measure within the economy-wide model, and attribute engineering costs to specific inputs. As such, using SAGE or any other CGE model in a rulemaking requires significant time and resources to adapt engineering cost estimates for use in the model and to modify the model, as needed, to capture important sector-specific nuances in modeling the behavioral response to a regulation.

Therefore, deciding whether and how to utilize CGE models to analyze the social costs of regulations requires a weighing of the value added of additional insights that can be gained from an economy-wide analysis against the time and resource costs of developing a careful approach to accurately capture key compliance pathways and sector-specific behavioral responses within the CGE model. So while this approach was not yet available for use in this NPDWR rulemaking, the EPA will continue to evaluate the appropriateness of conducting an economy-wide analysis using SAGE or another CGE model for rulemakings.

In May 2023, the EPA used SAGE for the first time to analyze the social costs of a proposed regulation, the Greenhouse Gas Standards and Guidelines for Fossil Fuel-fired Power Plants. The analysis appears in an appendix of the Regulatory Impact Analysis and outlines the approach taken to ensure careful calibration of compliance cost estimates from the EPA's electricity sector model, the Integrated Planning Model (IPM), for use in SAGE. Connecting the outputs from a sectoral partial equilibrium model to a CGE model required significant attention and resources. The EPA needed to develop an approach to linking the SAGE model and the results from IPM that could adequately represent the regulatory requirements and detailed compliance response information from the technologically rich partial equilibrium model of the power sector in the

CGE model.[11] The EPA requested public comment on the use of the SAGE model and presentation of results, which the agency will review in developing the analysis for the final rule.[12]

At the time of the PFAS NPDWR proposal, SAGE was not yet available to analyze the social costs of a proposed rulemaking. In order to estimate the social costs of the PFAS rule using the SAGE model, the EPA anticipates that significant modeling and data development would be needed to adequately characterize the economy-wide impacts of the rule. The EPA would need to develop an analytic approach to reflect the engineering costs of the rule in the SAGE model, ideally by linking to it a sector model that captures the nuances of water utility behavior. In addition, the EPA would need to potentially modify the SAGE model to capture any missing market distortions in water markets that could be important determinants of overall social costs. Information to modify the SAGE model for this regulatory action is not currently readily available without a significant, potentially years-long effort by the EPA.

SDWA Section 1412(b)(3)(A) requires that the agency use "the best available peer-reviewed science" when setting standards. Because an updated model calibrated for use in a drinking water rule was not available at the time of the PFAS NPDWR proposal, the EPA was not able to utilize SAGE to model the social costs of the PFAS rule. As directed by SDWA, the EPA has used the best available peer-reviewed science in informing its benefit and cost estimates and assessing uncertainty in these estimates. For further discussion of what constitutes "best available peer-reviewed science" under SDWA, please see section I.A of the FRN for this action.

Individual Public Comments

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046004)

Attachment 1

BENEFIT-COST ANALYSIS OF EPA'S PROPOSED PER- AND POLYFLUOROALKYL SUBSTANCES NATIONAL PRIMARY DRINKING WATER REGULATION

Prepared by: Policy Navigation Group

May 2023

EXECUTIVE SUMMARY

The Association of Metropolitan Water Agencies (AMWA) and the American Water Works Association (AWWA) asked Policy Navigation Group (PNG) to prepare a social benefit-cost analysis of EPA's proposed rulemaking to set federal drinking water standards for certain per-

[11] For the working paper describing the effort, see: https://www.epa.gov/environmental-economics/evaluating-economy-wide-effects-power-sector-regulations-using-sage-model.
[12] https://www.regulations.gov/docket/EPA-HQ-OAR-2023-0072

and polyfluoroalkyl substances (PFAS). PNG also prepared an economic impact analysis of the proposal's effect on household income.

EVALUATION OF EPA'S BENEFIT-COST METHODOLOGY AGAINST BEST PRACTICES

The report first compares EPA's approach to estimate the social benefits and social costs with federal requirements for regulatory analysis and best practices in the field. EPA's methodology falls far short of best practices and these requirements. EPA failed to follow two important requirements of federal requirements for regulatory analysis by not considering all of the opportunity costs and by not conducting a formal uncertainty analysis. Omitting the effect of the rulemaking on the entire economy underestimates the rulemaking's social costs by over $1 billion. As EPA demonstrated in a recent rulemaking, EPA can – and must -- estimate the social costs of rulemaking throughout the economy.

Federal requirements for regulatory analysis require EPA to conduct a complete, mathematical, and transparent uncertainty analysis for regulatory actions with costs and benefits estimated to be greater than $1 billion. EPA failed to perform this analysis. The combined effect of these omissions is that EPA underestimates the social costs and fails to convey the full uncertainty of the social benefit estimates. By not presenting the full range of uncertainty in the estimate, EPA presents a misleadingly large benefit estimate.

In addition, EPA's cost models substantially underestimate the installation costs of PFAS treatment systems as evidenced by actual cost data from water systems and by expert analysis by a water sector engineering firm. For smaller systems, the majority of the systems that EPA projects will require treatment, EPA underestimates the capital costs by a factor of five.

EPA also fails to account for other social costs such as additional costs from water rate increases and the non-market costs of greater greenhouse gas emissions. Since EPA has accounted for the social costs of regulation-induced greenhouse gas emissions in a recent rulemaking, the Agency should do so for this rulemaking.

EPA Response: See section 13.9 of the EPA response in this *Response to Comments* document. With respect to the commenter's assertion that the EPA's cost models "substantially underestimate the installation costs of PFAS treatment systems", please see section 13.3.3 of the EPA response in this *Response to Comments* document for the EPA's response to comments on treatment costs, including response to the AWWA B&V report. With respect to the commenter's assertion that the EPA fails to account for potential water rate increases, please see section 13.10 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's affordability analysis. With respect to the commenter's request that the EPA account for the social costs of greenhouse gas emissions in this rulemaking, please see section 13.11 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's assessment of the social costs of greenhouse gases for the final rule.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046022)

Economy-Wide Effects

The social costs extend beyond the water sector. EPA's proposed rule increases the price of a fundamental good. Businesses and households consume water and will pay price increases for the same good. Therefore, society will incur additional costs of the proposed rule as business and household costs rise. These effects are characterized as additional (or reduced) spending by other industries and households as a result of the activities of the water sector. To provide an example, the food and beverage industry uses large quantities of water; the demand for water will remain constant as the price increases under the proposed regulation. As the food industry spends more on water, it must spend less on other equipment and inputs. These shifts in spending are part of the economy-wide effects of a rulemaking. The more a regulation affects the price and the quantity of a good used as a factor of production, the greater the economy-wide effects across other sectors. In addition, the more a regulation affects demand for a good (like capital goods in this regulatory action) whose market is distorted by tax or other government policies, the greater the economy-wide effects.

This section describes existing methods for quantifying these effects and presents an estimate of the economy-wide social costs for EPA's proposed rule.

Economy-Wide Modeling (EWM)

The social costs are greater than the direct resource costs to achieve compliance. To be complete, an estimate of social cost should include both the opportunity cost of current consumption that will be foregone due to regulation, and the loss that may result if the regulation reduces capital investment and thus future consumption. To provide an example, the capital that will go to build PFAS treatment systems will no longer be available to build computers. The forgone productivity gains and economic growth given up because society invests in PFAS treatment rather than computers, for example, is the opportunity cost.

EPA asked its Science Advisory Board in 2015 as to the relevance and the use of economy-wide modeling (or "general equilibrium [GE]") for regulatory analysis. The SAB in its 2017 report endorsed EPA's use of these models since they "offer a more comprehensive assessment of the benefits and costs." [FN117: U.S. Environmental Protection Agency Science Advisory Board, "SAB Advice on the Use of Economy- Wide Models in Evaluating the Social Costs, Benefits, and Economic Impacts of Air Regulations," September 2017, iv.] EPA sought the SAB's advice on the proper times to conduct such an analysis. "The SAB panel's advice was that a GE analysis is most likely to add value when the cross-price effects and pre-existing distortions (e.g., taxes, market power, other regulations) are significant." [FN118: Alex Marten, Richard Garbaccio, and Ann Wolverton, "Exploring the General Equilibrium Costs of Sector-Specific Environmental Regulations" (U.S. Environmental Protection Agency National Center for Environmental Economics, April 2019), 2.] EPA sought to investigate those conditions when shifting capital and labor to regulatory compliance and when existing market distortions increased the social costs. EPA concluded:

We find that even for small regulations both the output substitution and tax interaction effects are significant, and ex ante compliance cost estimates tend to substantially underestimate the social cost of regulation independent of the sector subject to regulation or the composition of inputs required for compliance. This result is robust across a large number of regulatory scenarios and a series of sensitivity analyses over parametric and structural assumptions. [FN119: Marten, Garbaccio, and Wolverton, 2.]

EPA's National Center for Environmental Economics (NCEE) has recognized that social costs include the effect when consumption and investment shifts due to large-scale environmental regulations [FN120: Marten, Garbaccio, and Wolverton, 1.]. The total market costs of a regulatory action equals the sum of all opportunity costs incurred as defined by "the lost value of all goods and services that will not be produced and consumed as resources are moved away from production and consumption activities" toward treatment [FN121: Marten, Garbaccio, and Wolverton, 2.]. Using an inter-temporal computable general equilibrium model of the U.S. economy known as SAGE, EPA measures the relationship between these broader social costs and ex ante engineering compliance costs. These additional costs are also known as the general equilibrium effects that capture the supply and demand impacts across other sectors and markets.

EPA modeled the GE effects of a $100 million regulation in different sectors of the economy to measure how higher prices and capital shifts affected the entire economy. For the water sector, the report found the economy-wide reduction in consumption is 15 to 18 percent. In other words, the social costs of a regulation in the water sector are expected to be 15 to 18 percent higher than the engineering costs.

In the recently signed proposed rule for greenhouse gas standards for new and existing fossil fuel-fired electricity generating units (EGU), EPA applied SAGE in its proposed economic analysis [FN122: U.S. Environmental Protection Agency, "Regulatory Impact Analysis for the Proposed New Source Performance Standards for Greenhouse Gas Emissions from New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units," app. B.]. EPA found that social costs including economy-wide effects are 35 percent greater than its engineering cost estimates. EPA's annualized engineering costs for the EGU proposal ($900 million) are comparable to EPA's annualized engineering costs for proposed MCLs. Therefore, the economy-wide costs of this regulatory action are also likely to be significant.

The analysis applies this range of additional social costs from NCEE's runs of EPA's SAGE model for the water sector to the estimated economic cost of the proposal. The annual GE effects amount to $1.1 B per year. Ultimately, consumers pay this cost through higher prices for goods and services and less income from lower economic growth.

EPA Response: See section 13.9 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-053385)

zII. BENEFIT-COST ANALYSIS BEST PRACTICES

1. Summary of Circular A-4 and EPA's Economic Analysis Guidelines

Circular A-4

Since 1981, the U.S. Office of Management and Budget (OMB) has issued regulatory analysis guidance and directives to Executive branch agencies to promote best practices, to promote public transparency, and to ensure the different agency estimates are comparable. OMB's directive, Circular A-4 Regulatory Analysis, was last issued in 2003 and provides directives for the best practices to estimate the potential social benefits and social costs of a regulatory action using best economic principles [FN3: On April 6, 2023 OMB proposed revisions to Circular A-4. This analysis uses the 2003 Circular A-4 that is in place at the time of this report.].

EPA failed to follow two important requirements of Circular A-4 by not considering all of the opportunity costs and by not conducting a formal uncertainty analysis. The combined effect of these omissions is that EPA underestimates the social costs and fails to convey the full uncertainty of the social benefit estimates. By not presenting the full range of uncertainty in the estimate, the EA presents a misleadingly large benefit estimate.

Opportunity Cost

One important principle in benefit-cost analysis – and in economics in general – is the opportunity cost of a resource:

"Opportunity cost" is the appropriate concept for valuing both benefits and costs. The principle of "willingness-to-pay" (WTP) captures the notion of opportunity cost by measuring what individuals are willing to forgo to enjoy a particular benefit…. The use of any resource has an opportunity cost regardless of whether the resource is already owned or has to be purchased. That opportunity cost is equal to the net benefit the resource would have provided in the absence of the requirement. For example, if regulation of an industrial plant affects the use of additional land or buildings within the existing plant boundary, the cost analysis should include the opportunity cost of using the additional land or facilities [FN4: U.S. Office of Management and Budget, "Circular A-4: Regulatory Analysis," September 17, 2003, 18.].

EPA's EA only includes engineering cost estimates. While the prices of the goods and labor EPA includes in the engineering analysis generally reflects their opportunity costs, EPA does not include the opportunity costs that occur in other sectors in society.

Other sectors have opportunity costs when the price of drinking water increases in response to this rulemaking and when this rulemaking shifts capital and labor to the water sector for compliance. EPA's analysis shows that the required regulatory activities will shift capital and resource use substantially. EPA states that the maximum spending level would approach $10 billion in one year using its estimates [FN5: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," March 2023, 9–13.]. EPA predicts household costs for drinking water will also rise by hundreds of dollars per year [FN6: U.S. Environmental Protection Agency, 8–69.]. These costs will be borne not only by households, but also by businesses that purchase water for their

operations. EPA's rule will therefore raise the costs of an input to almost all businesses. The price increase will have additional and substantial social costs. EPA has conducted extensive modeling of the economy-wide costs from regulations in the water sector but does not include these results in its analysis. In addition, as discussed in Section IV.2, EPA has recently conducted a regulatory economic analysis that accounts for opportunity costs and finds them significant [FN7: U.S. Environmental Protection Agency, "Regulatory Impact Analysis for the Proposed New Source Performance Standards for Greenhouse Gas Emissions from New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units," May 2023, app. B.]. Therefore, EPA has the methodologies, data, and experience to comply with Circular A-4 and present the more complete social costs of the rule.

EPA Response: See section 13.9 of the EPA response in this *Response to Comments* document. Please also see section 13.11 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's assessment of the social costs of greenhouse gases for the final rule.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046007)

Formal Uncertainty Analysis

EPA's benefit and cost models use data and mathematical relationships that are uncertain. Describing the uncertainty helps policy officials and the public understand the quality and the likelihood of the benefit and cost estimates. Uncertainty can be described in words, with some quantification, and with formal, statistical approaches that ensure all of the available information about the uncertainty is used. In Circular A-4, OMB discusses situations when agencies must conduct a formal, mathematical uncertainty analysis:

For major rules involving annual economic effects of $1 billion or more, you should present a formal quantitative analysis of the relevant uncertainties about benefits and costs. In other words, you should try to provide some estimate of the probability distribution of regulatory benefits and costs…For rules that exceed the $1 billion annual threshold, a formal quantitative analysis of uncertainty is required [FN8: U.S. Office of Management and Budget, "Circular A-4: Regulatory Analysis," September 17, 2003, 40– 41.].

Specific analytical approaches OMB recommends for formal uncertainty analyses include the following:

• Numerical sensitivity analysis. EPA must examine how the results vary with plausible changes in key assumptions, choices of data inputs, and alternative analytic approaches. "Sensitivity analysis is especially valuable when the information is lacking to carry out a formal probabilistic simulation. Sensitivity analysis can be used to find 'switch points' - critical parameter values at which estimated net benefits change sign or the low cost alternative switches;" [FN9: U.S. Office of Management and Budget, 41.]

• Probabilistic analysis of large, multiple uncertainties. EPA must formally simulate and examine identified uncertainties through expert judgment and, for example, Delphi methods. "Experts can be used to quantify the probability distributions of key parameters and relationships. These solicitations, combined with other sources of data, can be combined in Monte Carlo simulations to derive a probability distribution of benefits and costs;" [FN10: U.S. Office of Management and Budget, 41.]

In its EA, EPA only conducted a partial mathematical uncertainty analysis. Since EPA estimates that the effect of the rule is above $1 B in one year, EPA did not comply with the requirements of Circular A-4. The most significant omission is that EPA fails to model the quantitative effect of the uncertainty in EPA's causal determination that PFOA and PFOS are associated with certain health effects. As discussed in Appendix B, other public health agencies do not find a causal relationship between PFOS and PFOA exposure and key health effects that EPA quantifies as social benefits. This difference has several important implications. First, these findings show that EPA's methodology has significant uncertainty. Second, these findings show that EPA's quantified benefits are biased to be too high. If these other agencies are correct, there is no dose-response relationship and thus the benefits from reduced exposure for these adverse effects is zero. Instead of its qualitative discussion, EPA should present a distribution of benefit estimates including the probability that studies that show no relationship or an inverse relationship between PFAS and certain adverse effects are true.

Instead of a formal uncertainty analysis, EPA provides a list of limitations. The words in these lists do not modify EPA's social cost and benefit numbers, however. EPA's list of limitations is significant [FN11: U.S. Environmental Protection Agency, "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," 5–39 & 6–108.]. Table 33 in Appendix A gives the limitations EPA listed in the analysis. However, there are two problems with EPA's list. While EPA does list some limitations and uncertainties with some directional information, EPA could – and must – incorporate these uncertainties into its display of quantified estimates.

Many of the limitations that EPA discloses could be quantified and incorporated into a formal uncertainty analysis. For example, EPA states that its value of statistical life (VSL) is the major value in its benefits estimate. However, EPA does not provide a distribution of potential values even though EPA acknowledges uncertainties in its VSL estimate. Other federal agencies, however, and researchers have put together distributions of potential VSL values [FN12: See, for example, Banzhaf, H. (2022). The Value of Statistical Life: A Meta-Analysis of Meta- Analyses. Journal of Benefit-Cost Analysis, 13(2), 182-197. doi:10.1017/bca.2022.9]. EPA could easily incorporate uncertainty in the VSL value into its formal uncertainty analysis.

EPA Response: With respect to the commenter's assertion that the EPA's uncertainty analysis did not follow the OMB Circular A-4 guidance, the EPA disagrees; see section 13.9 of the EPA response in this *Response to Comments* document.

With respect to the commenter's specific assertion that the EPA failed to model the quantitative effect of the uncertainty in the EPA's causal determination that PFOA and PFOS are associated

with certain health effects, the EPA disagrees with the commenter's assertion that this factor was ignored. The EPA has used the best available scientific information to inform the agency's assessment on health effects associated with PFOA and PFOS exposure and benefits associated with reduced exposure. The EPA has reviewed information available from peer reviewed studies and other agency assessments on health effects associated with PFAS exposure, and although these studies and assessments may not determine health effect causality associated with exposure, this does not mean that the assessments have determined that the effects are non-causal as the commenter incorrectly describes. The commenter states that the EPA should provide a distribution of benefits in the uncertainty analysis, and stated in that analysis, the EPA should assess the impact of negative or inverse relationships on health effects from PFAS exposure. The EPA clarifies that in the EA, uncertainty within the exposure-response relationships for the quantified adverse health effects is already assessed. Specifically, the slope factors that express the effects of serum PFOA, serum PFOS, and THM4 on health outcomes (birth weight, CVD, RCC, and bladder cancer) are based either on the EPA meta-analyses or high-quality studies that provide a central estimate and a confidence interval. This modeling is described within Section 6.1.2 of the EA (USEPA, 2024b) and section XII of the FRN for this action. Because the EPA has quantified uncertainty associated with the exposure-response slope factors used in benefits analysis, the EPA has followed A-4 guidance recommendations related to uncertainty analysis using the best available scientific information.

The economic analysis does not model VSL uncertainty; however, the agency is not required to do so. Moreover, the economic analysis does incorporate several other sources of uncertainty and the major sources of uncertainty were considered in the EA (see Appendix L of the EA; USEPA, 2024c). See also section 13.4.4 of the EPA response in this *Response to Comments* document. The EPA, under the SDWA, uses the best available peer review science to inform the regulatory impact analysis. The agency in line with the SDWA requirements used the agency's default VSL estimate provided in the EPA's Guidelines for Preparing Economic Analyses (USEPA, 2016a) which has been peer reviewed by the SAB. In developing the VSL estimate the EPA commissioned a report from meta-analytic experts to evaluate methodological questions raised by the EPA and the SAB on combining estimates from the various data sources. In addition, the agency consulted several times with the SAB Environmental Economics Advisory Committee (SAB-EEAC) on the issue. With input from the meta-analytic experts, the SAB-EEAC advised the agency to update its guidance (USEPA, 2007c). Until updated guidance is available, the agency determined that a single, peer-reviewed estimate applied consistently best reflects the SAB-EEAC advice received to date. The EPA default VSL estimate and its update methodology was vetted and endorsed by the SAB and is applied in relevant analyses while the agency continues its efforts to update its guidance on this issue. Furthermore, as indicated in the EA, and given public comment, the agency is aware of the potential uncertainty associated with the VSL used in the PFAS rule analysis and although not explicitly quantified in the rule analysis the EPA has considered the potential uncertainty in its assessment of the benefits of the final rule.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045988)

Section 8.5: Guidance for conducting regulatory analysis not followed

EPA did not follow the requirements of OMB Circular A-4 (2003) in developing the PFAS NPDWR. While EPA's economic analysis (EA) includes a partial uncertainty analysis, under Circular A-4, the agency is required to complete a full formal uncertainty analysis, quantifying uncertainties because the rule has an annual economic effect of $1 billion or more. Simply adjusting the discount rate from 3% to 7% (the latter rate being more representative of current inflation conditions) inverses the cost-benefit result. As detailed in the PNG Analysis of these comments, AMWA believes strongly that the agency should employ a numerical sensitivity analysis and a probabilistic analysis of large, multiple uncertainties. This analysis is especially important because the uncertainty of certain health effects and limitations outlined in EPA's EA (specifically Table 33, Appendix A) could – and should – be quantified and included in a formal uncertainty analysis.

EPA Response: With respect to the commenter's assertion that the EPA's uncertainty analysis did not follow the requirements under OMB Circular A-4, the EPA disagrees; see section 13.9 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045986)

Section 8: HRRCA/Economic Analysis for the proposed NPDWR

Section 8.1: Evaluation of benefit-cost analysis

AMWA and AWWA commissioned Policy Navigation Group (PNG) to prepare a benefit-cost analysis of EPA's proposed rulemaking to set federal drinking water standards for certain PFAS. The report (Attachment 1), "Benefit-Cost Analysis of EPA's Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation" (PNG Analysis) compares EPA's approach to estimate the social benefits and social costs with federal requirements for regulatory analysis and best practices in the field. PNG also prepared an economic impact analysis of the proposal's effect on household income.

EPA's methodology in its proposal falls short of the best practices for these requirements. Specifically, EPA failed to conduct a formal uncertainty analysis and neglected to consider all the opportunity costs of its proposal. Per EPA's Guidelines for Preparing Economic Analyses [[FN20: EPA. (2010) Guidelines for Preparing Economic Analyses. Chapter 8: Analyzing Costs. https://www.epa.gov/environmental-economics/guidelines-preparing-economic-analyses].], the social costs of a rule represent the total burden that a regulation will impose on the economy. Social costs are "defined as the sum of all opportunity costs incurred as a result of a regulation where an opportunity cost is the value lost to society of any goods and services that will not be produced and consumed as a result of a regulation." [FN20: EPA. (2010) Guidelines for Preparing Economic Analyses. Chapter 8: Analyzing Costs. https://www.epa.gov/environmental-economics/guidelines-preparing-economic-analyses].

EPA Response: See section 13.9 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046016)

IV. ESTIMATES OF THE SOCIAL COSTS FROM EPA'S REGULATORY ACTION

EPA's proposed rule will cause a range of social costs above and beyond those included in EPA's EA. The direct costs to society, as EPA discusses, are primarily the treatment and engineering costs non-compliant water systems will incur to comply. These social costs include the capital resources required for PFAS treatment, the O&M costs associated with installation and implementation of treatment strategies, and the 0other monitoring and administrative costs to maintain compliance.

Additional market costs that EPA does not quantify include the near-term additional costs water systems face due to scarcity in the labor force and supply chain constraints; the opportunity costs associated with periods of time required to install treatment technologies; and the economy-wide general equilibrium (GE) effects as the regulation shifts resources from consumption of other goods and services to very specific capital investments.

There are other non-market social costs associated with the proposed rule, as well. Treatment systems require electricity and, as water systems' energy consumption rises, society will carry the social costs of increased carbon dioxide emissions.

EPA Response: See section 13.9 of the EPA response in this *Response to Comments* document. Please also see section 13.11 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's assessment of the social costs of greenhouse gases for the final rule.

American Water Works Association (AWWA) (Doc. #1759, SBC-046163)

5.2 Monte Carlo Simulation for Design and Performance Variability

Water treatment system design is a practice that evolves non-uniformly across the country. Decisions in the design process are driven in some cases by rigorous engineering standards and in others by regional and geographic considerations, or owner and operator preferences. The result is a landscape of treatment systems across the United States that cannot be effectively modeled by clear and simple rules and frameworks. Additionally, water quality characteristics vary both regionally and locally, and these variations cannot be fully captured in the model with distinct data. These water quality characteristics may improve or hinder performance as well as increase costs to ensure water quality downstream is not altered and complies with other regulations.

To compensate for this uncertainty, Monte Carlo methods were applied to simulate variation and to account for unknowns in major factors influencing design, operation, and, ultimately, cost for

PFAS reduction systems. The @RISK Probabilistic Risk Analysis Software by Lumivero, which functions through an Excel add-in, was utilized for the Monte Carlo analysis.

Monte Carlo methods consist of randomizing inputs (e.g., loading rate, GAC media life, RO recovery) according to a defined distribution and number of iterations while calculating the impact to the outputs (e.g., number of vessels, media replacement frequency, cost). As the number of variables undergoing Monte Carlo analysis increases, computer processing power and the time to simulate one scenario both increase exponentially. Thus, Monte Carlo analysis was limited to only major factors considered to exert significant influence on design, performance, and cost of the individual systems. The major factors subjected to Monte Carlo are shown in Table 5-4.

Table 5-4 Major Factors for Monte Carlo Analysis

[Table 5-4: Docket ID: EPA-HQ-OW-2022-0114-1759]

With the exception of RO recovery, all Monte Carlo inputs were assigned a triangular distribution. A triangular distribution is a probability distribution where the probability decreases linearly on either side of the most likely value (highest probability) to the minimum and maximum, at which point the probability is zero. Triangular distributions were used where typical industry design values exist. RO recovery was modeled using a uniform distribution where each value between the minimum and maximum have an equivalent probability of occurrence.

The result of the Monte Carlo analysis is a distribution of possible costs for each technology (i.e., low [10th percentile], high [90th percentile], and most probable). For each modeled scenario, each of these costs was stored as a modeled output for each system represented in the occurrence database for use in determining the overall national cost of compliance with the modeled limit.

EPA Response: This comment describes the steps taken in AWWA's B&V report. The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. See section 13.3.3 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046124)

Exhibit B

Memorandum

To: Earthjustice

From: Dennis Guignet, PhD.

Subject: Review of the Economic Analysis for the Proposed PFAS NPDWR Date: May 26, 2023

Purpose

The purpose of this memorandum is to evaluate the U.S. Environmental Protection Agency's Economic Analysis of the proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation, and to identify ways the economic analysis (EA) can be further improved.

As a trained economist with a PhD in Agricultural and Resource Economics, and over a decade of experience, I am qualified to identify analytical strengths and weaknesses in the EA, and recognize potential areas where the EA can be further strengthened. I served as a research economist in the National Center for Environmental Economics at the U.S. Environmental Protection Agency (EPA) for seven years (from 2011 to 2018). During that time, I helped develop, review, and revise EAs of regulatory actions. I have taught environmental economics courses at the University of Maryland and American University, as well as a graduate and undergraduate-level course in benefit-cost analysis at Appalachian State University, where I am currently employed as an Assistant Professor of Economics. My research focuses on applied quantitative analysis, benefit-cost analysis of environmental policies, and the estimation of environmental and human health benefits, with a particular focus on toxic chemicals. I have 25 publications in peer-reviewed journals, and significant related experience that adds to my qualifications (see the attached Exhibit 1 for my full curriculum vitae).

Overall, based on my professional experience, the EA that has been developed for the proposed PFAS National Primary Drinking Water Standards (NPDWS) is one of the most well-organized, thorough, and transparent EAs I have reviewed. The quantified benefits entail reduced mortality and non-fatal health outcomes from decreased exposures to PFAS, including reduced risks of cardiovascular disease, low infant birthweight, and renal cell carcinoma. Additionally, reduced risk of bladder cancer due to the co-removal of non-PFAS pollutants is a co-benefit that is quantified. For all four health outcomes, the number of avoided fatal and non-fatal cases that result from each regulatory option, relative to the baseline, are estimated. These quantified benefits are monetized based on the Value of a Statistical Life (VSL) for reduced fatal cases (i.e., reduced mortality risks), and based on avoided cost-of-illness (COI) estimates for reduced non-fatal cases (i.e., reduced morbidity risks). Both are common and well-accepted approaches for monetizing (i.e., assigning a dollar value to) human health-related benefits in policy analysis.

The quantified costs mainly include public water system (PWS) costs for implementing treatment and non-treatment technologies when the proposed maximum contaminant levels (MCLs) are exceeded, as well as monitoring and reporting costs, and administrative costs to PWSs and implementing agencies.

This memorandum is organized as follows. First, key strengths of the EA are highlighted. Then I discuss potential areas where the analysis could be improved.

Strengths of the Economic Analysis.

There are several strengths of the EA that are worth highlighting. These features should be maintained and potentially built upon for the final rule EA.

1. The entire EA is centered on a detailed, data-driven Monte Carlo simulation model that has been calibrated based on existing federal and state data on point-of-entry water concentrations of PFOS, PFOA, and other PFAS.

This carefully laid approach relies on existing data to project baseline and policy scenarios under the various regulatory options. Point-of-entry pollutant concentrations are predicted across PWSs, while at the same time accounting for various system-specific factors. A particularly advantageous feature of this approach is in enabling data-driven, comprehensive sensitivity analyses. The analysis utilizes Monte Carlo simulations entailing 4,000 iterations. This allows the Agency to derive a distribution of benefit and cost estimates, and in turn quantitatively and simultaneously account for key points of analytical uncertainty by providing a range of possible net benefit calculations (e.g., a 90% confidence interval). Monte Carlo simulations like this are a common and defensible approach to account for uncertainty (EPA 2014), and are the most thorough way to simultaneously account for numerous sources of uncertainty in economic analyses (Boardman et al. 2018; OMB 2003).

As outlined in the Office of Management and Budget's Circular A-4, the Executive Branch's seminal guidance for conducting regulatory analysis, there are basically three broad approaches for accounting for analytical uncertainties (OMB 2003). In terms of increasing levels of complexity and rigor, these approaches include:

• A qualitative discussion of the main uncertainties;

• A quantitative sensitivity analysis, such as a "partial sensitivity analysis" or "worst- and best-case analysis"; and

• A probabilistic quantitative analysis using Monte Carlo simulations.

In cases where the necessary data and information are not available to assess the likelihood and outcomes of various contingencies under alternative assumptions, then a qualitative discussion of the key uncertain assumptions and potential implications for the results of the EA should be included. And in cases where the available information is limited, EPA does in fact include such qualitative assessments; for example, see Table 5-22 and Tables 6-48 through 6-53 in Chapters 5 and 6, respectively.

Other more quantitative sensitivity analyses are recommended when some quantitative information is available, but where information on the probability of alternative contingencies (or outcomes) is not. For example, "partial sensitivity analysis" is when one varies one assumption at a time, and assesses how the estimated net benefits vary across alternative assumptions (Boardman et al. 2018). This approach has two main drawbacks. First, varying only one assumption at a time may not fully bound the plausible range of results, especially in cases where there may be interactive or cascading effects across assumptions. Although one could vary multiple sets of assumptions at a time, there are only so many distinct scenarios an analyst can reasonably estimate. The second weakness is that even with a large menu of distinct scenarios, one can say nothing about the likelihood of any one scenario or results of central tendency (e.g., an average), due to the lack of an estimated probability distribution.

An alternative type of quantitative sensitivity analysis sometimes labelled "worst- and best-case analysis" (Boardman et al. 2018), allows analysts to bound the plausible range of net benefits. This is done by estimating a worst-case scenario, where for all key analytical decision points, model parameters, etc., the "worst-case" plausible assumptions are made that would result in the highest estimates of the costs and lowest estimates for the benefits. Then on the other extreme, a best-case scenario is estimated, where the underlying key assumptions are set such that the analysis will yield the highest plausible estimates for the benefits and lowest estimates of the costs. This overcomes the first weakness described above by varying all key assumptions at once, and thus providing upper- and lower-end bounds on the net benefits, and it accounts for interactive and cascading effects across assumptions. The second weakness, however, is still not addressed. One still would not know where the eventually realized benefits and costs are most likely to fall within those bounds. In other words, "worst- and best-case analysis" can reasonably bound the range of plausible net benefits, but tells us nothing about how likely one scenario is over another, or where within that range we are most likely to fall.

This final weakness is overcome by the third, and most thorough type of analysis of uncertainty – Monte Carlo simulations. Detailed Monte Carlo simulations form the underlying foundation for the entire EA for the proposed PFAS NPDWR. By taking advantage of existing data on PFAS concentrations in drinking water sources, as well as past treatment decisions of PWSs (discussed below in comment #2), the Agency was able to estimate a range of benefits and costs, as well as a probability associated with each potential realization of these estimates. In short, this yields several advantages by allowing the Agency to (i) assess the simultaneous impacts across multiple key assumptions, (ii) account for the likelihood of those assumptions and the resulting estimates of the benefits and costs that would be realized, and finally (iii) account for a range based on, for example, the 90% confidence interval, as well as the estimates of the benefits and costs that will be realized, on average. The Agency went through great efforts to gather the necessary data to not only pursue this most rigorous approach to account for analytical uncertainty, but they did so in a way that accounts for numerous points of uncertainty, and that relies squarely on existing data (as opposed to, for example, best professional judgment).

EPA Response: See section 13.9 of the EPA response in this *Response to Comments* document. The commenter's analysis provides support for the EPA's approach to assess uncertainty in the economic analysis for the PFAS NPDWR. The EPA agrees with the commenter that the methods used to assess uncertainty for this economic analysis are rigorous and effective for assessing the impact of various uncertain data sources on the benefit-cost results.

Earthjustice et al. (Doc. #1808, SBC-046136)

16. Uncertainty around the cost of illness (COI) estimates for each non-fatal health endpoint that was quantified is not accounted for.

The quantified examination of analytical uncertainty is quite thorough throughout the EA with respect to other "upstream" analytical steps, and in points where it is not, EPA is still transparent

in describing any shortcomings. Nonetheless, the reliance on just central COI estimates is a weakness that could be addressed. For example, a sensitivity analysis could be conducted based on the statistical distribution of the COI estimates from the literature, or perhaps other bounding values if the primary studies did not estimate the COI values using statistical methods. That said, perhaps such an exercise is not worth the additional effort if this source of uncertainty is expected to be trumped by numerous other points of uncertainty that are addressed in the Monte Carlo simulations. If this is expected to be the case, then EPA should make such assertions explicit in the EA.

EPA Response: The EPA acknowledges that COI uncertainty was not evaluated in the economic analysis. With the exception of COI estimates for changes in birth weight from Klein and Lynch (2018), the primary studies used to develop COI-based values for CVD (O'Sullivan et al., 2011), RCC (Ambavane et al., 2020), and bladder cancer (Greco et al., 2019) did not report statistical uncertainty estimates. Estimates in Klein and Lynch (2018) were reported at several discrete evaluation points defined by the magnitude of birth weight change and the baseline birth weight, which required interpolation of the reported estimates. Derivation of statistical uncertainty surrounding the interpolated array of COI values would have necessitated additional analysis of the restricted-access data used by Klein and Lynch (2018) which was not feasible within the regulatory development timeframe. Furthermore, even if quantified, the statistical uncertainty in the COI-based values is far from the comprehensive reflection of the overall uncertainty because of the retrospective nature of this valuation method. Impacts of future changes in medical technology, clinical practices, and healthcare markets on COI are challenging to quantify.

Earthjustice et al. (Doc. #1808, SBC-046130)

Potential Areas to Improve the Economic Analysis.

Although the EA for the proposed PFAS NPDWS is quite thorough and transparent, there are several areas where the EA can be further improved. The below comments entail suggestions on where further clarification or support would be helpful, as well as a few cases where additional or revised analysis should be considered.

7. The analysis assumes that population is held constant based on 2021 levels for the entire 80-year study period.

If population is projected to increase over this time, then this constant population assumption would result in an underestimate of the benefits and of the costs. The EA would be improved if EPA considers available projections and/or current population trends when estimating future benefits and costs. EPA recognizes this area for improvement, and in Chapter 6 (Table 6-48) EPA discusses how they intend to account for population trends in the final rule EA. I encourage the Agency to pursue such revisions for the final rule EA.

8. Concentrations of PFOS, PFOA, and other PFAS at system entry points are simulated/projected based on data of past occurrences, and as such EPA is assuming that entry point PFAS concentrations are constant over time.

This assumption is explicitly stated on page 4-23, but the validity of this assumption is unclear. There are assumptions being made here in terms of stock PFAS concentrations in water sources, and implicitly the future use and releases of PFAS into drinking water sources. The high degree of persistence of PFAS, along with various confounding trends over time that the EA mentions (e.g., voluntary phaseout programs, industry trends, and trends in human exposure [FN1: For example, on page 2-1 of the EA it is noted that that PFOA human blood levels have been decreasing.]) make it difficult to assess the validity of this assumption. Put plainly, how representative are the data of current and recently observed PFAS concentrations compared to those expected in the future under the baseline (i.e., business as usual) scenario? To the extent that baseline stock concentration levels and the use of PFOS, PFOA, and other PFAS chemicals in industrial processes and consumer products, and subsequent releases into the environment, have been decreasing, then both benefits and costs in the EA would be overestimated. The opposite is true if current baseline trends suggest an increase in future concentration levels of these chemicals at PWS points-of-entry.

The EA would be improved by providing additional support for the assumption that future baseline PFAS concentrations will be similar to recently observed concentrations, and/or by adding discussion of the resulting uncertainties regarding this assumption to Table 4-34.

9. Do the occurrence and concentrations of PFAS in water at PWS points-of-entry vary depending on whether the source is surface water or groundwater?

The Monte Carlo simulations used to predict baseline and policy scenario levels of these pollutants is very thorough in accounting for key factors that may lead to differences in pollutant levels (e.g., system size). However, it does not seem that the water source was accounted for when estimating point-of-entry concentration levels. If observed concentrations in the past vary across surface versus ground water sources in the data used to calibrate the Monte Carlo simulations, then this is another source of heterogeneity that should be explicitly accounted for to improve those models.

The agency was careful to make distinctions in the technology cost curves based on water source, so perhaps such heterogeneity is also important for modelling the occurrence and concentrations of PFAS at PWS points-of-entry.

EPA Response: In response to item #7, the EPA agrees with the commenter's assertion that benefit and cost estimates would be improved if the EPA considered population growth. However, the EPA was limited by the availability of appropriate data for use in such analyses. For instance, the health benefits models evaluated in the economic analysis require information on populations stratified by location, race/ethnicity, age, and sex to accurately predict health risks among stratified populations. While total population projections per geographical location (e.g., county, state) are publicly available (e.g., U.S. Census forecasts), such projections do not

typically include projections for additional strata, such as race/ethnicity, age, and sex. This is an important component of understanding future health risks, as different strata of populations experience different baseline health risks and are expected to differ in terms of population growth. Population projections that do include strata-specific forecasts, such as Woods and Poole (2023), typically do not project such populations far out into the future (current Woods and Poole projections go through 2060, whereas the economic analysis period of analysis goes through 2105). Using such projections would require the EPA to extrapolate beyond the final year of available population projections, which could introduce uncertainty into the analysis. Additionally, such population projections are proprietary, and the methods used to forecast future populations are not often well-documented.

In response to item #8, there is not sufficient data to meaningfully illustrate nation-scale temporal trends of PFAS occurrence, however the PFAS included in the final regulation have been found to be very stable and persistent in the environment. Therefore the EPA believes the assumption that these contaminants would remain present at current concentrations in the baseline scenario is reasonable. Further, the EPA anticipates that actively produced and/or used PFAS such as Gen-X Chemicals (HFPO-DA) may potentially increase over time as long as their use continues. See section 3.1.2 of the EPA response in this *Response to Comments* document on regulatory determinations and statutory criterion #2 for a discussion of occurrence of PFHxS, PFNA, and HFPO-DA.

In response to item #9, the EPA examined several occurrence model variants that included source water type. Information was shared between source water type and system size because they are so strongly associated. The variant that included just system size performed best in cross validation (Cadwallader et al., 2022).

Earthjustice et al. (Doc. #1808, SBC-046177)

Unmodeled sources of uncertainty in both cost estimates

There are some unmodeled sources of uncertainty that were not included in both estimates. One factor for which inclusion would increase cost would be the potential for competition for supplies and supply chain issues driving up prices if thousands of PWS nationwide try to install treatment at the same time. On the other hand, there are sources of uncertainty not included in both estimates that would have the impact of decreasing overall costs, including:

• Innovation in the marketplace

• Innovation/new technology for PFAS destruction/disposal

• Future options for point-of-use (POU) compliance

• Increasing the number of PWS that consolidate with other PWS that meet MCLs instead of installing treatment.

In the case of this last option, according to EGLE, state primacy agencies focus on finding a safe source prior to exploring treatment options. Michigan expects up to 33% of PWS and 26% of CWS to connect to another system before installing treatment, indicating that EPA's estimate of 6-7% of systems with <3.536 MGD design flow is not only reasonable, but possibly low (Smith, personal communication May 23, 2023). This omission of non-treatment options by AWWA is the source of at least $159 million in difference between the AWWA and EPA cost estimates. If Michigan's results are found to hold true nationwide, up to $362 million in savings could be realized in comparison to the AWWA cost estimate.

EPA Response: In response to commenter's statement regarding "…competition for supplies and supply chain issues driving up prices if thousands of PWS nationwide try to install treatment at the same time," see section 13.3.3 of the EPA response in this *Response to Comments* document.

In response to the commenter's points about sources of uncertainty that would decrease overall costs, the EPA generally agrees that water system interconnecting as well as technological innovation and emergence of new technologies for PFAS removal and PFAS destruction could decrease overall future costs associated with the rule. The EPA specifically notes that if in the future POU devices are certified to meet the final MCLs, costs may be lower (see Section 5.3.3.1 of USEPA, 2024b). The EPA does not have sufficient data to quantify the decreases in costs from these sources of uncertainty at this time.

In response to the commenter's point about percentage of non-treatment options, see section 13.3.6 of the EPA response in this *Response to Comments* document.

13.10 EPA's Affordability Analysis

Summary of Major Public Comments and EPA Responses

The EPA asked for comment on the national level analysis of affordability of SSCTs and specifically on the potential methodologies presented in the EA for the proposed rule Section 9.12. A couple of commenters recommended the EPA not use median household income (MHI) in the affordability analysis. The EPA decided to retain the MHI measure of income in its primary national level SSCT affordability methodology given the value is easily understandable and available, providing a central tendency for income which is representative of a whole community's ability to pay and is not unduly influenced by outlier values. However, in this rulemaking, the EPA recognizes the value in examining alternative measures of a community's ability to afford an SSCT, so the agency chose to include supplemental analyses that use alternative metrics, specifically 1 percent of MHI, 2.5 percent of lowest quintile income (LQI), and an analysis accounting for financial assistance. These supplemental analyses help to characterize affordability when considering the marginal impact, disadvantaged community groups, and subsidization.

Some commenters stated that the data the EPA used to inform current water rates from the 2006 Community Water System Survey (CWSS) is outdated. While dated, the data from the 2006

CWSS remains the best available dataset for this national level analysis and affordability determination for the following reasons: (1) the CWSS survey used a stratified random sample design to ensure the sample was representative and (2) these responses can be extrapolated to national estimates since the survey has a known sampling framework; and the data can be organized by system size, source, and ownership (USEPA, 2020b).

Some commenters recommended the EPA extend the affordability analysis to medium and large systems. The EPA disagrees with this recommendation, as the purpose of this analysis is to determine if available SSCTs are affordable, per SDWA Section 1412(b)(4)(E)(ii). Therefore, the EPA chose to continue to analyze small system technologies rather than include medium and large systems.

Some commenters stated the EPA used national median household in the affordability analysis. These commenters are incorrect; the EPA clarifies that the agency did not use the national MHI. MHIs used in the analysis were derived using the CWSS. The EPA used MHI's for the zip codes provided by small systems in the CWSS. This approach allows the EPA to capture the incomes of communities served by small systems, many of which are rural.

Some commenters specifically disagreed with one of the EPA's supplemental affordability analyses that examined the impact of the rule when accounting for the financial assistance through BIL and other sources that are generally available to small systems. These commenters stated that the EPA should not assume that this funding will be available or enough to cover the small system capital costs associated with the rule. The EPA conducted this supplemental analysis in response to the recommendations of the SAB, which stated, "[i]f this funding is readily available to many or most systems facing affordability problems, it seems appropriate to take the availability of this funding into account in determining national level affordability. (USEPA, [2002])." The EPA disagrees with these commenters as this significant funding will be generally available, and the EPA continues its efforts to help PWSs access it. It is therefore reasonable to consider the burden reduction in the supplemental affordability analysis.

Some commenters disagreed with the EPA's affordability determination because they stated it was based on inaccurate treatment cost information. A couple of commenters presented their own estimates for small system household costs and compared these estimates to the EPA's affordability threshold and concluded the rule is unaffordable. The EPA disagrees with many of the underlying assumptions in the commenters' cost estimates which, on whole, result in overestimated household costs. These commenters cited cost information that is not representative of the range of treatment costs nationally, and the EPA disagrees with the commenter's cost model that systematically overestimates capital operation and treatment costs. The EPA updated the affordability analysis for the national affordability determination using the updated treatment cost curves (discussed in section 13.3.3 of the EPA response in this *Response to Comments* document) and found for systems serving between 25 and 500 people, that the upper bound estimated annual household treatment costs for GAC exceed the expenditure margin. Lower bound estimated annual household treatment costs for GAC do not exceed the expenditure margin; for more information see section XII. These exceedances are primarily

driven by capital costs and attributable to the use of high-cost materials (e.g., stainless steel) in the upper bound estimates. Systems using low-cost materials, but with source water characteristics otherwise set to the upper bound (e.g., influent PFAS at approximately 7,000 ng/L, influent TOC at 2 mg/L), would fall below the expenditure margin. Although costs increase in some scenarios, the increases are not significant enough to change the conclusions about affordability. Technologies are affordable for all small systems when the technologies do not use the high-end materials. Technologies that do not use high end materials are available for small systems. For more information on the EPA's response to comments on treatment costs section 13.3.3 of the EPA response in this *Response to Comments* document. The EPA also disagrees that there are no affordable compliance technologies for small systems as the EPA has demonstrated that SCCTs are available below the affordability threshold using the best available peer reviewed information to support the agency's cost estimates.

Individual Public Comments

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042992)

H. Health Risk Reduction and Cost Analysis

Having reviewed Section XIII of the proposed NPDWR, EGLE DWEHD does not have major issues with EPA's Health Risk Reduction and Cost Analysis (HRRCA). However, based on EPA's definition of a small system, it is possible that the impact of the proposed NPDWR on very small PWS (e.g., manufactured housing communities, child-care providers, schools) may be significant. EGLE DWEHD asks that EPA consider these categories of PWS when making final determinations.

EPA Response: See section 13.10 of the EPA response in this *Response to Comments* document. The EPA notes that for both the proposed and final, the HRRCA includes costs estimates for all public water systems subject to the rule, including very small public water systems serving 25 people or more. For the EPA's estimates of system level costs for all system sizes, see Appendix C of the EA. For the EPA's affordability analysis of household level costs at small systems, see Chapter 9 of the EA.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043640)

2) Affordability

1. The USEPA does not adequately consider the potential economic burden on utilities' ratepayers, especially for low income and historically disadvantaged communities, which will dramatically affect the affordability of drinking water.

A. An AWWA report (April 2021) summarized the limitations of the current affordability analytical framework used by EPA, including:

i. The income distribution in America is increasingly bimodal, such that reliance on a central tendency estimate of income is a misleading criterion when considered in isolation.

ii. USEPA's proposed rule entailing substantial capital and operational costs can have implications for low-income households within large water systems. However, USEPA's household-level affordability analysis only represented small systems (serving population of 10,000 or fewer).

It is no longer reasonable to use Median Household Income (MHI) as a measure of affordability; instead, Lowest Quintile Income (LQI) provides a more appropriate index by which to assess affordability challenges. USEPA focused on the affordability of small systems as they might be the least likely to afford compliance treatment technologies, if needed. However, large systems and their customers, especially low-income households should also be considered, which is what the LQI is targets. It is recommended that USEPA incorporates LQI into its affordability analysis for medium and large systems.

BWWB has conducted rate and affordability analysis to capture the impacts of the proposed PFAS Rule on the utility debt level and LQI. Please refer to the key points No.4 in the Executive Summary Letter and Appendix-C for additional details.

EPA Response: For the EPA response on the use of MHI and other indicators in the affordability analysis and the EPA's response to comments recommending the EPA include large systems in the analysis, see section 13.10 in this *Response to Comments* document. Regarding the commenter's system-specific rate and affordability analysis, see the EPA response to comment Doc. #1602, SBC-043630 in section 13.10 in this *Response to Comments* document. While the EPA recognizes that there are likely site-specific instances with affordability concerns, there are also site-specific instances where there are not affordability concerns, and this level of accuracy is appropriate for a national level analysis.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043630)

3. The USEPA model considered adding PFAS treatment costs to utilities in a vacuum without addressing the impact of other compliance and infrastructure needs occurring in tandem (e.g., Lead and Copper Rule Revisions (LCRR) compliance, non-revenue water control, AWIA related risk reduction and aging infrastructure renewal).

Based on the existing utility challenges with aging infrastructure and other regulatory driven investments, the combined capital cost impact on BWWB for the next 5 years is estimated to be $90 million (excluding the PFAS Rule).

The rate and affordability impacts associated with the obligations identified above, excluding the PFAS Rule, are already significant and challenging and as outlined below:

Table 1. Rate and affordability analysis results, based on combined ongoing and emerging compliance and infrastructure needs (excluding impacts of proposed PFAS Rule)

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1602]

Affordability has become an ever-increasing challenge throughout the US, and certainly in greater Birmingham due, in part, to increasingly stringent compliance rules and aging infrastructure challenges. The income distribution in America is increasingly bimodal, such that reliance on a central estimate of income, the Median Household Income (MHI), which USEPA implemented in its analysis, is a misleading criterion. Low income, and historically disadvantaged American families are struggling with increased water rates even before this rule was proposed; it is no longer reasonable to use MHI as a measure of affordability; instead, Lowest Quintile Income (LQI) provides a more appropriate index by which to assess affordability challenges. Water rates representing 2% of the LQI are considered a threshold measurement of affordability. As shown in Table 1, addressing the existing and emerging challenges facing BWWB over the next five years, excluding PFAS, could yield an average bill percentage of 2.74% of LQI and place a staggering 38.0% of households below the affordability threshold. This group of customers would likely struggle with affordability even before the impact of the PFAS Rule is considered. In that scenario, which is the reality facing BWWB, BEFORE consideration of the impacts of the proposed PFAS Rule, it would take someone on minimum wage to work 8.9 hours per month (based on current federal minimum wage rates) just to pay the average water bill in 2028. This does not even address other utility costs such as wastewater which are significantly higher than the water bills in Birmingham.

4. Both the magnitude of the financial impact caused by the proposed PFAS Rule as well as the prolonged duration of the financial consequences could significantly affect drinking water affordability in the next 30 years. It appears that USEPA did not adequately consider the potential economic burden of the proposed PFAS Rule on utilities' ratepayers, especially for low income and historically disadvantaged communities in large water systems, which will dramatically affect their affordability of service. USEPA only considered LQI in the small system (serving a population of 10,000 or fewer) affordability analysis; nevertheless, low-income families served by larger systems also face notable affordability challenges that should be considered. If USEPA's PFAS Rule is finalized as proposed, it could add at least $166 million of capital cost over three years above and beyond the cost impact on BWWB identified in Table 1 above. In addition, the annual O&M cost would likely increase by more than $4 million resulting from operation of a GAC system for PFAS removal and media disposal as non-hazardous waste. Table 2 summarizes the potential impact on BWWB's ratepayers if the compliance cost of the proposed PFAS Rule were added to the costs previously identified in Table 1.

Table 2. Rate and affordability analysis results, based on combined compliance costs (with PFAS Rule, non- hazardous waste)

[Table 2: See Docket ID EPA-HQ-OW-2022-0114-1602]

When considering the combined compliance costs (including the PFAS Rule, and assuming a non-hazardous waste scenario), the average monthly water bill is projected to become $68.48 in 2028, which constitutes a 43.6% increase over a five-year period (i.e., 2023 to 2028).

The average water bill would represent 3.17% of the LQI and 40.0% of BWWB's customers would be below the affordability threshold by 2028. Low income, and historically disadvantaged American families can simply not afford the increased water rates associated with the proposed PFAS Rule. Furthermore, the additional utility debt level would be projected to increase by 17.9% by 2028, creating long-term affordability impacts for BWWB's customers. BWWB has a high debt burden and has been working diligently on a debt reduction plan to reduce borrowing, maintain or improve our bond rating and lower the cost of borrowing on our customers. Adding a potential $185,483,000 in additional debt would result in rate impacts lasting as long as 30 years.

EPA Response: The commenter's affordability analysis starts from existing conditions regarding borrowing, debt, and typical monthly bills and adds an estimated $90 million over 5 years for compliance with infrastructure and regulatory requirements other than the PFAS rule. The commenter does not explain the source of this estimate or specify the assumptions used. The commenter then adds the estimated cost of PFAS compliance at the Shades Mountain Filter Plant. As discussed in detail in response to this commenter in section 13.3.3 of the EPA response in this *Response to Comments* document, the estimated capital costs for the Shades Mountain Filter Plant are based on straight-line extrapolation from a single case study. The estimated O&M costs for the Shades Mountain Filter Plant use unit costs for GAC media that do not account for large volume price discounts. Taken together, these uncertainties suggest that the commenter's analysis may overestimate the affordability impacts of the PFAS rule. Alternately, this specific system may be a case where affordability impacts are greater than typical. The EPA expects there are also site-specific systems where affordability impacts are lower than estimated in the EPA's national analysis. The EPA's affordability analysis under SDWA is a national level assessment of the affordability impacts of a new rule and not a system specific analysis.

For the EPA's response on the use of MHI and other indicators in the affordability analysis and the EPA's response to comments recommending the EPA include large systems in the analysis see, section 13.10 in this *Response to Comments* document. For the EPA's response to comments on simultaneous compliance, see section 10.4.2 in this *Response to Comments* document. For the EPA's response to comments on environmental justice, see section 14.10 in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043063)

The affordability assessment relies on data that fails to capture financial challenges for many communities and relies on dated, inaccurate information. The affordability analysis should be updated to reflect community affordability and anticipated challenges more accurately for lower-income populations.

EPA Response: See section 13.10 of the EPA response in this *Response to Comments* document.

Illinois Farm Bureau (IFB) (Doc. #1630, SBC-043139)

[The most glaringly overlooked and/or underestimated data includes:]

• Failure to use non-metro median income data. The cost- benefit analysis that the agency prepared relies solely on national median income which is not representative of the entire country. They fail to consider the non-metro median income which is causing this rule to negatively impact rural communities.

EPA Response: See section 13.10 of the EPA response in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043262)

2. Affordability Calculation and Considerations

Calculations to determine affordability are based on the national median household income (MHI). This proposed rule states the median household income for a population of 301-3,300 is $53,596. For small urban communities this works but small rural communities often have median incomes below the national median. Federal agencies such as Rural Development at the U.S. Department of Agriculture (USDA) use Non-Metro Median Household Income to determine affordability. The Economic Research Service at USDA defines persistent poverty [https://www.ers.usda.gov/webdocs/publications/47002/30445_rdrr100full_002.pdf?v=41479#:%7E:text=ERS%20has%20defined%20counties%20as,%2Fbriefing%2FRurality%2FTypology.] counties as 20 percent or more of their populations have been poor over the last 30 years. The U.S. has nearly 400 persistent poverty counties and almost 15 percent of the nation's non-metro population live in persistent poverty counties. Additionally, this report states the poverty rate is highest in the completely rural communities (not adjacent to metro counties). These numbers demonstrate the need for rural communities to have independent calculations from national averages when determining affordability.

Table 9-8 page, 9-20 of the Economic Analysis states, "Household water costs derived from 2006 Community Water System Survey (USEPA, 2009), based on residential revenue per connection within each size category, adjusted to 2020 dollars based on the Consumer Price Index for All Urban Consumers: Water and Sewer and Trash Collection Services in U.S. City Average." This survey is outdated, and water rates have risen substantially since 2006. Also as previously stated, these rates are based on metro areas and do not account for the rate challenges that occur in rural areas where economy of scale can't be used to spread costs among many users.

Page 9-22, Section 9.12.2 Supplemental Affordability Analysis states, "In the following sub-sections, EPA estimated small system affordability based on; (1) an incremental approach with expenditure margins of 1.0 percent of annual MHI and 2.5 percent of the lowest quintile of annual household income, and no additional adjustment for total current annual water expenditures, and (2) taking into account nationally available financial assistance when assessing affordability." However, assessments are not included in this calculation. Additionally, many

rural systems are highly dependent on large agricultural or industrial users. The calculations are on residential, but businesses and other users must be accounted for in this process.

EPA Response: The EPA agrees with the commenter that small rural communities often have median incomes below the national median. As discussed in section 13.10 of the EPA response in this *Response to Comments* document, the agency did not use the national MHI. The MHIs used in the analysis were derived using the CWSS. The EPA used MHI's for the zip codes provided by small systems in the CWSS. This approach allows the EPA to capture the incomes of communities served by small systems, many of which are rural. Regarding the income measure used in the affordability analysis for the proposed and final rule, and in response to comments on the EPA's use of the CWSS, see section 13.10 in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043264)

Table 9-14, page 9-27 Economic Analysis states, "To evaluate affordability, EPA compared incremental costs per household for each technology against an expenditure margin."

The tables are titled "Total Annual Cost per Household…" but the text references incremental costs. Affordability determinations should be compared to total costs. Additionally, this analysis assumes 100% financial assistance for capital costs. The assumption that every system will receive financial assistance is flawed for reasons previously stated. Many small systems throughout rural America are unaware that financial assistance is available and if aware don't have staff and resources to apply. Outreach is a critical component to ensure the most marginalized communities can access these funds and to date, this has not happened.

Additionally, this analysis assumes a household cost of $1,081 to $1,153 annually. This is unaffordable and unsustainable in many rural communities. Larger systems use economy of scale to reduce cost, but this is not an option for many small systems. Regionalization where voluntary and locally supported can be an option but should not be assumed in all situations where geography, economic and environmental justice eliminate regionalization as an option.

EPA Response: In the affordability determination for the final rule, the EPA retained the approach using total costs, as recommended by this commenter.

The EPA disagrees with the commenter's assertion that the EPA's assumption of 100 percent financial assistance is flawed, as significant funding will be generally available, and the EPA continues its efforts to help PWSs access it. It is therefore reasonable to consider the burden reduction in the supplemental affordability analysis, as recommended by the SAB. For more information see section 13.10 of the EPA response in this *Response to Comments* document.

The single household costs range referenced by the commenter ($1,081 to $1,153) were the EPA's estimates at proposal of centralized RO for systems serving between 25 and 500 people assuming capital costs are 100 percent covered by financial assistance. For most water systems, the EPA expects that centralized RO will be the costliest of the BAT options and the EPA does not expect it to be commonly utilized as a compliance approach. In both the proposed and final

analyses, the EPA presented household cost estimates for GAC, IX, and POU devices, all of which are expected to have significantly lower associated household costs than centralized RO. These costs are 73 to 87 percent lower than those discussed by the commenter. For more information, including the EPA's household level cost estimates for all SSCTs, see Chapter 9.12 of the EA.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043486)

[They have identified the following areas of concern regarding the agency's development of this rule:]

• Failure to use non-metro median income data. The cost-benefit analysis that the agency prepared relies solely on national median income which is not representative of the entire country. EPA fails to consider the non-metro median income, where this rule will have a disproportionate impact.

EPA Response: See section 13.10 of the EPA response in this *Response to Comments* document.

Raptor Pharm & Tox, Ltd (Doc. #1644, SBC-043425)

The US EPA failed to consider EJ impacts appropriately. The benefit-cost-analysis was performed using improper values, such as using the median household income, which does not account for, and will ultimately harm the poor and EJ communities.

EPA Response: For the EPA's response to comments on the EPA's use of MHI and other metrics in the affordability analysis, see section 13.10 of the EPA response in this *Response to Comments* document. For the proposed and final rule, the EPA conducted an EJ analysis that examined the demographic distribution of baseline PFAS exposure in drinking water and the distribution of costs and benefits of the rule; please see Chapter 8 of the EA (USEPA, 2024b) for more information on this analysis. For the EPA's response to comments on the agency's EJ analysis, see section 14.10 in this *Response to Comments* document.

Raptor Pharm & Tox, Ltd (Doc. #1644, SBC-043421)

EPA wrongly uses the MHI (median household income) in its benefit-cost analysis. The MHI is not a good indicator of much of anything other than the median household income. Use of the MHI does not serve or achieve any environmental justice (EJ) cause. In fact, use of the MHI will result in policies that completely ignore the needs of our EJ and children's health communities. Instead of basing the impacts on the MHI, benefits and costs need to be based on impacts to our EJ communities and our children.

2.5% of the MHI as an affordability threshold is not at all responsive to the needs of the poor. To say that the poor can absorb a water bill of $1,384 per year is outrageous. For a family making

$15/hour, the affordability threshold would be $780 – almost half of the affordability threshold for a family making the median household income.

What this means is that for the smallest water systems, the expenditure margin is $273, not $877 – that's 3x smaller for the working poor at $15/hr, than the median household income. Now, consider a water system where the poor are making even less than $15/hr, and that expenditure margin becomes even more narrow.

In other words – the policy as written, based on the benefit-cost analysis, is not taking into account the potential costs to the EJ community, and will have disproportionate harms on the poor, children, and ultimately the EJ community.

EPA Response: For the proposed and final rule, the EPA conducted both an EJ analysis pursuant to EO 14096 and an affordability analysis pursuant to SDWA Section 1412(b)(4)(E)(ii). The affordability analysis does not explicitly consider EJ impacts, which are examined separately in Chapter 8 of the EA. The commenter's assertion that the EPA "is not taking into account the potential costs to the EJ community" is incorrect, as the EPA did assess the distribution of costs of the final rule across demographic groups in its EJ analysis. For more information on the EPA's EJ analysis, see Chapter 8 of the EA (USEPA, 2024b). The commenter's assertion that the EPA did not consider disproportionate harms on children is also incorrect, pursuant to SDWA Section 1412(b)(3)(C), the EPA evaluated the effects of the contaminants on the general population and sensitive subpopulations including infants, children, pregnant women, the elderly, and individuals with a history of serious illness.

The EPA disagrees with the commenter regarding the appropriateness of the EPA's expenditure margin; the commenter's recommended expenditure margin is based on a minimum wage. The EPA disagrees for the same reason the EPA chose to retain the MHI; it provides a central tendency for income which is representative of a whole community's ability to pay and is not unduly influenced by outlier values. The EPA further notes that in this rulemaking, the EPA recognizes the value in examining alternative measures of a community's ability to afford an SSCT, so the agency chose to include supplemental analyses that use alternative metrics. These supplemental analyses help to characterize affordability when considering the marginal impact, disadvantaged community groups, as cited by this commenter. For the EPA's response to comments on the use of MHI and other indicators in the affordability analysis, see section 13.10 in this *Response to Comments* document.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043212)

The expenditure margins for SSCT affordability analysis overestimates the ability for residents in small rural communities to afford the cost of PFAS treatment. The analysis for communities with population 25-500 indicates rate increases from $25/month on the low end to $60/month on the high end. Significant financial assistance will be required to assist those smaller systems.

EPA Response: In response to the commenter's statement that the EPA "overestimates the ability for residents in small rural communities to afford the cost of PFAS treatment," the

EPA disagrees and relied on a longstanding methodology to determine if the rule is affordable at the national level. The EPA agrees that financial assistance will play a key role in helping small systems achieve compliance and reducing the burden on households served by small systems. For the EPA's response to comments on financial assistance available to help water systems comply with the PFAS NPDWR, see section 2 in this *Response to Comments* document.

California Farm Bureau Federation (Doc. #1704, SBC-045070)

[For example, the U.S. Chamber analysis highlights the following:]

• Failure to use non-metro median income data. The cost-benefit analysis that the agency prepared relies solely on national median income which is not representative of the entire country. EPA fails to consider the non-metro median income, where this rule will have a disproportionate impact.

EPA Response: See section 13.10 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045113)

3) The National-level analysis of affordability of SSCTs and specifically on the potential methodologies presented:

We have seen costs for a small TNC system significantly higher than what we see in table 22 and 23. At least one small TNC treating PFAS with GAC is quoted to cost much more, $25,000 for the replacement of 4 x 10-inch diameter by 54-inch-tall filters (permitted to treat 5gpm). Vermont has NTNC systems that would need treatment systems of the same or similar scale (5gpm); therefore, they would be likely burdened with the same costs. It appears that the costs in table 22/23 are more applicable to community systems. A non-community system will not have multiple "households" to carry the cost. Different tables for community systems and non-community systems may be more accurate than going purely by size. Cost per household makes sense for community systems. Perhaps the cost should be per gallon or per system or some other unit than cost/household.

a. GAC/RO/IX may require additional pre-treatment. That should be included in the cost estimates. We have experience in Vermont where a system treating for PFAS has GAC filters that get approximately 1/3 to 1/2 of its expected PFAS-treatment life (on paper) due to removal of other contaminants. More guidance about pre-treatment standards should be developed as part of an implementation or treatment optimization guideline so that systems are investing money wisely in treatment and will not have to bear undue costs in the future.

b. For RO, the permeate will need to be re-mineralized post RO treatment. This should also be included in the cost estimate.

EPA Response: The EPA clarifies that the cost ranges that the commenter refers to presented in Table 22 and 23 of the preamble for the proposed rule are estimates of household level costs, not system level costs. Therefore, it is not appropriate to compare the EPA's figures in those tables directly to the cost quote for GAC cited by the commenter. On a system level basis, updated cost curves the EPA developed for the final rule estimate a range of capital costs of approximately $161,000 to $396,000 for a 5 gallon per minute facility using GAC to treat groundwater. Thus, the commenter's quote of $25,000 does not support a conclusion that costs for small NTNC systems would be significantly higher than the EPA's compliance cost estimates, and in fact, the EPA's affordability analysis was based on estimated facility costs higher than those cited by commenter for this treatment scenario. The EPA included costs for NTNCs in its national cost estimate. The commenter is correct, however, that the EPA's affordability analysis is applicable only to community water systems. For the EPA's responses on the need for pre- and post-treatment, and the extent to which these processes were included in the EPA's cost estimates, see sections 10.1 and 13.3.3 in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045915)

Furthermore, for small system compliance technologies, EPA identifies use of point-of-use RO, where currently not proposed as a compliance option because the regulatory options proposed require treatment to concentrations below the current NSF/ANSI certification standard for POU device removal of PFAS. EPA is anticipating third parties will develop new standards, and its affordability conclusions reflect the costs of devices certified under the current standard, not a future standard [FN163: 88 Fed. Reg. at 186687, Table 20 n.1-2: "POU RO is not currently listed as a compliance option because the regulatory options under consideration require treatment to concentrations below the current NSF International/American National Standards Institute (NSF/ANSI) certification standard for POU device removal of PFAS. However, POU treatment is reasonably anticipated to become a compliance option for small systems in the future if NSF/ANSI or other independent third-party certification organizations develop a new certification standard that mirrors EPA's proposed regulatory standard. The affordability conclusions presented here reflect the costs of devices certified under the current standard, not a future standard, which may change dependent on future device design. EPA's work breakdown structure (WBS) model for POU treatment does not cover systems larger than 3,300 people (greater than 1 million gallons per day [MGD] design flow), because implementing and maintaining a large- scale POU program is likely to be impractical."]. Also, POU systems are "at the kitchen sink" applications of which the "concentrate" is often sent to a sewer [FN164: See EPA document on WaterSense Draft Specification for Point-of-Use Reverse Osmosis Systems Supporting Statement: https://www.epa.gov/watersense/point-use-reverse-osmosis-systems.]. This also pushes additional costs to individuals / rate payers, creating a disproportional cost burden to individuals served by small systems [FN165: 88 Fed. Reg. at 18688, Table 23.]. EPA has underestimated administrative costs related to this rulemaking.

EPA Response: The EPA clearly states that the POU device household cost estimates costs reflect the costs of devices certified under the current standard not a future standard. The

POU device household cost estimates for final are at most 35 percent of the expenditure margin. The EPA does not believe costs under a future standard would increase significantly and are not likely to exceed the expenditure margin. Importantly, the EPA has identified other affordable SSCTs (i.e., GAC, IX, RO for some systems); therefore POU devices are not the only option. The EPA determined that there are several affordable treatment technologies for small systems available to comply with the final rule. In response to the comment that "POU 'concentrate' is often sent to the sewer" and "pushes additional costs to individuals / rate payers, creating a disproportional cost burden to individuals served by small systems," please see the EPA's response to comments about management of spent drinking water treatment residuals containing PFAS in section 10.4 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-047713)

5. ECONOMIC IMPACTS

EPA estimates the average cost per household from the proposed MCLs. EPA uses the cost estimates from its models which underestimate current PFAS treatment costs. This analysis presents revised household cost estimates using the updated treatment cost data.

EPA also found that the severe household impact would be lessened by increased federal spending to water systems to address emerging chemicals such as PFAS. Since federal funds are largely limited to capital expenditures and since the likely costs are much higher than EPA's estimates, this report compares the level of increased federal funding to water systems' compliance needs.

1. Household (HH) Impact

Multiplying the number of systems by the average population by CWS size determines the total population served by system size. Dividing these totals by the average household size [FN130: U.S. Census Bureau, "Table HH-4. Households by Size: 1960 to Present," November 2022, https://www.census.gov/data/tables/time-series/demo/families/households.html.] gives an estimate the number of households per CWS size. Dividing B&V's annualized costs by the number of households results in total cost per household from treatment costs alone. Household costs range from $110 annually for large systems serving over 1 million people to $10,000 per household for the smallest systems serving less than 100 people (see Table 27). For the largest size categories – CWSs serving between 100,000 to 1 M people – 12 M, households are expected to see a $120 annual increase in drinking water expenses.

Table 28 summarizes these costs as percentages of the annual household income for different income groups. For the lowest quintile income [FN131: A quintile is one of five equal groups (20 percent of all HHs each) ranked by income from lowest to highest. The lowest quintile income used in this analysis is $23,584.], costs average 15 percent and 0.75 percent of annual income for small and large CWSs respectively. For households at the national median household income ($70,784) [FN132: U.S. Census Bureau, "Income in the United States: 2021," September 2022, https://www.census.gov/library/publications/2022/demo/p60-276.html.] costs reach 15 percent of

annual income for the smallest systems. For households with income at 200 percent of the poverty level, costs range from 0.2 percent of annual income for large systems to 20 percent for small systems. With households of four, costs are a higher percentage of annual income, averaging 13 percent for small systems and 0.67 percent for large systems. Cost estimates for single households reach up to 81 percent of their annual income at the small CWS.

Table 27: Annualized Cost per Household (HH) from Treatment Costs

[Table 27: see docket ID EPA-HQ-OW-2022-0114-1738]

Table 28: Annualized HH Cost from Treatment Costs as a Percentage of Annual Income

[Table 28: see docket ID EPA-HQ-OW-2022-0114-1738]

Due to the initial year that includes up-front administrative startup costs, treatment administration costs, and 12-month monitoring costs, households in the initial year could bear additional economic impacts above those resulting from annualized costs. The following table presents the impacts on households from these administrative costs and includes an estimation of how the lowest quintile of households are impacted.

Table 29: Additional HH Impacts from Administrative Costs

[Table 29: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. See section 13.3.3 of the EPA response in this *Response to Comments* document. The commenter's conclusions rely on AWWA B&V's overestimated costs, therefore, produce overestimated household level cost estimates. The commenter also derived cost per household using the number of systems and average population for each size category. The commenter did not provide sufficient data for a direct comparison between these two methods, but the EPA believes its approach is more representative of typical costs per household because the agency computed costs per household using the median population per system. The EPA notes that AWWA's letter states that the B&V model predicts household costs for systems serving 25 to 100 people is $3,570 (see Table 11-1 of AWWA's comment letter). It is unclear how this commenter used the same cost model but arrived at an estimate $10,000 dollars per household for the same system size category. Finally, in Table 29, the commenter added administrative costs but did not identify the source of these estimated costs or the assumptions implicit in these estimates. Overall, the EPA disagrees with the commenter's findings about the household costs of the PFAS rule as percentages of annual income.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045989)

Section 8.6: Affordability and environmental justice

AMWA encourages EPA to:

● evaluate and consider this proposed rulemaking's effects on water affordability nationwide, particularly as the high costs of treatment and disposal will be passed disproportionately onto disadvantaged and rural communities, and

● examine the rule's effects on environmental justice.

EPA's analysis does not take into account how the costs of treatment will be spread across U.S. households, and AMWA is concerned the highest costs will be concentrated on many of the nation's most vulnerable populations. EPA should both consider this proposed rulemaking in light of the rising concerns about long-term water affordability and should address the unequal impact of costs in the final rulemaking or accompanying guidance. Furthermore, AMWA urges EPA to consider how the proposed rulemaking will impact communities where PFAS are disposed of and how to support PWS and communities equitably. Ultimately, EPA should consider the unintended effects of this proposed rulemaking on vulnerable populations and address how the agency will support an equal distribution of negative impacts from increased costs and disposal in final rulemaking and implementation.

To understand the impact of this rulemaking, EPA must first consider the greater concerns about water affordability in the United States. Despite the much appreciated $50 billion of federal investment in the water sector from recent legislation, American water infrastructure still requires billions more to maintain adequate infrastructure, prepare for climate change resilience, and protect public health. The American Society of Civil Engineers' (ASCE) Failure to Act study [FN26: ASCE. (2021). Failure to Act: Economic Impacts of Status Quo Investment Across Infrastructure Systems. https://infrastructurereportcard.org/wp-content/uploads/2021/03/FTA_Econ_Impacts_Status_Quo.pdf] found that the US water sector in 2021 needed over $400 billion to meet engineering standards, and these costs will only increase with additional treatment, climate change, and inflation. The existing water system financing model assumes that most of the money for addressing local water supply issues, whether that issue is aging infrastructure, water quality, lead pipes, cybersecurity, or water supply reliability, can be dealt with largely with local resources (i.e., customer water rates). Given the large funding gap needed without considering PFAS, it is essential that the EPA adequately assess costs in its final rulemaking and create the NPDWR with accurate estimates.

EPA should create the final rulemaking in light of this rule's impacts on water affordability, including how it will increase household water rates across the country. Nationally, many customers can already not afford their drinking water bills. A 2020 analysis by Circle of Blue [FN27: Circle of Blue. (2020, October). Customer Water Debt Data and 12 US Cities. https://www.circleofblue.org/2020/world/chart-customer-water-debt-data-in-12-u-s-cities/] examined the amount of residential debt in 12 large U.S. cities. The analysis found that in some cities, the average resident with water debt owed on average over $600, and that in four cities over 30% of residents had water debt [FN6: Missouri Department of Natural Resources. (2023). Understanding data. https://dnr.mo.gov/monitoring/understanding-data]. This report reflects that households across the US are struggling to pay their water bills already, so EPA should greatly consider how to prepare for any rate increases from the proposed rulemaking.

Specifically, this proposed NPDWR will increase rates at an unsustainable level for households served by smaller, rural water systems. To examine how this proposed rulemaking would increase household rates across the country, Black & Veatch researchers examined estimated costs by PWS size [FN21: Associated Press. (2022, June 1). Inflation taking bite out of new infrastructure projects. https://www.usnews.com/news/business/articles/2022-06-19/inflation-taking-bite-out-of-new-infrastructure-projects]. The researchers found that customers in small systems, which are overwhelmingly in rural areas, may face significantly larger household costs of PFAS treatment than what households served by large utilities will see. PNG's analysis estimates that on an annualized basis, household costs will increase $110 to $10,000 depending on system size (Attachment 1, Table 27), which equates to a large percent of annual household incomes, particularly in rural areas (Attachment 1, Table 28; also included below). According to the latest annual Bankrate annual emergency savings survey [FN28: Bankrate. (2023, February 23). Bankrate's annual emergency savings report. https://www.bankrate.com/banking/savings/emergency-savings-report/], over 50% of Americans do not have the funds on hand to cover a $1000 emergency expense. An increase of over $1,000 for water treatment, therefore, is unimaginable for many households. Without substantial and recurring federal government subsidies and EPA's honest examination and preparation, these geographic and PWS system size inequities in costs of PFAS treatment will perpetuate with this rulemaking's finalization.

Table 28. Annualized HH Cost from Treatment Costs as a Percentage of Annual Income

[Table 28: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: In response to the comment regarding the impact disposal of PFAS containing treatment residuals on nearby communities, see section 11.4.4 of the EPA response in this *Response to Comments* document. In response to comments on the EPA's estimates of treatment costs, see section 13.3.3 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's assertion that the "EPA's analysis does not take into account how the costs of treatment will be spread across U.S. households" because the EPA examined the distribution of costs for systems anticipated to install treatment to comply with the final rule across demographic groups. When examining costs anticipated to result from the rule, the EPA found that cost differences across demographic groups were small, with no clear unidirectional trend in cost differences based on demographic group. For more information on the findings of the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA, 2024b). Also, see EPA's complete response to comments on the EJ analysis in section 14.10 in this *Response to Comments* document.

The EPA disagrees with the commenters assertion that the NPDWR "…will increase rates at an unsustainable level for households served by smaller, rural water systems." See section 13.10 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1738, SBC-047713 in section 13.10 in this *Response to Comments* document. In response to comments regarding the sufficiency of federal funding available to help water systems comply with the rule, see section 2.4 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045631)

Accounting for Financial Assistance

In its affordability analysis, EPA also cites that an additional analysis was conducted accounting for funds that are nationally available, such as the DWSRF program and funds from BIL. As EPA notes in the proposal, $800 million is available annually for systems addressing emerging contaminants like PFAS. EPA also announced the availability of $1 billion annually through the Emerging Contaminants in Small or Disadvantaged Communities grant program. Both programs are appropriated through Fiscal Year 2026. These programs make $1.8 billion available for fiscal years 2024, 2025, and 2026 (a total of $5.4 billion).

The EPA estimates that the total capital cost needs for small systems will range from 1.1 to 2.5 billion; however, as previously noted the cost analysis used by the EPA is significantly flawed and underestimates financial impacts on communities. The occurrence analysis also presents several issues in characterizing the total small system impacts. For a more accurate comparison to available funding, and therefore potential offsetting of household costs, data from Black & Veatch was considered. Black & Veatch estimates that the total capital cost for small systems for a 4 ppt PFOA and 4 ppt PFOS rule will exceed $21.6 billion based on the occurrence data collected by Corona Environmental (Black & Veatch, 2023; Corona, 2021). This is a stark difference from EPA's estimate of $1.1 to $2.5 billion total capital cost for small systems.

Even if the occurrence analysis from the EPA is used these estimates are substantially low. Policy Navigation Group estimated the number of systems that would potentially exceed the MCLs using data from the EPA (PNG, 2023). Using these figures and the estimated capital costs for each system size from Black & Veatch, the total capital cost exceeds $10 billion. This is approximately more than the EPA's estimate by a factor of four.

The availability of $5.4 billion for these systems will help alleviate the costs for individual households. That impact, however, is limited to systems that receive financial assistance. Unless EPA plans to work with states to develop a method for distributing these funds equally to all impacted water systems, the financial assistance will not be evenly distributed across small systems. This approach will inaccurately depict the financial impacts to households in communities where financial assistance is not provided. Therefore, AWWA recommends that the EPA not consider this financial assistance in assessing household affordability for small systems.

EPA Response: See section 13.10 of the EPA response in this *Response to Comments* document for the EPA's response to comments on the agency's affordability determination and methods for proposal and the final NPDWR. As discussed in Chapter 9.13 of the EA for the final rule, the EPA determined that there are several affordable treatment technologies for small systems available to comply with the rule. The commenter references one of several supplemental affordability analysis conducted by the agency, which, as discussed in section 13.10 of the EPA response in this *Response to Comments* document, as significant federal funding will be generally available, it is therefore reasonable to consider the burden reduction in the supplemental affordability analysis. Regarding the availability of BIL funding in comparison

to the compliance costs of the rule, see section 13.3 of the EPA response in this *Response to Comments* document.

Further, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs; see section 13.3.3 of the EPA response in this *Response to Comments* document. As detailed in section 13.3.3 of the EPA response in this *Response to Comments* document, the B&V overestimates system level capital costs for small systems (for example, by excluding package plants from consideration) and overestimates the number of small systems that will exceed the final MCLs. For the final rule, the EPA estimates that the total amount of initial capital treatment technology expenditures for small systems nationally ranges between approximately $1.8 and $3.5 billion and disagrees with the commenter's estimates total capital cost for small systems for a 4 ppt PFOA and 4 ppt PFOS rule will exceed $21.6 billion based on the occurrence data collected by Corona Environmental. The commenter's conclusions rely on AWWA B&V's overestimated costs, therefore, produce a significant overestimate of the total small system capital costs as a result of the rule. Regarding the EPA's occurrence analysis, see section 6 of the EPA response in this *Response to Comments* document. For the EPA's response to Corona (2021), see Doc. #1713, SBC-045902 in section 6.8 in this *Response to Comments* document.

Regarding PNG's analysis included in AMWA's comment letter, see the EPA response to comment Doc. #1738, SBC-046019 and Doc. #1738, SBC-047713 in sections 13.3.3 and 13.10, respectively, in this *Response to Comments* document. As detailed in that response, the EPA's review of the PNG report finds substantial discrepancies between the annual treatment costs cited and the values presented in the B&V report. For most system size categories, the annual treatment cost per affected PWS used by PNG is significantly greater than the values presented in the B&V study. The PNG provides no documentation or other information that explains where these extensive cost increases originate. This discrepancy potentially also applies to AMWA's estimate of small system capital costs.

American Water Works Association (AWWA) (Doc. #1759, SBC-045566)

6. The affordability assessment relies on dated, inaccurate data and an approach that fails to capture affordability challenges for many communities. The affordability analysis should be updated to more accurately reflect household affordability and anticipated challenges for lower-income populations.

EPA Response: The data from the 2006 CWSS remains the best available dataset for this national level analysis. For the EPA's complete response to comments on use of the CWSS survey in the affordability analysis, see section 13.10 in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045630)

11. Household Affordability and Small System Compliance Technologies

As noted in the first section, it is critical that drinking water be affordable and that smaller systems more susceptible to affordability challenges have access to compliance technologies. This is true for all consumers, and particularly for those in environmental justice communities. The proposal highlights several variations of the household affordability analysis beyond the EPA's previously utilized approach, including an approach that has been developed and recommended by AWWA and other water sector Associations (AWWA, 2021b). AWWA appreciates that the agency is interested in utilizing recommendations previously made by stakeholders regarding alternative metrics for this analysis.

These comments have already highlighted significant concerns about EPA's underlying approach to the cost analysis and the anticipated inaccuracies of the EPA's WBS Model. EPA should refine that approach and re-evaluate the affordability analysis for any rule.

As part of its analysis, Black & Veatch assessed household impacts of the various rule options (Black & Veatch – See Appendix B). Table 11-1 provides an overview of those results for Options 1a (4 ppt PFOA and 4 ppt PFOS) and 1c (10 ppt PFOA and 10 ppt PFOS) in comparison with EPA's estimated expenditure margins for the affordability analysis. As shown in Table 10-1, the household costs for each of these options significantly exceed the expenditure margin for systems serving less than 1,100 persons.

Table 11-1: Comparison of EPA Affordability Margin and Treatment Cost Estimates

[Table 11-1: See Docket ID EPA-HQ-OW-2022-0114-1759]

It is also important to note that these household costs are only reflective of treatment costs, monitoring costs are not included here, which for smaller systems will have a greater household impact. A treatment technology that is not considered as part of this analysis is the use of point-of-use reverse osmosis (POU RO) systems. While POU RO may become available in the future following NSF/ANSI certification standard that is based on achieving levels at or below the proposed MCLs, it is currently not a compliance option. AWWA agrees with the agency's decision to not include POU devices in its analysis of rule compliance affordability for small systems. Certification is currently not available, and demonstration of effectiveness is a critical aspect of including compliance technologies in this analysis. NSF/ANSI certification will be necessary if any rule considers POU RO as a small system compliance technology.

EPA should re-consider the proposal as the small system household costs for centralized water treatment exceed EPA's estimated expenditure margins for these systems, a more affordable POU treatment option is not available, and EPA has not identified a small system variance technology.

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. See section 13.3.3 of the EPA response in this *Response to Comments* document. The commenter's conclusions rely on AWWA B&V's overestimated costs, therefore, produce a significant overestimate of the total small system capital costs as a result of the rule. Overall, the EPA disagrees with the commenter's findings and suggestion that the rule is not affordable for small systems. See the

EPA response to comment Doc. #1759, SBC-045631 in section 13.10 in this *Response to Comments* document.

The commenter is correct that the affordability analysis does not include the household level impact of monitoring costs because including those costs is not the purpose of this analysis. Because the analysis is conducted to pursuant to SDWA Section 1412(b)(4)(E)(ii)], which requires the "the Administrator shall include in the list any technology, treatment technique, or other means that is affordable", the EPA examines the affordability of treatment technologies. The EPA notes that treatment technology costs represent the large majority of overall costs for water systems that will be triggered into treatment under the final rule. The EPA does not anticipate that if the agency were to include monitoring costs in a supplemental affordability analysis that it would not change the EPA's affordability conclusions because they are small in comparison to treatment costs. For example, a water system that serves 500 people and takes 4 quarterly samples to comply with the rule is expected to incur an additional cost of approximately $12 dollars per year per household (or about $1 per month) associated with the analytical costs of the rule.[13]

Regarding POU's, consistent with the commenter's recommendation, the EPA did not include POU devices as a compliance option in the decision tree for the final rule. At this time, the EPA is not including point-of-use (POU) devices in the national cost estimates because the final rule requires treatment to concentrations below the current NSF/ANSI certification standard for POU devices. However, POU treatment is reasonably anticipated to become a compliance option for small systems in the future if NSF/ANSI or other independent third-party certification organizations develop a new certification standard that mirrors the EPA's final regulatory standard. In the event POU treatment becomes a valid compliance option, national costs could be lower than estimated in this application of the SafeWater MCBC. For the EPA's response to comments on POU devices, see section 10.5 in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043939)

Further, EPA substitutes its cost-benefit analysis for an evaluation of affordability. EPA says it interprets the applicable SDWA standard to require an evaluation of "reasonable cost based on large and metropolitan water systems,"[FN9: 88 Fed. Reg. at 18668.] but its reasonableness determination merely refers back to the cost-benefit analyses it prepared in the EA and HRRCA. The primary discussion of affordability contained in the Proposed Rule relates to its potential impacts on small water systems; no due consideration is given to the affordability of the Proposed Rule to ratepayers of larger, urban water systems. [FN10: Id. at 18686–88.]

WUWC therefore recommends that EPA reconsider the proposed MCLs and determine if the proposed numeric MCLs of 4.0 ppt for PFOA and PFOS, and the HI of 1.0 for the other four

[13] Assuming a water system takes 4 samples per year ($309 each) and including the costs of analyzing FRBs ($273 dollars each), the annual analytical costs are $2,328 dollars (excluding PWS labor to take the samples and review results). Using the average American household size of 2.53 people per household, this cost would spread out among 198 households, and amount to approximately $12 per household.

covered PFAS, will be economically feasible. The analysis should consider affordability to ratepayers of water utilities of all sizes and take into account all categories of costs that will arise as a legal consequence of the Proposed Rule.

EPA Response: The commenter is incorrect; the EPA did not "substitute its cost-benefit analysis for an evaluation of affordability." The EPA performed both of these analyses. As required by SDWA Section 1412(b)(4)(E)(ii), the EPA identified any technology, treatment technique, or other means that is affordable, as determined by the Administrator in consultation with the states, for small public water systems. The EPA's long-standing methodology for determining whether there are affordable compliance technologies for a new drinking water standard for small systems compares the cumulative cost of providing drinking water that complies with the new standard to an affordability threshold equal to 2.5 percent of median household income (63 FR 42032). For the EPA's response to commenters recommending the EPA include large systems in the affordability analysis, see section 13.10 in this *Response to Comments* document. For the EPA's response to comments on the determination of feasibility, see section 5 in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1841, SBC-044843)

The Cost of Complying with the Proposed Standards Are Significantly Higher for Small Systems than EPA Estimates

In addition to underestimating the number of systems out of compliance with the proposed MCLs, EPA's estimated costs for these systems to come into compliance are significantly less than those from the AWWA analysis. A comparison of the average annualized cost for the size categories for which EPA provides information suggest that the Agency's numbers are as much as eleven times below those estimated by AWWA (Table 5).

Table 5. Comparison of Estimated Annualized Cost/System for Systems with Exceedances of the Proposed MCLs

[Table 5: See Docket ID EPA-HQ-OW-2022-0114-1841] [FN 171: USEPA Economic Analysis, page C-11 (Table C-11). [FN 172: AWWA WITAF 56, Appendix A, Table A-1.]

As indicated in Table 5, EPA's estimates are ten times lower for the three smallest size systems and only slightly better for the larger systems. While EPA presents individual breakdowns by water source (ground, surface) and ownership (public, private), the Table includes only information for private systems using surface water which represent the Agency's highest estimated per system costs. The AWWA results appear to be averaged over all system types, so the difference between the two estimates is likely even greater than shown.

EPA Response: In Table 5 of this commenter's letter, the commenter appears to list some of the EPA's 5th percentile estimates for surface water system costs under the regulatory alternative of PFOA and PFOS MCLs at 5 ppt. The commenter incorrectly characterizes these as "the agency's highest estimated per system costs." However, by definition, these estimates are

the EPA's lower end estimates of costs (i.e. 5th percentile), and the commenter is comparing them to a point estimate, possibly an average, although the B&V report does not specify the metric presented. The commenter also references information from a March 2023 version of the B&V report, the EPA notes that that report was since updated with changes that had a downward effect on the B&V cost estimates. The updated B&V report that was submitted to the EPA as a public comment does not appear to include an updated set of these exact estimates, so an updated comparison is not possible. Regardless of the incompatible comparison points from Table 5, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. See section 13.3.3 of the EPA response in this *Response to Comments* document. The commenter's conclusions rely on AWWA B&V's overestimated costs, therefore, produce a significant overestimate of the total small system costs as a result of the rule. For reasons explained above, the EPA disagrees with this commenter's assertion that compliance costs significantly higher for small systems than the EPA estimated.

American Chemistry Council (ACC) (Doc. #1841, SBC-047719)

The 10-fold difference for the smaller systems raises serious concerns about the ability of these systems to pass along the compliance costs to ratepayers. [FN173: Compliance with this regulation may overlap with the requirements of the Lead and Copper Rule Revisions that will compound stress on systems' limited resources.] EPA's current analysis of the household costs for the two smallest size systems expected to exceed the proposed MCLs suggest that households served by these systems may not be able to accept the increase in rates required to comply with the proposal. [FN174: USEPA Economic Analysis, page C-37 (Table C-37).]

EPA Response: The EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. See section 13.3.3 of the EPA response in this *Response to Comments* document. The commenter's conclusions rely on AWWA B&V's overestimated costs, therefore, produce a significant overestimate of the total small system costs as a result of the rule.

The EPA notes that implementation timing associated with this PFAS rule and the proposed LCRI has the potential to overlap. To the extent implementation overlaps, some rule start-up, administrative, and sampling/service line inventory costs associated with both rules could affect a large number of PWSs and states. The more significant costs of installing and operating PFAS treatment technology in a similar time frame with installing and operating CCT and/or conducting service line replacement are expected to fall on some systems, although neither the specific requirements nor the timeframes for compliance under the LCRI have not been established in a final rule. The EPA does not have sufficiently detailed PFAS occurrence, and LSL/GRR service line and 90th percentile lead tap sample data to explore the potential treatment cost interactions of the two rules. The EPA further notes that SDWA Section 1412(b)(3)(C)(i)(III) requires that the EPA include quantifiable and non-quantifiable costs that are likely to occur solely as a result of compliance with the rule including monitoring, treatment and other costs and excluding costs resulting from compliance with other proposed or promulgated regulations. For

the EPA's response to comments on simultaneous compliance, see section 10 in this *Response to Comments* document.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043489)

Rural Communities Will Be Disproportionately Impacted

Farmers and ranchers often serve as the backbone of rural communities throughout the country. Our members raise their families, support their neighbors, and bring jobs to these less populated and underdeveloped areas. The pristine farmland that is often situated away from bustling urban centers allows our members to produce the safest and highest quality food products in the world. However, rural communities have far fewer resources to address expensive federal regulatory requirements. Drinking water utilities in rural areas will undoubtably experience more challenges in meeting the 4ppt standard outlined in this proposed rule. They will incur capital costs, annual operating and maintenance costs, life-cycle costs, and annualized costs. Simply put—it will be infeasible for many rural communities to meet the standards outlined in this proposed rule and the exorbitant costs will inevitably be handed down to the water users. Specifically, the costs associated with acquiring and maintaining technology, obtaining appropriate testing, and methods related to disposal and destruction of contaminated environmental media (i.e. water, soil, air) will weigh heavily on rural communities.

EPA Response: In response to the commenter's statement that "rural communities will be disproportionately impacted," the EPA notes that in the agency's EJ analysis for the final rule, the agency examined the distribution of costs across demographic groups and across multiple water system size categories. When examining costs anticipated to result from the rule, the EPA found that cost differences across demographic groups were small, with no clear unidirectional trend in cost differences based on demographic group. Additionally, the agency found that incremental household costs to all race/ethnicity and income groups generally decrease as system size increases, which is expected due to economies of scale. For further discussion of the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA, 2024b) and section 14.10 of the EPA response in this *Response to Comments* document. To alleviate potential cost disparities identified by the EPA's analysis, there may be an opportunity for many communities to utilize BIL (P.L. 117-58) funding to provide financial assistance for addressing emerging contaminants. BIL funding has specific allocations for both disadvantaged and/or small communities and emerging contaminants, including PFAS. Additionally, if a water system, project or project cost is not eligible under the DWSRF, it may be eligible under other programs. These might include the U.S. Department of Agriculture's Rural Development program, the U.S. Department of Housing and Urban Development's Community Development Block Grant program, the Clean Water State Revolving Fund, the newly authorized Water Infrastructure Finance and Innovation Act (WIFIA) funding, or other federal, non-federal or state funding sources.

California Farm Bureau Federation (Doc. #1704, SBC-045072)

Rural Communities Will Be Disproportionately Impacted

Unfortunately, rural communities often have far less resources and the economy of scale to address expensive federal regulatory requirements. For this reason, we believe that drinking water utilities in many rural areas will experience additional challenges in meeting the 4ppt standard outlined in this proposed rule as they seek to comply. Such agencies often end up incurring capital, annual operating and maintenance, life-cycle, and annualized costs, resulting in such costs being passed on to water users. We are specifically concerned about the costs associated with acquiring and maintaining technology, obtaining appropriate testing, and methods related to disposal and destruction of media which we project will weigh heavily on rural communities.

EPA Response: In response to the commenter's statement that "rural communities will be disproportionately impacted," the EPA notes that in the agency's EJ analysis for the final rule, the agency examined the distribution of costs across demographic groups and across multiple water system size categories. When examining costs anticipated to result from the rule, the EPA found that cost differences across demographic groups were small, with no clear unidirectional trend in cost differences based on demographic group. Additionally, the agency found that incremental household costs to all race/ethnicity and income groups generally decrease as system size increases, which is expected due to economies of scale. For further discussion of the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA, 2024b) and section 14.10 of the EPA response in this *Response to Comments* document. To alleviate potential cost disparities identified by the EPA's analysis, there may be an opportunity for many communities to utilize BIL (P.L. 117-58) funding to provide financial assistance for addressing emerging contaminants. BIL funding has specific allocations for both disadvantaged and/or small communities and emerging contaminants, including PFAS. Additionally, if a water system, project or project cost is not eligible under the DWSRF, it may be eligible under other programs. These might include the U.S. Department of Agriculture's Rural Development program, the U.S. Department of Housing and Urban Development's Community Development Block Grant program, the Clean Water State Revolving Fund, the newly authorized WIFIA funding, or other federal, non-federal or state funding sources.

13.11 Greenhouse Gas Emissions Associated with the Rule

Summary of Major Public Comments and EPA Responses

Several commenters recommend "…that the agency consider the social costs of carbon as part of any PFAS rule's cost analysis to be comprehensive as well as to understand how this rule may have unintended consequences like increased social costs relating to carbon dioxide emissions." Commenters asserted that "[n]ot including the social costs of carbon and other social costs hinders the Administrator from having all necessary information to set the PFOA and PFOS drinking water standard at a level that maximizes health risk reduction benefits at a cost that is justified, given those benefits." Commenters pointed to the greenhouse gas (GHG) emissions associated with production, reactivation, and delivery of treatment media, focusing on GAC in particular; construction associated with the installation of the treatment technology at EPTDS; electricity used to operate treatment technologies; and transportation and disposal of drinking

water treatment residuals to comply with the PFAS NPDWR. Two commenters provided their own quantified estimates for some aspects of CO_2 emissions. One commenter estimated that the climate disbenefits from CO_2 emissions associated with increased electricity use for additional pumping, lighting, and ventilation in treatment plants would be "$2.5M to $6.8M at 2.5 and 1.5 percent discount rates, respectively, in 2026; and $3.6M to $8.6M at 2.5 and 1.5 percent discount rates, respectively, in 2046." Another commenter used a life cycle analysis paper that provides one estimate for the carbon footprint of producing and using GAC and estimates that the climate damages from the CO_2 emissions associated with increased GAC media use "…could have a social cost of more than $160 million annually." One commenter stated that the EPA has performed this analysis in other rulemakings, specifically a 2023 proposed air rulemaking, and notes that in that regulatory impact analysis (RIA), "EPA included the social cost of carbon for the electricity required to operate the air pollution controls."

The EPA disagrees with commenters that SDWA requires the EPA to quantify and consider the climate disbenefits associated with GHG emission increases from this final rule in the HRRCA. The HRRCA requirements of SDWA 1412 (b)(3)(C) require the agency to analyze "quantifiable and nonquantifiable costs…that are likely to occur *solely* as a result of compliance with the maximum contaminant level" (emphasis added). Therefore, the EPA considered as part of its HRRCA analysis the compliance costs to facilities, including the costs to purchase electricity required to operate the treatment technologies. Since the climate disbenefits from GHG emissions associated with producing electricity necessary to operate the treatment technologies account for climate impacts associated with the CO2 emissions and associated costs to society, they do not qualify as compliance costs to PWSs that are part of the required HRRCA analysis under SDWA. For this reason, the EPA included compliance costs to PWSs but not climate disbenefits from GHG emissions associated with the production, reactivation, and delivery of treatment media; construction associated with the installation of the treatment technology at EPTDS; electricity used to operate treatment technologies; and transportation and disposal of drinking water treatment residuals in the cost consideration for the final PFAS NPDWR.

The EPA is committed to understanding and addressing climate change impacts in carrying out the agency's mission of protecting human health and the environment. While the EPA is not required by SDWA 1412(b)(3)(C) to consider climate disbenefits under the HRRCA the agency has estimated the potential climate disbenefits caused by increased on-site electricity demand associated with removing PFAS from drinking water. As explained in section V of the preamble for this action, the EPA's final rule is based on the EPA's record-based analysis of the statutory factors in SDWA 1412(b), and this disbenefits analysis is presented solely for the purpose of complying with EO 12866. Circular A-4 emphasizes that agencies "should monetize quantitative estimates whenever possible," including not only for anticipated direct effects of the rule but also for "any important ancillary benefits and countervailing risks." The scope of the monetized climate disbenefits analysis is limited to the climate impacts associated with the CO_2 emissions from increased electricity to operate the treatment technologies that will be installed to comply with the PFAS NPDWR.

The EPA did not quantify the potential CO_2 emissions changes associated with the production and delivery of treatment media, construction required for the installation of treatment technology, and transportation and disposal of treatment residuals. The EPA recognizes that many activities directly and indirectly associated with drinking water treatment produce GHG emissions; however, the agency determined that it could not accurately quantify all the potential factors that could increase and decrease greenhouse gas emissions that are not solely attributable to the direct onsite operations of the plant beyond increased electricity use at the plant. The EPA has information, to varying degrees, that the agency could use to potentially estimate emissions from some of these activities. To accurately understand the total potential climate disbenefits of this rule, the EPA should consider GHG emissions in the baseline scenario where the agency also takes no action. However, the EPA lacks the data needed to consider the potentially significant climate disbenefits and other costs to society of the EPA taking no action (i.e., not finalizing the PFAS NPDWR). If the EPA does not finalize the rule, this could likely trigger other activities that would increase GHG emissions. For example, significant climate disbenefits may be realized from the public increasing purchases of bottled water in an effort to avoid PFAS exposure from drinking water provided by PWSs. More members of the public switch to drinking bottled water if they do not trust the safety of their utility supplied drinking water (Grupper et al. 2021, Levêque and Burns, 2017). Bottled water has a substantially larger carbon footprint than the most highly treated tap water, including the significant energy necessary to produce plastic bottles and transport water from where it is bottled to the point of consumption (Gleick and Cooley, 2009). This carbon footprint can be hundreds of times greater than tap water on a per volume basis (e.g., see Botto, 2009). In addition, this is the first drinking water regulation in which the EPA has estimated disbenefits associated with increases or reductions in GHG emissions. The EPA expects that the approach for quantifying such benefits or disbenefits will continue to evolve as our understanding of the potential relationships between quality of drinking water treatment, impacts on consumer behavior, and other factors influencing GHG emissions improves. Considering the limitations described above and consistent with past EPA rulemakings,[14] the EPA is limiting the scope of the analysis to the major sources of emissions from the direct operation of treatment technologies. The EPA did not quantify the CO_2 emissions associated with production of treatment technologies, construction, transportation and disposal, as these activities are not solely attributable to the direct onsite operations of the plant and are beyond the scope of this analysis.

Furthermore, while some data exists to inform an estimate of the CO_2 emissions associated with production and reactivation of GAC, the EPA did not do so in this analysis due to significant uncertainties associated with the future CO_2 emissions associated with these technologies. The carbon footprint of GAC is likely to reduce over time, as research continues on novel applications for PFAS removal (e.g., advanced reduction/oxidation processes, novel sorbents,

[14] Recent examples include *New Source Performance Standards (NSPS) for the SOC Manufacturing Industry and National Emission Standards for Hazardous Air Pollutants (NESHAP) for the SOC Manufacturing Industry and Group I and Group II polymers and Resins Industry, NESHAP Gasoline Distribution NRPM, Supplemental Effluent Limitations Guidelines (ELGs)* and *Standards for the Steam Electric Power Generating Point Source Category.*

foam fractionation, sonolysis, among others), alternative sources of materials to produce GAC (e.g., biomass and other waste materials), and use of carbon capture technology expands in the future. Given these compounding uncertainties, the EPA did not quantify the climate disbenefits of GAC production and reactivation.

In this rule, the EPA determined that increased electricity use is the major source of emissions from the direct operation of treatment technologies to remove PFAS. In this analysis conducted pursuant to EO 12866, the EPA first quantified the CO_2 emissions from the additional electricity that is expected to be used for pumping, building lighting, heating, ventilation, and operation of other technology-specific equipment to remove PFAS. The EPA then monetized the climate disbenefits resulting from these CO_2 emissions by applying the social cost of carbon dioxide (SC-CO_2) estimates recommended by the commenter, as described below.

After considering public comments that recommended the EPA consider the climate disbenefits of the rule, the EPA conducted an analysis similar to the one recommended by one commenter. As suggested by the commenter, the EPA used the estimates of consumption of purchased electricity available from the EPA's peer reviewed WBS cost models to estimate the national electricity use associated with operation of PFAS removal treatment technologies. The EPA deviated from the commenter's suggested approach when estimating associated CO_2 emissions over time from producing electricity. The commenter estimates carbon emissions in a single year and presents that value as a constant reoccurring annual cost. Instead, the EPA estimated how CO_2 emissions would change through 2070, the calendar year to which the EPA has estimated CO_2 emissions from electricity production. The EPA applied readily available information from the latest reference case of the EPA's IPM to represent CO_2 emissions associated with electricity production over time.[15] Given that emissions from producing electricity are expected to significantly decrease over time, this is a logical application consistent with other agency rulemakings estimating future emissions from the power sector including the EPA's final *Good Neighbor Plan* (USEPA, 2023k) and the EPA's *New Source Performance Standards for GHG Emissions from New, Modified, and Reconstructed Electric Utility Generating Units* (USEPA, 2023l). Finally, the EPA monetized the climate disbenefits resulting from the estimated CO_2 emissions by applying the SC-CO_2 estimates presented in the regulatory impact analysis of the EPA's December 2023 Final Rulemaking, "Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review" (USEPA 2023m). These are the same SC-CO_2 estimates the EPA presented in a sensitivity analysis in the RIA for the agency's December 2022 supplemental proposed Oil and Gas rulemaking that the commenter recommended for use in this action. The SC-CO_2 estimates incorporate recent research addressing recommendations of the National Academies of Science, Engineering, and Medicine (NASEM 2017), responses to public comments on the December 2022 supplemental proposed Oil and Gas rulemaking, and comments from a 2023 external peer review of the accompanying technical report. The methodology underlying the SC-CO_2 estimates is described in the agency's technical report,

[15] See https://www.epa.gov/power-sector-modeling

Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances, (USEPA, 2023n), and is included in the docket for this final rule. For additional details on the climate disbenefits analysis see Chapter 9.1 of the EA for the final PFAS NPDWR.

Individual Public Comments

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-052965)

Third, EPA's cost estimate fails to account for the increased costs associated with increased health risks from the GHG emissions that will result from these treatment processes. Reactivation, disposal, incineration, and trucking of granulated activated carbon media will all result in additional greenhouse gas emissions. This treatment process (and its resulting emissions) does not currently exist at most plants so there will be an increase in overall emissions industry-wide. EPA should balance the benefits of pushing the MCL down to the PQL with the costs—financial, human health, and environmental—that will come from the added greenhouse gas emissions created through treatment [FN3: Beyond the factors that are not yet reflected in EPA's cost estimate, NACWA's members participated in a survey that proved that EPA's estimates were significantly lower than real world data from utilities that have already implemented treatment. EPA's estimate for capital costs was 2.9 times lower on average than the reported value for 60 utilities.].

EPA Response: See section 13.11 of the EPA response in this *Response to Comments* document. With regard to balancing the benefits and costs of the rule, see section 13.8 of the EPA response in this *Response to Comments* document. In regard to the survey data and conclusions from AWWA and AMWA referenced by the commenter, see section 13.3.3 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046025)

Estimated Electricity Consumption

Electricity consumption increases with CWS size and is slightly higher for surface water compared to ground water in larger systems. Table 22 summarizes the estimated electricity consumption per EPTDS.

Table 22: GAC and IX Energy Consumption per EPTDS (MWhr/yr)

[Table 22 see docket ID EPA-HQ-OW-2022-0114-1738]

Multiplying the averages from Table 22 by the number of entry points that exceed one or more MCLs gives the total energy consumption across all system entry points. To further break this down by treatment method, the analysis assumes 50 percent use GAC and 50 percent use IX. The total estimated electricity consumption for both GAC and IX ranges from 710 MWhr/year for systems serving 100,001-1M people to 26,000 MWhr/year for very large systems serving >1M people.

Table 23: GAC and IX Energy Consumption for All Entry Points that Exceed MCLs (MWhr/year)

[Table 23 see docket ID EPA-HQ-OW-2022-0114-1738]

Using EPA's emissions rate estimate of 0.000433 metric tons (Mt) of CO2/kWh, the analysis calculates the annual carbon dioxide emissions produced from both treatment methods. As shown in Table 24, the proposed rule is estimated to induce an additional 19,000 Mt of CO2 emissions annually.

Table 24: Total Estimated Additional CO2 Emissions from GAC and IX as a Result of EPA's

Proposed Rule

[Table 24: see docket ID EPA-HQ-OW-2022-0114-1738]

Results

The discounted SC- CO2 annual figures from Table 17 are multiplied by the annual CO2 emissions from treatment methods. The resulting costs range from $2.5M to $6.8M at 2.5 and 1.5 percent discount rates, respectively, in 2026; and $3.6M to $8.6M at 2.5 and 1.5 percent discount rates, respectively, in 2046. EPA uses the lower discount rates shown in Table 25 to discount future damages from GHG emissions.

Table 25: Total Estimated Annual Emissions Cost from the Proposed Rule ($ M)

[Table 25: see docket ID EPA-HQ-OW-2022-0114-1738]

These estimates likely underestimate this social cost since, as with EPA's engineering estimates, they likely understate electricity consumption for necessary buildings and for treatment operations. These estimates also do not include the GHG impacts of mining and using activated carbon and the carbon dioxide emissions of activating the carbon for use. The regulatory action will also require non-electricity energy consumption such as heavy truck transport and disposal of media.

4. Results

As shown in Table 26, the sum of all the annual social costs amounts to approximately $7,500 M.

Table 26: Summary of Annual Estimated Costs

[Table 26: see docket ID EPA-HQ-OW-2022-0114-1738]

*EPA uses a lower discount rate for the social costs of GHG emissions. Therefore, the SC- CO2 is in different units of value than the other social costs.

EPA Response: See section 13.11 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043080)

Social Costs of Carbon Dioxide

To comply with this rule, most water systems with PFAS exceeding the MCL(s) will need to install drinking water treatment facilities that rely on either GAC, IX, or RO. In many cases, it is likely that this will come with a new hydraulic profile for the water system and so additional pumping and electricity demand will be needed to maintain the current hydraulic pressure to the distribution system. Additionally, the use of GAC and IX requires a method of disposal via train or truck to a facility that is willing to accept the spent material. These activities can be anticipated to have a significant impact on the carbon footprint of drinking water systems nationally.

The EPA is currently heavily involved in addressing challenges with climate change and in advancing sectors towards reducing greenhouse gas emissions. The Proposal lacks an analysis of the social costs of carbon. Aqua recommends that the Agency consider the social costs as part of the cost analysis to be comprehensive as well as to understand how this rule may have unintended consequences like increased social costs relating to carbon dioxide emissions.

EPA Response: See section 13.11 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045919)

G. EPA fails to consider non-market social and other environmental costs

EPA should also estimate the social costs through economy-wide modeling of the lost productivity when higher water costs ripple through the economy and capital is diverted from other productive uses to build water treatment systems. We also note that there are potential costs to the environment by the use of GAC that are not accounted for by EPA. For example, a recent study from Maine found that PFAS mitigation using GAC may actually increase greenhouse gas emissions in the state: "greenhouse gas emissions for water treatment to bring PFAS down to the current interim standard are substantial, raising the footprint of an average user by 6.7–18 percent."[FN174: Benjamin McAlexander, "Estimated Greenhouse Gas Emissions from EPAS Treatment of Maine Drinking Water," Maine Policy Review, Vol. 31 at 41 (2022): https://digitalcommons.library.umaine.edu/mpr/vol31/iss1/4/.]. The report explains that GAC is sourced either directly from coal or generated by high-temperature treatment of biomass, and in some states (like Maine), there are no GAC manufacturers, so they must be transported by freight [FN175: Id. at 42.]. Also, the report discusses that GAC would be an "add-on" to many water treatment systems because it is not effective for typical drinking water contaminants like arsenic; thus, "[t]hese factors combined may mean substantial GHG emissions."[FN176: Id.]

EPA Response: See section 13.11 of the EPA response in this *Response to Comments* document. Additionally, see section 13.9 of the EPA response in this *Response to Comments*

document in response to comments recommending the EPA pursue economy wide modeling for this rulemaking.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-047697)

3. Non-Market Social Costs

Social Costs from Electricity/Energy Use of Treatment Systems

Complying with the proposed MCL will increase demand for electricity and other energy sources. Since some sources of electricity emit greenhouse gases (GHGs), increasing demand for electricity through this proposed regulatory action will incrementally increase total GHG emissions. EPA recently acknowledged this social cost of a proposed regulation in the Hazardous Organic NESHAP proposed rule and quantified the social costs [FN123: U.S. Environmental Protection Agency, "New Source Performance Standards for the Synthetic Organic Chemical Manufacturing Industry and National Emission Standards for Hazardous Air Pollutants for the Synthetic Organic Chemical Manufacturing Industry and Group I & II Polymers and Resins Industry," Proposed Rule (Federal Register, April 2023), 25197.]. This analysis applies a similar methodology to estimate the social costs from increased GHG emissions due to this proposed rule.

The social cost of carbon dioxide (SC-CO2) is defined as the discounted stream of damages caused by releasing one ton of CO2 today. EPA's models track the long-term damages from global warming to 2300. Since CO2 persists in the atmosphere, the value of avoiding a release today requires tracking the future damages caused by that ton over the next few centuries. Therefore, the SCC value for a given year is the discounted present value of the estimated stream of damages from today to 2300.

EPA's Report on the Social Cost of Greenhouse Gases, published as part of its regulatory impact analysis for Docket EPA-HQ-OAR-2021-0317, includes the cost of greenhouse gases by discount rate per year [FN124: U.S. Environmental Protection Agency, "Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances," September 2022, 120–21.]. Costs per metric ton range from $130 to $370 at 2.5 and 1.5 percent discount rates, respectively, in 2026; and $190 to $460 at 2.5 and 1.5 percent discount rates, respectively, in 2046 [FN125: The SC- CO2 is the discounted stream of damages caused by releasing one ton of CO2. EPA's models track the long-term damages to 2300. Since CO2 persists in the atmosphere, the value of avoiding a release today requires tracking the future damages caused by that ton over the next few centuries. Therefore, the SC- CO2 value for a given year is the discounted present value of that stream of damages from today to 2300.].

EPA's estimation process generates separate distributions of estimates based on different damage modules and near-term target discount rates of the social cost of each gas in each emissions year [FN126: U.S. Environmental Protection Agency, "Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances," 2.]. Table 16 gives EPA's values.

Table 17: SC-CO2 by Discount Rate and Emission Year ($/mt)

[Table 17: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: See section 13.11 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045616)

Social Costs of Carbon Dioxide

To comply with this rule, most water systems with PFAS exceeding the MCL(s) will need to install drinking water treatment facilities that rely on either GAC, IX, or RO. In many cases, it is likely that this will create a new hydraulic profile for the water system which requires additional facility pumping and consequently electricity demand. The use of GAC and IX also requires disposal of spent material involving transport of that material via train or truck to an appropriate facility. These activities can be reasonably anticipated to have a significant impact on the carbon footprint of water systems nationally.

EPA is currently heavily involved in addressing challenges with climate change and in advancing sectors of the U.S. economy towards reducing greenhouse gas emissions. Section 5 of President Biden's Executive Order 13990, notes that it is "essential that agencies capture the full costs of greenhouse gas emissions as accurately as possible, including by taking global damages into account" and that doing so "facilitates sound decision-making" (Biden, 2021).

The proposal lacks an analysis of the social costs of carbon. AWWA recommends that the agency consider the social costs of carbon as part of any PFAS rule's cost analysis to be comprehensive as well as to understand how this rule may have unintended consequences like increased social costs relating to carbon dioxide emissions.

In considering the social costs of carbon, the agency is encouraged to review a recent report by Policy Navigation Group (PNG, 2023). The current estimate for the social cost of carbon dioxide emissions varies, but a low estimate range is $130 to $190 per ton based on a recent EPA report (EPA, 2022h). In the Policy Navigation Report, they estimate the social costs of carbon using data from the EPA's current economic analysis and using available EPA guidance for estimating such costs. Policy Navigation Group estimates carbon emissions related to additional pumping, lighting, and ventilation associated with the PFAS proposed rule and concludes that the potential national social costs of the carbon emissions are $5 million annually. The $5 million would be in addition to the social costs associated with replacement of GAC and IX media as breakthrough occurs. Given that more than 4,300 water systems will rely on GAC and IX treatment for PFAS and will begin generating tens of thousands, if not hundreds of thousands of tons of spent GAC and IX resin it is important that the associated social costs are considered.

EPA estimated the total GAC and IX waste generation annually to perform a sensitivity analysis for managing these materials as hazardous wastes, but the estimated amount of waste generated is not reported. EPA estimated that water systems will need to install treatment for more than

64.8 million people to comply with the proposed rule; this will amount to more than 3 trillion gallons that will need to be treated annually. Calgon Carbon estimated one water treatment plant's GAC usage rate for PFAS treatment was as high as 0.07 pounds GAC per 1000 gallons (Calgon, 2023). Based on these figures, the annual demand for GAC could exceed 100,000 tons, which potentially has a carbon dioxide footprint of 850,000 tons (He, 2012). This could have a social cost of more than $160 million annually.

With such a significant potential impact on society, EPA should conduct the same analysis to determine the social costs of carbon associated with each of the treatment technologies and the rule options. This analysis should also be included as a matter of maintaining consistency across the agency's rulemaking processes. In two recent rulemaking, EPA estimated the social costs of the rule in recognition that changes to the operation of complex treatment systems can provide both benefits and unintended consequences (EPA, 2023f; EPA 2023g).

EPA Response: See section 13.11 of the EPA response in this *Response to Comments* document.

14 Statutory and Executive Order Reviews

14.1 Executive Order 12866: Regulatory Planning and Review and Executive Order 14094: Modernizing Regulatory Review

The EPA received no public comments on Executive Order (EO) 12866: Regulatory Planning and Review and Executive Order 14094: Modernizing Regulatory Review.

14.2 Paperwork Reduction Act (PRA)

The EPA received no public comments on the Paperwork Reduction Act (PRA).

14.3 Regulatory Flexibility Act (RFA)

Summary of Major Public Comments and EPA Responses

Pursuant to sections 603 and 609(b) of the Regulatory Flexibility Act (RFA), the EPA prepared an initial regulatory flexibility analysis (IRFA) for the proposed rule and convened a Small Business Advocacy Review (SBAR) Panel to obtain advice and recommendations from small entity representatives (SERs) that potentially would be subject to the rule's requirements. For the final rule, as required by section 604 of the RFA, the EPA prepared a final regulatory flexibility analysis (FRFA) for this action. The FRFA addresses the issues raised by public comments on the IRFA for the proposed rule. See section XIII.C of the final rule preamble and Section 9.4 of the Economic Analysis (EA) for more information on the IRFA, FRFA, and the SBAR Panel process.

The EPA received comments from a few commenters where they suggest that the EPA did not follow the process as required by the RFA / Small Business Regulatory Enforcement Fairness Act (SBREFA) to conduct an SBAR Panel or that the process was incomplete. In addition, a couple of these commenters claimed that the SERs and Panel members did not have an opportunity to consider the specific requirements in the proposed regulatory action for PFNA, PFHxS, HFPO-DA, and PFBS. The commenters stated that they believed the EPA must convene a separate SBAR Panel to consider regulation of these four PFAS and use of the Hazard Index approach before finalizing any regulation. A couple commenters also alleged that the EPA only presented the SERs with information on regulating PFOA and PFOS and that the EPA stated it would only consider other PFAS supported by the best available science. Commenters also stated that the EPA did not provide the SERs with the Maximum Contaminant Levels (MCLs), Maximum Contaminant Level Goals (MCLGs), or the technical details and analyses during the SBAR panel.

The agency strongly disagrees with these commenters that the EPA violated the RFA or that the SBAR Panel process was not fully complete. First, the RFA requires the EPA to prepare an IRFA for each proposed rule unless the EPA certifies the rule will not have a significant economic impact on a substantial number of small entities. A regulatory flexibility analysis

examines the type and number of small entities potentially subject to the rule, recordkeeping and compliance requirements, and significant regulatory alternatives, among other things. The EPA completed this analysis (see section 9.3 of the proposed rule EA (USEPA, 2023a)). Second, this IRFA was informed by the SBAR Panel that the EPA convened and concluded prior to rule proposal to obtain information and advice from SERs.

In regard to commenters' assertion that the EPA failed to provide specific MCLGs, MCLs, or other highly specific or specialized scientific information developed for the rule proposal, the EPA is not required under the RFA to provide specific numerical regulatory standards, such as MCLs or MCLGs, to small entities during the SBAR Panel process. As a part of the development of the National Primary Drinking Water Regulation (NPDWR), the EPA sought the input of the SERs via the SBAR panel process to inform the proposed rule and its proposed regulatory requirements, specifically seeking ways to minimize the regulatory burden on small entities. The proposed regulatory requirements had not been determined at that time because the EPA specifically wanted to seek the input from the SBAR panel and from other mandated consultations prior to proposing any economically significant regulation. The EPA therefore appropriately waited to determine many of the specific requirements such as the MCLs until after seeking the SERs' and SBAR panel's input on such specific numerical regulatory standard values. The SERS have an opportunity to comment on specific regulatory standard values during the public comment. Additionally, as described in the SBAR Panel materials, including the Panel report, available in the public docket (https://www.regulations.gov/document/EPA-HQ-OW-2022-0114-0048), the agency provided the SERs with a large amount of technical information, including information on the analytical measurement feasibility for the PFAS that the EPA is finalizing regulation, as well as the removal efficiencies of the available technologies and the ability for these PFAS to treat to or below the analytically feasible limits. The EPA also provided the system level estimated costs for treatment and monitoring, all of which are identical to the proposed and final rule treatment technologies and analytical methods for monitoring. The EPA further presented to SERs that, under the Safe Drinking Water Act (SDWA), the EPA must set the regulatory standard as close as feasible to the MCLG. Therefore, the EPA provided the SERs all of the information that the agency used in its evaluation of MCL feasibility as required by SDWA, and strongly disagrees that knowledge of the exact proposed regulatory standard values was necessary for the SERs to provide input on the EPA's feasibility determination. Furthermore, if the agency waited to consult with the SBAR panel until after it had made its MCL feasibility determination and developed other specific requirements of the regulation (e.g., monitoring requirements), the EPA would not have considered SER input prior to rule proposal.

As documented in the SBAR Panel materials, the EPA provided the SERs and Panel with a substantial quality and quantity of information and all of the information required under the RFA, including the number and type of entities potentially impacted; treatment technologies; analytical measurement information; potential compliance requirements and considerations that might be utilized directly relevant scope of the rule; small system level cost information; identification of all relevant federal rules which may duplicate, overlap, or conflict with the proposed rule; and, alternatives to reduce burden for small entities. The EPA notes that the Panel,

which consisted of representatives of the Small Business Administration Office of Advocacy, OMB, and the EPA, collectively developed the Panel's recommendations and concluded the Panel. Additionally, the EPA notes that though it is not required to adopt all of the Panels' recommendations, the EPA did consider all of the Panel recommendations and included nearly all of them as a part of the proposed or final rule including several flexibilities in monitoring requirements for small systems, such as the use of existing monitoring data to satisfy initial monitoring requirements and reduced initial monitoring requirements specifically for small groundwater systems (see section VIII of the final rule preamble), along with a nationwide two-year capital improvement MCL compliance extension (see section XII of the final rule preamble).

Finally, as noted by a commenter, and as provided in the SBAR Panel Report, the agency did provide to the SERs that it may include additional PFAS as supported by the best available science including if they were to be removed by the same technologies identified to SERs during the Panel process. Further, as demonstrated in Final Panel Report and Appendices, the EPA also presented multiple times to the SERs and other Panel members that the agency's final regulatory determinations for PFOA and PFOS outlined avenues that the agency is considering to further evaluate additional PFAS chemicals, other than PFOA and PFOS, and consider groups of PFAS as supported by use of the best available science for regulatory action in the development of the NPDWR. In this evaluation of other PFAS, in addition to noting for the SERs that the EPA would consider similar treatment technologies, the EPA also provided several other factors it would consider including the likelihood that the PFAS co-occur, the similarity of health effects and chemical structures, the environmental persistence characteristics, and the availability of accepted and approved analytical methods or indicators with comparable costs to those currently identified by the EPA to evaluate PFAS removal from drinking water, among other considerations. Further, it was specifically noted to the SERs that "EPA is evaluating regulating PFAS that are all able to be removed by the previously identified treatment technologies which also remove PFOA and PFOS. If a given PFAS or subclass of PFAS were to require a separate or different treatment technology compared to what is being considered for the removal of PFOA and PFOS, the EPA anticipates that the agency would evaluate those PFAS under a future regulatory action and would convene a separate SBAR Panel if it expects that such action would have a significant impact on a substantial number of small entities." The EPA did not identify any such PFAS. Moreover, the EPA provided to the SERs and Panel members background information related to health effects and drinking water occurrence on all six PFAS that the EPA is finalizing in this regulation, as well as SDWA regulatory development information related to the possible NPDWR regulatory standard constructs of MCLs (of which the Hazard Index is a proposed MCL standard) or Treatment Techniques. Based on all of these factors, the EPA strongly disagrees that the process was incomplete or that the requirements under the RFA were not satisfied.

Individual Public Comments

Raptor Pharm & Tox, Ltd (Doc. #1644, SBC-043426)

The US EPA also failed to properly conduct consultation with the small business community. The US EPA did not consider all impacted small businesses. The US EPA admits to only consulting with small business PWS's. That is improper, and US EPA must do a better job of identifying impacted small businesses as also including rate payers.

We thank the US EPA for the opportunity to comment.

EPA Response: The EPA disagrees that it failed to properly conduct consultation with small entities and refers the commenter to section 14.3 of the EPA response in this *Response to Comments* document. Additionally, as stated in section XIII.C of the final rule preamble, "For purposes of assessing the impacts of the final rule on small entities, the EPA considered small entities to be water systems serving 10,000 people or fewer. This is the threshold specified by Congress in the 1996 Amendments to SDWA for small water system flexibility provisions. As required by the RFA, the EPA proposed using this alternative definition in the FR (USEPA, 1998a), sought public comment, consulted with the Small Business Administration (SBA), and finalized the small water system threshold in the agency's Consumer Confidence Report (CCR) Regulation (USEPA, 1998b). As stated in the document, the alternative definition would apply to all future drinking water regulations."

Raptor Pharm & Tox, Ltd (Doc. #1644, SBC-043422)

In addition, EPA failed to consider the impacts of these regulations on small business entities. Yes, EPA consulted with operators of small PWS's. However, EPA did not consult with small businesses such as mine, or the millions of others, across the US, who will be significantly impacted by these costs. EPA needs to expand its outreach beyond just PWS's, because all small businesses are impacted by this rule. Thus, Raptor concludes that EPA did not fulfill its requirements with respect to consulting with impacted small businesses as it only considered a regulated entity as impacted by this regulation, when in fact, all rate payers, including small business rate payers, are actually impacted by this proposed regulatory action.

And, EPA needs to consider the impacts on the poor that are currently operating small businesses, or the poor who would have started small businesses but for the cost impacts of this proposal. When entrepreneurs cannot afford their family expenses, they clearly cannot afford to start new businesses. These impacts also need to be considered.

EPA Response: Please see the EPA response to comment Doc. #1644, SBC-043426 in section 14.3 in this *Response to Comments* document. As a part of the EPA's EA for NPDWRs, and as required under the SDWA, the agency evaluates costs to regulated entities (i.e., public water systems [PWSs]) and drinking water primacy agencies implementing NPDWRs. Additionally, as part of the development of the proposed and final rule, the agency held multiple

public outreach opportunities to seek the public's input on the NPDWR (see EPA's PFAS NPDWR website - https://www.epa.gov/sdwa/and-polyfluoroalkyl-substances-pfas - for more details).

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045925)

VII. The SBREFA Panel for This Rulemaking Did Not Have the Opportunity To Consider the Proposed Regulatory Action on PFNA, PFHxS, PFBS, and HFPO-DA

For purposes of considering impacts of the proposed rule on small entities, EPA completed an initial regulatory flexibility analysis on the proposed rule and convened a Small Business Regulatory Enforcement Fairness Act (SBREFA) panel under the Regulatory Flexibility Act (RFA) in May of 2022. While a SBREFA panel was convened for the PFOA and PFOS MCL, the panel was not presented with, nor did it specifically discuss, setting an MCL for PFNA, PFHxS, PFBS, or HFPO-DA. Rather, EPA indicated to the panel that it is developing a proposed MCL for PFOA and PFOS and "potentially other PFAS" and is "considering" groups or classes of PFAS [FN210: Final Report of the SBAR Panel on EPA Planned Proposed Rule Per and Polyfluoroalkyl Substances NPDWR at 7 (August 1, 2022): https://www.regulations.gov/document/EPA-HQ-OW-2022-0114-0048.]. The SBREFA panel also did not consider the Hazard Index approach for the four PFAS.

This lack of small entity input on a critical aspect of this proposed rule violates the RFA because EPA's proposed MCLs and MCLs for PFNA, PFHxS, PFBS, or HFPO-DA will have a significant impact on a substantial number of small entities. EPA acknowledges in the proposed rule that approximately 62,000 small public water systems could be impacted by the rule, which is a substantial number of small entities [FN211: 88 Fed. Reg. at 18732.]. The costs of complying with the rule (including monitoring and treatment) described in Section VI will be even more burdensome for small entities. Small entities will also have problems with the insufficient compliance timeline that does not provide for time needed to meet the practical requirements to deploy treatment technologies. EPA must convene a separate SBREFA panel to consider regulation of the four PFAS and use of the Hazard Index approach before it finalizes any regulation pertaining to these PFAS. It is critical, and required by the RFA, that EPA consider small business impacts of regulating these specific PFAS and the use of its novel Hazard Index approach.

EPA Response: The EPA disagrees that the SBAR Panel did not have an opportunity to consider the regulatory action or that the EPA must undertake a separate SBAR Panel. Please see section 14.3 of the EPA response in this *Response to Comments* document. Additionally, please see section 12.1 of the EPA response in this *Response to Comments* document regarding the MCL compliance timeline.

PFAS Regulatory Coalition (Doc. #1761, SBC-046090)

G. EPA's SBREFA panel review was incomplete.

The Regulatory Flexibility Act Section 609(b) requires EPA to conduct small business advocacy review panels when it is unable to certify that a rule will not have a significant economic impact on a substantial number of small businesses. The Small Business Regulatory Enforcement Fairness Act (SBREFA) mandates that these panels consist of representatives of the rulemaking agency, the Office of Management and Budget's Office of Information and Regulatory Affairs (OIRA), and the Small Business Administration's (SBA's) Chief Counsel for Advocacy. As explained by the SBA:

The panel solicits information and advice from small entity representatives (SERs), who are individuals that represent small entities affected by the proposal. SERs help the panel better understand the ramifications of the proposed rule. Invariably, the participation of SERs provides extremely valuable information on the real-world impacts and compliance costs of agency proposals. A Guide For Government Agencies: How to Comply with the Regulatory Flexibility Act (at 51)(2017).

In this case, EPA convened a SBREFA panel. But the panel's recommendations are only as useful and relevant as the information provided to the panel by EPA. In this case, EPA only presented to the SERs the proposal to regulate PFOS and PFOA and stated that it might consider other PFAS chemicals or even groups of PFAS as supported by use of the best available science. EPA never presented the SERs with the concept of the HI approach or how it might be implemented. Hence, the SBREFA panel had no input from the SERs on the HI approach, which ultimately became a critical aspect of the EPA Proposal. EPA should have reconvened the SBREFA Panel once it determined that it would include an HI approach in that Proposal.

In addition, the Panel recommended that EPA conduct and present costs of both non-hazardous and hazardous waste generation as a result of likely treatment mandates associated with the Proposal. The Panel's recommendation is entirely logical. EPA has already indicated an intention to address PFOA and PFOS (along with other PFAS substances) as hazardous constituents under RCRA. Moreover, EPA not only has proposed designating PFOS and PFOA as hazardous substances under CERCLA, but also plans to propose to add PFOA, PFOS, PFBS, and GenX as RCRA hazardous constituents.

Given these ongoing and planned regulatory actions, it is very likely that solid waste disposal facilities will refuse to accept waste that contains these PFAS, greatly increasing disposal costs of treatment residuals and other contaminated media. EPA's Regulatory Impact Analysis must recognize these impacts. Instead, EPA claims it need not address these costs by claiming that such wastes "are not currently" regulated as hazardous wastes. 88 Fed. Reg. 18701. It agreed to a preliminary sensitivity analysis "for illustrative purposes only," which is not a good faith effort to truly provide accurate impacts on costs likely associated with the EPA Proposal.

Finally, the Panel recommended that EPA provide for compliance extensions in recognition of likely laboratory capacity-related challenges. EPA responded that it or a state may grant up to a 2-year extension, but that it was not planning on granting any nationwide extensions, leaving small systems to seek state extensions. EPA should reserve its judgment on nationwide

extensions to see if, in fact, existing laboratory capacity is sufficient. Current experience with significant laboratory delays, coupled with a likely significant spike in demands over the next several years, makes it clear that EPA's pronouncement is premature.

EPA Response: The EPA disagrees that the SBAR Panel was incomplete or that the EPA must undertake a separate SBAR Panel. The commenter is also incorrect that the EPA did not present the SERs with information on other PFAS (including PFHxS, PFNA, HFPO-DA and PFBS) beyond PFOA or PFOS. Please see section 14.3 of the EPA response in this *Response to Comments* document regarding the RFA requirements and SBAR Panel process.

Regarding the costs of both non-hazardous and hazardous waste disposal, the EPA disagrees with the commenter's claim that the agency did not make a "good faith" effort in following the Panel's recommendation because the EPA presents these costs in both the proposed and final rule (see Appendix N of the Economic Analysis; USEPA, 2023b). Further, the EPA notes that neither a Comprehensive Environmental Response Compensation and Liability Act (CERCLA) hazardous substance designation, nor a Resource Conservation and Recovery Act (RCRA) hazardous constituent listing, is a RCRA hazardous waste listing. A CERCLA designation does not restrict, change, or recommend any specific activity or type of waste. The agency refers the commenter to section 10.4.2 of the EPA response in this *Response to Comments* document for additional information.

Finally, please see section 12.1 of the EPA response in this *Response to Comments* document pertaining to MCL compliance timeline and extension.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045478)

I. Background

A. The Office of Advocacy

Congress established the Office of Advocacy under Pub. L. 94-305 to represent the views of small entities before Federal agencies and Congress. Advocacy is an independent office within the U.S. Small Business Administration (SBA). As such, the views expressed by Advocacy do not necessarily reflect the views of the SBA or the Administration. The Regulatory Flexibility Act (RFA) [FN3: 5 U.S.C. §601 et seq.], as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA) [FN4: Pub. L. 104-121, Title II, 110 Stat. 857 (1996) (codified in various sections of 5 U.S.C. §601 et seq.).], gives small entities a voice in the rulemaking process. For all rules that are expected to have a significant economic impact on a substantial number of small entities, the RFA requires federal agencies to assess the impact of the proposed rule on small entities and to consider less burdensome alternatives.

The Small Business Jobs Act of 2010 requires agencies to give every appropriate consideration to comments provided by Advocacy [FN5: Small Business Jobs Act of 2010 (PL. 111-240) §1601.]. The agency must include a response to these written comments in any explanation or

discussion accompanying the final rule's publication in the Federal Register, unless the agency certifies that the public interest is not served by doing so [FN6:Id.].

Advocacy's comments are consistent with Congressional intent underlying the RFA, that

"[w]hen adopting regulations to protect the health, safety, and economic welfare of the nation, federal agencies should seek to achieve statutory goals as effectively and efficiently as possible without imposing unnecessary burdens on the public."[FN7:Id.]

B. The Proposed Rule

On March 29, 2023, EPA published its proposed National Primary Drinking Water Regulation (NPDWR) rulemaking, which includes the following per- and polyfluoroalkyl substances (PFAS):

• Perfluorooctanoic acid (PFOA),

• Perfluorooctane sulfonic acid (PFOS)

• Perfluorohexane sulfonic acid (PFHxS)

• Hexafluoropropylene oxide dimer acid (HFPO-DA) and its ammonium salt (also known as a GenX chemicals)

• Perfluorononanoic acid (PFNA)

• Perfluorobutane sulfonic acid (PFBS)

The proposed rule requires public water systems to monitor for these PFAS, notify the public of the levels of these PFAS, and reduce the levels of these PFAS in drinking water if they exceed the proposed standards. Reduction methods can include the installation of treatment technologies and disposal of PFAS residue from those treatment technologies such as granular activated carbon, anion exchange, nanofiltration and reverse osmosis or require switching to an alternative water source. The proposed rule would require compliance three years after promulgation.

The proposal contains several agency actions:

1. Proposed legally enforceable levels, called Maximum Contaminant Levels (MCLs), for PFOA and PFOS at 4 parts per trillion (ppt).

2. Proposed preliminary determination to regulate PFHxS, GenX chemicals, PFNA and PFBS, and mixtures of these PFAS.

3. Proposed MCLs for the above four PFAS at a unitless MCL of 1.0, based on a novel approach called a hazard index (HI), which is used to evaluate potential health risks from exposure to chemical mixtures.

4. Proposed health-based, non-enforceable Maximum Contaminant Level Goals (MCLGs) for these six PFAS. For PFOA and PFOS, the proposed MCLG is zero and for the PFAS mixture the agency proposes the same unitless 1.0 hazard index.

In advance of the proposed rule, EPA convened a small business advocacy review panel under SBREFA to consult with small entity representatives (SERs). EPA presented to the small entities some PFAS background, with only PFOA and PFOS specifically identified, and potential monitoring and reporting rule compliance considerations and treatment and feasibility considerations. EPA, however, did not provide the SERs with the identity of the other four PFAS, any MCL values, any MCLG values and the technical details and analyses supporting these additional elements.

EPA Response: The commenter is incorrect that that the SERs and SBAR Panel were not presented with information on other PFAS (including PFHxS, PFNA, HFPO-DA and PFBS) beyond PFOA or PFOS. The commenter is also incorrect that the EPA did not present technical details and analyses that support MCL values. Please see section 14.3 of the EPA response in this *Response to Comments* document regarding the RFA requirements and SBAR Panel process. The EPA notes that MCLGs are set as the maximum level of a contaminant in drinking water at which no known or anticipated adverse effect on the health of persons would occur, allowing an adequate margin of safety. The EPA notified the panel and SERs to the availability of the draft health documents under review by the EPA's Science Advisory Board that would be used to inform the MCLGs for PFOA and PFOS. The agency further notes that the toxicity assessments used to inform the health-based requirements for the four other PFAS were publicly available as well during the SBAR Panel process and during the rule proposal public comment period.

14.4 Unfunded Mandates Reform Act (UMRA)

The EPA received no public comments on the Unfunded Mandates Reform Act (UMRA).

14.5 Executive Order 13132: Federalism

Individual Public Comments

PFAS Regulatory Coalition (Doc. #1761, SBC-046091)

H. The Proposal fails to adequately explain consultation with local governments.

The Proposal contains a "federalism summary impact statement," and says a "summary report of the views expressed during federalism consultations is available in the Docket." 88 Fed. Reg. 18733-734. Yet, no specific document reference is provided. There is some discussion on this topic in the "Final Report of the Small Business Advocacy Review Panel on EPA's Planned Proposed Rule Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation." Dkt. No. EPA-HQ-OW-2022-0114-0048.

If EPA means to state that local government consultation was conducted within the SBREFA process, then this consultation fails to comply with SBREFA for the reason stated in Section G above – that EPA failed to present the key information included in the Proposal. Additionally, this consultation would have been limited to small entities, and did not extend to other local government entities. It also appears, from the EPA Proposal, that the Agency had one virtual meeting with a large group of organizations representing state and local governments, over a year ago, and then let those organizations submit written comments. If that is the full extent of consultation with local governments that EPA has conducted, then it has not complied with its legal obligations regarding federalism concerns.

EPA Response: The EPA disagrees that the proposal fails to adequately explain consultation with local governments. The EPA specifically consulted with state and local governments as a part of the Federalism consultation required under E.O. 13132 which is described in detail in section XIII.E. of the final rule preamble. Within this section, the EPA details the input received and how the agency evaluated and considered it as a part of the final rule development. Additionally, the commenter incorrectly states that the Federalism consultation summary report, which includes all input from those specifically consulted under E.O. 13132, including local governments, is not available in the public docket as it was provided for public review and comment upon the proposed rule publishing (see https://www.regulations.gov/document/EPA-HQ-OW-2022-0114-0706). The EPA further disagrees that the information provided to those consulted does not meet the EPA's legal obligations regarding federalism concerns as the EPA did present key information included in the proposal, such as PFAS drinking water health, occurrence, treatment, and cost information, as well as potential monitoring and Public Notification (PN) requirements.

14.6 Executive Order 13175: Consultation and Coordination with Indian Tribal Governments

Individual Public Comments

Oneida Nation (Doc. #1825, SBC-044273)

Tribal Consultation

The Oneida Nation has concerns about the lack of tribal consultation. The Federal Register notice for the proposed rulemaking, as originally published on June 27, 2021, determined that the rule would not have direct effect on tribal governments so held that tribal consultation was unnecessary. Tribal communities and natural resources that tribes, villages, and rancherias rely upon for subsistence and cultural practices are impacted by PFAS therefore consultation is absolutely necessary. The Oneida Nation requests that consultation be offered to tribes on proposed PFAS related rulemakings.

EPA Response: The EPA disagrees that the agency did not conduct the required Tribal consultation under E.O. 13175 as detailed in section XIII.F of the final rule preamble. This

section discusses the Tribal consultation that was held prior to rule proposal between February 7, 2022 through April 16, 2022. Additionally, the agency is unclear on what the commenter refers to as a Federal Register Notice (FRN) for the proposed rulemaking published on June 27, 2021, as this is not the date of the proposed rulemaking for the PFAS NPDWR which was published on March 29, 2023. To the extent that the commenter is referring to the EPA's proposed rule issued on March 29, 2023, the commenter is incorrect in stating that the EPA determined there would be no direct effect on Tribal governments. In fact, the agency did find that the proposed PFAS NPDWR would have Tribal implications and impose direct compliance costs on Tribal governments, which the federal government will not provide funds necessary to pay. In the EPA's development of the proposed and final rule, the EPA has presented information on these impacts (see section XIII.F of the final rule preamble).

14.7 Executive Order 13045: Protection of Children from Environmental Health and Safety Risks

Individual Public Comments

First Focus on Children (Doc. #1599, SBC-042334)

PFAS, otherwise known as "forever chemicals," pose serious risks to human health, but even more so to children's health. PFAS are man-made chemicals that are used in products that repel grease, water, and oil like water-resistant clothing or non-stick cookware. During and after production these chemicals leach into the air, water, and soil. Their strong chemical bonds mean that they don't break down in the environment or in the human body, meaning that PFAS levels in our blood will continue to increase over time with exposure.

The potential health complications from PFAS exposure are more severe for children, who consume more water in relation to their body mass in comparison to adults. Exposure at a young age also means that the chemicals will remain in their systems for the entirety of their lives. The CDC links increased PFAS exposure with changes in cholesterol, liver damage, and an increased risk of certain cancers. [FN1: "What are the health effects of PFAS?" Agency for Toxic Substances and Disease Registry, Centers for Disease Control and Prevention. November 1, 2022. https://www.atsdr.cdc.gov/pfas/health-effects/index.html.] Studies also show a clear link to a number of children's health issues.

Endocrine System Disruptions

PFAS are endocrine disruptors, meaning that they impact the body's hormonal regulation systems and may alter their function. Studies show that they may impair the production of developmental hormones like progesterone and testosterone, which are crucial for healthy development. [FN2: Rickard, Brittany P., Rizvi, Imran, and Fenton, Suzanne E. "Per- and poly-fluoroalkyl substances (PFAS) and female reproductive outcomes: PFAS elimination, endocrine-mediated effects, and disease." Toxicology, Vol. 465. January 15, 2022. https://www.sciencedirect.com/science/article/pii/S0300483X2100353X.] Children, who are

rapidly developing before, during, and after puberty, rely on appropriate hormonal balances to reach critical milestones in their development. Studies suggest that PFAS may impact thyroid function, which is linked to irregular menstruation and infertility in girls. [FN3: Ibid.] For both boys and girls, exposures to PFAS are shown to alter pubertal timing. [FN4: Ibid.]

Immune System Disruptions

PFAS may also inhibit immune system development, which is crucial during childhood. During the first years of life children develop their adaptive immune system and create antibodies that repeatedly recognize and attack foreign cells. This adaptive system is crucial for fighting infections and is the key to successful protection from disease via immunizations. However, exposure to PFAS is linked with immunosuppression in childhood. Research shows that PFAS suppress the immune system's response to vaccinations, leading to a decreased presence in antibodies in children with greater PFAS exposure. [FN5: von Holst, Haley, et al. "Perfluoroalkyl substances exposure and immunity, allergic response, infection, and asthma in children: review of epidemiologic studies." Heliyon, Vol. 7(10). October 12, 2021. https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8529509/.] Additionally, with antibodies diminished, new evidence suggests that exposure to PFAS, specifically FOS, may lead to an increased risk of infectious disease during childhood. [FN6: Ibid.]

As with many instances of water contamination, not all communities bear this burden equally. Children in low-income communities and communities of color are far more likely to be exposed to PFAS due to the greater presence of industrial manufacturing plants and lack of access to adequate healthcare. [FN7: National Academies of Sciences, Engineering, and Medicine; Health and Medicine Division; Division on Earth and Life Studies; Board on Population Health and Public Health Practice; Board on Environmental Studies and Toxicology; Committee on the Guidance on PFAS Testing and Health Outcomes. "Guidance on PFAS exposure, testing, and clinical follow up." National Academies Press (US). July 28, 2022. https://www.ncbi.nlm.nih.gov/books/NBK584707/.] By regulating PFAS, EPA eases the already taxing environmental toll that children in these communities face and makes strides to advance equity across the country.

Conclusion

Thank you for the opportunity to submit comments to this proposed rule. We are grateful that EPA is taking responsible steps to manage PFAS contamination and provide safe, clean drinking water for all. Please reach out to Abbie Malloy, Director, Health, Environmental, and Nutrition Policy, at abbiem@firstfocus.org with any questions.

Sincerely,

Bruce Lesley

President, First Focus on Children

EPA Response: The EPA acknowledges the information provided by the commenter and their support of the proposed regulation. In the development of the MCLGs for the regulated PFAS, the agency considered sensitive lifestages such as children, and determined the MCLGs considering these populations. Please see section 4.3.3 of the EPA response in this *Response to Comments* document and section 4 of the final rule preamble. The EPA agrees with the commenter that by regulating these six PFAS, the NPDWR will lower children's exposure to these and other PFAS in drinking water.

14.8 Executive Order 13211: Actions that Significantly Affect Energy Supply, Distribution, or Use

Individual Public Comments

Florida Section American Water Works Association - Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044493)

XV. Statutory and Executive Order Reviews, H. Executive Order 13211 : Actions That Significantly Affect Energy Supply, Distribution, or Use;

The Florid a Water Sector requests EPA reconsider its findings the proposed rule is not a "significant energy action" under Executive Order 13211. Either of the three treatment options provided by EPA will substantially raise energy use and costs at facilities with traditional treatment techniques. In a large state like Florida, the numerous facilities expected to need treatment changes will act as "sum of parts" increasing energy use significantly across the state. EPA should determine the energy consumption of the three recommended techniques and apply that to new national occurrence data for an improved national perspective. In addition, USEPA should calculate the increased greenhouse emissions from this energy use data using their calculator in order to understand the carbon footprint impact (please see https://www.epa.gov/energy/greenhouse-gas-equivalencies-calculator)

EPA Response: The EPA disagrees with the commenter that the drinking water treatment technologies identified under the final rule to address regulated PFAS will substantially raise energy use and costs at facilities with traditional treatment systems because, as discussed in section XIII.H of the final rule preamble, electricity consumed as a result of the final rule represents approximately 0.005 percent of total U.S. electricity consumption. Therefore, based on this finding, the EPA does not anticipate that this rule will have significant adverse effects on the supply, distribution, or use of energy as required to be evaluated under E.O. 13211. Regarding greenhouse gas emissions, based on this and other comments, for the final rule the EPA conducted an additional analysis of the disbenefits associated with operation of treatment technologies to comply with the standard. This analysis is summarized in section XIII.A.2 of the final rule preamble and in the EA for the final PFAS NPDWR (USEPA, 2024a). Please see section 13.11 of the EPA response in this *Response to Comments* document for further discussion.

14.9 National Technology Transfer and Advancement Act of 1995

The EPA received no public comments on the National Technology Transfer and Advancement Act of 1995.

14.10 Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations and Executive Order 14096: Revitalizing our Nation's Commitment to Environmental Justice for All

Summary of Major Public Comments and EPA Responses

Many commenters expressed support for the rule and the EPA's environmental justice (EJ) analysis, underscoring the rule's alignment with the administration's commitment to advancing EJ. Commenters point to evidence which suggests that PFAS exposure disproportionately affects communities with EJ concerns. Further, commenters state that these communities are particularly vulnerable to PFAS exposure and the associated health outcomes. Several commenters also assert that the rule is anticipated to benefit these communities with EJ concerns who are at a higher risk of PFAS exposure. Conversely, many commenters expressed concern about potential EJ implications of the final rule and urged the EPA to further consider these implications prior to final rule promulgation. Specifically, commenters presented concerns that the rule will disproportionately impact communities that already are overburdened with sociodemographic and environmental stressors. Additionally, several commenters voiced EJ concerns associated with implementation of the rule. Many commenters asserted that communities with EJ concerns may not have sufficient financial capacity to implement the rule (e.g., install treatment) and that this may further exacerbate existing disparities associated with PFAS exposure. Additionally, commenters stated that additional resources would likely be needed for communities with EJ concerns to successfully implement the rule, including targeted monitoring and sampling in these areas.

The EPA acknowledges commenters' support for this action and the agency's commitment to advancing EJ. Through this rule, the EPA reaffirms the importance of EJ considerations in agency activities, including rulemaking. The EPA acknowledges commenters' concerns regarding potential EJ implications of the rule. Under EO 14096, the EPA is directed to identify, analyze, and address disproportionate and adverse human health or environmental effects of agency actions on communities with EJ concerns. As such, the EPA believes that its EJ analysis accompanying the final rule has achieved this directive, because the EPA has assessed the demographic distribution of baseline PFAS exposure in drinking water as well as the anticipated distribution of benefits and costs that will result from the rule.

The EPA agrees with commenters that PFAS exposure may disproportionately affect communities with EJ concerns as the EPA's EJ analysis for the final rule demonstrates that some communities of color are anticipated to experience elevated baseline PFAS drinking water exposures compared to the entire sample population. Specifically, the percentage of non-Hispanic Black and Hispanic populations with PFAS in drinking water detected above baseline

thresholds is greater than the percentage of the total population served with PFAS exposure above these thresholds for all PFAS analytes examined in the EPA's analysis. The EPA believes that this action is likely to reduce existing disproportionate and adverse effects on people of color, low-income populations and/or Indigenous peoples. Across all hypothetical regulatory thresholds, elevated exposure—and thus reductions in exposure under the hypothetical regulatory scenarios—is anticipated to occur in communities of color and/or low-income populations. Additionally, the EPA's EJ analysis finds that across all health endpoints evaluated by the EPA, communities of color (i.e., Hispanic, non-Hispanic Black, and/or Other race/ethnicity groups) are anticipated to experience the greatest reductions in adverse health effects associated with PFAS exposure, resulting in the greatest quantified benefits associated with the final rule. As such, the EPA agrees with commenters that the rule is anticipated to benefit communities with EJ concerns. When examining costs anticipated to result from the final rule, the EPA finds that cost differences across both race/ethnicity and income groups are typically small, with no clear unidirectional trend in cost differences based on demographic group. Additionally, incremental household costs to all race/ethnicity and income groups generally decrease as system size increases, which is expected due to economies of scale. This is especially true if systems serving these communities are required to install treatment to comply with the final rule. To alleviate potential cost disparities identified by EPA's analysis, there may be an opportunity for many communities to utilize Bipartisan Infrastructure Law (BIL) (P.L. 117-58) funding to provide financial assistance for addressing emerging contaminants. BIL funding has specific allocations for both disadvantaged and/or small communities and emerging contaminants, including PFAS. For responses to comments regarding funding available through BIL, please see section 2.4 of the EPA response in this *Response to Comments* document.

The EPA acknowledges the potential for implementation challenges for communities with EJ concerns; however, in response to commenters' concerns that communities with EJ concerns may not have sufficient financial capacity to implement the rule, there may be opportunities for many communities to utilize external funding streams to address such challenges. The BIL, the Low-Income Water Household Assistance Program through the American Rescue Plan, and other funding sources may be able to provide financial assistance for addressing emerging contaminants. In particular, the BIL funding has specific allocations for disadvantaged and/or small communities to address emerging contaminants, including PFAS. For example, the Emerging Contaminants in Small or Disadvantaged Communities (EC-SDC) grants program, which does not have a cost-sharing requirement, will provide states and territories with $5 billion to provide grants to PWSs in small or disadvantaged communities to address emerging contaminants, including PFAS. Grants will be awarded non-competitively to states and territories.

Many commenters stated that the costs of the rule will disproportionately fall on communities with EJ concerns. Additionally, some commenters asserted that the EPA's EJ analysis does not appropriately consider the distributional impacts of rule costs, with one commenter incorrectly stating that the analysis "fails to consider how these increased compliance costs will impact EJ communities, as required by Executive Order 12898". Commenters recommended that the EPA

revise its analysis to reflect the impact that compliance costs of the rule will have on communities with potential EJ concerns.

The EPA disagrees with commenters that the EPA has failed to appropriately consider the impact that costs required to implement the rule may have on communities with potential EJ concerns. The agency has fulfilled its commitments in this rulemaking by conducting an analysis consistent with Executive Order 14096 and has shared information on the demographic distribution of impacts evaluated in its EJ analysis to facilitate the public's understanding on potential EJ impacts of the rule. As described above, the EPA's EJ analysis assesses the demographic distribution of both benefits and costs anticipated to result from the final rule. The EPA also disagrees that the costs of this action will disproportionately fall on communities with EJ concerns. In Section 8.4.2.2 of its EJ Analysis (found in Chapter 8 of the EA (USEPA, 2024a)), the EPA estimated the distribution of annualized incremental household costs across different race/ethnicity groups. As described in section XIII.J of the preamble for this action and as stated above in this summary, the EPA found that cost differences across race/ethnicity groups are typically small, with no clear unidirectional trend in cost differences based on demographic group. In some cases, the EPA found that communities of color are anticipated to bear minimally increased costs but in other cases, costs to communities of color are lower than those across all demographic groups. In response to commenters, in order to more comprehensively examine the impact of the distribution of costs of this action, the EPA has updated its analysis to also examine the distribution of benefits and costs across income groups. With respect to the distribution of costs, the EPA found that, similar to its findings based on race/ethnicity group, differences in annual incremental household costs across income groups were typically small with no unidirectional trend in cost differences based on income level.

For more information on the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA, 2024a) and Appendix M of the EA (USEPA, 2024b).

Individual Public Comments

Isabelle Dominguez (Doc. #1525, SBC-042626)

Though PFAS exposure is widespread, some communities are at a higher risk of exposure than others. A report by the Union of Concerned Scientists found that "low-income communities, communities of color, and Indigenous communities bear the brunt of the consequences of" nonaction concerning pollution, particularly the effects of PFAS in drinking water. [FN8: See generally ANITA DESIKAN, ET AL., UNION OF CONCERNED SCIENTISTS, ABANDONED SCIENCE, BROKEN PROMISES (2019), https://www.ucsusa.org/sites/default/files/2019-10/abandoned-science-broken-promises-web-final.pdf.] This is because such communities are more likely to live near industrial areas, where PFAS accumulation is higher. [FN9: Xindi C. Hu et al., Detection of Poly- and Perfluoroalkyl Substances (PFASs) in U.S. Drinking Water Linked to Industrial Sites, Military Fire Training Areas, and Wastewater Treatment Plants, 3 ENV'T SCI. TECH. LETTER 344, 345 (2016).] Moreover, these are

communities that, without funding from the federal government, cannot afford to upgrade their water systems to account for PFAS exposure. [FN10: See DESIKAN, ET AL., supra note 8, at 2.]

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding. The EPA acknowledges the commenter's submission of these citations and notes that Desikan et al. (2019) and Hu et al. (2016) are cited in the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in in Section 8.2 of the EA (USEPA, 2024a).

Linda Shosie (Doc. #1533, SBC-043957)

My main focus is to continue to empower underserved, disadvantaged EJ, and Hispanic/Latino communities, to influence, encourage and facilitate community engagement of those potentially affected, throughout the agency's regulatory, cleanup, and decision-making processes that may affect their environment and public health.

I was born, raised, and have lived my entire life in the Tucson South-side area. I currently live in the central part of Tucson, near the Davis- Monthan Air Force Base Installations (DM-AFB) and a little bit further from the Tucson International Airport (TIA) Superfund site. I love Tucson, which is a vibrant community surrounded by a beautiful desert environment. We are also the home of two tribal nations, the Tohono O'odham Nation and the Pascua Yaqui Tribe.

However, our community has suffered severe harm because of PFOA, PFOS, and other toxic chemicals in our drinking water supply, which increases the risk of cancer and other serious diseases. Groundwater contamination from the Tucson International Airport and several Air Force Installations in and around Tucson, has turned the area around my home into a federal Superfund site and has threatened my health and the health of countless Tucson South-side residents.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule.

The EPA acknowledges the commenter's submission of concerns about drinking water in Tucson, AZ. Other than under SDWA, the EPA is initiating actions under multiple environmental authorities— the RCRA, Toxic Substances Control Act (TSCA), Clean Water Act (CWA), and CERCLA—to identify past and ongoing releases of PFAS into the environment at facilities where PFAS has been used, manufactured, discharged, disposed of, released, and/or spilled. The EPA is conducting inspections, issuing information requests, and collecting data to understand the level of contamination and current risks posed by PFAS to surrounding communities and will seek to address threats to human health with all its available tools. The EPA works with its federal, state and Tribal regulatory partners through a comprehensive SDWA

compliance monitoring program to protect human health and the environment by ensuring that the regulated community complies with environmental laws/regulations through on-site visits by qualified inspectors, and a review of the information the EPA or a state/Tribe requires to be submitted. Additionally, due to the toxicity and persistence of PFAS chemicals, and the breadth and scope of PFAS contamination throughout the country, the EPA selected Addressing Exposure to PFAS as a new National Enforcement and Compliance Initiative (NECI) for Fiscal Years 2024-2027. PFAS contamination is a significant priority for the EPA and, while the regulatory framework for PFAS continues to develop across multiple statutes, the EPA has already taken a number of enforcement actions to ensure compliance with existing statutes, including action to address an imminent and substantial endangerment to communities. The EPA will increase those efforts, particularly where necessary to protect drinking water supplies, as part of this new initiative.

Linda Shosie (Doc. #1533, SBC-043960)

For decades, studies have demonstrated that people of color and disadvantaged, vulnerable, low-income, marginalized, and indigenous peoples are disproportionately burdened by environmental hazards as well as cumulative adverse health effects from multiple co-occurring contaminants. According to more recent reports released by the World Health Organization more than a quarter of all death and disease in the world is attributable to the environment. Published research also suggests that communities with higher populations of people of color maybe especially impacted by PFAS. These reports justify what many who live on the South-side of Tucson feel. You only need to spend a few minutes with a longtime South-side resident before they start listing family members who have diseases that they believe are linked to drinking contaminated water from the Tucson International Airport Area Superfund Site.

I strongly believe that the Tucson contamination and the resulting health problems were not an act of God, but resulted from careless, reckless, and criminal industry waste behavior, lax governmental oversight, weak regulations, poor enforcement and callous indifference to human suffering because of environmental racism." Furthermore, in my view the Tucson historical environmental injustices and health inequalities associated with the Tucson International Airport Superfund Site, are a clear picture of an ongoing structural federal response failure to protect people of color, and low wealth populations exposed to toxic chemicals that did not just slip through the cracks of our broken system, but it was directly intended to fail by design, inadequate scientific methods available for investigating health outcomes related to toxic chemicals, that rarely generates any meaningful actions.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule and the EPA response to comment Doc. #1533, SBC-043957 in section 14.10 in this *Response to Comments* document regarding the commenter's concerns related to PFAS contamination in Tucson, AZ, including Superfund sites.

Linda Shosie (Doc. #1533, SBC-043965)

A 24 square-mile area on Tucson South-side was designated a Superfund Site, when the EPA discovered trichloroethylene (TCE) contamination in the drinking water, but the EPA never cleaned up the contamination. TCE is a well-known human carcinogen. In 2010, 1,4-Dioxane, another probable human carcinogen, was discovered in Tucson South-side drinking water supplies. Later, the EPA detected PFAS in the area as well, when our community group demanded more testing.

Over 50,000 South-sides residents are forced to drink, breathe, bathe, and cook in water laced with unknown trace amounts of cocktail mixtures of all these chemicals resulting in many health problems in our community. This contamination and the resulting illnesses were not and are not an "act of God" but resulted from careless and criminal manufacturing and industrial behavior, lax governmental oversight, weak regulations, poor enforcement and callous indifference to human suffering because of environmental racism.

To illustrate this a little better, at present, the federal and state government has not acted swiftly to prevent the spread of PFAS from entering into the water remediation system, and to avert the repetition of the environmental harms on this community. No attention has been placed on the victims of the contamination. Instead, the impacts of the contamination on the people who drank, bathed, and cooked from that contaminated water have been ignored, minimized, neglected or denied.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule and the EPA response to comment Doc. #1533, SBC-043957 in section 14.10 in this *Response to Comments* document regarding the commenter's concerns related to PFAS contamination in Tucson, AZ, including Superfund sites.

Regarding the commenter's assertion that the federal government "has not acted swiftly to prevent the spread of PFAS," the EPA is working as expeditiously as possible to promulgate this final rule to reduce exposure to PFAS in drinking water. The EPA notes that concerns related to exposure to contaminants other than the six PFAS regulated as part of this action are outside the scope of this regulatory action. However, the EPA notes that the agency's PFAS Strategic Roadmap (see: https://www.epa.gov/pfas/pfas-strategic-roadmap-epas-commitments-action-2021-2024) lays out a whole-of-agency approach to addressing PFAS, beyond the six PFAS included in this regulatory action. The actions described in the Roadmap represent meaningful steps to safeguard communities from PFAS contamination. For additional discussion about the EPA's PFAS Strategic Roadmap, please see section 15 of the EPA response in this *Response to Comments* document.

Kevin Korro (Doc. #1538, SBC-042656)

In addition, I am a supporter of the efforts being made by the Environmental Protection Agency (EPA) to assist people, particularly in underdeveloped regions, in securing access to safe drinking water. It is vital that all communities have access to clean and drinkable water, and I applaud the work that the EPA is doing to address environmental injustices. It is imperative that all communities have access to clean and drinkable water.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's support of this action and the agency's work to advance EJ.

Alliance of Nurses for Healthy Environments (Doc. #1544, SBC-042670)

EPA's proposed drinking water standards also align with the Biden Administration's commitment to advance environmental justice. Communities of color and low-income communities have historically faced disproportionate exposure to pollution and cumulative adverse health effects from multiple co-occurring contaminants. Published research suggests that communities with higher populations of people of color may be especially impacted by PFAS. By regulating six dangerous PFAS in drinking water, EPA's proposal helps to reduce overall PFAS exposure, and improve drinking water safety in thousands of communities across the country.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's support of this action and its alignment with the federal government's commitment to advancing EJ.

Dylan Pilger (Doc. #1546, SBC-042677)

The EPA must comply with OMB Statistical Directive 15 and disaggregate Asian and Pacific Islander data.

My second recommendation to the EPA is the disaggregation of Asian and Pacific Islander data for conducting the environmental justice analysis. According to USEPA 2023j pages M1-M12, Asian and Pacific Islanders had higher rates of PFAS exposure. However, it is unclear what differences might exist between Asian and Native Hawaiian or Other Pacific Islander (NHOPI) subpopulations without disaggregating data sets. While it may be helpful for gaining greater statistical power due to greater sample size, aggregation of data obscures differences between these unique subpopulations (Quint et al., 2021). This is particularly relevant in a place like Hawai‘i, where NHOPIs have substantial health disparities when compared to Asians (Look et al., 2020). There are also disparities in socioeconomic status and level of education between NHOPIs and Asians in Hawai‘i. Data disaggregation has revealed substantial differences in the

impacts of COVID-19 to NH, PI, and Asians (Quint et al., 2021). Furthermore, available data on NHOPI and Asians demographics by census place demonstrates that the population of each ethnic group varies greatly depending on geographic region (Hawaii Health Matters, n.d.-a, n.d.-b), suggesting that their risks to exposure to PFAS would be very different. It is clear that by not complying and disaggregating NHOPI and Asian subpopulations in data sets, valuable information will be obfuscated. Therefore, while the OMB order may not always be followed, in this case it is absolutely crucial that the EPA comply.

EPA Response: The EPA disagrees that its EJ analysis must disaggregate Asian and Pacific Islander data in order to comply with the Office of Management and Budget (OMB) Statistical Directive 15 (SPD 15) because SPD 15 establishes standards for maintaining, collecting, and presenting Federal data on race and ethnicity and applies to "all Federal reporting purposes" (OMB, 1977). This term is not defined and does not clearly apply to analyses developed to support rulemaking efforts. SPD 15 is targeted primarily toward data collection efforts, the development of data for public consumption, and the enforcement of civil rights laws. As SPD 15 is not applicable in the context of rulemakings, the EPA is not required to revise its EJ analysis in accordance with the standards for data disaggregation set forth in the OMB directive. However, the EPA acknowledges that reporting results separately for these groups can help to reveal potential disparities that may exist across Asian and Pacific Islander subpopulations. In response to this comment, the EPA has added a qualitative summary of the literature provided by the commenter and has also updated its analysis to include separate Asian and Pacific Islander demographic groups. These updates are reflected in Chapter 8 of the EA (USEPA, 2024a) and Appendix M of the EA (USEPA, 2024b).

Ross Renick (Doc. #1553, SBC-042561)

Although, I do believe addressing the drinking water concern should be the priority as it is the most apparent and complete pathway to human ingestion, I see environmental justice concerns with the implementation.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document.

Brooke Young (Doc. #1554, SBC-043973)

In addition, special consideration must be given to low-income and marginalized communities in Colorado that are impacted by PFAS in drinking water. These communities often are close to industrial locations and landfills that contribute to the contamination of source water. In addition, these communities don't always have access to proper healthcare or safe drinking water. To ensure they are treated equitably, I urge the EPA to require state and local authorities to monitor the drinking water in these communities more closely, provide tailored programs, ensure PFAS information is disseminated in a way that is more accessible, and engage with these communities in a more effective manner which encourages public involvement.

In conclusion, I favor stricter regulations on public drinking water regarding PFAS contamination to protect all Colorado communities and safeguard public health nationwide. Also, to be more mindful of marginalized communities regarding the proposed PFAS National Primary Drinking Water Regulation so that PFAS contamination is addressed equitably across all Colorado communities.

Best regards,

Brooke Young

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's submission of concerns about drinking water in Colorado; please see the EPA response to comment Doc. #1533, SBC-043957 in section 14.10 in this *Response to Comments* document.

With respect to the commenter's request that the EPA "require state and local authorities to monitor the drinking water in these communities more closely", the EPA notes that as part of this action, the agency is setting forth requirements for all CWSs and NTNCWSs to monitor for the six PFAS regulated under the final rule. For more information on the EPA's monitoring requirements for the final rule, please see section VIII of the preamble for this action. Additionally, while beyond the scope of this regulatory action, the fifth Unregulated Contaminant Monitoring Rule (UCMR 5) was published on December 27, 2021. UCMR 5 requires sample collection for 30 chemical contaminants, including 29 different PFAS, between 2023 and 2025 using analytical methods developed by the EPA and consensus organizations. This action provides the agency and other interested parties with scientifically valid data on the national occurrence of these contaminants in drinking water. Consistent with the EPA's PFAS Strategic Roadmap, UCMR 5 will provide new data that will improve the agency's understanding of the frequency that 29 per- and polyfluoroalkyl substances (PFAS) and lithium are found in the nation's drinking water systems, and at what levels.

With respect to the commenter's request that the EPA "ensure PFAS information is disseminated in a way that is more accessible," as part of this action, the agency is setting forth CCR and PN requirements. Systems must prepare and deliver to its customers an annual CCR, which provides customers with information about their local drinking water quality as well as information regarding the water system's compliance with drinking water regulations. Additionally, all systems must give the public notice for all violations of the final rule. For more information on the EPA's CCR and PN requirements for the final rule and responses to comments on these requirements, please see section IX of the preamble for this action and section 9 of the EPA response in this *Response to Comments* document, respectively. Additionally, the EPA notes that the agency intends to produce risk communication materials that can be used by utilities and others as they deem appropriate to communicate about PFAS in drinking water. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems in communicating with and notifying

their customers. For discussion of risk communication materials that the agency intends to develop related to this action, please see section 1.2 of the EPA response in this *Response to Comments* document.

With respect to the commenter's request for public engagement, the EPA notes that prior to both proposing and finalizing this regulatory action, the EPA provided many opportunities for public involvement through various engagements, consultations, and a public hearing. Specifically, on March 2, 2022 and April 5, 2022, the EPA held public meetings related to EJ and the development of the proposed NPDWR. The meetings provided an opportunity for the EPA to share information and for communities to offer input on EJ considerations related to the development of the proposed rule. Additionally, the EPA notes that, as outlined in the PFAS Strategic Roadmap (see https://www.epa.gov/pfas/pfas-strategic-roadmap-epas-commitments-action-2021-2024), the agency has begun a national engagement effort including community engagement events focused on each EPA Region and Tribal partners, national webinars, and stakeholder listening sessions. The agency also plans to engage directly with affected communities in every EPA Region to hear how PFAS contamination has impacted their lives and livelihoods. For additional discussion about the EPA's PFAS Strategic Roadmap, please see section 15 of the EPA response in this *Response to Comments* document.

Michigan Farm Bureau (MFB) (Doc. #1562, SBC-043360)

From the standpoint of environmental justice and minimizing disproportionate impacts to vulnerable communities including those in poverty, there is no way to calculate the cost of implementing these MCLs without concluding there will be a significant impact to these vulnerable communities, which necessitates EPA to work with other agencies and legislative efforts to ensure sufficient financial resources are made available to assist these public water suppliers with what they need to comply with final MCL concentrations.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups.

Minnesota Pollution Control Agency (MPCA) (Doc. #1569, SBC-042497)

Section XV - Statutory and Executive Order reviews

Topic: Part J, Executive Order 12898: Federal Actions to address environmental justice (EJ) in minority populations and low-income populations.

MPCA comments: EPA conducted two analyses to evaluate the impacts of the proposed MCLs on EJ communities: an exposure analysis using EJ Screen (EPA's EJ screening and mapping tool) and an alternatives analysis using SafeWater MCBC. EPA concludes enactment of the proposed MCLs will not…" have disproportionately high and adverse human health or

environmental impacts on minority or low-income populations" and will "mitigate the disproportionate impacts of baseline PFAS exposure."

While MPCA agrees with EPA's conclusion, we wish to highlight the externalities associated with contamination of all types, not just PFAS, and the costs that are borne as a matter of practice by the affected communities and their ratepayers. (By externalities, we mean phenomena where an activity affects one or more parties with the extent of these effects not being reflected in the costs of the activity. Examples are costs for testing and monitoring for contamination, informing the public, studying potential treatment and/or infrastructure investments, public employee staff time, etc.) As put forward by Cordner et al (2021), low-income communities may be unable to cover unplanned and unexpected expenditures, especially when a source of PFAS contamination has not been identified for potential cost recovery. This fact, coupled with historic racial discrimination and inequitable enforcement of environmental regulations in low-income communities, may still result in disproportionate impacts from exposure to PFAS in drinking water moving forward. Again, prevention of further PFAS pollution is a critical piece of tackling the problem of these forever chemicals.

EPA Response: The EPA acknowledges the commenter's support of the conclusions of the agency's EJ analysis. Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding. With respect to the commenter's concerns regarding costs associated with "testing and monitoring for contamination, informing the public, studying potential treatment and/or infrastructure investments, public employee staff time, etc.," the EPA has adequately considered costs of these activities as part of its EA for the final rule. Please see sections 13.3.1-13.3.6 for responses to comments on the EPA's estimation of costs, including primacy agency costs and water system costs (including treatment costs, monitoring costs, administrative costs including consideration of PN, and non-treatment costs). For discussion of technical assistance available to disadvantaged and/or small communities, including the EPA's WaterTA program, please see the EPA responses to comment Doc. #1640, SBC-044378 and comment Doc. #1608, SBC-044005 in section 14.10 in this *Response to Comments* document.

With respect to the commenter's assertion about inequitable enforcement of environmental regulations, please see the EPA response to comment Doc. #1640, SBC-044378 in section 14.10 in this *Response to Comments* document.

The EPA also acknowledges the commenter's concern that "prevention of further PFAS pollution is a critical piece of tackling the problems of these forever chemicals." While beyond the scope of this rulemaking action, in 2021, the EPA published the PFAS Strategic Roadmap, which sets timelines by which the EPA plans to take specific actions and commits to new policies to safeguard public health, protect the environment, and hold polluters accountable. The actions described in the PFAS Strategic Roadmap each represent important and meaningful steps to safeguard communities from PFAS contamination. Cumulatively, these actions will build upon one another and lead to more enduring and protective solutions. In the Roadmap, the EPA

notes that the agency "will bring deeper focus to preventing PFAS from entering the environment in the first place—a foundational step to reducing the exposure and potential risks of future PFAS contamination." Additionally, in the Roadmap, the EPA notes that "intervening at the beginning of the PFAS lifecycle—before they have entered the environment—is a foundational element of EPA's whole-of-agency approach." For additional discussion about the EPA's PFAS Strategic Roadmap, please see section 15 of the EPA response in this *Response to Comments* document.

San Gabriel Valley Water Association (SGVWA) (Doc. #1580, SBC-042423)

Our comments are intended to be constructive and ensure that the PFAS MCL is implemented equitably so that everyone has access to safe drinking water. As currently drafted, this standard may result in disparities between communities that can afford the necessary treatment methods and those that cannot. We hope that you will consider our feedback with this goal in mind.

Thank you for taking the time to consider our input.

Sincerely,

President, Board of Directors

San Gabriel Valley Water Association

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document.

American Public Works Association (APWA) (Doc. #1584, SBC-042389)

May 24, 2023

Submitted electronically to: https://www.regulations.gov

Michael S. Regan

Administrator

U.S. Environmental Protection Agency

1200 Pennsylvania Avenue NW

Washington, D.C. 20460

Re: EPA's Proposed PFAS NPDWR; Docket ID No. EPA-HQ-OW-2022-0114

Dear Administrator Regan:

On behalf of the more than 31,000 members of the American Public Works Association (APWA), we appreciate the opportunity to submit comments on the proposed rule for a National Primary Drinking Water Regulation (NPDWR) for Per- and polyfluoroalkyl substances (PFAS).

APWA members are responsible for an array of water infrastructure including drinking water, stormwater, and wastewater. In these roles APWA members understand and appreciate the efforts made towards cleaner water and have a long history of achieving compliance with NPDWRs along with providing subject matter expertise to policymakers at all levels and branches of government.

As they design, build, and maintain infrastructure they are simultaneously implementing and reviewing the law and serve as a wealth of knowledge. Additionally, APWA continues to be a proud supporter of the Infrastructure Investment and Jobs Act (IIJA) and the resources provided to deliver safe drinking water and address emerging contaminants. For decades limited guidance and resources were provided regarding PFAS, yet many public works professionals were at the forefront learning and tackling pollution from "forever chemicals".

At the same time, we would like to therefore stress the scale of the proposed undertaking and the likely need for further resources for many communities, especially those that are small, disadvantaged, and lacking in professional capacity. Otherwise, the costs will fall disproportionately on vulnerable populations with limited incomes and who are already underserved.

This is the first new contaminant to be regulated in drinking water in nearly 30 years and the first since Congress significantly amended the Safe Drinking Water Act (SDWA) in 1996. For many this will be a new experience and entail an additional learning curve especially given while the EPA has used a Hazard Index before to inform risks of chemical mixtures, this is the first time the agency has chosen to do so for a federal drinking water maximum contaminant level (MCL).

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding. The EPA acknowledges that there will be a learning curve for communities implementing the regulation, and the agency has considered associated costs for primacy agencies and water systems as part of its economic analysis. Please see sections 13.3.1-13.3.6 of the EPA response in this *Response to Comments* document for more information. Additionally, to provide communities necessary time to make capital improvements, which will allow them more time to develop plans to comply with the regulation where needed, the EPA has authorized a two-year extension for capital improvements. Please see section 12.1 of the EPA response in this *Response to Comments* document for more information. For more information on the Hazard Index, please see section V.B of the preamble for this action and sections 4.3.2 and 5.2 of the EPA response in this *Response to Comments* document.

Center for American Progress (CAP) (Doc. #1586, SBC-042388)

More research on PFAS and the extent to which all Americans, specifically disadvantaged communities and children, are exposed to them is needed, including the effect of each individual PFAS on health and the impact of exposure levels. This research may call attention to the need for greater, more stringent regulation, but at this moment, this proposed rule is an important step

to ensure all communities have access to safe drinking water. We strongly urge the EPA to safeguard public health and finalize the rule as proposed.

Sincerely,

Jill Rosenthal

Director, Public Health Policy

Sarah Millender

Research Assistant, Health Policy

EPA Response: The EPA acknowledges commenter's support for "finaliz[ing] the rule as proposed." Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule.

Public Health, Seattle & King County (PHSKC) (Doc. #1594, SBC-042354)

As the regulatory landscape and the scientific knowledge around PFAS is changing at a rapid pace, we want to ensure that health risks to sensitive populations and communities that have faced systemic environmental injustices are not overlooked.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-043986)

Funding – To realize the health benefits of this proposed rule, water utilities must have the financial resources to ensure they can sustain the ongoing costs that will arise from constructing, operating, maintaining, and monitoring PFAS treatment systems for the safety and benefit of customers. Low-income assistance must also be provided.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044005)

[American Water joins other water organizations in urging the U.S. EPA, Congress, and other decision-makers to implement policies that will:]

• ensure all water and wastewater utility providers, regardless of ownership, have equal access to any and all Federal and/or state funding related to treating PFAS; and

• establish a permanent federally funded water and wastewater low-income customer assistance program.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding. Establishing a federally funded low-income customer assistance program is outside the scope of this rulemaking action, though, as discussed in section 14.10 of the EPA response in this *Response to Comments* document above, external funding sources, including those under BIL, are available to assist with potential rule implementation challenges. Furthermore, the EPA notes that the agency is investing substantial resources in providing technical assistance to communities to improve drinking water quality, including reducing contaminants of emerging concern in finished drinking water. The EPA anticipates that new and existing EPA Water Technical Assistance (WaterTA) programs for PWSs, including some aimed at small and/or disadvantaged systems, will be utilized to support effective implementation of these goals. The EPA's free WaterTA services support communities to identify water challenges, develop plans, build capacity, and develop application materials to access water infrastructure funding. To implement WaterTA, the EPA collaborates with states, Tribes, territories, community partners, and other key stakeholders. For more information regarding this program and other funding availability, please see sections 1.2 and 2.4 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-043978)

American Water joins other water organizations in urging the U.S. EPA, Congress, and other decisionmakers to implement policies that will:

• keep harmful PFAS out of our drinking water supplies and our communities;

• exempt all water and wastewater systems from financial liability for PFAS under CERCLA;

• ensure all water and wastewater utility providers, regardless of ownership, have equal access to any and all Federal and/or state funding related to treating PFAS; and

• establish a permanent federally funded water and wastewater low-income customer assistance program.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding. Regarding the commenter's request for a federally funded water and wastewater low-income customer assistance program, please see the EPA response to comment Doc. #1608, SBC-044005 in section 14.10 in this *Response to Comments* document. For discussion related to source water protection and keeping PFAS out of drinking water supplies, please see the EPA response to comment Doc. #1569, SBC-042497 in section 14.10 in this *Response to Comments* document. Additionally, the EPA notes that concerns related specifically to financial liability for PFAS contamination under CERCLA are outside the scope of this regulatory action.

Wisconsin Conservation Voters (Doc. #1611, SBC-042860)

We know these health-related risks can impact everyone, but that they are having a disproportionately high impact on low-income communities and communities of color.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document.

Oakland County Water Resources Commissioner (WRC) (Doc. #1615, SBC-042927)

The cost of compliance must be given serious consideration. This is critical to meet state and federal environmental justice goals. Communities that cannot afford the increased cost of regulatory compliance, like Pontiac and Royal Oak Township, will be overly burdened. This inequity must be proactively addressed in any additional EPA regulations.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044056)

34. EPA requests comment on all aspects of its EJ analysis, particularly its choice of comparison groups to determine potential demographic disparities in anticipated PFAS exposure and its use of thresholds against which to examine anticipated exposures.

a. CWUC is concerned that impacts of increased water rates will affect disadvantaged communities the hardest.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. With respect to the commenter's concern about increased water rates, in the EPA's small system affordability analysis, the EPA analyzed the household level cost impacts of the final rule on small system size categories and determined the rule is affordable for small systems. The EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a).

WaterPIO (Doc. #1624, SBC-043467)

8. Finally, and perhaps most importantly to an EPA that rightly is focusing on communities of color and disadvantaged areas facing economic challenges, the costs of the EPA's proposed regulations will significantly harm the public by dramatically increasing the cost of their tap water. Except for rare circumstances where chemical companies are paying for advanced treatment to be placed on public water – WaterPIO has been in the middle of these confidential

agreements – the American people will be the ones forced to pay the bill for the impacts of the EPA's actions. It won't be America's PFAS polluters.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. While the EPA cannot speak to the specifics of confidential agreements cited by the commenter, despite the commenter's assertion otherwise, the EPA notes that the American people are not paying the bill "for the impacts of EPA's actions" nor will this regulation "significantly harm the public by dramatically increasing the cost of their tap water." Rather, costs incurred will be to remove regulated PFAS from finished drinking water, resulting in an impact of improved public health protection from significantly reducing instances of associated illnesses and deaths. In some cases, such as those alluded to by the commenter, the PFAS is from direct contamination of a point source discharge of PFAS or a known group of PFAS sources. The EPA is aware that in particular instances such as these that drinking water utilities have recovered necessary treatment costs from those entities whose actions caused the source water contamination. And in the situations cited by the commenter, the *polluter's actions* are responsible for the increased cost, not the EPA's actions. In other cases of PFAS contamination, there are not identifiable parties to hold accountable, and, in those circumstances, it is both the EPA's core mission and its responsibility under the SDWA to ensure that populations served by that contaminated drinking water are not exposed to harmful concentrations of PFAS by developing and finalizing this regulation. The agency notes that the utilities that serve these people will often be able to utilize federal funding, such as that discussed in section 2.4 of the EPA response in this *Response to Comments* document, to help offset the treatment costs. Responsible parties may also help offset the costs of treatment. As discussed in multiple sections of this rulemaking and hundreds of documents in this administrative record, the PFAS that the EPA is regulating in this action pose a significant public health burden, and while there will be costs associated with rule implementation, those costs are associated with actions taken to protect the American people. See section XIII of the preamble to this regulation for information about the EPA's cost analysis for the final rule and the numerous health benefits to reducing exposure to these and other PFAS, as well as sections 13.3 and 13.4 of the EPA response in this *Response to Comments* document for responses to public comments about specifics of the rule's costs and benefits, respectively. With regard to the commenter's concern about the cost of tap water, in the EPA's small system affordability analysis, the EPA analyzed the household level cost impacts of the final rule on small system size categories and determined the rule is affordable for small systems. The EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a).

<u>Illinois Farm Bureau (IFB) (Doc. #1630, SBC-043141)</u>

Rural Communities Will Be Disproportionately Impacted

Farmers serve as the backbone of many rural communities throughout the country. Rural communities and/or underserve communities have far less resources to address expensive federal regulatory requirements. Drinking water utilities in rural areas will undoubtably experience more challenges in meeting the 4ppt standard outlined in this proposed rule. Rural communities will incur extensive costs to obtain and install new technology. Then, uncertainty with testing availability/costs and lack of clarity with disposal methods/ costs only exacerbate our concerns.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule. In response to the commenter's concern regarding disproportionate impacts on rural communities, as discussed in section 14.10 of the EPA response in this *Response to Comments* document, in the EPA's EJ analysis for the final rule, the agency examined the demographic distribution of costs across multiple water system size categories and found that incremental household costs to all race/ethnicity and income groups generally decrease as system size increases, which is expected due to economies of scale. For more information on the findings of the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA, 2024a). To alleviate potential cost disparities identified by the EPA's analysis, there may be an opportunity for many communities to utilize BIL funding to provide financial assistance for addressing emerging contaminants. BIL funding has specific allocations for both disadvantaged and/or small communities and emerging contaminants, including PFAS. Additionally, if a water system, project, or project cost is not eligible under the Drinking Water State Revolving Fund (DWSRF), it may be eligible under other programs. These might include the U.S. Department of Agriculture's Rural Development program, the U.S. Department of Housing and Urban Development's Community Development Block Grant program, the Clean Water State Revolving Fund (CWSRF), the newly authorized Water Infrastructure Finance and Innovation Act (WIFIA) funding, or other federal, non-federal, or state funding sources.

In EPA's small system affordability analysis, the EPA analyzed the household level cost impacts of the final rule on small system size categories and determined the rule is affordable for small systems. While the EPA did not separately present the impacts of the final rule on rural communities, many rural communities are served by small systems. The EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a). Additionally, please see section 13.10 of the EPA response in this *Response to Comments* document for the EPA's responses related to affordability.

Additionally, please see section 14.3 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's actions taken as required under the RFA/SBREFA.

Rural Community Assistance Partnership Incorporated (RCAP) (Doc. #1633, SBC-044143)

EPA should prioritize the compliance of systems serving small, disadvantaged, and Environmental Justice communities.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding. With respect to the commenter's suggestion that the EPA "prioritize the compliance of systems serving small, disadvantaged, and Environmental Justice communities," the EPA notes that compliance with the MCLs for PFAS for all regulated PWSs is mandatory beginning 5 years from the date of rule promulgation. This regulation is applicable to all systems nationwide and does not prioritize compliance of any subset of water systems. The EPA, through BIL funding as discussed in section 14.10 of the EPA response in this *Response to Comments* document, has specific allocations for disadvantaged and/or small communities (e.g., the EC-SDC Grant program), which will aid in working toward rule compliance in these communities. The EPA's SDWA Enforcement Response Policy explains how the EPA typically pursues enforcement cases involving a water system's violations of the SDWA. Furthermore, as discussed in the EPA response to comment Doc. #1608, SBC-044005 in section 14.10 in this *Response to Comments* document, the EPA intends to provide significant technical assistance to affected communities, including "small, disadvantaged, and Environmental Justice communities."

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043454)

CARE Comment Six – Based on Evidence of Significant, Adverse and Disproportionate Harm, The Proposed Standards Are Essential To Achieve Environmental Justice

CARE represents environmental justice communities in Will County, Illinois. CARE recognizes and appreciates EPA's Environmental Justice Analysis of the proposed rule. It is reasonable to conclude, as the EPA has, that communities that are most impacted by PFAS contamination now are those that stand to benefit the most from the proposed PFAS MCLs. [FN70: Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation, U.S. EPA, March 2023, EPA Document Number: EPA-822-P-23-001, p. 318.] This conclusion aligns with other research indicating that low-income, Black, and Latino communities are disproportionately burdened with PFAS. [FN71: See Attachment 2, Jahred M. Liddie, Laurel A. Schaider, and Elsie M. Sunderland, "Sociodemographic Factors Are Associated with the Abundance of PFAS Sources and Detection in U.S. Community Water Systems", https://doi.org/10.1021/acs.est.2c07255.] CARE's three primary EJ concerns are discussed below.

EPA Must Address Inconsistent Monitoring and Enforcement

The potential benefits to environmental justice communities, such as CARE members in Will County, from this proposal are vital and CARE agrees with the conclusion that EJ communities

could benefit from the proposal. However, as stated above in the discussions on Monitoring and Exemptions, if exemptions are granted to small communities and those that can not afford capital costs related to PFAS filtration, then the EJ analysis of the proposal is illusory, at best. Benefits to EJ communities will be compromised if Primary Agencies are permitted to grant years-long exemptions to small or under resourced communities.

EPA Must Address Disproportionate Cost Burdens

CARE affirms the EPA's acknowledgement that increased costs related to the proposal may compound burdens on people of color. [FN72: Federal Register, Vol. 88, No. 60, p. 18735.] CARE is concerned, however, that the funding EPA proposes could be appropriated by Primary Agencies and PWS's for other purposes, such as the replacement of lead service lines. CARE encourages the EPA to identify funds with the restricted purpose of alleviating economic burdens on EJ community households that are caused by this rule. If the cost burden on small water systems is eliminated, it could foreseeably eliminate the need for exemptions as well, thereby addressing much of the EJ risk from this proposed rule's implementation.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's agreement with the conclusions of the agency's EJ analysis.

Based on this comment, the EPA has added Liddie et al. (2023) to the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in in Section 8.2 of the EA (USEPA, 2024a).

Additionally, the EPA notes that primacy agencies who have adopted the 1998 *Variance and Exemptions Regulation* (USEPA, 1998c) may choose to grant exemptions on a case-by-case basis to encourage systems facing compelling circumstances to come into compliance with the MCLs in an appropriate period of time. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12.1 of the EPA response on extensions and exemptions in this *Response to Comments* document. The EPA agrees with the commenter's assertion that benefits to communities with EJ concerns may be compromised if exemptions are granted as exempting particular systems from rule requirements may result in inequitable public health protection due to inequitable implementation of the final rule.

<u>Aidan Cecchetti (Doc. #1640, SBC-044378)</u>

• EPA requests comment on all aspects of its EJ analysis, particularly its choice of comparison groups to determine potential demographic disparities in anticipated PFAS exposure and its use of thresholds against which to examine anticipated exposures. For more information, please see section XV.J of this preamble (pg. 18735 Federal Register Volume 88, Number 60).

O It is not clear to the commenters whether EPA considered the inequitable application and enforcement of NPDWRs in the performed EJ analysis. For example, did EPA's analysis take

into account the fact that communities of color, and particularly African Americans and Native Americans, are most likely to suffer from environmental harms not only because of unequal distribution of pollution, but also because of unequal enforcement of existing laws? Additionally, many of these same vulnerable communities not only suffer from a lack of resources to mitigate the environmental harms they suffer, but also suffer from administrative burdens when seeking funding through the state and federal programs that EPA's EJ analysis pointed to as ways to help alleviate cost disparities. This suggests that EPA's EJ analysis may have overestimated the potential effectiveness of funding provided by these programs to reduce disparities. Although EPA's EJ analysis suggested that the greatest reductions in exposure and health benefits could be experienced by communities of color, it is not clear to the commenters that the analysis provides an accurate prediction of the impact of the new PFAS regulations if it did not appropriately consider the issues above.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. The EPA disagrees with the commenter's assertion that NPDWRs are inequitably applied and enforced, as the record does not support this, and the commenter does not provide any supporting rationale to substantiate this claim. The EPA also disagrees with the commenter's suggestion that the EPA's EJ analysis does not provide an "accurate prediction of the impact of the new PFAS regulations" due to the omission of an assessment of NPDWR compliance and enforcement in its analysis as the agency used the best available peer-reviewed information to assess the potential EJ impacts of this action. The EPA assumes 100 percent compliance for its national level analysis in its economic analysis for the final rulemaking because the EPA has determined that the final rule is feasible given known occurrence concentrations and efficacy of the technologies available. Further, this is consistent with the approach taken in EAs for other NPDWRs (USEPA, 2005; USEPA, 2019; USEPA, 2020). As such, the EPA does not assess variable compliance or enforcement of NPDWRs as part of its EJ analysis. The EPA also notes that compliance with the MCLs for PFAS for all regulated PWSs is mandatory beginning 5 years from the date of rule promulgation. The EPA's SDWA Enforcement Response Policy explains how the EPA typically pursues enforcement cases involving a water system's violations of the SDWA.

In response to the commenter's concern about communities with EJ concerns gaining access to adequate funding, the EPA acknowledges that communities with EJ concerns may face administrative burdens when seeking funding through state and federal programs, such as application processes, additional program requirements, or other barriers, which may discourage program participation from disadvantaged communities. A key priority of BIL is to ensure that disadvantaged communities benefit equitably from this historic investment in water infrastructure. The EPA has collaborated with state SRF programs to share examples and build state capacity to target resources to disadvantaged communities. In addition to the technical assistance offered by the states to disadvantaged communities, the EPA has a substantial water technical assistance program (WaterTA) – in close collaboration with states – to provide

assistance directly to communities including those that lack the financial, managerial, and technical capacity to access federal water infrastructure funding. The EPA's WaterTA efforts are focused on disadvantaged and underserved communities, communities that have never accessed SRF funding before, and communities that are not currently receiving an equivalent kind of TA. For more information on WaterTA, please see the EPA response to comment Doc. #1608, SBC-044005 in section 14.10 in this *Response to Comments* document or https://www.epa.gov/water-infrastructure/water-technical-assistance-waterta.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043260)

Small and rural communities are not responsible for introducing PFAS into the environment or the public's drinking water. Most of the public water systems impacted by PFAS are small and face more challenges complying with federal regulations than more complex water treatment systems. The issues below are the concerns of the small, rural, and disadvantaged water systems that EPA must address before finalizing this rule, and responses to EPA's request for comment.

Cost and Household Affordability

According to EPA's water system inventory, approximately 81 percent of all Public Water Systems (PWS) serve 3,300 or fewer people (39,746 of the total systems), and those serving 500 or fewer account for about 54 percent of all PWSs (26,742 of the total systems). PWSs serving 3,301–50,000 people represent about 17 percent of all PWSs (8,422 of the total systems), and those serving more than 50,000 people account for only about 2 percent (1,025 of the total systems).

Although PWSs serving 3,300 or fewer people account for approximately 81 percent of all PWSs, they serve fewer than 8 percent of the population and households that receive their water from a PWS. Although PWSs serving more than 50,000 people account for only 2 percent of all PWSs, they serve more than half (59 percent) of the population and households that receive their water from a PWS.

Based on these numbers, this rule needs to accurately analyze the impact on our smallest, and most disadvantaged communities. However, this rule was written for large water systems. Small systems with fewer households trying to comply with this regulation will experience financial hardship.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. Regarding the commenter's concerns about impacts to small, rural, and disadvantaged water systems, please see the EPA response to comment Doc. #1630, SBC-043141 in section 14.10 in this *Response to Comments* document.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043500)

Costs to rural households: As part of the AWWA analysis, the annual financial impacts to individual households from costs associated with the installation and operation of drinking water treatment facilities for PFAS were determined. The financial impacts to individual households will vary by specific PFAS levels, system size, and other factors. However, the trend that gives us greatest concern is the exorbitant impact this rule will place on small, rural communities. As illustrated in the graph below, meeting the 4ppt standard will be wildly more expensive for public water systems that service less populated areas. These financial burdens will be passed on to the water users—effectively becoming an added tax on drinking water for some of America's most economically disadvantaged communities. The AWWA report estimates the annual costs of this proposal on communities with populations of less than 100 will be between $10,000 and $11,000 per household. Many families throughout the country are already paying higher prices for everything from housing to food—and now higher rates for water. The excessive cost of this rule may force these families to make hard decisions on which essential services they can afford.

[Table 2: See Docket ID EPA-HQ-OW-2022-0114-1642]

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. Regarding the commenter's concerns about impacts to small, rural communities please see the EPA response to comment Doc. #1630, SBC-043141 in section 14.10 in this *Response to Comments* document.

In response to the commenter's reference to the American Water Works Association (AWWA) Black and Veatch (B&V) report findings, the EPA disagrees with many of the underlying assumptions in the AWWA B&V report's cost estimates which, on whole, result in overestimated household costs. These commenters cited cost information that is not representative of the range of treatment costs nationally, and the EPA disagrees with the commenter's cost model that systematically overestimates capital operation and treatment costs. For the EPA's response to comments on treatment costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Raptor Pharm & Tox, Ltd (Doc. #1644, SBC-043420)

Impacts on Small Businesses and the Poor

Raptor has already outlined several issues that America's small businesses and America's poor will face as a result of this action. Lowering the drinking water standard down to levels that are not scientifically supported, and which are also cost prohibitive to most water providers, will ultimately raise prices.

Environmental Justice will suffer due to these drinking water standards. Raising prices on small businesses and the poor during amazingly high inflation, where borrowing costs have

skyrocketed, where spending is down considerably across the economy will hurt small businesses run by BIPOC individuals, such as our company, and the poor the most.

Right now, poor families and small businesses have a hard enough time paying their bills. And everywhere we look, prices keep going up. Poor individuals have to make trade-offs about what bills to pay. Many small businesses are doing the same. Water is essential to life. Raising the cost of water in order to achieve a drinking water standard that is not supported by the science, where the potential benefits are non-existent, based on poorly done studies, on children from populations that are not genetically similar to our own, is no way to make decisions or policy.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups. The EPA disagrees with the commenter's assertion that "Environmental Justice will suffer due to these drinking water standards" as the EPA believes that this action is likely to reduce existing disproportionate and adverse effects on communities with EJ concerns. In the agency's EJ analysis, across all health endpoints evaluated by the EPA, communities of color are anticipated to experience the greatest quantified benefits associated with the final rule.

Regarding the commenter's concern for impacts to "poor families," as discussed in section 14.10 of the EPA response in this *Response to Comments* document, in the EPA's EJ analysis for the final rule, the agency examined the distribution of costs across demographic groups and across multiple water system size categories. As discussed in section 14.10 of the EPA response in this *Response to Comments* document, when examining costs anticipated to result from the rule, the EPA found that cost differences across race/ethnicity and income groups were typically small, with no clear unidirectional trend in cost differences based on demographic group.

In response to the commenter's mention of impacts on small businesses, please see section 14.3 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's actions taken as required under the RFA/SBREFA. For discussion of impacts to small water systems, please see the EPA response to comment Doc. #1630, SBC-043141 in section 14.10 in this *Response to Comments* document.

Additionally, the EPA disagrees with the commenter's assertion that the standards promulgated as part of this final action are "not scientifically supported". The EPA notes that the PFAS NPDWR is informed by regulatory development requirements under SDWA and includes the EPA's analysis of the best available and most recent peer-reviewed science. For further discussion of PFAS adverse health effects, please see sections II.B, III.B, and IV of the preamble for this action. The EPA also disagrees with the commenter's incorrect assertion that "the benefits are non-existent." The EPA has prepared robust benefits estimates for this action by compiling and synthesizing the best available and peer-reviewed information. Additionally, the Administrator determined at proposal that the benefits of the rule justify its costs. For further discussion of the EPA's responses to comments related to the agency's benefits estimates for this

action, please see section 13.4 of the EPA response in this *Response to Comments* document. For other discussion of scientifically-based decisions the agency has made, please see sections 4 (MCLGs), 5 (MCLs), 10 (treatment technologies), and 13 (costs and benefits) of the EPA response in this *Response to Comments* document for further discussion.

J.R. Simplot Company (Doc. #1661, SBC-044152)

Financial Assistance for These Costs and Available Resources Are Limited

The executive summary suggests that various grant funds are available to help communities pay for the installation of PFAS treatment for CWS through the Infrastructure Investment and Jobs Act. [FN4: Federal Register. 2023. Volume 88 (60). P.18,638.] The annual operation and maintenance costs of PFAS treatment equipment is substantial and won't be covered by these grants, so the annual cost burden will be placed on utility customers with higher water bills and especially impact low-income environmental justice communities.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups. For the EPA's responses to comments on treatment costs, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

Blue Ridge Environmental Defense League (BREDL) (Doc. #1663, SBC-044383)

EPA must adhere to their environmental justice goals, policies, and guidance—and instruct federally funded state agencies to do the same.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document.

Blue Ridge Environmental Defense League (BREDL) (Doc. #1663, SBC-044386)

Federally funded agencies should be held to EPA's environmental justice goals, principles, and guidelines. A recent peer-reviewed study from the Harvard T.H. Chan School of Public Health found that: "People who live in communities with higher proportions of Black and Hispanic/Latino residents are more likely to be exposed to harmful levels of per- and polyfluoroalkyl substances in their water supplies than people living in other communities…"[FN1: Harvard T.H. Chan School of Public Health. 15 May 2023. "Communities of color disproportionately exposed to PFAS pollution in drinking water" [Press Release]. https://www.hsph.harvard.edu/news/press-releases/communities-of-color-disproportionately-exposed-to-pfas-pollution-in-drinking-water/?fbclid=IwAR0AmmpNzFs26Pu1lIjKQZfq8E3sxOoWgOkHX3dUgP3td6rChxdAaVTVWYI] It is incumbent upon EPA to ensure that all communities are notified about any PFAS detected in their drinking water.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule. Regarding the commenter's assertion that "it is incumbent upon EPA to ensure that all communities are notified about any PFAS detected in their drinking water", for information on the SDWA "right-to-know" requirements for this final rule, including information that will be reported as part of CCRs and through PN to water system consumers, please see section IX of the preamble for this action.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044435)

Page 18732. Section XV – Statutory and Executive Order Reviews

EPA requests comment on all aspects of its EJ analysis, particularly its choice of comparison groups to determine potential demographic disparities in anticipated PFAS exposure and its use of thresholds against which to examine anticipated exposures. For more information, please see section XV.J of this preamble.

Page 18735 says this EJ evaluation was "based on availability of PFAS occurrence data."

• PFAS occurrence data is still fairly limited since public water systems are just now discovering their sources are contaminated with PFAS. Data EPA is using is likely biased, highlighting systems able to test for PFAS and have access to the right information and resources. EPA should consider re-evaluating the EJ impact once more PFAS occurrence data is available.

• More investigation is needed into the smaller, lower income systems that have not yet discovered PFAS contamination. These systems may experience detections of PFAS but may not have the means to install, monitor and maintain ongoing treatment.

EPA Response: The EPA disagrees with the commenter's assertion that PFAS occurrence data used by the EPA is "limited" and "biased" as the EPA believes the occurrence data that underly its rule analyses, including the EJ analysis, are sufficiently representative and robust. As discussed in Section 8.3.1.2.1 of the EPA's EJ analysis in the EA (USEPA, 2024a), this analysis uses modeled entry point concentration estimates from the Bayesian hierarchical Markov chain Monte Carlo (MCMC) occurrence model which employs a statistically robust framework. These modeled occurrence estimates are informed by data from the third UCMR (UCMR 3) and a robust amount of more recently available state monitoring data. For systems not sampled under UCMR 3, the EPA used state monitoring data to inform occurrence estimates used in its EJ analysis.

Additionally, the EPA notes that following the compliance date of the final rule, systems will be required to submit compliance data to states. As part of the EPA's Six-Year Review process set forth under SDWA, the EPA requests the submission of compliance monitoring data and related information by states, which may include newly available PFAS occurrence data. For more information on the EPA's analysis of PFAS occurrence data, please see section VI of the

preamble for this action and section 6 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043733)

Environmental Justice Aspects

Aurora Water strives to provide safe, equitable and affordable water to all its customers. With the current proposed MCLs, the city will likely be forced to increase rates to maintain and pay for additional compliance costs. Considering the sharp increases in cost of living for other essentials such as energy, food and gas, increased water rates further stretch financial burdens for our most vulnerable communities. EPA should be considering the financial burdens that water systems will incur from this rule which will ultimately have to be passed on to their customers.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. Regarding the commenter's concerns about water rates, in the EPA's small system affordability analysis, the EPA analyzed the household level cost impacts of the final rule on small system size categories and determined the rule is affordable for small systems. The EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a).

Arizona Corporation Commission (Doc. #1680, SBC-044218)

2. Additional federal funding and flexibility should be made available to small and disadvantaged water systems.

Historically, PFAS testing and monitoring expenses have been the responsibility of the utility with the understanding that the costs are ultimately passed along to customers through rates. The same has been true of remediation measures. The proposed rule will require significant system upgrades for many small and rural water systems. The treatment for PFAS-contaminated water supplies can pose a huge financial burden on public water supplies, especially small water systems, and low-income communities.2 [FN2: Desikan A, Carter J, Kinser S, Goldman G. 2019. Abandoned Science, Broken Promises: How the Trump Administration's Neglect of Science Is Leaving Marginalized Communities Further Behind. Cambridge, MA: Union of Concerned Scientists, p. 13 https://www.ucsusa.org/resources/abandoned-science-broken-promises ("Nearly 40,000 more low-income households and approximately 300,000 more people of color live within five miles of a site contaminated with PFAS than expected based on US census data.").] The expenses related to cleanup, filtration, and maintenance have significant environmental justice implications with respect to who has access to safe drinking water. Most of these systems cannot cover the costs to monitor and upgrade systems to meet the new MCLs without a significant increase in customer rates. These costs will be crippling for systems with small

customer bases. This highlights the need for additional federal funding grants, extending existing grant opportunities or targeted funds to address small and rural systems. The EPA should also consider whether extending compliance deadlines for small and rural systems is warranted to mitigate rate shock in low-income communities.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. In response to the commenter's concern regarding disproportionate impacts on small and rural water systems, please see the EPA response to comment Doc. #1630, SBC-043141 in section 14.10 in this *Response to Comments* document.

The EPA acknowledges the commenter's submission of this citation and notes that Desikan et al. (2019) is cited in the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in in Section 8.2 of the EA (USEPA, 2024a).

For the final rule, the EPA is extending the MCL compliance deadline to take effect five years after rule promulgation for all systems subject to the rule. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12.1 of the EPA response on extensions and exemptions in this *Response to Comments* document.

Environmental Working Group (EWG) (Doc. #1721, SBC-045404)

PFAS pollution is particularly concerning for low-income communities and communities that face historically disproportionate exposure to pollution, cumulative adverse health effects of multiple co-occurring contaminants, and potentially insurmountable costs of water treatment or remediation. Recent research suggests that communities where most residents are people of color are likely exposed to higher levels of PFAS in their drinking water. [FN8: Jahred M. Liddie, Laurel A. Schaider, & Elsie Sunderland, Sociodemographic Factors Are Associated with the Abundance of PFAS Sources and Detection in U.S. Community Water Systems, 57 ENV'T SCI. & TECH. 7902 (2023), https://pubs.acs.org/doi/10.1021/acs.est.2c07255. See also Susan Lee, Avinash Kar, & Anna Reade, Dirty Water: Toxic "Forever" PFAS Chemicals are Prevalent in the Drinking Water of Environmental Justice Communities, NAT. RES. DEF. COUNCIL (2021), https://www.nrdc.org/sites/default/files/dirty-water-pfas-ej-communities-report.pdf; Genna Reed, PFAS Contamination is an Equity Issue and President Trump's EPA is Failing to Fix It, UNION OF CONCERNED SCIENTISTS (Oct. 30, 2019), https://blog.ucsusa.org/genna-reed/pfas-contamination-is-an-equity-issue-president-trumps-epa-is-failing-to-fix-it/.] Indigenous communities that rely on subsistence fishing, hunting, and agriculture are especially vulnerable when fish, wildlife, and crops are contaminated with PFAS. These communities are doubly exposed when PFAS is also present in their drinking water. EPA's proposed maximum contaminant levels align with EPA's commitment to advance environmental justice by addressing historical contamination and deterring ongoing releases of these toxic chemicals into the environment.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. The EPA acknowledges the commenter's support of the final rule and its alignment with the agency's commitment to advancing EJ. Based on this comment, the EPA has added Liddie et al. (2023) to the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in in Section 8.2 of the EA (USEPA, 2024a).

Natural Resources Defense Council (NDRC) et al. (Doc. #1723, SBC-044468)

May 28, 2023

Administrator Michael S. Regan

U.S. Environmental Protection Agency

EPA Docket Center, OW Docket

Mail Code 28221T

1200 Pennsylvania Avenue NW

Washington, DC 20460

Re: Per- and Polyfluoroalkyl Substances (PFAS): Proposed National Primary Drinking Water Regulations (Docket ID: EPA-HQ-OW-2022-0114)

Dear Administrator Regan,

The undersigned thirty-nine organizations strongly support the Environmental Protection Agency's proposal to set strong, scientifically supported drinking water standards for six per- and polyfluoroalkyl substances (PFAS) under the Safe Drinking Water Act. National standards to limit the concentration of PFAS in drinking water are necessary to protect human health, as EPA has documented in its proposal. And they are long overdue. We urge you to finalize the proposed standards as quickly as possible, with the changes recommended by many of our organizations in separately submitted comments.

In this letter, we write specifically to urge EPA to resist calls to weaken or withdraw the proposed standards based on concerns over water affordability. We are steadfast advocates for universal, affordable access to safe drinking water. EPA must not accept the premise that drinking water can be either safe from toxic PFAS or affordable, but that it cannot be both. It can and must be both. And EPA must lead the way. We offer recommendations below on how to do so.

* * *

EPA's proposed PFAS standards align with the Biden Administration's commitment to advance environmental justice. Communities of color and low-income communities have historically

faced disproportionate exposure to pollution and cumulative adverse health effects from multiple co-occurring contaminants. Published research suggests that communities with higher populations of people of color may be especially impacted by PFAS.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. The EPA acknowledges the commenter's support of the final rule and its alignment with the federal government's commitment to advance EJ. The EPA is working as expeditiously as possible to promulgate this final rule to reduce exposure to PFAS in drinking water.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043575)

May 29, 2023

Michael Regan, Administrator

Environmental Protection Agency

1200 Pennsylvania Ave NW

Mail Code: 1309

Washington, DC 20004

RE: Per- and polyfluoroalkyl substances (PFAS): Perfluorooctanoic acid (PFOA) and Perfluorooctanesulfonic acid (PFOS) National Primary Drinking Water Regulation Rulemaking, Docket No. EPA–HQ–OW-2022-0114

Dear Administrator Regan:

I am the General Manager of Public Utility District No. 1 of Thurston County (Thurston PUD), a regional governmental public utility district in Washington State responsible for the operation and management of 78 small Group A water systems serving a population of over 21,000 families, businesses, parks, and schools. We have tested all our Group A water systems for PFAS, and I would like to submit testimony on the proposed EPA PFAS maximum contaminant levels (MCL). Under the proposed MCLs, nine (9) of our water systems would require treatment, which means that 68.3 percent of the customers on Thurston PUD's 78 Group A water systems would be exposed to PFAS materials above the proposed MCL.

Thurston PUD management and staff are dedicated drinking water professionals, and we understand and appreciate the efforts made to attain cleaner water. Our utility has a long history of achieving compliance within drinking water standards. We are grateful for the resources provided to deliver safe drinking water and address emerging contaminants like per- and polyfluoroalkyl substances (PFAS), particularly through the Infrastructure Investment and Jobs Act. At the same time, we would like to stress the scale of the proposed undertaking and the need

for financial relief for many communities, especially those that are small, disadvantaged, and lacking in professional capacity. Otherwise, the costs associated with the EPA's proposal risks falling disproportionately on vulnerable populations. We have studied and concur with the attached letter submitted to your office by Lakewood Water District (Lakewood, WA), dated May 24, 2023, addressing PFAS contamination of drinking water relating to this rule. To reiterate:

1. Costs are systematically underestimated.

2. Federal funding support is exaggerated.

3. The proposed trigger levels are inappropriate.

4. The proposed Hazard Index approach is flawed.

5. Penalties for monitoring are counterproductive.

6. The timeline to implement is not feasible.

This is the first new contaminant to be regulated in drinking water in three decades and the first since Congress significantly amended the Safe Drinking Water Act (SDWA) in 1996. This is a new experience for many and will entail an additional learning curve especially given this is the first time EPA has chosen to use a Hazard Index for a federal drinking water MCL.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. The EPA disagrees with the commenter's assertion that "costs associated with the EPA's proposal risks falling disproportionately on vulnerable populations." As explained in section 14.10 of the EPA response in this *Response to Comments* document, when examining costs anticipated to result from the rule, the EPA found that cost differences across demographic groups were typically small, with no clear unidirectional trend in cost differences based on demographic group. The EPA also disagrees with the commenter's assertion that "federal funding support is exaggerated." As discussed in section 14.10 of the EPA response in this *Response to Comments* document, to alleviate potential cost disparities identified by the EPA's analysis, there may be an opportunity for many communities to utilize BIL funding to provide financial assistance for addressing emerging contaminants. For further discussion of BIL funding, please see section 2.4 of the EPA response in this *Response to Comments* document.

The EPA disagrees that the costs of the rule are underestimated; please see section 13.3 of the EPA response in this *Response to Comments* document for the agency's responses to comments regarding the EPA's methods for estimating costs, including updates to the EPA's cost models based on public comments. The EPA also disagrees with the commenter's assertion that "the proposed trigger levels are inappropriate" and that "penalties for monitoring are counterproductive"; for responses to comments on the EPA's monitoring requirements, including trigger levels, please see section 8 of the EPA response in this *Response to Comments* document

(specifically section 8.8 for discussion of trigger levels). The EPA also disagrees that the Hazard Index approach is flawed; for more information on the Hazard Index, please see section V.B of the preamble for this action and sections 4.3.2 and 5.2 of the EPA response in this *Response to Comments* document. Finally, the EPA disagrees with the commenter's assertion that the "timeline to implement is not feasible," particularly because the EPA has extended its MCL compliance deadline to 5 years following final rule promulgation. For response to comments on the EPA's compliance timeline, please see section 12.1 of the EPA response in this *Response to Comments* document.

U.S Conference of Mayors, National League of Cities and National Association of Counties (Doc. #1733, SBC-043892)

Further, many American households currently face a significant and widespread financial burden when it comes to water bills. This burden falls disproportionately on fixed- and low- income households who must dedicate a significant portion of their income to water. Given the Administration's focus on environmental justice, water rate affordability must be a part of the consideration in this proposed regulation.

In light of the Administration's Justice40 initiative, EPA should additionally recognize that the financial burden on low-income and environmental justice communities associated with meeting environmental requirements is an important aspect of environmental justice. The financial burden that increased rates will have on disadvantaged communities should be a consideration in this and other rules and regulations.

This burden can be alleviated by providing additional flexibility for local governments, a longer compliance timeframe, and additional direct funding for local governments.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups. Regarding the commenter's concern about water rate affordability, in the EPA's small system affordability analysis, the EPA analyzed the household level cost impacts of the final rule on small system size categories and determined the rule is affordable for small systems. The EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a).

With respect to the commenter's suggestion for a longer compliance timeframe, the EPA notes that the agency has extended its MCL compliance deadline to 5 years following final rule promulgation. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12.1 of the EPA response on extensions and exemptions in this *Response to Comments* document.

With respect to the commenter's note about Justice40, following the establishment of the Justice40 Initiative under Executive Order 14008 on January 27, 2021, the EPA received Interim Guidance to support the implementation of Justice40 which included six programs as part of the Justice40 pilot. Since establishing the pilot program, the agency has expanded the number of applicable programs, including those programs funded by BIL that match criteria for Justice40. For a list of the EPA's Justice40 Initiative covered programs, please see: https://www.epa.gov/system/files/documents/2022-07/Justice40%20Initiative%20Covered%20Programs%20List%20for%20EPA.pdf. Though the PFAS NPDWR does not fall under the EPA's list of Justice40 Initiative covered programs, this regulatory action will facilitate the goals of Justice40 as the agency's EJ analysis found that communities of color are anticipated to experience the greatest quantified benefits associated with the final rule, as described in section 14.10 of the EPA response in this *Response to Comments* document. Additionally, the EPA found that cost differences across race/ethnicity and income groups to be small and BIL funding will be available to provide financial assistance in cases where cost disparities may occur, with specific allocations for disadvantaged and/or small communities (see section 14.10 of the EPA response in this *Response to Comments* document for further discussion). Additionally, for discussion of technical assistance available to disadvantaged and/or small communities, including the EPA's WaterTA program, please see the EPA responses to comment Doc. #1640, SBC-044378 and Doc. #1608, SBC-044005 in section 14.10 in this *Response to Comments* document. For more information on the EPA's implementation of Justice40, please see: https://www.epa.gov/environmentaljustice/justice40-epa.

Florida Section American Water Works Association - Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044494)

XV.Statutory and Executive Order Reviews, J. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations.

The Florida Water Sector requests EPA more adequately address Environmental Justice concerns based on the expected increase electrical use, carbon/coal consumption, fuel consumption, and the expected higher utility bills for our low-income and disadvantaged communities.

In closing , we thank EPA for the opportunity to provide import ant input on behalf of the FSAWWA WUC. If you have any questions regarding this correspondence, or we can be of assistance in anyway, please contact me at mwallis@dwuinc.com or 850-337-3945

Sincerely,

Monica Wallis, Chair

FSAWWA Water Utility Council

on behalf of the FSAWWA

EPA Response: The EPA believes it has appropriately and adequately addressed EJ considerations in this regulation. See section 14.10 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups.

In response to the commenter's stated concerns regarding "expected increase electrical use, carbon/coal consumption, fuel consumption," please see section 13.11 of the EPA response in this *Response to Comments* document. In response to comments on the proposed rule, the EPA analyzed the climate disbenefits of CO_2 emissions associated with the increased electricity use at PWSs as a result of compliance with the PFAS NPDWR. For more information on this analysis, please see Section 9.2 of the EA (USEPA, 2024a).

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045990)

EPA should consider the distribution of PFAS nationwide and understand that without additional federal support, the burden of treating PFAS will fall disproportionately on communities of color. AMWA supports the Agency's goal of fairly treating all people regardless of race, color, national origin, or income, with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies [FN29: EPA. (2023, May 12). Environmental justice. https://www.epa.gov/environmentaljustice]. However, in this proposal and related activities, EPA has failed to examine or plan for whether communities are treated fairly with regard to the costs required to implement this proposed regulation. A recent study by Liddie, Schaider, and Sunderland19 analyzed over 7,000 community water systems and found that CWSs "serving higher proportions of Hispanic/Latino and non-Hispanic Black residents had significantly increased odds of detecting several PFAS." This finding indicates that communities of color may be more likely to be in an area with industrial or other sources of PFAS contamination and that their community will likely have to treat more PFAS out of their water, increasing customer rates. In its final rulemaking, AMWA encourages EPA to consider how to partner with CWSs to ensure that communities of color are both equally protected from PFAS in drinking water and not disproportionately required to pay for contamination their communities did not create.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups.

Based on this comment, the EPA has added Liddie et al. (2023) to the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in in Section 8.2 of the EA (USEPA, 2024a).

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045985)

Environmental justice and climate change impacts are huge issues PWSs must address and are at the forefront of this Administration's priorities. However, this proposal not only puts underserved and disadvantaged communities at risk, but it will also significantly raise drinking water rates of some of the most vulnerable populations. A recent study by Liddie, Schaider, and Sunderland (2023) [FN 19: Liddie, Schaider, and Sunderland. (15 May 2023). Sociodemographic Factors Are Associated with the Abundance of PFAS Sources and Detection in U.S. Community Water Systems. Environmental Science & Technology. DOI: 10.1021/acs.est.2c07255], found that "[Community water systems] serving higher proportions of Hispanic/Latino and non-Hispanic Black residents had significantly increased odds of detecting several PFAS." Consequently, the costs of PFAS removal will not only fall on ratepayers, but it will disproportionately affect Hispanic/Latino and non-Hispanic Black ratepayers. EPA should reflect on this conclusion and work to reduce burdens on these communities when finalizing this proposal.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups. The EPA disagrees with the commenter's assertion that this action "puts underserved and disadvantaged communities at risk" and will "significantly raise drinking water rates of some of the most vulnerable populations;" please see the EPA response to comment Doc. #1644, SBC-043420 in section 14.10 in this *Response to Comments* document. Additionally, in the EPA's small system affordability analysis, the EPA analyzed the household level cost impacts of the final rule on small system size categories and determined the rule is affordable for small systems. The EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a).

Based on this comment, the EPA has added Liddie et al. (2023) to the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in Section 8.2 of the EA (USEPA, 2024a).

In response to the commenter's concerns about climate change impacts for PWSs, please see section 13.11 of the EPA response in this *Response to Comments* document. In response to comments on the proposed rule, the EPA analyzed the climate disbenefits of CO_2 emissions associated with the increased electricity use at PWSs as a result of compliance with the PFAS NPDWR. For more information on this analysis, please see Section 9.2 of the EA (USEPA, 2024a).

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045206)

7. CT DPH supports EPA's stated commitment to environmental justice for PFAS pollution. EPA's commitment to environmental justice reinforces the CT DPH's efforts to promote health

equity in disadvantaged communities. We support EPA's efforts and commitments to assisting disadvantaged communities.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's support of the EPA's commitment to EJ and commitments to assisting communities with EJ concerns.

City of Thornton, Colorado (Doc. #1748, SBC-044786)

Cost increases will disproportionately impact disadvantaged communities who may then have difficulty affording enough treatment media to meet the proposed MCL.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across demographic groups. With respect to the commenter's concern about communities affording treatment upgrades to comply with the final rule, the EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a).

City of Thornton, Colorado (Doc. #1748, SBC-044792)

Thornton's preliminary engineering efforts do indicate that an MCL of 4 ppt is technologically feasible to achieve but the City does note that this comes at a significant cost burden. However, Thornton is concerned with the environmental justice impact of the proposed rule. Rate increases, anticipated to be up to 19% over the next decade, to support the treatment of PFAS will be equally applied to all customers but will disproportionally impact our poorer residents. Thornton is also concerned that it will be financially challenging for many disadvantaged communities to meet the proposed MCL. Communities that are in a financial position, such as Thornton, will be able to target treating down toward the MCLG, whereas disadvantaged communities may choose to barely meet the MCL in an effort to save money rather than protect health as much as possible. These disadvantaged communities are usually collocated in heavily industrialized or heavily polluted areas and are disproportionately impacted by these compounds.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups. With respect to the commenter's concern that potential rate increases "will disproportionately impact our poorer residents," please also see the EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, which can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a).

The EPA concurs with the commenter that an MCL of 4.0 ppt for PFOA and PFOS is technologically feasible. With respect to the commenter's concern that the EPA's MCLs of 4 ppt carry a "significant cost burden", please see section 13.3 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's cost estimates for the final rule.

Harris County Attorney's Office (HCA) (Doc. #1751, SBC-045262)

PFAS exposure may disproportionally affect environmental justice communities. HCA asks EPA to ensure these residents and other low-resourced communities do not bear the brunt of cleanup costs.

Unfortunately, PFAS contamination appears to be ubiquitous across the county. One 2015 report indicates PFAS are found in the blood of 97% of Americans. [FN4: Perfluoroalkyl and Polyfluoroalkyl Substances (PFAS), Nat'l Inst. Env't Health Scis., https://www.niehs.nih.gov/health/topics/agents/pfc/index.cfm#footnote1 (last visited May 23, 2023); Ryan C. Lewis et al., Serum Biomarkers of Exposure to Perfluoroalkyl Substances in Relation to Serum Testosterone and Measures of Thyroid Function among Adults and Adolescents from NHANES 2011–2012, 12(6) Int'l J. Env't Rsch. Pub. Health 6098–6114 (2015).] Another study concluded that over 200 million Americans likely receive water with PFAS. [FN5:David Q. Andrews & Olga V. Naidenko, Population-Wide Exposure to Per- and Polyfluoroalkyl Substances from Drinking Water in the United States, 7(12) Env't Sci. & Tech. 931–936 (2020).] But, as with many environmental harms, recent studies indicate that environmental justice (EJ) communities appear to bear the disproportional brunt of PFAS pollution. For example, a study published on May 15th of this year concludes PFAS detection is positively associated with the number of PFAS sources and proportions of people of color who are served by the community water systems (CWS) studied. The study also concluded that CWS contaminated with PFAS serve greater proportions of Hispanic/Latino and non-Hispanic Black populations and contain greater numbers of PFAS sources within their watersheds. [FN6: Jared M. Liddie et al., Sociodemographic Factors are Associated with the Abundance of PFAS Sources and Detection in U.S Community Water Systems, 57(21) Env't Sci. & Tech. 7902, 7902 (2023) ("CWS watersheds with PFAS sources served higher proportions of Hispanic/Latino and non-Hispanic Black residents compared to those without PFAS sources. CWS serving higher proportions of Hispanic/Latino and non-Hispanic Black residents had significantly increased odds of detecting several PFAS.")] Reports by the Union of Concerned Scientist and the Natural Resource Defense Counsel also indicate PFAS exposure may disproportionately impact environmental justice communities. [FN7: Anita Desikan et al., Abandoned Science, Broken Promises, Union of Concerned Scientists, 13-14 (2019) https://www.ucsusa.org/sites/default/files/2019-10/abandoned-science-broken-promises-web-final.pdf ("Low-income communities, Indigenous communities, and communities of color may face increased contamination risks from an endocrinedisrupting class of chemicals known as PFAS (polyfluoroalkyl and perfluoroalkyl substances"); Susan Lee et al,, Dirty Water: Toxic "Forever" PFAS Chemicals Are Prevalent in the Drinking Water of Environmental Justice Communities, Nat. Res. Def. Council, 4 (2021) ("PFAS pollution is more intense in [Californian]

communities already overburdened by multiple sources of pollution and by other factors that make them more sensitive to pollution, putting those vulnerable communities at greater risk of harm from PFAS exposure").]

HCA is concerned that the cost of PFAS cleanup could be passed onto blameless residents. By EPA's own estimates, the total annual cost per household for the various potential compliance technologies is notably higher for the systems that serve a population of 25-500 than those that serve 501-3,300 and 3,301-10,000. Some residents in states that have enacted their own drinking water standards for PFAS have faced notable hikes in their water bills. [FN8: Danica Jefferies, Water PFAS clean-up costs could trickle down, NBC News, (Apr. 24, 2023) https://www.nbcnews.com/datagraphics/water-pfas-clean-costs-trickle-rcna80504.] The possibility that low-resource and overburdened communities served by PFAS heavy systems could face additional economic damage is especially troubling. HCA is concerned that a nationwide spike in demand for PFAS removal technologies will cause the price of compliance to rise drastically, and expensive drinking water bills will impact vulnerable members of the community living on fixed incomes.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups. With respect to the commenter's concern related to the cost of compliance technologies and the impact of "expensive drinking water bills," please also see the EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, which can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a) and section 13.3 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's cost estimates for the final rule.

Based on this comment, the EPA has added Liddie et al. (2023) to the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in in Section 8.2 of the EA (USEPA, 2024a). The EPA notes that Desikan et al. (2019) and Lee et al. (2021) are also cited in the EPA's literature review in Section 8.2.

American Water Works Association (AWWA) (Doc. #1759, SBC-045632)

12. Executive Order 12898 – Achieving Environmental Justice

AWWA and our members have first-hand knowledge and experience of how the increased costs associated with new regulations such as the ones proposed here directly impact the customers of our water system members. Many water systems are small, public, or quasi-public entities. Increased compliance costs are necessarily passed on to customers in the form of high rates for their drinking water. As a result, unjustified compliance costs have a disproportionate impact on economically disadvantaged customers as they are least able to afford these rate increases. This is disproportionate impact is particularly acute with respect to water infrastructure for several reasons. First, water systems serve local customers, they do not have the ability to spread costs

out across a national customer-base. Second, because household water use is a necessity and most households cannot meaningfully scale back on their needs for drinking water when prices increase. Consequently, they are unable to take steps to reduce their water bills when water systems are forced to increase rates.

Congress amended the SDWA in 1996, recognizing that the Act's prior requirements, and associated economic burdens on water systems and the States were making the SDWA unworkable. [FN26: S. Rep. No. 104-169 at 2, 11, 17 (1995); H.R. Rep. No. 104-632 at 9 (1996); see also S. Rep. No. 104-169 at 12−13 (noting that the prior version of the Ac was the "quintessential example of an arbitrary Federal law imposing burdens on consumers and the taxpayers of other governments with no rational relationship to the public benefits that might be realized.").] As a member of Congress explained at the time, "[c]ustomers will pay for safe drinking water . . . [b]ut are not willing to pay for complying with drinking water rules that provide only marginal increases in health protection at significant costs, particularly when there is so much uncertainty concerning both the occurrence and real threat to public health of many contaminants." [FN27: H.R. Rep. No. 104-632 at 9 (quoting Ronald Dungan, President of the National Association of Water Companies).]

EPA's current analysis also fails to consider how these increased compliance costs will impact environmental justice communities, as required by Executive Order 12898. As you know, Executive Order 12898 directs each Federal agency to "make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations." EPA should revise its environmental justice analysis to reflect the burdens that the compliance costs associated with the new proposed requirements would place on environmental justice communities and further consider whether these additional burdens are appropriate in light of these impacts.

AWWA further notes that prematurely issuing national primary drinking water regulations for contaminants when the occurrence data indicates that it only occurs in drinking water at levels of public health concern in localized areas would cause communities, rather than those responsible for the pollution, to foot the bill for the problem. To avoid this inequitable result EPA should focus on using its other authorities to address any necessary clean ups, rather than pass the costs on in the form of higher rates due to increased SDWA compliance costs.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups. With respect to the commenter's concern about water rates, please also see the EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, which can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a) and section 13.3 of the EPA response in this *Response to Comments* document for responses to comments on the EPA's cost estimates for the final rule. The EPA disagrees with the commenter's assertion that its analysis "fails to consider how these increased

compliance costs will impact environmental justice communities" because the EPA has presented the distribution of costs anticipated to result from the final rule across demographic groups in its EJ analysis; for further discussion, please see section 14.10 of the EPA response in this *Response to Comments* document.

The EPA notes that while the commenter states that PFAS "only occurs at levels of public health concern in localized areas" in this part of their comment letter (thereby implying that the EPA has overestimated the magnitude and importance of PFAS occurrence in drinking water), in other parts of their comment letter, the commenter claims that the EPA has underestimated PFAS occurrence (and therefore costs). The EPA disagrees with the commenter's assertion that the EPA is "prematurely issuing national primary drinking water regulations for contaminants when the occurrence data indicates that it only occurs in drinking water at levels of public health concern in localized areas" just as the agency disagrees with other commenters' other assertions that the EPA has significantly underestimated PFAS occurrence; for responses to comments related to the EPA's analysis of PFAS occurrence data, please see sections 3.1.2, 3.2.2, and 6 of the EPA response in this *Response to Comments* document.

Center for Environmental Health et al. (Doc. #1764, SBC-044239)

Radhika Fox

Assistant Administrator

Office of Water US Environmental Protection Agency

1200 Pennsylvania Avenue NW, Washington, DC 20460

Re: Docket ID No. EPA-HQ-OW-2022-0114: Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

Dear Assistant Administrator Fox:

We write to urge EPA to center environmental justice in the finalization of its Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation [FN1: US EPA. "PFAS National Primary Drinking Water Regulation Rulemaking", 88 Fed. Reg. 18,638 (Mar. 29, 2023) (the "Proposal").]. The undersigned organizations represent a diverse set of stakeholders across the State of North Carolina, considered by many to be the 'ground zero' of polyfluoroalkyl substances (PFAS) contamination in the US, and their allies across the nation. The proposed regulation is an important fulfillment of some of the commitments EPA made to regulate this persistent class of toxic chemicals. With enforcement of National Primary Drinking Water Standards (NPDWS) for PFOS and PFOA, EPA can finally begin to "turn off the tap" of PFAS at the source based on health-protective toxicity assessments.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's support of this action and the EPA's commitment

to regulate PFAS. Through this action, the EPA reaffirms the importance of EJ considerations in agency activities, including rulemaking.

Center for Environmental Health et al. (Doc. #1764, SBC-044245)

PFAS have been detected in drinking water supplies of nearly 200 million Americans, yet people of color and low-income Americans are particularly likely to have high levels of PFAS in their drinking water [FN5: J.M. Liddle, L. Schaider, and E.M. Sunderland. Sociodemographic Factors Are Associated with the Abundance of PFAS Sources and Detection in U.S. Community Water Systems. ACS Environmental Science and Technology, (May 15, 2023), DOI: 10.1021/acs.est.2c07255]. This is most likely due to the history of redlining and discriminatory zoning practices that incentivized companies to manufacture PFAS (and thousands of other toxic chemicals) near the most vulnerable communities. We urge the agency to quickly finalize the NPDWS proposal and improve its process of iteratively engaging these communities in its implementation and future enforcement actions. When PFAS is no longer detected in the drinking water of the most disadvantaged communities in North Carolina, it will surely confirm a reduction of these 'forever chemicals' in all of our bodies and the environment.

Sincerely,

Center for Environmental Health

Toxic Free North Carolina

Cape Fear River Watch

Clean Cape Fear

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's support of this action; the agency is working as expeditiously as possible to finalize the PFAS NPDWR. Through this action, the EPA reaffirms the importance of EJ considerations in agency activities, including rulemaking. With respect to the commenter's request for the EPA to "improve its process of iteratively engaging these communities," please see the EPA response to comment Doc. #1554, SBC-043973 in section 14.10 in this *Response to Comments* document.

Based on this comment, the EPA has added Liddie et al. (2023) to the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in Section 8.2 of the EA (USEPA, 2024a).

Sierra Club of Hawa''i (Doc. #1771, SBC-044731)

Environmental Justice

Water is a foundation for all life. However it is also a finite and threatened resource and in the face of climate change, access to clean safe drinking water will only become more difficult with disproportionate impacts on low-income communities of color. Our communities deserve to feel secure in their drinking water sources and not be reliant on expensive bottled water or filtration systems. Knowing the health and environmental impacts of Per- and Polyfluoroalkyl substances we cannot continue to turn a blind-eye to the contamination of our drinking water sources. The EPA's proposed standards will help provide a level of security that has not existed before.

Importantly, these standards create legal limits of PFAS chemicals in the water supply, meaning that legal action can be taken if the contaminants exceed these limits and are not addressed. The establishment of legal limits also provides clarification on the expectations for the use of PFAS chemicals and on the standards for providing safe, healthy drinking water for the public.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's support of this action and the EPA's commitment to regulate PFAS. Through this action, the EPA reaffirms the importance of EJ considerations in agency activities, including rulemaking.

Silent Spring Institute (Doc. #1784, SBC-045804)

5. EPA should target support towards communities and water systems that bear the brunt of PFAS contamination, including, but not limited to, small water systems, rural or isolated systems, overburdened systems, communities of color, low-income communities, and communities in proximity to PFAS-manufacturing and media-disposal facilities.

Our research and that of others demonstrates that PFAS contamination and remediation is an environmental justice issue. EPA's conclusion that "the proposed rule is anticipated to mitigate the disproportionate impacts of baseline PFAS exposure" is consistent and should be emphasized. We acknowledge, and support, that the proposed rule incorporates monitoring flexibilities and EPA's plans to provide financial assistance to support disadvantaged systems and communities for remediation.

Here, we highlight additional and recent research to emphasize why EPA should target support to systems and communities with disproportionate exposures to PFAS. Research from the Union of Concerned Scientists indicated a disproportionate number of low-income households (15% more than expected based on U.S. Census data) and of people of color (22% more than expected) living within 5 miles of a PFAS-contaminated site. [REF30: Desikan A, Carter J, Kinser S, Goldman G. Abandoned Science, Broken Promises: How the Trump Administration's Neglect of Science Is Leaving Marginalized Communities Further Behind. Cambridge, MA: Union of Concerned Scientists; 2019.] Recently, we identified that public water systems serving communities with higher proportions of non-Hispanic Black residents and Hispanic residents were more likely to detect PFAS contaminants, both from compiled state data [REF5: Liddie JM, Schaider LA, Sunderland EM. Sociodemographic factors are associated with the abundance of

PFAS sources and detection in U.S. community water systems. Environ Sci Technol. 2023.] and using the UCMR3. [REF31: Schaider L, Hernandez A, Swartz C, Liddie J. Socioeconomic disparities in exposures to unregulated industrial contaminants in U.S. public drinking water supplies [Conference Abstract]. International Society for Environmental Epidemiology; 2022.] We also note that Tribal communities were underrepresented in the UCMR3, which may mean that the extent of PFAS contamination among Tribal communities was underestimated. [REF32: Mok K, Salvatore D, Powers M, et al. Federal PFAS Testing and Tribal Public Water Systems. Environ Health Perspect. 2022;130(12):127701.]

Rural and isolated systems may not only have very high PFAS levels, but also may struggle to implement treatment technologies, cover analytical costs, or both. For example, the highest levels of PFOS and PFHxS measured in the UCMR3 were on the island of Saipan, located in the U.S. territory of the Northern Mariana Islands. Since the UCMR3, public water systems in both the islands of Saipan and Guam faced challenges in treating and monitoring PFAS in part due to the rural and isolated nature of these systems. These challenges highlight the environmental justice implications and the need for EPA to ensure equitable implementation and to plan support to focus on systems and communities that bear the brunt of PFAS contamination, cleanup, and remediation.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups. The EPA acknowledges the commenter's support of this action and the findings of the agency's EJ analysis. For responses to comments related to potential impacts of disposal of PFAS contaminated treatment residuals on communities adjacent to disposal facilities, please see section 10.4.3 of the EPA response in this *Response to Comments* document. With respect to the commenter's concerns regarding impacts on rural systems, please see the EPA response to comment Doc. #1630, SBC-043141 in section 14.10 in this *Response to Comments* document.

Based on this comment, the EPA has added Liddie et al. (2023) to the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in in Section 8.2 of the EA (USEPA, 2024a). The EPA notes that Desikan et al. (2019) is also cited in the EPA's literature review in Section 8.2.

In response to the commenter's assertion that "Tribal communities were underrepresented in the UCMR3," the EPA considers it important that all states, Tribes, and Territories are represented and have the opportunity to participate in the UCMR program. Therefore, for those PWSs that are not included as a census, the UCMR program uses a statistically-derived set of 800 small PWSs for the nationally representative sample (selected from all PWSs serving 10,000 or fewer people for UCMR 3) that is population-weighted within each geographic and source water category, ensuring that any PWS has an equivalent likelihood of selection and no group within the population is under-represented. The statistically-derived set of 800 small PWSs for the national sample also ensures UCMR is not biased towards any communities. Biasing the UCMR monitoring design by selecting communities in a non-random manner would compromise the

utility of the dataset in making accurate estimates of national contaminant occurrence used in regulatory decision-making. For UCMR 3, the agency worked with the Tribes, Alaska Natives, the Indian Health Services (His), and the states to determine how to classify each Tribal system for consideration in the statistically-based selection of the nationally representative sample of 800 small PWSs. Based on Tribal Consultation and the changes that were made, the EPA does not agree with the statement that Tribes were underrepresented in the nationally representative sample of small PWSs for UCMR 3 (USEPA, 2012). SDWA, as amended by Section 2021 of America's Water Infrastructure Act of 2018, expanded the number of PWSs included in UCMR 5 and future cycles, subject to the availability of appropriations. For example, in UCMR 5, all PWSs serving 3,300 or more people, and a nationally representative sample of small PWSs serving less than 3,300 people are required to monitor. The addition of these small PWSs ensures a similar rate of Tribal and non-Tribal systems participating in the UCMR program moving forward, subject to the availability of appropriations (USEPA, 2021).

Additionally, the EPA is working with Tribal PWSs to offer voluntary PFAS sampling. Sampling is ongoing, and many of these results have been compiled here: https://sdwis.epa.gov/ords/sfdw_pub/f?p=SDWIS_FED_REPORTS_PUBLIC:TRIBAL_PFAS. The EPA is also working with Tribal drinking water systems to ensure they have resources to address PFAS and other emerging contaminants. The Bipartisan Infrastructure Law has made substantial resources available to Tribes to help them identify and address PFAS and other emerging contaminants in drinking water through both the Drinking Water Infrastructure Grants Tribal Set-Aside and EC-SDC Grant programs, with more information found here: https://www.epa.gov/tribaldrinkingwater and https://www.epa.gov/dwcapacity/emerging-contaminants-ec-small-or-disadvantaged-communities-grant-sdc. There are no cost-sharing requirements for these programs. Federally recognized Tribes are eligible to access funds from both grant programs through the EPA Regional offices and are encouraged to reach out directly to the Regional Tribal Coordinators listed here to get more information on how to monitor for PFAS: https://www.epa.gov/tribaldrinkingwater/regional-tribal-drinking-water-coordinators. For further discussion regarding small Tribal water systems, please see the EPA response to comment Doc. #1598, SBC-042336 in section 1.4 in this *Response to Comments* document.

PFAS Project Lab (Doc. #1786, SBC-044717)

Environmental justice considerations

The burdens of PFAS exposure are not evenly distributed along geographic, racial or ethnic, and socioeconomic lines, and it is critical that EPA act now to ensure that communities are more evenly protected. A study utilizing CalEnviroScreen assessed the interplay between PFAS pollution and environmental justice communities and found that higher potential exposure to PFAS-contaminated water overlapped with communities experiencing the most disproportionate pollution and socioeconomic burdens (Lee et al. 2021). Notably, the most vulnerable communities (as determined by CalEnviroScreen) had either the highest levels of PFAS pollution or had not been tested for PFAS pollution at all. Silent Spring Institute also identified that water

systems serving communities with higher proportions of non-Hispanic Black residents and Hispanic residents were more likely to detect PFAS contaminants (Schaider et al. 2022).

Moreover, our PFAS Project Lab analyzed UCMR3 testing of PFAS levels in public drinking water systems (PWSs), and found that populations served by Tribal PWSs were significantly underrepresented in past nationwide PFAS sampling efforts, compared with populations served by non-Tribal PWSs. Moreover, predicted sampling for UCMR5 (2023-2025) will still exclude Tribal PWSs at a rate higher than the rest of the population. This research was published in Environmental Health Perspectives (Mok et al. 2022). It is thus critical that adopted regulations and funding take into account ways to support Tribal Nations and PWSs in addressing reporting and remediation under promulgated drinking water standards. Relatedly, the Tribal PFAS Working Group (TPWG) was formed in April 2020 and seeks to address and reduce impacts of PFAS on Tribal lands. We are honored to participate regularly with the TPWG, which has informed our understanding of their concerns about PFAS for Tribal Nations in the U.S. Continued collaboration between EPA and TPWG will be beneficial in implementing drinking water regulations.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's submission of these citations and notes that Lee et al. (2021) and a 2023 publication by Jahred M. Liddie, Laurel A. Schaider, and Elsie M. Sunderland (Liddie et al., 2023) are cited in the literature review conducted to supplement the EPA's EJ analysis for this rule, which can be found in in Section 8.2 of the EA (USEPA, 2024a).

With respect to the commenter's assertion that "populations served by Tribal PWSs were significantly underrepresented," please see the EPA response to comment Doc. #1784, SBC-045804 in section 14.10 in this *Response to Comments* document.

Bailey Smith (Doc. #1787, SBC-045807)

Second, this rule would benefit marginalized communities who are at higher risks of PFAS exposure, including those living nearby sites at which PFAS is used in large quantities (e.g., neighborhoods adjacent to military bases). [FN2: See e.g., Jared Hayes & Scott Faber (EWG), Suspected and Confirmed PFAS Pollution at U.S. Military Bases, EWG.ORG (Apr. 2, 200), https://www.ewg.org/news-insights/news/updated-map-suspected-and-confirmed-pfaspollution-us-military-bases; Tom Perkins, At least 12 military bases contaminating water supply with toxic PFAS, THEGUARDIAN.COM (June 6, 2022), https://www.theguardian.com/us-news/2022/jun/06/military-basescontaminating-water-supply-pfas.]

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's support of this action and agrees that the final rule is anticipated to benefit communities with EJ concerns.

Bailey Smith (Doc. #1787, SBC-045812)

II. EPA's Proposed Rule Protects Those At Heightened Risk of PFAS Exposure

EPA has stated that its proposed rule is "anticipated to mitigate the disproportionate impacts of baseline PFAS exposure."[FN43: Proposed Rule, supra note 3 at 18735.] This comment focuses on the disproportionate impacts of PFAS exposure with respect to neighborhoods adjacent to military communities. The Environmental Working Group has discovered that some of the highest PFAS detections in the United States exist on or near military sites. [FN44: Hayes & Faber, supra note 2.] Also, Department of Defense testing has revealed that dangerous levels of PFAS contaminate the water supplies in areas around twelve military bases. [FN45: Perkins, supra note 2.]

As a student at Georgetown University Law Center, I was enrolled in a course about toxic chemicals; during one of our class sessions, we were visited by two guest speakers. These two women lived in a neighborhood adjacent to a military site and their families suffered immeasurable heartache because of PFAS contaminating their drinking water. One woman's son was born with an incurable defect due to her unknowingly drinking PFAS-contaminated water while pregnant. The other woman had been previously diagnosed with cancer. These are real people who have been affected by PFAS contamination, and no one should have to endure what these women have experienced.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule. Through this action, the EPA reaffirms the importance of EJ considerations in agency activities, including rulemaking.

The EPA acknowledges the commenter's submission of information on elevated PFAS levels near military sites. The EPA notes that the literature review conducted to supplement the EJ analysis for this rule, which can be found in Section 8.2 of the EA (USEPA, 2024a), acknowledges and discusses sources of exposure to PFAS, including military sites.

Ohio Environmental Council (Doc. #1794, SBC-045325)

EPA's proposed drinking water standards also align with the Biden Administration's commitment to advance environmental justice. Communities of color and low-income communities have historically faced disproportionate exposure to pollution and cumulative adverse health effects from multiple co-occurring contaminants. Published research suggests that communities with higher populations of people of color may be especially impacted by PFAS. By regulating six dangerous PFAS in drinking water, EPA's proposal helps to reduce overall PFAS exposure, and improve drinking water safety in thousands of communities across the country.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final

rule. The EPA acknowledges the commenter's support of this action and its alignment with the federal government's commitment to advancing EJ.

Green America (Doc. #1809, SBC-045340)

This rule will especially benefit Black and brown communities who are disproportionately impacted by PFAS contamination. I urge the EPA to quickly finalize the regulations of these six PFAS chemicals and then address all other types of PFAS.

Names of 11,877 Signers:

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1809]

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule. The EPA agrees that that the final rule is anticipated to benefit communities with EJ concerns. The EPA acknowledges the commenter's support of this action and is working as expeditiously as possible to finalize the PFAS NPDWR. Additionally, with respect to the commenter's recommendation to "address all other types of PFAS," the EPA notes that the agency's PFAS Strategic Roadmap (see: https://www.epa.gov/pfas/pfas-strategic-roadmap-epas-commitments-action-2021-2024) lays out a whole-of-agency approach to addressing PFAS, beyond the six PFAS included in this regulatory action. The actions described in the Roadmap represent meaningful steps to safeguard communities from PFAS contamination. For additional discussion about the EPA's PFAS Strategic Roadmap, please see section 15 of the EPA response in this *Response to Comments* document.

Environmental Working Group et al. (Doc. #1810, SBC-044689)

EPA's proposed drinking water standards also align with the Biden Administration's commitment to advance environmental justice. Communities of color and low-income communities have historically faced disproportionate exposure to pollution and cumulative adverse health effects from multiple co-occurring contaminants. Published research suggests that communities with higher populations of people of color may be especially impacted by PFAS. By regulating six dangerous PFAS in drinking water, EPA's proposal helps to reduce overall PFAS exposure, and improve drinking water safety in thousands of communities across the country.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's support of this action and its alignment with the EPA's commitment to advance EJ.

National Wildlife Federation Action Fund (Doc. #1811, SBC-045344)

The PFAS crisis is widespread, contaminating the blood of humans, fish, and wildlife worldwide. Communities of color and low-income communities are particularly impacted by PFAS exposure, where health impacts are often compounded because these communities tend to face cumulative effects from multiple environmental injustices and public health hazards.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document.

National Wildlife Federation Action Fund (Doc. #1811, SBC-045342)

The PFAS crisis is widespread, contaminating the blood of humans, fish, and wildlife worldwide. Communities of color and low-income communities are particularly impacted by PFAS exposure, where health impacts are often compounded because these communities tend to face cumulative effects from multiple environmental injustices and public health hazards.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044676)

Additionally, nowhere in the proposed rule preamble does EPA thoroughly consider the effects on environmental justice and energy consumption. The real-world consequences from this rule (increased rates and energy use/consumption for treatment technologies) will impact all ratepayers, but particularly low- income and overburdened communities. PFAS levels in drinking water may be a very low public health priority for environmental justice communities and that reality should be accommodated in the rule. Otherwise, we risk spending unprecedented dollars on a low-priority community health issue. EPA could address this concern by allowing alternative implementation schedules based upon a State or EPA-approved community Integrated Plan.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups. The EPA disagrees with the commenter's assertion that the EPA has not "thoroughly considered the effects on environmental justice and energy consumption." With respect to EJ, as discussed in section 14.10 of the EPA response in this *Response to Comments* document, the agency has fulfilled its commitments as set forth under EOs 12898 and 14096 by conducting an EJ analysis for the final rule; for more information, please see Chapter 8 of the EA (USEPA, 2024a). With respect to energy consumption, as part of the proposal, the agency evaluated whether regulation of PFAS as part of this NPDWR will substantially raise energy use and costs at facilities with traditional treatment systems. As discussed in section XIII.H of the final rule preamble and the EPA response to comment Doc. #1737, SBC-044493 in section 14.8 in this *Response to*

Comments document, electricity consumed as a result of the final rule represents approximately 0.005 percent of total U.S. electricity consumption. Additionally, after considering public comments, the agency has estimated the potential climate disbenefits caused by increased on-site electricity demand associated with removing PFAS from drinking water. For more information, please see section 9.2 of the EA (USEPA, 2024a) for the final rule and section 13.11 of the EPA response in this *Response to Comments* document.

Regarding the commenter's concerns about the impact to ratepayers, in the EPA's small system affordability analysis, the EPA analyzed the household level cost impacts of the final rule on small system size categories and determined the rule is affordable for small systems. The EPA's affordability determination for the final rule, using longstanding EPA methodology and supplemental affordability analyses, can be found in Chapter 9.13 of the EA for the final rule (USEPA, 2024a).

The EPA disagrees with the commenter's assertion that "PFAS levels in drinking water may be a very low public health priority for environmental justice communities" as, once fully implemented, the final rule is anticipated to prevent thousands of deaths and reduce tens of thousands of serious PFAS-attributable illnesses. The Administrator has determined that the benefits of reducing PFAS in drinking water through this regulatory action justify the costs. For the quantified benefits analysis, the EPA relied on peer-reviewed literature and synthesis of multiple high-quality studies to evaluate the effects of PFAS exposure on human health. For responses to comments on the EPA's comparison of costs and benefits of this action, please see section 13.8 of the EPA response in this *Response to Comments* document. Additionally, as discussed in section 14.10 of the EPA response in this *Response to Comments* document, based on the results of its EJ analysis, the EPA believes that this action is likely to reduce existing disproportionate and adverse effects on communities with EJ concerns. In the agency's EJ analysis, across all health endpoints evaluated by the EPA, communities of color are anticipated to experience the greatest quantified benefits associated with the final rule.

In response to the commenter's suggestion that the EPA allow "alternate implementation schedules", the EPA notes that the agency has extended its MCL compliance deadline to 5 years following final rule promulgation; please see section 12.1 of the EPA response in this *Response to Comments* document for further discussion. Please also see the EPA response to comment Doc. #1638, SBC-043454 in section 14.10 in this *Response to Comments* document for discussion of exemptions.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044654)

Additionally, nowhere in the proposed rule preamble does EPA thoroughly consider the effects on environmental justice and energy consumption. The real-world consequences from this rule (increased rates and energy use/consumption for treatment technologies) will impact all ratepayers, but particularly low-income and overburdened communities. PFAS levels in drinking water may be a very low public health priority for environmental justice communities and that

reality should be accommodated in the rule. Otherwise, we risk spending unprecedented dollars on a low-priority community health issue. EPA could address this concern by allowing alternative implementation schedules based upon a State or EPA-approved community Integrated Plan.

EPA Response: Please see the EPA response to comment Doc. #1816, SBC-044676 in section 14.10 in this *Response to Comments* document and section 14.10 of the EPA response in this *Response to Comments* document.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044632)

Additionally, nowhere in the proposed rule preamble does EPA thoroughly consider the effects on environmental justice and energy consumption. The real-world consequences from this rule (increased rates and energy use/consumption for treatment technologies) will impact all ratepayers, but particularly low-income and overburdened communities. PFAS levels in drinking water may be a very low public health priority for environmental justice communities and that reality should be accommodated in the rule. Otherwise, we risk spending unprecedented dollars on a low-priority community health issue. EPA could address this concern by allowing alternative implementation schedules based upon a State or EPA-approved community Integrated Plan.

EPA Response: Please see the EPA response to comment Doc. #1816, SBC-044676 in section 14.10 in this *Response to Comments* document and section 14.10 of the EPA response in this *Response to Comments* document.

South Carolina Water Quality Association (Doc. #1819, SBC-044610)

Additionally, nowhere in the proposed rule preamble does EPA thoroughly consider the effects on environmental justice and energy consumption. The real-world consequences from this rule (increased rates and energy use/consumption for treatment technologies) will impact all ratepayers, but particularly low-income and overburdened communities. PFAS levels in drinking water may be a very low public health priority for environmental justice communities and that reality should be accommodated in the rule. Otherwise, we risk spending unprecedented dollars on a low-priority community health issue. EPA could address this concern by allowing alternative implementation schedules based upon a State or EPA-approved community Integrated Plan.

EPA Response: Please see the EPA response to comment Doc. #1816, SBC-044676 in section 14.10 in this *Response to Comments* document and section 14.10 of the EPA response in this *Response to Comments* document.

Wet Weather Partnership (Doc. #1820, SBC-044588)

Additionally, nowhere in the proposed rule preamble does EPA thoroughly consider the effects on environmental justice and energy consumption. The real-world consequences from this rule (increased rates and energy use/consumption for treatment technologies) will impact all ratepayers, but particularly low-income and overburdened communities. PFAS levels in drinking water may be a very low public health priority for environmental justice communities and that reality should be accommodated in the rule. Otherwise, we risk spending unprecedented dollars on a low-priority community health issue. EPA could address this concern by allowing alternative implementation schedules based upon a State or EPA-approved community Integrated Plan.

EPA Response: Please see the EPA response to comment Doc. #1816, SBC-044676 in section 14.10 in this *Response to Comments* document and section 14.10 of the EPA response in this *Response to Comments* document.

Sharon Levy (Doc. #1824, SBC-044276)

Pregnant women, young children, low income communities and people of color are extremely vulnerable.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for discussion of the EPA's EJ analysis and EJ considerations for the final rule, including funding and the EPA's analysis of costs across race/ethnicity and income groups. Additionally, pursuant to SDWA section 1412(b)(3)(C), the EPA evaluated the effects of the contaminants on the general population and sensitive subpopulations including infants, children, pregnant women, the elderly, and individuals with a history of serious illness.

Anonymous (Doc. #2318, SBC-047304)

I support that they are trying to help a lot of communities, including communities that face disadvantages because studies show that many low-income communities and minority communities are more likely to be given drinking water that is of lower quality and filled with a higher amount of chemicals.

EPA Response: Please see section 14.10 of the EPA response in this *Response to Comments* document for responses to comments regarding the EPA's EJ analysis and EJ considerations for the final rule. The EPA acknowledges the commenter's support of the agency's work to advance EJ through this action.

14.11 Consultations

14.11.1 Science Advisory Board

Individual Public Comments

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042873)

EPA's health advisories for perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS) are still considered "interim" and the Science Advisory Board (SAB) made several recommendations (EPA-SAB-22-008) [FN3: https://sab.epa.gov/ords/sab/f?p=100:0:11519146227520:APPLICATION_PROCESS=REPORT_DOC:::REPORT_ID:1105] when they reviewed EPA's scientific justification for setting the standards. On its website, EPA states "In the proposed rule, EPA presents updated noncancer toxicity values based on evaluating additional scientific information. These updated values are different from those used to calculate the 2022 interim HAs, which EPA based on the best available science at that time. EPA is accepting public comments on its proposed NPDWR, including on the proposed maximum contaminant level goals (MCLGs), other supporting information, and the draft 2023 toxicity values for PFOA and PFOS which are based on the best available science. Note that the MCLGs in the proposed rule are zero. The 2022 interim Health Advisories for PFOA and PFOS will continue to remain available as EPA finalizes a national primary drinking water regulation for those contaminants." It does not appear that EPA reconvened the SAB to discuss how they responded to the SAB's recommendations; MWWA recommends that those experts be convened to re-review EPA's new rationale. If EPA drops its health advisories because of this rulemaking process, there should be reasoning provided to the public for why the values are now different than the Interim Health Advisory levels. There was much press generated around the Interim Health Advisories in the parts per quadrillion, and as we will discuss later in our comments, communication related to PFAS is important. MWWA knows that PFAS contamination concerns are contributing to a loss of public confidence in tap water. If there has been a change to the way that EPA is viewing the science, the public deserves to hear in plain language why contaminants that were once deemed dangerous at parts per quadrillion are now being regulated with MCLs in the parts per trillion.

EPA Response: Please see section 4.1.3 of the EPA response in this *Response to Comments* document for responses to comments related to peer review of the science underlying the MCLGs for PFOA and PFOS. The agency also notes that the EPA's interim health advisories for PFOA and PFOS are beyond the scope of this rulemaking. The EPA further notes that commenter's characterization of Health Advisories appears to be incorrect and directs the commenter to relevant information on the EPA website (https://www.epa.gov/sdwa/drinking-water-health-advisories-has). Unlike MCLs, Health Advisories are non-regulatory, health-based values and are not developed with considerations of factors such as treatment technologies, costs, or analytical methods. Regarding the EPA's final MCLs, including feasibility, please see section 5 of the EPA response in this *Response to Comments* document.

The agency agrees with the commenter that public communication is extremely important and refers the commenter to section 1.2 of this document for additional information pertaining to the PFAS NPDWR communications.

Superfund Settlements Project (SSP) and RCRA Corrective Action Project (RCAP) (Doc. #1631, SBC-043429)

For all six PFAS addressed in the Proposal, EPA failed to use the best available, peer-reviewed science, importantly truncating the role of the Science Advisory Board ("SAB").

EPA Response: The EPA disagrees. See sections 4.1.2 and 4.1.3 of the EPA response in this *Response to Comments* document for comments related to the EPA's use of the best available science and peer review of the science underlying the MCLGs for PFOA and PFOS. Pertaining to the EPA's use of the best available science and peer review of the science underlying the Hazard Index MCLG for a mixture of HFPO-DA, PFNA, PFHxS, and/or PFBS and the individual MCLGs for HFPO-DA, PFNA, and PFHxS, please see sections 4.3.1, 4.3.2, and 4.3.3 of the EPA response in this *Response to Comments* document.

Superfund Settlements Project (SSP) and RCRA Corrective Action Project (RCAP) (Doc. #1631, SBC-043438)

Second, the SDWA expressly requires EPA to use "(i) the best available, peer-reviewed science and supporting studies conducted in accordance with sound and objective scientific practices; and (ii) data collected by accepted methods or best available methods (if reliability of the method and the nature of the decision justifies use of the data)." [FN60: 42 U.S.C. § 300g-1(b)(3)(A).] The Proposal fails to meet this basic instruction, most strikingly in the truncated or absent role SAB played in the developed of MCLGs and MCLs for all six PFAS. Coupled with inadequate data and insupportable analyses, EPA has presented a proposal that is legally and technically flawed.

EPA Response: The EPA disagrees that it did not seek adequate consultation from the Science Advisory Board (SAB) in the development of the NPDWR. SDWA Section 1412(e) requires that the EPA "request comments" from the SAB "prior to proposal" of the MCLG and NPDWR. Consistent with this statutory provision, the EPA consulted with the SAB from 2021 – 2022. Additionally, the statute does not dictate on which scientific issues the EPA must request comment from the SAB. See section IV of the final rule preamble and sections 4.1.2 and 4.1.3 of the EPA response in this *Response to Comments* document for comments related to the EPA's use of the best available science and peer review of the science underlying the MCLGs for PFOA and PFOS. Pertaining to the EPA's use of the best available science and peer review of the science underlying the Hazard Index MCLG for a mixture of HFPO-DA, PFNA, PFHxS, and/or PFBS and the individual MCLGs for HFPO-DA, PFNA, and PFHxS, please see section IV of the final rule preamble and sections 4.3.1, 4.3.2, and 4.3.3 of the EPA response in this *Response to Comments* document.

National Association of Manufacturers (NAM) (Doc. #1655, SBC-043196)

EPA's SAB not consulted on four of the six PFAS

The SDWA requires EPA to consult with the Science Advisory Board (SAB) prior to proposal of a maximum contaminant level goal and national primary drinking water regulation. [FN3: 42 U.S.C. § 300g-1(e).]

As opposed to PFOA and PFOS, the EPA did not seek input from the SAB for the proposed regulations on PFNA, PFHxS, PFBS, and GenX. EPA should re-propose a rule on these substances after the SAB has had adequate time to review and provide input.

EPA Response: The EPA disagrees with the commenter's assertions. As required by the SDWA, the EPA consulted with the SAB on the scientific questions the agency deemed most important to this rulemaking. Furthermore, the statute does not dictate on which scientific issues the EPA must request comment from the SAB. See section 4.3.2 of the EPA response in this *Response to Comments* document regarding peer-review requirements under SDWA prior to proposal of an MCLG and NPDWR.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045901)

IV. The Science Supporting the Proposed MCLs for PFOA and PFOS Is Not the Best Available Science

A. The science supporting the MCLs and MCLGs for PFOA and PFOS does not meet the statutory standard for use of the best available science

1. The period for SAB review was inappropriately truncated

The robustness of SAB review for the MCLs for PFOA and PFOS was severely diminished by exceedingly short timelines for each step of the process and by a lack of critical expertise. As described below, the peer review process was compromised and inconsistent with sound and objective scientific practices.

The Federal Register notices announcing the beginning of the process and the availability of supporting documents were November 10, 2021 and November 16, 2021, respectively [FN79: See 86 Fed. Reg. 62526 where EPA announced the meeting, but the draft documents were not released until Nov. 16, 2021, as announced at: https://www.epa.gov/newsreleases/epa-advances-science-protect-public-pfoa-and-pfos-drinking-water.]. The final report of the SAB was provided to EPA on August 22, 2022, only 279 days after documents were made available for review and only 243 days after the first meeting of the SAB. This is notably shorter than less complex reviews. For comparison, the SAB review of EPA's Assessment of the Potential Impacts of Hydraulic Fracturing for Oil and Gas on Drinking Water Resources, a 2015 document that was under 1,000 pages, took 400 days to complete [FN80: See SAB report available at: https://sab.epa.gov/ords/sab/f?p=100:12:10700493575905.]. This was 43% longer than the

amount of time the SAB spent reviewing the four substantive PFAS documents. The SAB Panel which reviewed EPA's Draft Toxicological Review of Ethyl Tertiary Butyl Ether and Draft Toxicological Review of tert-Butyl Alcohol (tert-Butanol), two technical documents like the PFOA and PFOS assessments but totaling only 547 pages, took 392 days to complete [FN81: See SAB report available at: https://sab.epa.gov/ords/sab/f?p=100:12:10700493575905.]. This was almost 40% longer for the review of documents what were approximately one-third the size of the relevant documents here.

If a member of the public wanted "timely consideration" of their comments by the SAB, comments were due on December 30, 2021. This provided a mere 44 days for the peer reviewers, and the public, to review over 1,750 pages of highly technical scientific assessments. The EPA Proposed Approaches to the Derivation of a Draft Maximum Contaminant Level Goal for Perfluorooctanoic Acid (PFOA) (CASRN 335-67-1) in Drinking Water (PFOA Draft Assessment) contained 59 pages of references and supporting studies, and the EPA Proposed Approaches to the Derivation of a Draft Maximum Contaminant Level Goal for Perfluorooctane Sulfonic Acid (PFOS) (CASRN 1763-23-1) in Drinking Water (PFOS Draft Assessment) contained 51 pages of references and supporting studies. With approximately 17 references per page, this equates to over 1,800 scientific references. These two Draft Assessments were not the only documents SAB was reviewing. In this same window, SAB was also asked to review EPA's Draft Framework for Estimating Noncancer Health Risks Associated with Mixtures of Per- and Polyfluoroalkyl Substances (PFAS) and EPA's Analysis of Cardiovascular Disease Risk Reduction as a Result of Reduced PFOA and PFOS Exposure in Drinking Water, and these documents' associated appendices [FN82: See the SAB meeting page for the review available at: https://sab.epa.gov/ords/sab/f?p=114:19:12110592892742:::19:P19_ID:963.].

The length of review time provided was simply not commensurate with the breadth of scientific information the SAB and the public were asked to review. Nor was the review time commensurate with the importance and economic significance of the proposed rulemaking this peer review was conducted to inform. In fact, requests were made for extensions, but EPA and the SAB denied those requests [FN83: See EPA response to Mr. Chaitovitz from Eric Burnseson, Director, Standards and Risk Management Division, Office of Ground Water and Drinking Water, EPA, dated May 5, 2023, stating that the provided comment period was "reasonable" and "EPA will not be extending the comment period for the proposed rule."].

2. The SAB reviewers did not have adequate expertise required by EPA's own policies

The review was also compromised by a lack of expertise on critical endpoints that EPA relied upon. SAB policies recognize that there may be cases when experts are unable to reach consensus [FN84: SAB Handbook for Members and Consultants Serving on the EPA Science Advisory Board (SAB Handbook), at page 6, available at: https://sab.epa.gov/ords/sab/r/sab_apex/files/static/v403/Serving%20on%20the%20EPA%20Science%20Advisory%20Board%20SABSO-12-001.pdf.]. However, in this case, for one of the most critical endpoints that EPA relied upon in both assessments, the immunological endpoint, the SAB panel included only one reviewer with expertise in immunological effects [FN85: See SAB

Determination Memo and List of Candidates where expertise of candidates is described. Only one chosen panelist, Dr. DeWitt, has expertise in immunotoxicology. Documents available at: https://sab.epa.gov/ords/sab/f?p=114:18:12110592892742:::RP,18:P18_ID:2601.]. The EPA Peer Review Handbook notes that "selected experts should include a range of technically legitimate points of view that fall along the continuum."[FN86: EPA Peer Review Handbook at page 72.] In order to have a range of points of view, the SAB panel should have included more than one expert in immunotoxicology. Another critical endpoint for PFOA and PFOS and needed to inform the review of the EPA report Analysis of Cardiovascular Disease Risk Reduction as a Result of Reduced PFOA and PFOS Exposure in Drinking Water is cardiovascular expertise. Unfortunately, the SAB panel included only one expert with cardiovascular expertise [FN87: See SAB Determination Memo and List of Candidates where expertise of candidates is described. Only one chosen panelist, Dr. Lipworth, has expertise in cardiovascular disease. Documents available at: https://sab.epa.gov/ords/sab/f?p=114:18:12110592892742:::RP,18:P18_ID:2601.]. In addition, the SAB panel lacked any expertise in clinical medicine. While the SAB sought candidates that included expertise as a "physician/clinician with a focus on cardiology,"[FN88: See SAB determination memo at page 1.] the final SAB panel did not include any physicians or clinicians [FN89: We note that EPA received nominations for 41 candidates, which included a physician, but EPA chose not to put this expert on the SAB panel. See list and biosketches of candidates at: https://sab.epa.gov/ords/sab/f?p=100:18:16490947993:::RP,18:P18_ID:2601#pf.]. Thus, due to the multiple gaps in expertise, the SAB panel was critically deficient.

3. Peer review principles were not followed in the SAB process, largely due to a lack of time for review

When the chartered SAB panel was reviewing the draft report from the SAB, chartered SAB members noted that some of the flaws in the EPA documents, including the PFOA and PFAS Draft Assessments, could not be fixed [FN90: See Chartered SAB public meeting July 20, 2022 at 1:36-1:42 video available at: https://www.youtube.com/watch?v=UzDtzYDJB_I.]. One chartered SAB panelist questioned how the SAB could approve documents that didn't reflect the current state of practice and questioned if EPA should just start over. This panelist did not think the flaws could be quickly corrected. A second chartered SAB member suggested that, if the Draft Assessments were a manuscript, they should have been rejected. The overarching concerns were significant [FN91: Id.]. However, these comments were tempered by the requests from EPA leadership to the SAB to recognize the time constraints that EPA placed upon themselves to move the PFAS drinking water rulemaking along in a timely manner.

The final SAB report acknowledges and recognizes the time constraints. The SAB letter to the Administrator notes concerns about the study evaluation and evidence synthesis process used by EPA and urges EPA to address these problems [FN92: See SAB report to the EPA Administrator Aug 22, 2022, at page 2, available at: https://sab.epa.gov/ords/sab/f?p=100:18:16490947993:::RP,18:P18_ID:2601#report.]. EPA states in its response to the SAB comments that it made significant revisions [FN93: See EPA Response to the Final SAB Recommendations, referred to as USEPA 2023f in the proposed

rule.]. However, these revisions did not undergo additional peer review. Instead, they are now the basis of economically significant rulemaking. When a journal manuscript is rejected, it must undergo another round of peer review after revisions are incorporated before going to publication. Consistent with this approach, one of the chartered SAB members recommended that the revised documents undergo another, albeit limited, form of peer review [FN94: See Chartered SAB public meeting July 20, 2022 at 2:26-2:32 video available at: https://www.youtube.com/watch?v=UzDtzYDJB_I.]. In response to this suggestion, an EPA staff member, the Director of the EPA SAB, interrupted the discussions of the SAB members to clarify the role of the SAB and steered the SAB chartered members away from recommending additional peer review [FN95: Id.]. There is nothing in the SAB handbook that precludes the SAB or the chartered SAB members from making a recommendation that the documents warrant additional peer review after substantial revisions are made by the Agency [FN96: See SAB Handbook for Members and Consultants Serving on the EPA Science Advisory Board (SAB Handbook), available at: https://sab.epa.gov/ords/sab/r/sab_apex/files/static/v403/Serving%20on%20the%20EPA%20Science%20Advisory%20Board%20SABSO-12-001.pdf.].

The changes made by EPA in developing the Public Comment Draft Toxicity Assessment and Proposed Maximum Contaminant Level Goal for Perfluorooctanoic Acid (PFOA) in Drinking Water and Public Comment Draft Toxicity Assessment and Proposed Maximum Contaminant Level Goal for Perfluorooctane Sulfonic Acid (PFOS) in in Drinking Water (Public Comment Draft Assessments) are significant enough that another peer review should have been conducted. For instance, as noted in the EPA Response to the Final SAB report, EPA developed many new elements to its assessment approach,[FN97: See EPA Response to the Final SAB Recommendations, at pages 14-16, and 20 where EPA notes that they have: defined inclusion and exclusion criteria at each stage of the systematic literature review for PFOA and PFOS; added a new protocol to describe study quality evaluation procedures for epidemiological and animal toxicological studies; developed an evidence integration approach; and revised the non-cancer health effects synthesis and integrations sections, available at: https://sab.epa.gov/ords/sab/f?p=100:12:17203034137454.] including elements such as a protocol. Consistent with today's best available scientific approaches, protocols are typically publicly released and reviewed before an assessment is conducted [FN98: See EPA ORD Staff Handbook for Developing IRIS Assessments, released December 2022, which describes how the systematic review protocol is part of the IRIS Assessment Plan which is released early in the assessment process for public comment, at chapter 1, available at: https://cfpub.epa.gov/ncea/iris_drafts/recordisplay.cfm?deid=356370#tab-3.]. But, in this case, the protocol and other important modifications to the risk evaluation approach are being released for the first time as part of the MCL draft documentation, thus skirting the statutorily required SAB review (as discussed earlier in these comments). For this reason and for the additional reasons cited above, the underlying scientific evaluations do not meet the statutory standard.

EPA Response: Regarding the commenter's claims that the underlying scientific evaluations do not meet the statutory standard and that the EPA did not seek adequate

consultation from the SAB in the development of the NPDWR, SDWA Section 1412(e) requires that the EPA "request comments" from the SAB "prior to proposal" of the MCLG and NPDWR. Consistent with this statutory provision, the EPA consulted with the SAB from 2021 – 2022. Further, the EPA disagrees with this commenter's assertions regarding the SAB review timing, panel expertise, and peer review practices. See detailed responses to each of these assertions below.

First, the EPA disagrees with the commenter's characterization of the SAB review as "truncated." and notes that under no statutes or EPA policies are there minimum or maximum times for SAB reviews. Comparisons to other SAB review timeframes are also not relevant as there are many factors, including SAB panel and chartered body availability and agency statutory mandates, that could impact the length of an SAB review. The EPA points out that the commenter provided one example, however in contrast there are examples of other SAB reviews which have been completed of comparably complex materials in similar amounts of time, for recent examples see *Review of EPA's draft IRIS Toxicological Review of Hexavalent Chromium* (USEPA, 2023c; the SAB Cr(VI) Review Panel met virtually on February 15, 2023 to hear a presentation by the EPA staff, final SAB report dated September 27th, 2023) and *Science Advisory Board Report on the Scientific and Technical Basis of the Proposed Rule Titled "Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review"* (USEPA, 2023d; the SAB's Science Supporting Decisions workgroup received the supplemental rule material on August 26, 2022, to consider with the rule material published on December 6th 2022, final SAB report dated March 6th, 2023). The EPA also notes that for review of the materials supporting this PFAS drinking water rulemaking that the panel members as well as the SAB chartered members did not raise any concerns with regard to the time provided to review the materials and produce the final report. The EPA did not place "time constraints… upon themselves," but must follow the regulatory schedule explicitly described in the SDWA.

Second, the EPA disagrees with the commenter's claim that "[t]he SAB reviewers did not have adequate expertise required by the EPA's own policies." When the SAB Staff Office determines that additional expertise will be needed to address an advisory topic, it publishes an FRN announcing the formation of an ad hoc panel that reports to the chartered Clean Air Scientific Advisory Committee (CASAC) or SAB. The announcement provides an opportunity for the public to nominate experts to these ad hoc panels. The SAB Staff Office also invites comments on Lists of Candidates. This provides an opportunity for the public to be informed about the candidate experts being considered and for the public to provide information, analysis, or documentation for the EPA to consider before finalizing membership on committee or panels. As Lists of Candidates become available, they are placed on the SAB homepage (https://sab.epa.gov). The SAB Staff Office received nominations for the 41 candidates based on their expertise and willingness to serve, and selected panel members as detailed in the memo *Formation of the per- and polyfluoroalkyl substances (PFAS) Review Panel under the Science Advisory Board (SAB),* available online at: https://sab.epa.gov/ords/sab/r/sab_apex/sab_bkup/0?detmemo_id=2601&request=APPLICATIO

N_PROCESS%3DDETER_MENO&session=9389297743683. Expertise, knowledge, and experience are the primary factors that determine whether an individual is invited to serve on an SAB Panel. In forming panels to provide expert advice, SAB staff screen candidates for conflicts of interest and consider overall balance of the panel in terms of the points of view presented, as mandated by the Federal Advisory Committee Act. At the SAB, a balanced panel is characterized by inclusion of the necessary domains of knowledge, the relevant scientific perspectives (which, among other factors can be influenced by work history and affiliation), and the collective breadth of experience to address the charge adequately. The EPA emphasizes that the SAB is a technical advisory body, not a committee designed to reflect stakeholder views. For more information see *Overview of the Panel Formation Process at the Environmental Protection Agency Science Advisory Board* (USEPA, 2010). Therefore, given the opportunity for public input and the panel selection process followed by the EPA for this PFAS Review Panel, the commenter is incorrect in stating the EPA did not "follow its own policies." Further, the panel represented a balanced and appropriate range preeminent experts in their field. The SAB Staff Office identified current members of the SAB Chemical Assessment Advisory Committee (CAAC) and the SAB Economic Analysis Committee (EAC) augmented with subject matter experts with expertise in one or more of the following areas: toxicology, specifically reproductive/developmental, hepatic, immunology and neurotoxicology; epidemiology with expertise in immunology, endocrinology, reproductive/ developmental and cardiology; physiologically-based pharmacokinetic (PBPK) modeling; physician/clinician with a focus on cardiology; risk assessment; toxicity of chemical mixtures; economist with expertise in health related benefit cost analysis and valuing avoided adverse health outcomes; and, dose response relationships in economic models. Regarding the commenter's specific opinion that the EPA should have included a physician on the panel, the EPA notes that this was one of several areas of expertise the agency believed could be appropriate to review the cardiovascular disease (CVD) risk reduction methodology. The EPA notes that the panel included experts in the pertinent fields to review this work (i.e., cardiovascular disease, applied epidemiology and economics) including Dr. Loren Lipworth; a Professor of Medicine, Dr. David Savitz; a Professor of Epidemiology, Dr. Lala X. Ma; an Assistant Professor of Economics, Dr. James K. Hammitt; a Professor of Economics and Decision Sciences, among other expert panel members.

Third, the EPA disagrees with the commenter that "[P]eer review principles were not followed in the SAB process, largely due to a lack of time for review." As discussed above, the EPA provided adequate time for the review process and received timely feedback from the SAB. Regarding the commenters suggestion that the EPA should seek a second peer review of the materials, the EPA notes that the chartered SAB panel did not review the documents themselves and relied on the SAB report for their discussion. SAB panelists who did review the materials and developed the final SAB report (USEPA, 2022) disagreed with the chartered panelists who stated the EPA should "start over." As the commenter suggested, "There is nothing in the SAB handbook that precludes the SAB or the chartered SAB members from making a recommendation that the documents warrant additional peer review after substantial revisions are made by the Agency." The SAB, however, did not recommend this in their final report (USEPA,

2022). See section IV of the final rule preamble and sections 4.1.2 and 4.1.3 of the EPA response in this *Response to Comments* document for comments related to the EPA's use of the best available science and peer review of the science underlying the MCLGs for PFOA and PFOS. Pertaining to the EPA's use of the best available science and peer review of the science underlying the Hazard Index MCLG for a mixture of HFPO-DA, PFNA, PFHxS, and/or PFBS and the individual MCLGs for HFPO-DA, PFNA, and PFHxS, please see section IV of the final rule preamble and sections 4.3.1, 4.3.2, and 4.3.3 of the EPA response in this *Response to Comments* document.

Regarding the request for extension to the public comment period for the proposed rule, please see section 17.1 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045896)

A. EPA violated SDWA's Requirement to seek SAB review before proposing this regulation and the MCL for PFNA, PFHxS, PFBS, and HFPO-DA

Section 1412(e) of SDWA requires that EPA request comments from the SAB prior to proposal of a MCLG and NPDWR:

The Administrator shall request comments from the Science Advisory Board (established under the Environmental Research, Development, and Demonstration Act of 1978) prior to proposal of a maximum contaminant level goal and national primary drinking water regulation. The Board shall respond, as it deems appropriate, within the time period applicable for promulgation of the national primary drinking water standard concerned. This subsection shall, under no circumstances, be used to delay final promulgation of any national primary drinking water standard [FN53: 42 U.S.C. [sec] 300g-1(e).].

Unlike PFOA and PFOS, EPA did not seek input from the SAB on the MCL for PFNA, PFHxS, PFBS, and HFPO-DA. EPA offers no explanation for this departure from SDWA requirements. This error is likely in part due to the flawed attempt to rush to propose a regulatory determination and a regulation/MCL at the same time (discussed further below). SAB could not have reviewed the assessments within the "time period applicable" because they were proposed simultaneously. The typical process creates up to two years between a proposed regulatory determination and a final determination and a regulatory proposal. EPA must respect this detailed process that Congress set up in SDWA to allow scientific peer review by the SAB and adequate public comment. Based on SDWA requirements, if it wishes to finalize this MCL for these substances, EPA must re-propose the rule after SAB has an opportunity to review.

EPA Response: The EPA disagrees that it did not seek adequate consultation from the SAB in the development of the NPDWR. As the commenter provides, SDWA Section 1412(e) requires that the EPA "request comments" from the SAB "prior to proposal" of the MCLG and NPDWR, though it does not dictate on which scientific issues the EPA must request comment from the SAB. Consistent with this statutory provision, the EPA did so and consulted with the

SAB from 2021 – 2022. See section 4.3.2 of the EPA response in this *Response to Comments* document regarding peer-review requirements under SDWA prior to proposal of an MCLG and NPDWR. Pertaining to the EPA's concurrent preliminary regulatory determination for PFHxS, PFNA, HFPO-DA, and PFBS and proposed NPDWR, please see section 3.3 of the EPA response in this *Response to Comments* document. The agency further clarifies for the commenter that, as it relates to the EPA's regulatory determinations, the SDWA does not require any consultation with the SAB when making preliminary or final regulatory determinations. Consequently, the commenter has no basis for their assertion that the SAB did not have adequate review time due to the EPA's concurrent preliminary regulatory determination and proposed NPDWR.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045876)

A. Health data do not support the proposed determinations to regulate PFNA, PFHxS, PFBS, and HFPO-DA (and mixtures of these PFAS) either individually or as a mixture

1. EPA did not perform human health assessments for all four contaminants and failed to conduct appropriate peer review

It is critical that, before finalizing a human health assessment, EPA ensures that appropriate peer review is conducted [FN9: U.S. EPA, Peer Review Handbook, 4th edition, 2015, available at: https://www.epa.gov/sites/default/files/2015-10/documents/epa_peer_review_handbook_4th_edition_october_2015.pdf.]. This peer review must be fit for purpose, and, as EPA states, Influential Scientific Assessments (ISIs) and Highly Influential Scientific Assessments (HISAs), including those that are more novel or complex and have greater cost implications, should undergo more extensive and more involved peer reviews. Despite EPA's own recognition that "[t]he mechanism of the peer review should match the importance and complexity of the work product," the SAB did not review the science for PFHxS, HFPO-DA, PFNA, and PFBS. [FN10: Id. at 54.] This is in sharp contrast to the process that occurred for PFOA and PFOS.

EPA Response: The EPA disagrees that the health data do not support the SDWA statutory criterion for individual regulation of PFHxS, PFNA, and HFPO-DA and regulation of mixtures of these three PFAS and PFBS is not supported (please see sections 3.1.1 and 3.2.1 of the EPA response in this *Response to Comments* document). The EPA also disagrees that appropriate peer review was not conducted or that the EPA must perform the health assessments. Rather, the SDWA requires that the EPA use the "best available, peer-reviewed science and supported studies conducted in accordance with sound and objective scientific practices." See sections 4.3.1, 4.3.2, and 4.3.3 of the EPA response in this *Response to Comments* document related to peer review of the science underlying the Hazard Index MCLG for a mixture of HFPO-DA, PFNA, PFHxS, and/or PFBS and the individual MCLGs for HFPO-DA, PFNA, and PFHxS. Additionally, the commenter mischaracterizes what constitutes Influential Scientific Information (ISI) or Highly Influential Scientific Assessment (HISA) and how the EPA manages peer review for ISIs or HISAs. A scientific assessment is considered HISA when the agency or the OMB

Office of Information and Regulatory Affairs (OIRA) Administrator determines that the dissemination could have a potential impact of more than $500 million in any one year on either the public or private sector or that the dissemination is novel, controversial, or precedent-setting, or has significant interagency interest. Neither the EPA Administrator, the Centers for Disease Control (CDC) director, nor the Administrator of OIRA have determined that the human health assessments for these four PFAS are HISAs.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045878)

While EPA has completed health assessments for HFPO-DA and PFBS, they were not reviewed by the SAB and did not undergo an appropriate peer review. HFPO-DA and PFBS underwent external peer review that was managed by a contractor, not the SAB. As stated in the EPA Peer Review Handbook, "HISAs or other scientific work products associated with highly visible or controversial environmental issues, or products that include novel scientific methods or approaches, are most suited to review by the SAB."[FN14: Id. at 66.] This is because the SAB process is far more robust than the processes run by external contractors. For instance, the SAB strives to reach consensus in all their reports because their final product is meant to be a consensus advisory report [FN15: U.S. EPA, SAB Handbook for Members and Consultants, available at: https://sab.epa.gov/ords/sab/r/sab_apex/files/static/v403/Serving%20on%20the%20EPA%20Science%20Advisory%20Board%20SABSO-12-001.pdf.]. EPA provides no explanation why it used external contractors instead of the more robust SAB process.

The external peer reviewers of the contractor-led HFPO-DA and PFBS reviews did not strive to reach consensus, and, in fact, the final HFPO-DA report provided non-consensus opinions. Even the second round of external peer review of the HFPO-DA assessment cannot make up for the fact the peer-review process was not nearly as robust as an SAB process would have been. The second peer review report also provided EPA, and the public, with non-consensus opinions. When assessments are controversial and also considered to be HISAs because of the important and costly rulemakings that rely on them, a contractor-led external peer review is simply not as robust as SDWA-required SAB review. As such, the health assessments EPA relies on for the four contaminants in the regulatory determination are not of sufficient scientific quality and rigor and should be properly peer reviewed by the SAB to support an adequate regulatory determination.

EPA Response: The EPA disagrees. See section 4.3.3 of the EPA response in this *Response to Comments* document related to peer review of the toxicity assessments for HFPO-DA and PFBS. Additionally, the commenter mischaracterizes what constitutes a HISA and how the EPA manages peer review for HISAs. A scientific assessment is considered HISA when the agency or the OMB OIRA Administrator determines that the dissemination could have a potential impact of more than $500 million in any one year on either the public or private sector or that the dissemination is novel, controversial, or precedent-setting, or has significant

interagency interest. Neither the EPA Administrator, the CDC director, nor the Administrator of OIRA have determined that these toxicity assessments are HISAs.

American Water Works Association (AWWA) (Doc. #1759, SBC-045645)

These public comment drafts also include the USEPA's attempts to respond the Scientific Advisory Board's detailed comments and review (August 2022) of the following four draft documents:

• Proposed Approaches to the Derivation of a Draft Maximum Contaminant Level Goal for Perfluorooctanoic Acid (PFOA) (CASRN 335-67-1) in Drinking Water (December 2021) (USEPA 2021a);

• Proposed Approaches to the Derivation of a Draft Maximum Contaminant Level Goal for Perfluorooctane Sulfonic Acid (PFOS) (CASRN 1763-23-1) in Drinking Water (December 2021) (USEPA 2021b);

• Draft Framework for Estimating Noncancer Health Risks Associated with Mixtures of Per- and Polyfluoroalkyl Substances (PFAS) (December 2021) (USEPA 2021c); and

• Analysis of Cardiovascular Disease Risk Reduction as a Result of Reduced PFOA and PFOS Exposure in Drinking Water (December 2021) (USEPA 2021d).

The USEPA made substantial revisions and added new material, which is now included in the public comment drafts, to address the extensive comments made by the Science Advisory Board (SAB). In addition, the USEPA responded to the SAB comments in the following report:

• USEPA Response to Final Science Advisory Board Recommendations (August 2022) on Four Draft Support Documents for the USEPA's Proposed PFAS National Primary Drinking Water Regulation (USEPA 2023i).

The revisions to the 2023 public comment drafts include the following, none of which have been peer-reviewed by the SAB, and therefore have to be peer-reviewed during this 60 day public comment period (which will end on May 30, 2023):

• A review of mechanistic data, which was lacking in the December 2021 draft documents, and synthesis of mechanistic data with the animal and human data. The SAB specifically stated "(US)EPA should include an evaluation of mechanistic/mode of action data for those effects considered as the potential basis for the reference doses (RfDs) and cancer slope factors (CSFs)." (p. 2 of introductory letter, USEPA 2022a);

• Newly derived candidate RfDs for total cholesterol are now included in the proposed MCLG documents to align with the cardiovascular disease (CVD) benefits analysis. The SAB specifically stated "(US)EPA should ensure that recommendations for the draft MCLG documents relating to evidence identification and synthesis are applied to the CVD endpoint." (p. 4 of introductory letter, USEPA 2022a);

• USEPA quantified benefits of changes in high-density lipoprotein cholesterol (HDLC) in relation to PFOA and PFOS;

• USEPA quantified benefits of changes in elevated blood pressure in relation to PFOS (although this had not requested by the SAB);

• Addition of quantified benefits of birth weight associated with reductions in PFOA/PFOS (SAB requested that USEPA consider risk reduction for additional endpoints);

• Newly derived candidate RfDs for decreases in birth weight (which is sometimes described as low birth weight) in relation to PFOA and PFOS, which were needed to align with quantified birth weight benefits. However, low birth weight has a specific definition (i.e. birth weight below 2500 grams), and this is not the endpoint for which the RfD is derived. The tiered risk assessment approach described in the December 2021 Draft Framework for Estimating Noncancer Health Risks Associated with Mixtures of Per- and Polyfluoroalkyl Substances (PFAS) was replaced with a data-driven/menu-based framework for the selection of component-based approaches for PFAS mixture assessment, and the interpretation of any approach as being "screening" or preliminary was minimized. The SAB specifically stated, "Methods analogous to those classified by USEPA as 'Screening Level' or 'Tier 1' in the framework are potentially being used by states in a decision-making capacity. Issuance of this framework without recognition of that fact may create confusion for public water supplies and risk communication challenges for the public." (p. 93-94, USEPA SAB 2022a).

The above changes to the underlying documents and assessments are not exhaustive; however, the comments below are largely focused on a review of these proposed changes.

EPA Response: Please see section 4.1.3 of the EPA response in this *Response to Comments* document related to peer review of the science underlying the MCLGs for PFOA and PFOS. Regarding the derivation of candidate RfDs, please see section 4.2.2 of the EPA response in this *Response to Comments* document and the methodology described in Appendix E and Chapter 4 of the Final Human Health Toxicity Assessments for PFOA and PFOS (USEPA, 2024c; USEPA, 2024d; USEPA, 2024e; USEPA, 2024f). See sections 4.3.1, 4.3.2, and 4.3.3 of the EPA response in this *Response to Comments* document related to peer review of the science underlying the Hazard Index MCLG for a mixture of HFPO-DA, PFNA, PFHxS, and/or PFBS and the individual MCLGs for HFPO-DA, PFNA, and PFHxS.

In regard to improvements to the CVD analysis based on SAB recommendations, these were clearly laid out in section XV.K.1.c of the FRN for proposal. Further, the agency is not obligated to seek SAB review of every quantified adverse health effect included in a Health Risk Reduction and Cost Analysis (HRRCA); the agency relied on the best available peer reviewed data for the changes in infant birth weight benefits referenced by the commenter.

3M Company (Doc. #1774, SBC-045655)

EPA's interpretation of the data it selected is also flawed and has not been peer-reviewed, in violation of the SDWA. EPA created the HI-MCL after SAB review, and based it on HealthBased Water Concentrations (HBWC) for the four HI substances that were not submitted to SAB. This violates the SDWA, which requires that EPA request comments from the SAB "prior to proposal of a maximum contaminant level goal and national primary drinking water standard." [FN3: SDWA [sec][sec] 1412(b)(3)(A)(i) and (g)]

EPA Response: The EPA disagrees. See section 4.3.2 of the EPA response in this *Response to Comments* document related to peer-review requirements under SDWA prior to proposal of an MCLG and NPDWR. The EPA disagrees that it did not seek adequate consultation from the SAB in the development of the NPDWR. As the commenter states, SDWA Section 1412(e) requires that the EPA "request comments" from the SAB "prior to proposal" of the MCLG and NPDWR. Consistent with this statutory provision, the EPA did so and consulted with the SAB from 2021 – 2022. Additionally, the statute does not dictate on which scientific issues the EPA must request comment from the SAB.

3M Company (Doc. #1774, SBC-045659)

b. History of this Rulemaking Process

EPA began the process of setting this NPDWR in March 2020, when EPA solicited public comment on the preliminary regulatory determinations for contaminants on the fourth CCL. This publication included a preliminary determination to regulate PFOA and PFOS in drinking water. The following year, in March 2021, EPA published its final determination to regulate PFOA and PFOS. [FN24: See 86 FR 12282.] In November 2021, EPA requested feedback from the Science Advisory Board (SAB) [FN25: The Scientific Advisory Board (SAB) is a Federal Advisory Committee made up of subject matter experts. SAB reviews technical information used by EPA for quality and relevance. The board provides advice on EPA proposed regulations and on specific questions posed by the EPA Administrator. SAB's Drinking Water Committee formed a PFAS Review Panel of 16 experts on the scientific and technical aspects of PFAS. As subject matter experts, specifically chosen to provide guidance on the scientific aspects of EPA regulations, their recommendations and analysis should have been taken seriously by EPA when it received feedback on this proposed rule.] on four draft documents related to this rulemaking:

• EPA's Proposed Approaches to the Derivation of a Draft Maximum Contaminant Level Goal for Perfluorooctanoic Acid (PFOA) (CASRN 335-67-1) in Drinking Water

• EPA's Proposed Approaches to the Derivation of a Draft Maximum Contaminant Level Goal for Perfluorooctane Sulfonic Acid (PFOS) (CASRN 1763-23-1) in Drinking Water

• EPA's Analysis of Cardiovascular Disease Risk Reduction as a Result of Reduced PFOA and PFOS Exposure in Drinking Water

• Draft Framework for Estimating Noncancer Health Risks Associated with Mixtures of Per- and Polyfluoroalkyl Substances (PFAS)

In the first two of these documents, EPA proposed an approach to calculating MCLGs for PFOA and PFOS based on an immune effects endpoint. In other words, EPA's proposed MCLGs were based on the exposure to PFOA and PFOS that the Agency determined was expected to result in negative impacts to immune system function. In its Review of EPA's Analyses to Support EPA's National Primary Drinking Water Rulemaking for PFAS (the "SAB Final Report"), the SAB strongly criticized many of EPA's approaches and requested EPA provide significant clarification. SAB's criticisms included:

• "EPA should provide additional transparency and completeness in its evidence identification methodology, including development of a protocol with clear inclusion/exclusion criteria and study evaluation approaches."

• "Studies, particularly human studies, that were included in the 2016 health effects summary documents (HESDs) should be considered in the same manner as the more recent studies."

• "EPA needs to provide additional details and transparency for all quantitative modeling, including that used for CSF [cancer slope factor] development, toxicokinetic modeling, and benchmark dose modeling for POD derivation. It is essential that details of the Benchmark Dose (BMD) modeling that forms the basis of the PODs are transparently available for evaluation of the methods, approaches, and results."

• "EPA should provide a stronger and more transparent justification for the choice of benchmark responses (BMRs)"

When EPA ultimately published its proposed PFAS NPDWR in March 2023, EPA shifted from relying on the immune effects endpoint to cancer endpoints for PFOA and PFOS in the proposed NPDWR.

EPA also submitted to the SAB in November 2021 its Draft Framework for Estimating Noncancer Health Risks Associated with Mixtures of Per- and Polyfluoroalkyl Substances for SAB review which would, according to EPA, "inform development of the MCLGs and NPDWR for PFOA and PFOS." (emphasis added). This Draft Mixture Framework did not present an MCL framework for the four Hazard Index (HI) PFAS, nor did it set proposed health-based water concentrations (HBWCs) for the HI PFAS. In this draft document, EPA acknowledged that HBWCs "would need to be calculated in order to develop component HQs [hazard quotients] and an overall PFAS mixture HI," but made no such calculation. In other words, EPA never submitted draft HBWCs to SAB for review. [FN26: Moreover, EPA "emphasized" to the SAB "that the draft mixtures document is not a regulation, does not impose legally binding requirements on EPA, states, tribes, or the regulated community, and might not apply to a particular situation based on the circumstances." (USEPA SAB 2023, p. 1-2.)]

In March 2023, EPA proposed this NPDWR regulating PFOS, PFOA, PFHxS, HFPODA, PFNA, and PFBS, including HBWCs for the HI PFAS.

EPA Response: Please see section 4.1.3 of the EPA response in this *Response to Comments* document related to peer review of the science underlying the MCLGs for PFOA and PFOS. Pertaining to the EPA's use of the best available science and peer review of the science underlying the Hazard Index MCLG for a mixture of HFPO-DA, PFNA, PFHxS, and/or PFBS and the individual MCLGs for HFPO-DA, PFNA, and PFHxS, please see sections 4.3.1, 4.3.2, and 4.3.3 of the EPA response in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045664)

c. EPA's Interpretation of the Data It Uses as the Basis of the MCLGs and MCLs is Flawed and Has Not Undergone Peer Review in Violation of the SDWA

The HI MCL also violates the SDWA's mandate that EPA solicit peer review from its SAB prior to issuing a proposed MCL. [FN36: SDWA [sec][sec] 1412(b)(3)(A)(i) and (g).] In 2021, EPA provided SAB with its Draft Framework for Estimating Noncancer Health Risks Associated with Mixtures of Per- and Polyfluoroalkyl Substances (PFAS) (USEPA 2021c). That document was an external peer review draft, which was not revised and published for public review until March 2023 (USEPA 2023e). This means that the Proposed Rule employs techniques regarding data requirements for mixture Health-Based Water Concentrations" but never sets out proposed HBWCs for the HI PFAS or for EPA's currently proposed HI-based MCL for those substances. In the mixtures framework document, EPA itself said that "because there are no EPA-published HBWCs (e.g., Health Advisories, MCLGs) at this time for other PFAS with federal or state assessments/RfVs (e.g., PFBS (EPA), GenX chemicals (EPA), PFHxS (ATSDR), and PFNA (ATSDR)) or chemicals categorized under PFAS 1 or PFAS 2, these values would need to be calculated in order to develop component HQs and an overall PFAS mixture HI." [FN37: Draft Framework for Estimating Noncancer Health Risks Associated with Mixtures of Per- and Polyfluoroalkyl Substances (PFAS), 35 (November 2021)] In other words, EPA expressly did not submit its "mixtures" document as a potential MCL for public review prior to the publication of the Proposed Rule. Indeed, EPA proposed the HBWCs only after SAB reviewed its proposed mixtures framework. As a result, neither the HBWCs that form the basis for the HI-MC, nor the HI-MCL itself have been properly submitted to the SAB or peer-reviewed as required by the SDWA. [FN38: See SDWA [sec] 1412(g)]

EPA Response: The EPA disagrees. See sections 4.3.1, 4.3.2, and 4.3.3 of the EPA response in this *Response to Comments* document related to peer review of the science underlying the Hazard Index MCLG for a mixture of HFPO-DA, PFNA, PFHxS, and/or PFBS.

14.11.2 National Drinking Water Advisory Council

Individual Public Comments

Dylan Pilger (Doc. #1546, SBC-042678)

The National Drinking Water Advisory Council must include Indigenous representation.

My third recommendation to the EPA is that the National Drinking Water Advisory Council include representation from Indigenous communities. First, environmental contamination is a major health concern for Indigenous communities (Gracey & King, 2009). Therefore, it is important that these communities be included in decision-making processes regarding any environmental health hazards. This will also be essential for developing rules which are sensitive to the unique needs of Indigenous populations (Sproat, 2011). Second, as sovereign governmental entities tribes have valuable experience that can be beneficial in these discussions. For example, the South Australian Government has had immense success in collaborating with the Ngarrindjeri nation to protect water sources (Hemming et al., 2019). In 2015, they won the "Australian Riverprize for best practice in water management." Finally, this recommendation is in line with Articles 25 and 26 of the United Nations Declaration on the Rights of Indigenous People (UNDRIP) which states (United Nations, 2008):

"Article 25

Indigenous peoples have the right to maintain and strengthen their distinctive spiritual relationship with their traditionally owned or otherwise occupied and used lands, territories, waters and coastal seas and other resources and to uphold their responsibilities to future generations in this regard.

Article 26

1. Indigenous peoples have the right to the lands, territories and resources which they have traditionally owned, occupied or other-wise used or acquired.

2. Indigenous peoples have the right to own, use, develop and control the lands, territories and resources that they possess by rea-son of traditional ownership or other traditional occupation or use, as well as those which they have otherwise acquired.

3. States shall give legal recognition and protection to these lands, territories and resources. Such recognition shall be conducted with due respect to the customs, traditions and land tenure systems of the indigenous peoples concerned."

For these reasons, I strongly urge the EPA to include Indigenous representation on the National Drinking Water Advisory Council.

EPA Response: The EPA is required under the SDWA to consult with the National Drinking Water Advisory Council (NDWAC) both prior to proposing and promulgating an NPDWR (see section XIII.K.2 of the final rule preamble for more information on how the EPA fulfilled this statutory obligation). However, the membership of the NDWAC is outside of the scope of this regulation. The agency refers the commenter to the EPA's NDWAC website (https://www.epa.gov/ndwac) where information is provided on public solicitation for membership nominations.

14.11.3 Secretary of Health and Human Services

The EPA received no public comments on the agency's consultation with the Department of Health and Human Services.

15 Outside Scope of Proposed NPDWR

15.1 Outside Scope of Proposed NPDWR

Summary of Major Public Comments and EPA Responses

The following comments in this section are beyond the scope of this rulemaking. Under the *Administrative Procedure Act* notice-and-comment process for rulemakings, the EPA considers all relevant and timely-submitted comments and responds to all significant comments received during the public comment period. The EPA's final PFAS National Primary Drinking Water Regulation (NPDWR) is based on the administrative record, including the EPA's consideration of these comments. The EPA is promulgating data-driven drinking water standards that are based on the best available science and meet the requirements of the Safe Drinking Water Act (SDWA). The EPA directs commenters to the following sections of this *Response to Comments* document for further information on specific topics related to the final NPDWR:

1. **General information**, to include discussion on the SDWA rulemaking process and risk communications;
2. **Background**, to include discussion on statutory framework, chemistry, production, uses and human health effects of PFAS as well as funding considerations;
3. **Preliminary Regulatory Determinations** for PFHxS, PFNA, HFPO-DA, PFBS, and mixtures of these four PFAS;
4. **Maximum Contaminant Level Goals** for PFOA and PFOS, individual PFAS (PFHxS, PFNA, HFPO-DA) and mixtures of these PFAS and PFBS;
5. **Maximum Contaminant Levels,** to include discussion on feasibility of the final standards for PFOA and PFOS, individual PFAS (PFHxS, PFNA, HFPO-DA) and mixtures of these PFAS and PFBS;
6. **Occurrence**, to include discussion on the Unregulated Contaminant Monitoring Rule (UCMR), state drinking water data, and PFAS co-occurrence;
7. **Analytical methods**, to include discussion on validated EPA methods to support the monitoring requirements of the final NPDWR;
8. **Monitor and Compliance Requirements**, to include discussion on use of previously acquired data, compliance calculations and violations, and monitoring requirements to assure water systems provide safe drinking water to the public;
9. **SDWA Right-to-Know Requirements**, to include discussion on Consumer Confidence Report (CCR) Requirements, as well as Public Notification (PN) Requirements;
10. **Treatment Technologies**, to include discussion on *Best Available Technologies (BATs)* and *Small System Compliance Technologies (SSCTs)* and management of treatment residuals;
11. **Rule Implementation and Enforcement**, to include discussion on requirements for primacy, enforcement related topics, and primacy agency record keeping and reporting requirements;

12. **Exemptions and Extensions**, to include discussion on supply chain and labor challenges that may affect the compliance timeline;
13. **Health Risk Reduction and Cost Analysis**, to include discussion on quantifiable and non-quantifiable costs and benefits of the final NPDWR, benefits from co-removal, uncertainties, affordability, and the social costs of carbon
14. **Statutory and Executive Order Reviews**
15. **Outside Scope of Proposed NPDWR** (this section)
16. **Potential Final Code of Federal Regulations (CFR) Changes**
17. **EPA's Next Steps and Timeline**

The regulation of the PFAS covered by promulgation of this NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. The EPA also recognizes the importance of actions that are beyond the scope of this regulatory action. While the EPA is not obligated to respond to comments that are beyond the scope of this rulemaking, many of the comments provided in this section deal with cross-cutting and non-drinking water topics that may be applicable to other actions on PFAS as discussed in the EPA PFAS Strategic Roadmap. For instance, the EPA has received comments on on-going PFAS rulemakings in non-drinking water programs; PFAS remediation and clean-up actions; limiting the use of certain PFAS in commerce; PFAS source water control such as controlling PFAS in wastewater discharges and other discharges; assigning liability for PFAS pollution, among others. While the EPA recognizes the importance of all of these actions in protecting public health and the environment from the harmful effects of PFAS pollution, comments on these topics are beyond the scope of this regulatory action. Through other actions, the EPA is fully committed to reduce PFAS pollution and human health exposure and implement policies that safeguard communities and public health, protect the environment, and hold polluters accountable. For more information, please see the EPA PFAS Strategic Roadmap where these actions that are part of the EPA's whole-of-agency approach to addressing PFAS are further described (cited in the final rulemaking docket for this final NPDWR and found here: https://www.epa.gov/pfas/pfas-strategic-roadmap-epas-commitments-action-2021-2024.). Furthermore, commenters can view the EPA's progress on various activities discussed in the strategic roadmap by visiting the EPA's PFAS Strategic Roadmap: Second Annual Progress Report, available at https://www.epa.gov/system/files/documents/2023-12/epas-pfas-strategic-roadmap-dec-2023508v2.pdf. The individual out-of-scope comment excerpts are included below.

Individual Public Comments

North Penn Water Authority (NPWA) (Doc. #1470, SBC-043296)

Other Concerns

Lastly, if the federal government is concerned about improving the caliber of the public water supply, then I would suggest that efforts be redirected to areas that are more pressing. Instead of imposing burdensome regulations on water quality down to infinitesimally low levels in the

range of single digit parts per trillion, which will have a questionable benefit to customers, there are better ways to expend our resources.

First, there is more of a critical need for the replacement of aging infrastructure, like pipes in the ground that have exceeded their useful lifespans. Second, the reliability of a continuous, uninterrupted, low cost energy supply is critical to the operations of any water system that needs to run water through treatment plants and distribute it to thousands of people through many miles of pumps, pipes, and storage tanks every minute of every day. All of this continuous movement of water is vitally important to our customers, and it can all be stopped cold without sufficient power. Yet, the cost of energy has been skyrocketing in recent years, and the reliability of power supplies has been continually diminished by current government policies that promote less dependable sources of energy. The average American consumer of public water will get a much better "bang for their buck" if efforts are more focused on these areas instead.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Darlene Price (Doc. #1471, SBC-042305)

See attached file(s) I have proof positive that local and state officials are allowing the potential poisoning and cover-up of an entire echo system in the Daniel Boone National Forest and the Cumberland River in Kentucky. Please see the attached letter/file outlining this proof. I have over a thousand documents obtained from official open records requests and from reliable confidential sources. My team "TRUTH or POLITICS" have completed a 4 hour documentary entitled, "Lake Cumberland, what really lies beneath" parts 1 & 2 which can be viewed on YouTube at this link: https://www.youtube.com/watch?v=gdlPzooZFkw. I am willing to forward any and all of these shocking documents for anyone to view. I am also willing to give live testimony. We now have numerous individuals who are getting sick from this colossal blunder. I have too many documents to upload and will have to explain what many of these documents actually are. The Mayor of Somerset, Kentucky and his city council have brought into Kentucky over 50 million gallons of extremely toxic waste in the form of "leachate" from four different landfills. They have processed this toxic waste through a highly defective (over 100 documents from 2016 to current) wastewater treatment plant, which ultimately runs into the Cumberland River. Millions of people and countless wildlife get their drinking water down stream from this defective plant. Now a recent test of local drinking water here in Pulaski County revealed that "Forever Chemicals" are in fact in the drinking water. In the attached letter are more details and my contact information. Please allow me to help by testifying at any upcoming hearings on this issue.

DARLENE FITZGERALD PRICE, J.D.

March 28, 2023

Comment on Proposed Rule by the Environmental Protection Agency:

www.regulations.gov, Docket ID: EPA-I-IQ-OW-2022-0114.

RE: Local public officials and state officials are knowingly engaging in the massive pollution and cover-up of Lake Cumberland and the Cumberland River; located in the Daniel Boone National Forest, Kentucky by allowing "Forever Chemicals" to enter the water-ways unchecked and unchallenged.

To Whom it May Concern,

I am entering this letter in support of the EPA proposed rule on "Forever Chemicals"

(www.regulations.gov, Docket ID: EPA-HQ-OW-2022-0114) I am a retired Special Agent now Criminal Defense Investigator/Expert Witness, with over 35 years of experience in criminal investigations. As one of my part time jobs, I am an investigative journalist here in my home state of Kentucky. I have been working on a story that to call shocking, would be an understatement. We have completed a two part documentary that you can now view on YouTube entitled, "Lake Cumber, what really lies beneath" Parts 1 and 2.

Lake Cumberland in Pulaski County, Kentucky, is located in the beautiful Daniel Boone National Forest. It is a very active tourism location for swimming, boating, fishing, hiking, camping and water-skiing. It is also the primary source of drinking water for much of the people and wildlife in Kentucky and throughout Tennessee. Pitman Creek in Pulaski County, Kentucky flows directly into Lake Cumberland. Lake Cumberland flows into the

Cumberland River, a primary water source that flows down stream to Nashville, Tennessee.

As a result of numerous records that I have received from the State EPA and the State Water district via open records requests, I have serious concerns regarding the water contamination in Lake Cumberland and the Cumberland River.

My primary concern is that we have numerous documents that demonstrate that the City of Somerset has a highly defective wastewater treatment facility from at least 2016 through 2023. Despite this facility being repeatedly threatened by the State EPA, they have since 2019 added to this facility even more serious contaminates from landfill runoff called leechate. My investigation clearly demonstrates that this was done in order to secure at least $300,000.00 a year by the Mayor of Somerset and the Somerset City Counsel. This information is of particular concern if the notice of hexavalent chromium came after the introduction of leechate to this treatment facility. My research demonstrates that leechate from demolition landfills hold some of

the most dangerous contaminates. Some of these landfills will have leechate that most certainly contains asbestos and "Perfluorooctanoic acid" also known as "C8" and "Forever Chemicals"; as well as C6 hexavalent chromium. Normal purification processes will not remove these types of contaminates which are known to be highly carcinogenic and lethal to wildlife.

The documents that I have received from the State Water District, the State EPA, the Regional Health Department and the City of Somerset tell a most gruesome story. These documents clearly demonstrate that Sinking Creek and Pitman Creek, which empty out into Lake Cumberland, have numerous, repeated serious "Out of Compliance Violations" for: E-Coli, Chronic Ceriodaphnia Dubia Pkv; CBOD; Suspended Solids, Total Ammonia Nitrogen (as N), and MOST CONCERNING is the June 8, 2018, letter referring to "hexavalent chromium" limits — also known as C-6. These many violations run at least from 2016 to 2022. These violations were serious enough that the State Water Department repeatedly threatened that, "Violations of the above cited statutes(s) and/or regulation(s) are subject to a civil penalty per day per violation. Violations carry civil penalties of up to $25, 000 per day per violation depending on the statutes/regulations violated." Yet, in the State EPA, the State Water District and Somerset's answers and/or documents provided, there were zero fines or penalties levied on either the City of Somerset or the wastewater treatment plant; even though numerous violations have been sited over at least a period of six (6) years.

At this point, The City of Somerset Wastewater Treatment Plant alone has introduced at least 50 million gallons of Industrial Waste Leachate from four (4) different industrial waste landfills, not to mention the thousands of gallons of industrial waste from the local businesses that send their industrial waste to this defective plant. These businesses include medical facilities that are permitted for some of the worst contaminates imaginable, including C-6 & C-8. These landfills and businesses are permitted for "Industrial Waste" while the City of Somerset's wastewater treatment plant has only a general permit that is over twelve (12) years old.

Even more concerning is the reaction / cover-up from the Kentucky State Water District and the Kentucky EPA. Case in point, one of the documents in my possession is an email between Diana Robertson, Pretreatment Coordinator for KY Div. of Water, "As a follow-up to an earlier conversation, there are currently no federal or state wastewater standards/limits for PFOA (C8), PFOS or PFAS. As a result, wastewater treatment plants in Kentucky are not routinely sampling for those parameters. I wouldn't expect to see sampling of industrial user discharges for those parameters either as there are no applicable limits." In other words, she is refusing to test not only Pitman Creek or Lake Cumberland for these deadly chemicals, but apparently the State of KY Water District hasn't been and is NOT going to test for either these "forever chemicals" or asbestos even though there is a very real chance that this facility, and who knows how many others, are introducing them to our precious water sources. You can't find what you are not looking for.

Moreover, there ARE standards/limits for PFOA (C8), PFOS or PFAS that were set by DuPont. DuPont paid out over $4 Billion dollars in settlement agreements regarding this very thing in the state of Virginia. In these suits, the federal courts ruled that there were limits and that those

limits were set by DuPont themselves; and that limit is 70 parts per trillion. That is the equivalent of 7 grains of sand in an Olympic-sized swimming pool. Anything more has been deemed UNSAFE! The fact that a high-level bureaucrat in the State Water Division has no knowledge of this I find incredible. Furthermore, what is even more incredible is in an interview with the Somerset Wastewater Treatment Director, she stated that she had no idea what was in the leechate from the landfills that is now running through this defective system and into Lake Cumberland.

Several months ago, the federal EPA did a press conference and announced that there are NO SAFE LEVELS OF PFOAs (C8), PFOS or PFAS, in drinking water. As a result of what I have uncovered above, a local concerned attorney has tested his drinking water, and sure enough, it now contains PFOA (C8), PFOS or PFAS. I have been contacted by numerous people in the surrounding area that are now sick from this contamination.

This is just a sampling of this heart-wrenching investigation thus far. What I'm hoping for is that these EPA regulations and regulations like it, will indeed pass and not only protect our drinking water, but our entire echo-system surrounding our beautiful Daniel Boone National Forest.. We have already posted this story (Lake Cumberland, what really lies beneath) on You Tube, Face Book and on local cable T.V. in April 2022. The video will illustrate many of the documents of proof along with location videos and interviews. I know that this documentary is too long. However, when you are making extraordinary accusations, you must have extraordinary proof. Any assistance that I can give to you on this very important issue, I will be happy to provide. Feel free to contact me for any additional information. Thank you for your time.

Sincerely,

Darlene F. Price, J.D.

Producer/Hist of Truth or Politics

Washington, DC 20460

RE: EPA's Proposed PFAS NPDWR; Docket ID No. EPA-HQ-OW-2022-0114

We all know chemical manufacturers will alter an existing PFAS compound and circumnavigate the law. Can we address this situation? Please see attached outline of regulation to end this alteration in order to comply philosophy.

Sincerely

Jorge Diaz Castello diazcastello@gmail.com

786 381 8592

Section 1. (Title)

Title This legislation shall be known as the "Chemical Compound Alteration Prevention Act."

Section 2. (Purpose)

The purpose of this act is to prohibit chemical manufacturers from altering a chemical compound in order to circumvent regulatory compliance. This section aims to prevent the production and sale of chemicals that may be harmful to human health or the environment. Chemical compounds that are altered to circumvent regulatory compliance can be just as dangerous as the original chemical compound and can pose a significant risk to public health and the environment.

One example of a chemical compound that has been altered to circumvent regulatory compliance is PFAS (Per- and Polyfluoroalkyl Substances). PFAS are a group of man-made chemicals that have been used in a wide range of industrial and consumer products, including non-stick cookware, waterproof clothing, and firefighting foam. PFAS are persistent, meaning they do not break down easily in the environment, and can accumulate in the human body over time. PFAS have been linked to a range of health effects, including cancer, immune system dysfunction, and reproductive and developmental harm.

In response to regulatory action on PFAS, some chemical manufacturers have started producing "generation X" substitutes, which are chemical compounds that are structurally similar to PFAS but are not specifically regulated. However, research has shown that some generation X substitutes may be just as harmful as PFAS, and may even be more persistent in the environment.

Therefore, it is essential to prohibit chemical manufacturers from altering chemical compounds to circumvent regulatory compliance, and to promote the production and sale of safer and more environmentally friendly alternatives.

Section 3. (Definitions)

Definitions For the purposes of this act, the following definitions shall apply: (a) "Chemical manufacturer" means any entity that produces, imports, or sells a chemical compound or substance, including but not limited to manufacturers of pharmaceuticals, industrial chemicals,

consumer products, and food additives. (b) "Chemical compound" means any substance composed of two or more elements that are chemically combined in fixed proportions. (c) "Regulatory compliance" means adherence to any federal, state, or local law, regulation, or guideline that governs the production, importation, or sale of chemical compounds or substances. "Chemical facility" means any physical plant or other site where chemicals are produced, processed, stored, altered, or otherwise handled, including but not limited to manufacturing plants, warehouses, distribution centers, and laboratories.

Section 4. (Prohibition)

(a) Chemical manufacturers shall not intentionally alter the molecular structure of a chemical compound in order to circumvent regulatory compliance.

(b) Each chemical facility subject to this regulation shall appoint a “designated person” who is responsible for ensuring compliance with this regulation. The “designated person” shall be trained and certified in chemical safety and shall be personally liable for any violations of this regulation by the chemical facility. Each chemical facility shall have only one designated person. In the event of a violation, the designated person may be subject to civil or criminal penalties, including fines, imprisonment, or other appropriate sanctions. This provision will not only make the manufacturer of the altered chemical liable but also the chemical plant “designated person”.

(c) Chemical manufacturers shall not distribute or sell any chemical compound that is intentionally altered in violation of this regulation.

(d) Chemical manufacturers and chemical facilities shall maintain records of their compliance with this regulation, including but not limited to records of chemical composition, production processes, and safety data.

(e) Any “designated person” who violates this regulation may be subject to civil or criminal penalties, including fines, imprisonment, or other appropriate sanctions, as determined by the [enforcement agency].

Section 4 outlines the core prohibition of the draft legislation, which is the prohibition against chemical manufacturers altering chemical compounds to circumvent regulatory compliance. This provision is intended to prevent chemical manufacturers from using loopholes or technicalities to bypass regulatory requirements, and to ensure that all chemicals are subject to appropriate regulatory oversight.

Furthermore, Section 4 places the responsibility for ensuring compliance with relevant laws and regulations squarely on the shoulders of chemical manufacturers. Chemical manufacturers are expected to take proactive steps to ensure that their products comply with all applicable laws and regulations. They are also liable for any harm caused by their products, which ensures that they are accountable for the safety of their products and the potential harm they may cause.

By prohibiting the production and sale of harmful chemical compounds and holding chemical manufacturers accountable for their actions, Section 4 seeks to ensure that public health and the environment are protected from the potential harms of chemical exposure.

Section 5. (Penalties)

(a) Any chemical manufacturer found to have altered a chemical compound in order to circumvent regulatory compliance shall be subject to civil and criminal penalties.

(b) Civil penalties for a violation of this act shall be assessed by the appropriate regulatory agency and may include fines, injunctions, or other appropriate relief.

(c) Criminal penalties for a violation of this act shall be assessed by the appropriate law enforcement agency and may include fines, imprisonment, or both.

(d) Any person who suffers harm as a result of a violation of this act may bring a civil action for damages against the chemical manufacturer and the "designated person" of the facility where the chemical was produced/altered.

Penalties may include both civil and criminal consequences, as well as restitution for any harm caused by the violation.

Civil penalties may be assessed by the appropriate regulatory agency and can include fines, injunctions, or other relief. Criminal penalties may be assessed by law enforcement agencies and may include fines, imprisonment, or both.

Additionally, any person who suffers harm as a result of a violation of this act may bring a civil action for damages against the chemical manufacturer. This provision ensures that individuals who have been harmed by the actions of chemical manufacturers have recourse to seek compensation for their damages.

Section 6. (Enforcement)

(a) The enforcement of this law shall be a joint effort of the following federal agencies:

(i) U.S. Environmental Protection Agency (EPA)

(ii) U.S. Food and Drug Administration (FDA)

(iii) U.S. Consumer Product Safety Commission (CPSC)

(a) The federal agencies listed above shall have the power to investigate alleged violations of this law, and to bring civil or criminal enforcement actions against any chemical manufacturer that violates this law.

(b) Any person or entity that violates this law shall be subject to penalties as provided by law, including but not limited to fines, injunctive relief, and/or imprisonment.

(c) The federal agencies listed above shall have the power to promulgate rules and regulations necessary to implement this law.

(d) The federal agencies listed in subsection (a) shall establish a joint task force to coordinate their enforcement efforts and share information regarding violations of this law.

(e)The joint task force shall be responsible for:

(i) Developing a standardized process for investigating and enforcing violations of this law.

(ii) Sharing information regarding violations of this law, including but not limited to information regarding the identity of violators, the nature of the violations, and any enforcement actions taken.

(iii) Coordinating the enforcement efforts of the federal agencies listed in subsection (a), including but not limited to conducting joint investigations and pursuing joint enforcement actions.

(a) The federal agencies listed in subsection (a) shall provide annual reports to Congress regarding their enforcement efforts under this law, including but not limited to the number of investigations conducted, the number of enforcement actions taken, and the penalties imposed on violators.

(b) Citizen suits. Any person or organization may bring a civil action against any chemical manufacturer that violates this law if the federal agencies listed in subsection (a) have not commenced a civil or criminal action with respect to such violation within 60 days after the person or organization has provided notice of the violation to the appropriate federal agency and to the alleged violator. In any such civil action, the court may award costs of litigation (including reasonable attorneys' and expert witness fees) to any prevailing or substantially prevailing party, whenever the court determines such an award is appropriate.

These provisions would help to ensure that the federal agencies responsible for enforcing the law are coordinating their efforts effectively, and that they are sharing information and resources to maximize their effectiveness. By requiring the agencies to establish a joint task force and provide annual reports to Congress, the legislation would also provide transparency and accountability regarding the agencies' enforcement efforts.

Section 7. (Severability)

Severability If any provision of this act or the application thereof to any person or circumstance is held invalid, the remainder of the act and the application of such provision to other persons or circumstances shall not be affected thereby.

Section 8. (Effective Date)

Effective Date This act shall take effect on the date of its passage.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Sophia Milone (Doc. #1487, SBC-042704)

Also, due to the harm PFAS and other chemicals pose to public health and their longeivity, they should be treated as stringently as the EPA treats things like greenhouse gases: their emission should be reduced with the goal of emitting none, because any amount released is not safe. In order to ensure everything possible is being done to limit the emission of, consumption of, and exposure to PFAS, PFOA, and PFOS, the EPA should assess and remediate existing areas with high levels of these compounds. This will likely require funding for state-controlled remediation processes, but will assist communities suffering the most from chemical exposure and provide a framework for assessing affected areas in the future. (Attached is a list of effects from PFAS exposure).

[Figure: see docket ID EPA-HQ-OW-2022-0114-1487]

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #1506, SBC-042575)

We recommend that the EPA holds companies responsible for the impact their chemicals (PFAS) have on families in affected areas. This means not only notifying residents that their water is contaminated, but paying for them to relocate to a safer area if they choose to do so. If the residents do not want to move, the companies should cover all costs of safe bottled water until they can reduce the PFAS concentration to an acceptable amount. All residents who were exposed to dangerously high concentrations of PFAS should be entitled to free medical testing (covered by the responsible chemical company). If it is determined that residents acquired a disease as a result of the high PFAS exposure, the responsible chemical company will cover all medical costs related to the disease.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #1506, SBC-042577)

All PFAS should be banned in pregnancy/infant products, only essential PFAS should be present in other products (Benesh, 2020). Chemicals that are similar in structure/function to known PFAS should be required to undergo more rigorous and extensive testing before they are released to the public. This could mean animal testing and third party testers to ensure the safety of the new chemical.

Due to the extremely harmful effect PFAS have on individuals, employees of chemical companies should be held accountable for their decisions. More specifically, top employees who approved decisions which led to high concentrations of PFAS or attempted to hide the danger of PFAS should face criminal charges. All chemical companies and subcontractors who work with PFAS or similar chemicals should be required to sign an agreement taking full responsibility if any of their chemicals causes adverse human health problems. This agreement should be a part of their license to distribute/synthesize any chemicals (not limited to PFAS), making them liable for damages.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

John Pate (Doc. #1508, SBC-042580)

As you can see I Have a small contamination of my well. For the past Five years of testing I have not had above contamination until the new regulations were put in place. See attached file(s).Is it illegal to dump PFAS into the environment with knowledge of a contamination of a well. Because with Reverse osmosis system the brine solution that is dumped into our septic tanks which make a makes a toxic environment dump site when we have septic tank pumped out we do not need to report the contamination. Which then is used as biosolids out environment. Then let us take on step further people with a contaminated well use the outside spigot to wash cars, water grass or plants outside are those people also in violation of dumping PFAS into the environment. These are question should be addressed.

[Attachment 1: see docket ID EPA-HQ-OQ-2022-0114-1508].

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Liliana Salcido (Doc. #1509, SBC-042585)

Furthermore, all of this research and disclosure to the public should be funded and supported by the Federal government. In cases of danger and harm to the general public, there should be government intervention at the Federal level to ensure public health. Companies should not be regulating themselves when it comes to public safety because they have a conflict of interest when it comes to protecting their profits over the health and safety of humans. In a capitalist democracy, the citizens and consumers should have the right to make informed decisions based on full disclosure from both corporations and the government when it comes to consuming products, which in this case is water– our purest source of life and sustenance. If companies are regulating themselves and doing their own scientific research, they will be biased and they will choose to not disclose the harm their hazard waste and products create for human beings.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Jon Raclin (Doc. #1511, SBC-042595)

A utilitarian approach would be to utilize as much sun and wind energy as possible from large wind and solar fields to cut the costs of the policy down, so that the price of living doesn't rise as much, and use that stored energy to filter the water facilities under this policy change.

I think there should be two economic filters to this EPA change to help the public acclimate with this new billion dollar cost. The public is the three hundred million citizens that pay taxes to pay for the government's functioning. The EPA is the government's environmental sector. One filter is that the government should take a 6 month period of some payment to pay for wind farms or solar farms. This would pay for natural energy the water filtration cities would use across the nation. Additionally the second filter is that the population that spends the most on non necessary purchases, should be required to pay higher taxes, as to hold more accountability with their financial wealth.

This combination strategy bears the financial weight on multiple payment plans as to divide the weight and keep the entire economy afloat, and not allocate the entire multi billion dollar bill on one singular field of tax that won't be paid off for decades. The combination strategy is the one I want to see flourish because as a business major, I plan to own and run wind farms and solar farms and even lead the technology with the most recent science and make a powerful economic force that is helping the world.

This combination strategy protects and provides for the plan evenly and with green ambitions. The length of detail this new EPA regulation contains is revolutionary but also just the beginning. I see many more laws and discoveries as to chemicals we are banning and limiting in our mass production sectors.

I'd imagine if I were to tell a crowd my opinions about this combination strategy would be accepted and agreed upon. My combination strategy incorporates many evenly distributed finances and roles. The energy and technology used for this new regulation will have to be sourced from somewhere, and while we are continuing to protect our environment, we should go about this massive governmental rule change responsibly and source our energy from the natural sources; wind and sun.

5. Act and Reflect on the Outcome. You will submit your comments to the Federal Register when the public comment period opens. In the meantime, for this last step, as described previously, you will individually submit a 200-word reflection.

● Discuss some of the challenges you encountered in working through the five steps of decision-making, what insights you gained from the process, and what questions bubbled up as a result.

● How did my decision turn out? What is what you expected it would be going into this assignment?

● Can my recommendations be implemented with great care and attention to the concerns of all stakeholders?

Vojin's Input

I found the five-step decision-making process to be a very helpful tool in day-to-day life. At first, knowing that the decisions I made would affect the entire population was a bit intimidating but after breaking it down into manageable parts it became a lot easier. In researching this issue, the first step was identifying what shareholders would be most affected by and trying to gain insight into their perspective. After analyzing that I would compare the pros and cons to hopefully make the decision that would help the largest group of people.

The main challenge I encountered was balancing my beliefs and values with those of the shareholders. The difficult part was coming to a decision that would be fair to all parties without alienating one. The future consequences of my decision were also taken into consideration since the shareholders could be affected down the line.

The insight that was gained was mainly considering how our decisions would affect everyone involved. Also, what I realized was that by researching the issue in advance and weighing out the pros and cons we could make the process of coming to the best possible outcome much easier.

Questions that came up for me were mostly around how my decisions would affect me or the shareholders. I would try to take into consideration all the concerns and how people would be affected. I also wanted to make sure that the decision I made could be one that would attend to all shareholders.

Southern Methodist University Dedman School of Law (Doc. #1512, SBC-042597)

I have researched the effects of PFAS, and I would like to address two concerns I have with the proposed rule:

(1) As PFAS are "forever chemicals," meaning they do not naturally break down, more should be done to regulate these chemicals before they can make it to water supplies. Regulations should be as stringent as possible to avoid prolonged low-dosage exposure in our communities.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Southern Methodist University Dedman School of Law (Doc. #1512, SBC-042599)

1. Regulating PFAS From the Source

Across the country, PFAS are leeching into our water supplies at an alarming rate. [FN1: Chris Hubbuch, UW-Madison Researchers Seek to Understand How Forever Chemicals Move Through Soil, THE JOURNAL TIMES, (Dec. 22, 2022) (updated Jan. 31, 2023) https://journaltimes.com/news/stateand-regional/uw-madison-researchers-seek-to-understand-how-forever-chemicals-move-through-soil/article_6d376f99-1c52-5ce7-8545-0c372a92285e.html? utm_medium=social&utm_source=twitter&utm_campaign=user-share.] Because the over 6,000 PFAS do not all move or behave in the same ways, it can be challenging for researchers to decipher exactly how they reach water systems and where they come from. [FN2: Id.] Researchers have said that the presence of PFAS should be presumed in 57,412 sites across all 50 states. [FN3: Sharon Udasin, Scientists Say 'Forever Chemicals' may be Contaminating 57,000 US Sites, THE HILL (Oct. 12, 2022) https://thehill.com/policy/equilibrium-sustainability/3684169-scientists-say-foreverchemicals-may-be-contaminating-57000-us-sites/.] PFAS are used in a variety of materials, such as nonstick and water-resistant coatings, fire suppressants, and household goods. One recent study even found high levels of PFAS in school uniforms used by American and Canadian children. [FN4: Diamond et. al., Per- and Polyfluoroalkyl Substances in North American School Uniforms, Environ. Sci. Technol. 2022, 56, 19, 13845–13857, https://doi.org/10.1021/acs.est.2c02111.] Even if drinking water is made safer through PFAS regulation, the risks of these harmful chemicals are still present in our homes and communities. While the anticipated addition of PFAS as hazardous substances for purposes of CERCLA liability will hold the most egregious polluters accountable, more can be done to stop PFAS from entering our communities in the first place.

While the proposed NPDWR regulates some of the oldest and most harmful contaminants, it does not regulate all PFAS chemicals. [FN5: Stephanie Ebbs, EPA Announces Limits on Some 'Forever Chemicals,' But Just a Fraction are Covered, ABC NEWS, (March 14, 2023), https://abcnews.go.com/Health/epa-announces-limit-forever-chemicalsdrinking-water/story?id=97853947.] Efforts need to be made to eventually regulate all potentially harmful PFAS, even if the regulations would conflict with current industry practices. Actions such as the recent significant new use rule requirements for PFAS under § 5(a)(2) of the Toxic Substances Control Act (TSCA) are an important part of this. [FN6: Docket ID No. EPA-HQ-OPPT-2022-0867.] I suggest that further steps are taken to regulate a broader range of PFAS in a broader range of industries using the EPA's authority under the TSCA. Preventing PFAS from the source will further strengthen the proposed NPDWR requirements, while also limiting the amount of PFAS citizens are exposed to from sources other than drinking water.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Christian Garcia (Doc. #1513, SBC-042605)

While the proposed NPDWR sets maximum contaminant levels for six PFAS chemicals, it does not cover all PFAS compounds, and the set limits may not be stringent enough adequately. Notably, the current NPDWR is limited to public water systems, but more than 23 million US households are obtaining drinking water from private wells. [FN16: Allen D. Woolf, et al., Drinking Water from Private Wells and Risks to Children, American Academy of Pediatrics, https://publications.aap.org/pediatrics/article/151/2/e2022060644/190540/Drinking-Water-From-Private-Wells-and-Risks-to?autologincheck=redirected (last visited Apr. 21, 2023).]

Although the EPA and most states offer some guidance for the construction, maintenance, and testing of private wells, most states only regulate the construction of new private water wells. [FN17: Id.] Currently, water systems servicing less than 25 people, including private wells, are not subject to federal and state regulations under the Safe Water Act of 1974. [FN18: 42 U.S.C. §§300f-300j-26.] Yet, these private wells often contain the same PFAS levels and cause the very PFAS exposure that the EPA is trying to protect the public from. [FN19: Allen D. Woolf, et al., Drinking Water from Private Wells and Risks to Children, American Academy of Pediatrics, https://publications.aap.org/pediatrics/article/151/2/e2022060644/190540/Drinking-Water-From-Private-Wells-and-Risks-to?autologincheck=redirected (last visited Apr. 21, 2023).] These households should have the same guidance and access to resources as public water systems, such as access to federal funding to improve their water infrastructure under the Bipartisan Infrastructure Law. [FN20: U.S. ENVIRONMENTAL PROTECTION AGENCY, Water Infrastructure Investments, https://www.epa.gov/infrastructure/water-infrastructure-investments (last visited Apr. 21, 2023).]

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Emma Jenevein (Doc. #1514, SBC-042708)

PFAS needs to be regulated at the source, in addition to remedial regulation of PFAS present in drinking water

While it is essential that EPA establish an NPDWR to provide for the design, installation, maintenance, and enforcement of PFAS monitoring and removal procedures; PFAS contamination must also be addressed at the source to limit the need for remediation. Silent Spring Institute, a nonprofit research organization that studies the links between environmental chemicals and disease, has published several peer-reviewed studies concerning PFAS exposure associated with drinking water, [FN16: Laurel A. Schaider et al., Pharmaceuticals, perfluorosurfactants, and other organic wastewater compounds in public drinking water wells in a shallow sand and gravel aquifer, SCIENCE OF THE TOTAL ENVIRONMENT (Jan. 15,

2014), https://pubmed.ncbi.nlm.nih.gov/24055660/. See also Xindi C. Hu et al., Detection of poly-and perfluoroalkyl substances (PFASs) in US drinking water linked to industrial sites, military fire training areas, and wastewater treatment plants, ENV'T SCI. & TECH. LETTERS (Oct. 11, 2016), https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5062567/.] food packaging, [FN17: Laurel A. Schaider et al., Fluorinated compounds in US fast food packaging, ENV'T SCI. & TECH. LETTERS (2017), https://pubmed.ncbi.nlm.nih.gov/30148183/.] diet, [FN18: Herbert P. Susmann et al., Dietary habits related to food packaging and population exposure to PFASs, ENVIRONMENTAL HEALTH PERSPECTIVES (Oct. 2019), https://pubmed.ncbi.nlm.nih.gov/31596611/.] and consumer products. [FN19: Katherine E. Boronow et al., Serum concentrations of PFASs and exposure-related behaviors in African American and non-Hispanic white women, JOURNAL OF EXPOSURE SCI. & ENV'T EPIDEMIOLOGY (Jan. 8, 2019), 29(2), https://www.nature.com/articles/s41370-018-0109-y.] To address these sources of PFAS contamination, EPA should take steps to limit the number of consumer products containing PFAS. For example, PFAS contamination in drinking water has been closely associated with the use of PFAS-containing firefighting foams. [FN20: Xavier Dauchy et al., Per-and polyfluoroalkyl substances in firefighting foam concentrates and water samples collected near sites impacted by the use of these foams, CHEMOSPHERE (Sept. 2017), https://pubmed.ncbi.nlm.nih.gov/28531559/. See also Xavier Dauchy et al., Poly-and perfluoroalkyl substances in runoff water and wastewater sampled at a firefight, ARCHIVES OF ENV'T CONTAMINATION & TOXICOLOGY (Feb. 2019), https://pubmed.ncbi.nlm.nih.gov/30515647/.] Many states have enacted legislation to restrict or ban the use of PFAS-containing firefighting foam. [FN22: See e.g., S.B. 1044, 2022 Leg., Reg. Sess. (Cal. 2022); H.B. 19-1279, 74th Gen. Assemb. Reg. Sess. (Colo. 2019); S.B. 0561, 102nd Gen. Assemb., Reg. Sess. (Ill. 2021); S.B. 439-A, 2019–2020 Leg. Sess., Reg. Sess. (N.Y. 2020); L.D. 1505, 130th Gen. Assemb., Reg. Sess. (Me. 2021).] EPA should consider a federal ban on firefighting foams containing PFAS compounds to eliminate this particular source of drinking water contamination.

Presently, EPA is considering registering PFOA, PFOS, PFBS, and GenX as hazardous substances under the Resource Conservation and Recovery Act (RCRA). [FN22: U.S. ENV'T PROTECTION AGENCY, EPA Responds to New Mexico Governor and Acts to Address PFAS Under Hazardous Waste Law (Oct. 26, 2021), https://www.epa.gov/newsreleases/epa-responds-new-mexico-governor-and-acts-address-pfas-under-hazardous-waste-law.] EPA is also considering listing PFOA and PFOS as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). [FN23: U.S. ENV'T PROTECTION AGENCY, Key EPA Actions to Address PFAS (March 14, 2023), https://www.epa.gov/pfas/key-epa-actions-address-pfas.] By registering PFAS compounds as hazardous materials, EPA can help prevent releases of PFAS into drinking water from contaminated sites, freeing up resources for further remediation of PFAS contamination.

In summary, to effectively protect public health and provide for enforceable regulation of PFAS, any national drinking water standards must adopt a class-based approach. EPA must also expand

its regulation of PFAS beyond drinking water standards to address the sources of PFAS contamination.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Emma Jenevein (Doc. #1514, SBC-042706)

PFAS needs to be regulated at the source, in addition to remedial regulation of PFAS present in drinking water.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Ruoyu Zhang (Doc. #1520, SBC-042749)

While regulating Per- and polyfluoroalkyl substances (PFAS) in drinking water is an important step, other contaminants such as lead and arsenic also pose a significant threat to human health and necessitate strict regulation by the Environmental Protection Agency (EPA). Lead and arsenic are toxic metals that can lead to severe health problems, particularly in children and pregnant women. Lead exposure can cause developmental delays, behavioral problems, and lower IQ in children, while arsenic exposure has been linked to developmental effects, skin lesions, and cancer.

Despite the critical health risks of lead and arsenic, these contaminants are still present in many drinking water sources across the nation. Although the EPA has established maximum contaminant levels for lead and arsenic, these levels are inadequate and require more stringent regulation and enforcement through regular monitoring and enforcement actions. Such efforts would entail a significant investment in water treatment infrastructure. However, the long-term advantages of protecting public health would outweigh the costs. Furthermore, regulating lead and arsenic in drinking water alone is insufficient. It is critical to regulate these contaminants in other sources of exposure, such as soil and air pollution, requiring a concerted effort between the EPA and other federal, state, and local agencies, industry, and community stakeholders.

In conclusion, while regulating PFAS in drinking water is crucial, it is also imperative to recognize that other contaminants, such as lead and arsenic, pose a significant threat to public health and require stringent regulation by the EPA. Taking a comprehensive approach to regulate contaminants in drinking water and other sources of exposure will ensure safe and healthy environments for all.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Samantha Matterson (Doc. #1527, SBC-042631)

From an economic lens, this action does not fully address the negative externalities of this issue. PFAS are used in over 21 industries and in over 43 use categories, their use and production are expansive and widespread (Glüge et al., 2020). The companies that produce these chemicals continue to produce chemical waste and pollution, as well as directly harm those who are not involved in the production of the chemicals. In addition, the funding for the removal of the chemicals from the water comes at least in part from taxpayer dollars. Essentially, American citizens must pay to not get poisoned, when the government could step in and stop the poisoning from happening in the first place. The companies that produce these chemicals get to continue to profit while American citizens suffer. There should be more financial penalties for companies who continue to pump PFAS into the environment. That money could go toward removing PFAS from drinking water to supplement taxpayer dollars already going into this project. People and companies who are physically responsible for the presence of these chemicals should also be held financially responsible.

Overall, I think this action is necessary and is a step in the right direction. However, I believe that in order for it to be an effective dynamic solution to this issue, there needs to be added legislation or promised future legislation to ensure that companies producing PFAS are held responsible. Further, legislation needs to ensure that companies are producing less if not none of these harmful PFAS to stop them from entering the drinking water and environment in the first place. Every citizen and corporation has a responsibility to the future of our country and our planet, reducing the levels of PFAS is a start, but more action is required if future generations want a safe and healthy place to call home.

Water Environment Federation (WEF) (Doc. #1529, SBC-043316)

Long-term Impacts

Focus upstream to stop PFAS at the source instead of at the utilities where PFAS is received. Consider the scope of climate change impacts that regulations will impose on progress.

• Background levels: Background levels in some soils are higher than are found in drinking water and water resource recovery facilities. Clarification is needed on how EPA will manage this imbalance in existing and regulated concentrations.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Water Environment Federation (WEF) (Doc. #1529, SBC-043318)

• Climate Change: Soil loss, increased fertilizer prices, water shortages, increased GHG emissions due to transportation and/or adoption of high temperature processes, and increasing temperatures represent some of the real-time impacts of climate change. Targeting core programs that aim to recover resources, create renewable energy, and clean water will only exacerbate these impacts. WRRFs are engaged in a number of actions to mitigate climate change. Among others, WRRFs are adopting technologies and approaches such as water reuse, smart technology, and green infrastructure. They are also working to directly reduce greenhouse gas contribution through energy efficiency, resource recovery, and renewable energy development. Premature PFAS requirements could divert from some of these important activities.

• Biosolids: In the absence of a national PFAS regulation for biosolids, States are left to enact a patchwork system of restrictions. These restrictions reference the proposed NPDWR for guidance. A 45-year history of biosolids research has supported Title 40 CFR Part 503 – Standards for Use or Disposal of Biosolids. Banning biosolids will create a public health and economic crisis, forcing residents to bear the sharp increase in management costs due to increased shipping and landfilling, halting farmer access to a local and renewable alternative to synthetic fertilizer, and reversing climate benefits realized through sustainable biosolids management like carbon sequestration.

WEF members have diligently and proudly upheld the regulations set forth in the Clean Water Act for decades. It was because of this foresight by the EPA, that this pivotal environmental protection set precedence to protect our precious water resources that included the expansion and upgrade of water resource recovery facilities. It is this same foresight, that we ask the EPA to consider the short and long-term impacts that the proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation will have on the very systems that the Clean Water Act established and expanded. WEF asks that the EPA focus proposed regulations on stopping

PFAS at the source and work in concert with the thousands of water resource recovery facilities across the country to identify innovative, streamlined, and appropriately resourced solutions together.

Thank you for this opportunity to provide comment.

Sincerely,

Walt T. Marlowe, P.E., CAE

Executive Director

Water Environment Federation

To: OW-Docket

Subject: Proposed PFAS National Primary Drinking Water Regulation

Follow Up Flag: Follow up

Flag Status: Completed

The Safe Drinking Water Act must be amended to include regulation requirements that apply to all water systems not just public. It should include by name, Federal, State, City, Military (all branches), Business, Private and Public water systems. All entities should be required to comply with the PFAS drinking water regulations. There are people working and living on military facilities. There are communities that can be affected by cross contamination with private, military or federal water systems. To make this work they all must be included in the SDWA requirements and held responsible for the safety and good of all. If you do not do this you will end up with another Red Hill.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Linda Shosie (Doc. #1533, SBC-043958)

From the 1940's, to mid-1980's, the military and aeronautic industries at the Tucson International Airport Area (TIAA), have been disposing their industrial toxic wastes into drainage channel disposal pits, poisoning our sole source of water aquifer, and land.

A 24 square-mile area on Tucson South-side was designated a federal Superfund Site, when the EPA discovered hexavalent chromium and other chlorinated solvents, including, trichloroethylene (TCE) in the 1980's, but the EPA never cleaned up the contamination. Then, in 2002, 1,4-Dioxane, a probable human carcinogen, was discovered in the drinking water supplies around the site in addition to the TCE contamination that originally sparked concerns. Later, the EPA detected PFAS in the area as well, when our community group demanded more testing.

Thousands of South-sides residents are forced to drink, bathe, and cook in water contaminated with all these industrial chemicals at doses large enough to result in many health problems in our community.

I personally lost my 19-year-old daughter to a rare form of cancer, and another of my daughters is a cancer survivor. My son was also diagnosed with a rare skin disease, and my grandson was born with a birth defect, my granddaughter with kidney disease, in 2017, my 5 yr. old niece "Princess Mia" died of a rare childhood brain cancer. Her last words to her mom were, "why am I not pretty anymore." In 2019, my husband was also diagnosed with prostate cancer and had to undergo cancer treatment to remove it. Unfortunately, he does not have health care insurance to cover those costs. So, he had to pay out of pocket for those expenses as well as out of pocket expenses for his ongoing health care monitoring. Many of my friends and neighbors have experienced disease and loss as well. I believe that the high rates of disease in my own family and neighborhood are associated with the contamination of our drinking water. Our community deserves better!

I formed the EJTF in 2014, several years after my daughter's death, to educate people in my community about the different chemicals in their water supply and to advocate for stronger public water regulations and health protections so no one else would have to go through the pain that I have experienced.

I have personally gone door-to-door to talk with local residents who are exposed to the contaminated drinking water. I have purchased and handed out hundreds of cases of bottled water, along with a flyer to raise public awareness about the contaminants in our water supply.

When I founded the EJTF, our primary focus was on community concerns about the lack of response to address the long-term environmental health problems occurring in the community resulting from community-wide exposures to TCE. In addition to advocating for the cleanup and regulation of TCE, I began to look into what other chemicals had contaminated our water supplies.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Linda Shosie (Doc. #1533, SBC-047690)

As alarming as it was to discover that contamination, I was equally distressed to learn that Tucson Water knew of elevated PFAS levels in the water supply for many years before that

information was made public. The public needs access to information about the levels of PFAS in their drinking water supplies, as well as information about what those levels mean and when they can present risk to health, so people can make informed decisions about the water, that they and their family's drink. The EJTF is also committed to disseminating that information.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Greenville Utilities Commission (Doc. #1534, SBC-042638)

PFAS compounds should be regulated at the point of use by the manufacturers. The proposed rule notes these compounds are harmful to the cardiovascular and immune systems. It also mentions harmful metabolic, musculoskeletal, and liver effects from PFAS compounds. These effects could be limited if the government would restrict the use of these compounds at the source rather than requiring the water industry to remove them once in the environment.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Sarah Taylor (Doc. #1535, SBC-042641)

However, the EPA can help prevent these forever chemicals from infiltrating our drinking waters and ultimately harming our bodily health. One suggestion includes introducing a regulation requiring fire departments to use fluorinated firefighting foam as opposed to the current spray foam loaded with PFAS. Additionally, there should be national standards established regarding drinking, surface, and groundwaters. To aid in the authoritative power of this regulation, federal recourse can be established to groups that to do not comply with the regulation.

These changes will take time and cooperation from individuals and companies nationwide. However, as a unified team with a striving goal in mind to help fight against the toxic lifecycle of PFAS, these changes can be accomplished. The EPA can help make a giant step forward in the elimination of these toxic forever chemicals.

Best,

Sarah Taylor

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Brian Hackman (Doc. #1539, SBC-042907)

Finally, USEPA has been extremely derelict from the standpoint of controlling micropollutants like prions that can form by mRNA biological therapeutic injections into animals and humans. During the COVID era, wastewater testing showed in certain locations that when mRNA

injection cycles were accomplished, like in Cedar Rapids, IA, that the mRNA component showed up using PCR tests immediately after the injections, with the a large group of the population becoming infected, or testing positive for COVID by PCR (polymerase chain reaction) testing, two weeks later after injection. With now peer reviewed studies that show the mRNA (messenger ribonucleic acid) injections caused transmittable illness and suppressed immune systems within 10 months of the mRNA injection, USEPA would be better to direct its authority to manage environmental exposure of mRNA technologies which have acute effects and may have more chronic effects seen in less than 2 years, than the PFAS chemicals that have been environmentally available and exposing the population for over 70 years. Measurable health outcomes need to balance the cost of treatment and be demonstratable.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Cordell Spires Jr. (Doc. #1541, SBC-042662)

The better approach would be to limit the use of PFAS to only those considered essential, while fostering the development of safer alternatives. This would incentivize further development of alternatives that do not require PFAS. [FN-16: Id.] Remediation of water that has been contaminated with PFAS is costly, energy intensive, and cannot fully reverse the damage, so regulating PFAS in this way would prevent any contaminations from getting out of hand. [FN-17: Id.] This approach would also reduce the likelihood of replacing well-studied hazardous chemicals with poorly studied but structurally similar PFAS that have the potential to be similarly hazardous. [FN-18: Id.] Further, the approach would be simpler and less expensive to implement. [FN-19: Id.] Simpler, cheaper, class-based methods also typically result in more frequent testing, which improves compliance and detection of emerging risks. [FN-20: Id.] This approach would also encourage the selection of treatment approaches that effectively reduce total PFAS exposure when remediating PFAS-contaminated sites since the approach would limit all non-essential PFAS. [FN-21: Id.]

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Greater Cincinnati Water Works (GCWW) (Doc. #1550, SBC-042693)

While we appreciate EPA's goal of protecting public health, based on EPA's estimate, only 20% of PFAS exposure comes from drinking water. EPA's efforts would be better used to accelerate the elimination of sources of PFAS which are polluting our water resources and causing exposure through other avenues. Regulation of industrial sources of PFAS has moved more slowly than regulation of drinking water. As an example, USEPA recently issued a press release stating they were taking the first-ever federal Clean Water Act enforcement action to address PFAS discharges at Washington Works facility near Parkersburg WV. This is a facility notorious for its PFAS releases and contamination identified decades ago. Significantly extending the

compliance schedule for the PFAS drinking water rule will allow time for industrial sources to be identified and properly regulated. This will reduce source water concentrations and potentially avoid expensive treatment for many water utilities. Stopping the pollution at its source is a better use of federal resources and eliminates cost shifting for cleanup to drinking water customers.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Gabriella Thoppil (Doc. #1551, SBC-042700)

Support for Proposal and Request for Reform

The proposed NPDWR and MCLGs represent the response and recovery of the issue of PFAS in our public drinking water, as it only holds water systems and agencies accountable for testing and treating water that has already been contaminated with PFAS. However, the root of the problem is that PFAS continue to be used and developed by manufacturers and distributors and inevitably find a way to enter our water. Thus, while I fully support the proposed regulation, I propose that EPA reform this regulation to increase water testing efforts to identify and enforce registration of pollutant dischargers and to establish stewardship programs.

Though EPA has taken crucial steps to combat the usage and development of PFAS through Significant New Use Rules (SNURS), which require manufacturers and processors of PFAS to report new chemicals under the Toxic Substances Control Act (TCSA), the growing list of PFAS since their introduction in the 1940s indicates that tens of thousands of types of PFAS have been entering our water sources just over the last 5 years. [REF10: CompTox Chemicals Dashboard. Accessed April 20, 2023. https://comptox.epa.gov/dashboard/chemical-lists/pfasmaster; REF11: Perfluoroalkyl and Polyfluoroalkyl Substances (PFAS). Accessed April 20, 2023. https://www.niehs.nih.gov/health/topics/agents/pfc/index.cfm; REF12: States Environmental Protection Agency U, of Water O. PFAS Strategic Roadmap: EPA's Commitments to Action 2021—2024.; REF13: Risk Management for Per- and Polyfluoroalkyl Substances (PFAS) under TSCA | US EPA. Accessed April 20, 2023. https://www.epa.gov/assessing-and-managing-chemicals-under-tsca/risk-management-and-polyfluoroalkyl-substances-pfas] Currently, the SDWA only requires water systems to test for and report unregulated PFAS to the EPA every five years, which is not frequent enough to keep up with this rate of pollution. [REF12: States Environmental Protection Agency U, of Water O. PFAS Strategic Roadmap: EPA's Commitments to Action 2021—2024]. I propose that EPA enforce water testing at least every 1-3 years. This effort would provide state and regional governments with timely data to help them more rapidly investigate and identify all point sources of PFAS discharge and enforce the registration of PFAS-discharging operations into the National Pollutant Discharge Elimination System (NPDES) [REF14: NPDES Permit Basics | US EPA. Accessed April 20, 2023. https://www.epa.gov/npdes/npdes-permit-basics] As the Clean Water Act (CWA) legally requires operations that discharge pollutants into the water to obtain a free NPDES permit, the increased water testing will help ensure more PFAS dischargers are being monitored and held

accountable. [REF14: NPDES Permit Basics | US EPA. Accessed April 20, 2023 https://www.epa.gov/npdes/npdes-permit-basics] This effort will be worthwhile because studies have shown that the NPDES permit system has resulted in lower water pollution levels since its implementation in the 1970s. [REF14: NPDES Permit Basics | US EPA. Accessed April 20, 2023. https://www.epa.gov/npdes/npdes-permit-basics; REF15: Keiser DA, Shapiro JS, Altonji J, et al. Consequences of the Clean Water Act and the Demand for Water Quality. Q J Econ. 2019;134(1):349-396. doi:10.1093/QJE/QJY019] Furthermore, I propose that EPA continue to implement programs like the 2010/2015 PFOA Stewardship Program to encourage companies that generate any PFAS to either reduce or eliminate their usage of PFAS. [REF16: Fact Sheet: 2010/2015 PFOA Stewardship Program | US EPA. Accessed April 20, 2023. https://www.epa.gov/assessing-and-managing-chemicals-under-tsca/fact-sheet-20102015-pfoa-stewardship-program] The 2010/2015 PFOA Stewardship Program proved to be highly successful, as most of the eight major companies in the PFAS industry had either completely stopped manufacturing and importing PFOA or entirely abandoned PFAS. [REF16: Fact Sheet: 2010/2015 PFOA Stewardship Program | US EPA. Accessed April 20, 2023. https://www.epa.gov/assessing-and-managing-chemicals-under-tsca/fact-sheet-20102015-pfoa-stewardship-program] The success of this program suggests that inviting more companies to participate in similar stewardship programs could yield equally productive results.

Feasibility/Rebuttals

I anticipate that the current regulation proposed by EPA would generate resistance from water systems because the NPDWR and MCLGs would require them to invest in improved technologies and resources to meet the new standards. From their perspective, this regulation would mean that water systems have to bear increased responsibilities for the upstream transgressions of entities who use and discharge PFAS. For this reason, my suggestions for reform would help communicate to water systems that manufacturers and distributors of PFAS are also being held accountable. Conducting more frequent water tests would be a feasible change since it utilizes existing infrastructure, and implementing more stewardship programs would require little to no financial investment from EPA as program development would entail recycling and updating processes from the 2010/2015 program. Furthermore, water systems would benefit from financial support to implement the operational changes needed to meet the NPDWR and MCLGs. EPA could develop a system where manufacturers and distributors of PFAS directly fund their local water systems by enforcing fines or taxes for PFAS discharge, and perhaps even require entities to pay sizable fees to purchase NPDES permits. [REF14: NPDES Permit Basics | US EPA. Accessed April 20, 2023. https://www.epa.gov/npdes/npdes-permit-basics] Such implementations would effectively help fund water systems to meet NPDWR and MCLG requirements and also incentivize entities to abandon PFAS usage altogether. While such operations are sure to be displeased with these new financial costs, in this day and age of climate environmental accountability, many other industries and entities that contribute to environmental pollution are increasingly facing similar financial obligations. Although access to safe and reliable public drinking water is technically the legal responsibility of water systems that test and

treat it, accountability must begin with the ones responsible for contaminating our water sources with irresponsible PFAS usage, development, and discharge.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Brooke Young (Doc. #1554, SBC-043972)

[Some actions the EPA can do to address these challenges as part of the proposed PFAS drinking water regulation include:]

• Require routine statewide monitoring and testing to ensure that point sources are not contaminating our waters and that our drinking water is safe for public consumption.

• Require source water protection plans to be developed.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Brooke Young (Doc. #1554, SBC-043970)

[Some actions the EPA can do to address these challenges as part of the proposed PFAS drinking water regulation include:]

• Require that sites contaminated with PFAS compounds undergo cleanup and remediation to prevent future exposure to the public.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Great Lakes Water Authority (GLWA) (Doc. #1558, SBC-042549)

Reduction/Elimination of PFAS

GLWA supports source reduction and pollution prevention in the case of PFAS, just as it has with other chemicals in the past. To that end our Industrial Pretreatment Program team on the water reclamation side instituted a Pollutant Minimization and Source Evaluation Program for PFOS and PFOA in 2020. However, the development and administration of these programs are costly in terms of financials and work hours. It is our strong belief that those who manufacture and profit from these chemicals should be responsible for any needed remediation and the ultimate costs to eliminate PFAS concentrations that pose a threat to our health and the environment. GLWA strongly supports a "polluter pays" model where those who produced and profited from PFAS pollution bear the liability and costs of its remediation – not the public.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Per- and polyfluoroalkyl substances (PFAS): Perfluorooctanoic acid (PFOA) and Perfluorooctanesulfonic acid (PFOS) National Primary Drinking Water Regulation Rulemaking Proposed Rule Docket ID No. Docket ID: EPA-HQ-OW-2022-0114 Modification of CFR Citation 40 CFR 141; 40 CFR 142

Information on Environmental Protection and PFAS containment with Geosynthetic Systems

Introduction

In response to the recent publication of the Notice of Proposed Rule Making for Per- and polyfluoroalkyl substances (PFAS): Perfluorooctanoic acid (PFOA) and Perfluorooctanesulfonic acid (PFOS) National Primary Drinking Water Regulation Rulemaking, I offer the following comments and information (including references and attached appendices, “A” and “B”).

I compliment the EPA for the statements and inclination to promulgate regulations designed to protect the drinking, groundwater and surface waters of the United States from potential PFAS contamination. While potential regulations are not yet complete, there are certainly materials and systems available that can make significant and real contributions to the effort to contain PFAS and protect water resources.

I recommended that the regulations put forth require the use of a geosynthetic barriers, geosynthetic composites containing adsorbents and adsorbents and the use of composite liner system (geomembrane and geosynthetic clay liner) as these systems has been demonstrated (by EPA) to be the most effective barrier methodology, regardless of the classification of the materials (hazardous, non-hazardous or designated for beneficial reuse). This submittal contains references to EPA reports and studies as well as test data generated, using EPA protocols that support the effectiveness of geosynthetic systems and their components.

Statement of EPA request(s)

The Agency is requesting comment on this action, including this proposed NPDWR and MCLGs, and have identified specific areas where public input will be helpful for EPA in developing the final rule.

Respondent comments

I would like to ensure that EPA is aware of all pertinent information related to the effective use of geosynthetic materials for waste containment. The Geosynthetic Institute (Dr. George Koerner, Folsom, PA) website contains an index of the U.S. EPA documents that are related to the use of geosynthetics. The complete list is attached as Appendix "A' a link to the webpage is here: http://www.geosynthetic-institute.org/epa.html. Clearly, geosynthetic materials have been well examined and proven to be effective.

Relative to PFAS containment there has been research in recent years to examine this specific question. As PFAS has a special chemical structure and functionality, it is perhaps not prudent to employ standard chemical principals for chemical resistance such as grouping similar chemicals and molecular structures and projecting similar performance. PFASs as a group differ from other chemicals and investigations specific to PFAS were and are appropriate. Several published documents listed in the references in addition to continuing work in this area has demonstrated that the permeability of PFASs through geomembranes is quite low, and similar to that of PCBs and aromatic hydrocarbons.

EPA 9090 testing is a historically important testing protocol that was developed to demonstrate the chemical resistance of geosynthetic materials. EPA document EPA/600/S2-90/041 outlines the application of this testing protocol. I believe the contribution of EPA 9090 type testing is limited, relative to PFAS, However Appendix "B" references prior EPA publication in this area.

I recommend that the existing USEPA Disposal Rule for either Subtitle C or Subtitle D Regulations be applied to PFAS containment. Specifically, a 'composite liner' consisting of two components: An upper component consisting of a 60-mil polyethylene flexible membrane liner (FML), and a lower component consisting of either at least a two-foot layer of compacted soil with a hydraulic conductivity of no more than 1 x 10-7 cm/s, or a geosynthetic clay liner (GCL) containing at least 0.75 lb/ft2 of sodium bentonite. If 'composite liner' is not redefined to include a lower component GCL, then the allowance of an alternative liner design/system should be included as GCLs have demonstrated improved performance.

Further, to the required construction of containment systems, several companies now offer materials similar to geosynthetic clay liners (GCLs) that contain absorbents specific to PFAS materials. These should be required as a component of the barrier system. Testing has demonstrated that these materials readily absorb multiple PFAS varieties at a broad range of concentrations and have very high retention rates. A landfill cell, properly installed and tested for integrity, that is constructed with a composite liner system using a GCL-type product with PFAS absorption capabilities should be considered to be the stateof-practice at this time, offering the greatest potential for successful PFAS containment and long-term storage.

Conclusion

The benefits and successes of utilizing geosynthetic barriers in containment systems has been well documented by the EPA and other industry organizations. Geosynthetics have been tested and successfully evaluated in great detail over a long period of use in a very wide range of applications by EPA. PFAS varieties can be contained by current regulated geosynthetic barriers and new technologies exist to even further improve PFAS containment performance.

I thank the EPA for the consideration provided. I am more than willing to respond to any additional EPA inquiry on this or other related topics.

Sincerely,

Boyd Ramsey

Appendix A. U.S. EPA Geosynthetic Related Documents

Appendix B. U.S. EPA. 1990. Project Summary: Fundamental Approach to Service Life of Flexible Membrane Liner's (FML's).

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document. The EPA notes that the commenter points out specific use of "geosynthetic barriers, geosynthetic composites containing adsorbents and adsorbents and the use of composite liner system (geomembrane and geosynthetic clay liner) as these systems has been demonstrated (by EPA) to be the most effective barrier methodology." Please see section X of the final rule preamble and section 10 of the EPA response in this *Response to Comments* document for additional discussion on treatment technologies including BAT identification and evaluation. Additionally, please see section 5.1.4 of the EPA response in this *Response to Comments* document for the agency's evaluation of feasibility with respect to treatment.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042726)

May 23, 2023

Mr. Michael S. Regan, Administrator

U.S. Environmental Protection Agency

EPA Docket Center, OLEM Docket, Mail Code 28221T

1200 Pennsylvania Avenue, NW

Washington, DC 20460

RE: Docket ID No. EPA-HQ-OW-2022-0114

Dear Administrator Regan:

Maine Water Utilities Association appreciates the opportunity to comment on the Environmental Protection Agency's proposed National Primary Drinking Water Regulation. MWUA is a State association. We are a membership organization for those working or interested in the drinking water profession with more than 109 water systems as members. Our mission includes bringing together water utilities, consultants, manufacturers, vendors, regulators, academia, and other interested parties to network, educate, and advocate.

Our objective and goal is to provide public health protection to all that are customers of Maine Public Water Systems' (PWS). Maine PWS take this role very seriously and work hard to ensure that the water provided to residents and visitors across the state meets all Safe Drinking Water Act standards.

We are providing the following comments on EPA's proposed National Primary Drinking Water Regulation Rulemaking for per- and polyfluoroalkyl substances (PFAS). We note that EPA has engaged in rulemaking on several major rules that impact the water sector, with public comments all due within the past month, making it hard to give each the thorough review it requires. This regulation is complicated, with new concepts not well understood by the drinking water profession. We were hopeful that EPA would honor our request to extend the public comment period to give more time for thoughtful review on a regulation that will have substantial impact on our industry and more importantly our ratepayers. Unfortunately, our request was denied We fully support efforts to expand verified public health protections, but EPA needs to consider the challenges associated with implementation of the proposed PFAS rule before finalizing these standards.

General Comments:

MWUA and our members are very comfortable offering our expertise and opinions as they relate to the very real impact that new drinking water standards will have on our operations and related services. However, our ability to offer comments and opinions on more nuanced toxicological principles is well beyond our area of expertise. We are not toxicologists, nor epidemiologists, so we will leave it to other experts to comment on the appropriateness of the standards from a public health protection standpoint. We question why drinking water seems to be the sole focus of regulation while potentially higher PFAS exposures exist in consumer products (including food packaging, stain- and water-repellent fabrics, nonstick products, polishes, waxes, paints, cleaning products), food, personal care products/makeup, pesticides, and dust, and these potential sources of exposure are not simultaneously being regulated. We will note that there was a study of rainwater conducted by the National Atmospheric Deposition Program and the highest total concentration of PFAS was nearly 5.5 parts per trillion (ppt) in a single sample from

Massachusetts; with that said, have higher concentrations of PFAS falling from the atmosphere than EPA's proposed drinking water standards. The proposed drinking water standards assume that 20% of a person's exposure is allocated to drinking water, while 80% is comprised of all other potential exposure pathways. If we are to have meaningful health risk reduction shouldn't the current Administration be truly taking a whole government approach in addressing PFAS exposure by regulating all means of PFAS exposure simultaneously? Addressing only 20% of a person's potential exposure while the remaining 80% of exposure is allowed to continue unfettered seems irresponsible.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042468)

May 26, 2023

Michael S. Regan

Administrator

Environmental Protection Agency 1200 Pennsylvania Avenue, N.W.

Mail Code: 4607M

Washington, DC 20460

Administrator Regan,

San Antonio Water System (SAWS) is appreciative for the opportunity to comment on the proposed PFAS National Primary Drinking Water Regulation. While SAWS is in support of requests put forward to the Environmental Protection Agency (EPA) to extend the public comment period given the complexity and scope of the proposed rule, we have completed an initial evaluation of this proposed regulation and the available data. We respectfully request that EPA review and consider these comments:

• The EPA must establish a complete manufacturing, importation, and usage ban, for all PFAS and its derivatives. Companies must be prohibited from producing or importing products that use these chemical compounds. In the absence of a ban, regulation, and elimination of PFAS will always be a moving target. Once an actual ban is in place, then the EPA should start setting regulatory limits for health effects and exposure.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Endocrine Society (Doc. #1579, SBC-042425)

To improve the public health protection of the regulation, we recommend that the EPA:

•Ensure the availability of sufficient funds to assist in remediation efforts; funds should be generated through fees on the manufacturers of PFAS, and not rate payers and/or homeowners;

•Establish a process to include private well owners in assistance funding to prevent further impacts; and

•Work with other agencies to prevent further contamination by advancing additional strong regulations that prevent all non-essential uses of PFAS.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Association of State and Territorial Solid Waste Management Officials (ASTSWMO) (Doc. #1583, SBC-042405)

[Overall, as movement is made toward better regulation and oversight of these contaminants, ASTSWMO's membership recognizes a corresponding need for research, communication, and improved understanding within the following areas:]

• remediation technologies to remove PFAS from all environmental media;

• destruction and disposal technologies for PFAS-containing materials and waste streams;

• solidification and stabilization technologies to minimize PFAS in landfill leachate and methods to assess treatment effectiveness to aid in addressing capacity limitations; and

• acceptable levels of PFAS in compost, biosolids, wastewater sludge and industrial byproducts that are suitable for land application.

Advances in the key research areas listed above, along with establishing prevention programs to support the reduction and removal of PFAS from use, need to take place concurrently with this proposed rulemaking. More specifically, expanded coordination across all federal Agencies needs to be prioritized to reduce, and conceptually eliminate, PFAS present in consumer products and food supplies, which ultimately get into the water supplies and waste streams.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

American Public Works Assocation (APWA) (Doc. #1584, SBC-042391)

APWA is committed to limiting exposure to PFAS and protecting the environment. At the same time, we want to ensure efforts do not impose unintended consequences by unnecessarily directing resources away from other water system priorities like noncompliance with existing pollutant MCLs, replacement of lead service lines, microplastics, cybersecurity, or conservation and resiliency efforts to address changes in climate such as increased droughts or flooding. The reallocation of resources by communities may also mean deferring on maintenance, which could

risk failure of water infrastructure and be ultimately more costly in terms of quality of life in dollars, public health, and the environment.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Cape Fear Public Utility Authority (CFPUA) (Doc. #1588, SBC-042383)

Effective PFAS regulation begins at the source

CFPUA and our customers appreciate EPA's work to begin establishing drinking water regulations for PFAS such as PFOA, PFOS, and GenX in drinking water. While such regulations are necessary, we note the most cost-effective, equitable approach to reducing Americans' exposure to PFAS in their drinking water is keeping PFAS out of source water in the first place. Those who manufacture PFAS or use it in their manufacturing should be the primary focus of EPA's regulatory efforts, and they should be the ones to bear the burden of compliance with regulations regarding the PFAS they discharge into sources of drinking water. EPA acknowledges this in its PFAS Strategic Roadmap, which lists among its guiding principles a focus on source control as "a foundational step to reducing the exposure and potential risks of future PFAS contamination" and a pledge to hold "polluters and other responsible parties accountable for their actions and for PFAS remediation efforts."

We thank you for the opportunity to comment and be heard on this important matter and look forward to working alongside our partners at EPA and North Carolina Department of Environmental Quality to ensure continued access to safe, reliable drinking water for the community we serve.

Respectfully submitted,

Kenneth Waldroup, P.E.

Cape Fear Public Utility Authority

Executive Director

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Public Health, Seattle & King County (PHSKC) (Doc. #1594, SBC-042361)

For decades manufacturers have profited from use and development of PFAS chemicals. PFAS are now ubiquitous in products, processes, and the blood of nearly every resident of our county. Residents with PFAS contaminated drinking water experience a fear of not knowing how PFAS in their drinking water will impact their health or the health of their children, creating a life-long fear and anxiety about what is to come. The companies that have profited by polluting our land,

water, air, food supply and homes should be required to pay for the removal and cleanup of existing chemicals.

Provide homeowners that do not have access to public water systems with resources to identify and remediate PFAS in their drinking water. EPA should provide homeowners with private wells and small group systems with information on how to test their water and remediate if PFAS are detected at levels above the set MCLs. They should also provide educational information on how residents with elevated PFAS in their drinking water can reduce their risks of health impacts. In addition, EPA should invest in research that will identify low-cost filtration methods to remove PFAS from drinking water sources for individual homeowners on private drinking water sources such as private and small group drinking water wells.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Public Health, Seattle & King County (PHSKC) (Doc. #1594, SBC-042359)

Adopt a wholistic approach for PFAS at the EPA, which includes regulating their use so that their sources in drinking water, food, and indoor and outdoor environments are removed. The best way to prevent human exposures to PFAS and long-term, expensive cleanup efforts, is to restrict the use of these forever compounds now. The staggering costs to cleanup PFAS in the environment completely overshadow the profits to a small number of companies as highlighted in a new analysis conducted in the European Union [Link: https://chemsec.org/reports/the-top-12-pfas-producers-in-the-world-and-the-staggering-societal-costs-of-pfas-pollution/], not to mention the health costs to society [Link: https://pubs.acs.org/doi/10.1021/acs.est.1c03565]. We urge EPA to identify all nonessential PFAS that are in commerce and prohibit them from use, and to determine whether safer alternatives exist for all PFAS that are deemed essential before they enter or continue to enter the market.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

National Tribal Water Council-Tribal PFAS Working Group (NTWCTPWG) (Doc. #1598, SBC-042342)

PFAS Source Elimination

The proposed regulation does not appear to speak to PFAS source management and source elimination. As long as the manufacture and use of the multitude of PFAS chemicals remains poorly regulated or unregulated, these chemicals will continue to be discharged into the environment and taken up by humans and other beings. Further, the tribes will have to shoulder PFAS drinking water treatment (PFAS removal) costs, which will only grow over time as the presence and concentration of these PFAS chemicals in the environment and water supplies in particular continues to grow. While the EPA may not have the tools in the SDWA to regulate the

manufacture and use of PFAS chemicals, it does hold these authorities under TSCA and should more clearly demonstrate that it is aware of the much larger problem, a veritable elephant in the room.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042895)

Source Investigations:

In Massachusetts, MassDEP stated that when a PWS detected PFAS in the drinking water above the MMCL, MassDEP would initiate an investigation into the potential sources of contamination and the identification of potentially responsible parties. There have been so many detections in Massachusetts that MassDEP has not had the resources in its Bureau of Waste-Site Clean-up to perform timely follow up investigations. MassDEP has only initiated contamination investigations for 48 PWS thus far, and there have been 170 PWS detections. This delay has left PWS and their ratepayers funding investigations and remediation in the absence of a responsible party. Proper resources must be allocated to identify the source of contamination and hold that party responsible for the remediation costs.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042905)

Closing:

Thank you for the opportunity to provide these comments. Public water suppliers understand the importance of ensuring that the drinking water that reaches their customers meets SDWA requirements and protects the public's health. Water suppliers work hard each day to meet these goals and satisfy their customers' expectations. As we have all come to be keenly aware, the issue of emerging contaminants is a monumental challenge. Our members will be tasked with meeting any and all regulatory requirements and standards; therefore, EPA has an obligation to address our implementation concerns prior to finalizing the rule. EPA should also be using its authority to regulate the production of PFAS – it would be much more cost-effective to prevent PFAS from entering our environment and water supplies than it is going to be to clean up the contamination. We look forward to working collaboratively with EPA and MassDEP to ensure our PWS are able to meet their mandate of continued protection of public health.

Jennifer A. Pederson Executive Director

APPENDIX A - TREATMENT TIMELINE

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1601]

[Table 2: See Docket ID EPA-HQ-OW-2022-0114-1601]

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Arlington County Virginia (Doc. #1603, SBC-043020)

Further, it is water utilities that will now face the tarnish of violating EPA regulations, which exposes us to additional financial penalties, but even more damaging will be the resultant erosion of public confidence in the public water systems. Our public water systems are among the most important and impactful public health systems and also play an important role in preserving our environment by reducing industrial bottled water consumption. The proposed regulations will undermine confidence in these systems by imposing extraordinary rate increases and confusing consumers with inordinately low levels of PFAS exposure in water while other ingestion media, to include food, have been found to contain PFAS at levels thousands of times higher than the proposed regulatory standard for water.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-043977)

American Water calls for sound policies that will ensure compliance by all water utilities – whether privately or municipally owned – while protecting customers and communities from the high cost of monitoring and mitigating PFAS. This includes advocating for policies that hold polluters accountable. American Water's operating utilities in most of our states are currently plaintiffs in the Multi-District Litigation against multiple PFAS manufacturers because we firmly believe that the ultimate responsibility for the cleanup of these contaminants should fall to those who created the problem.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044003)

Funding

American Water calls for sound policies that will ensure compliance by all water utilities – whether privately or municipally owned – while protecting customers and communities from the high cost of monitoring and mitigating PFAS. This includes advocating for policies that hold polluters accountable. American Water's operating utilities in most of our states are currently plaintiffs in the Multi-District Litigation against multiple PFAS manufacturers because we firmly believe that the ultimate responsibility for the cleanup of these contaminants should fall to those who created the problem.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Prince William County Service Authority (Doc. #1609, SBC-042842)

2. EPA should re-prioritize its efforts to remove sources of PFAS from the environment. Prioritizing drinking water for regulation places the financial burden of PFAS removal on the public instead of the polluter.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Prince William County Service Authority (Doc. #1609, SBC-042830)

EPA Should Prioritize its PFAS Efforts on Eliminating Sources of Contamination

The Service Authority supports EPA's efforts to reduce PFAS in the environment. However, instead of prioritizing regulation of sources of PFAS, EPA proposes to regulate PFAS through drinking water, a significant divergence from the "polluter pays" principle. PFAS compounds continue to be manufactured and used in a wide variety of industrial and consumer products and processes. Water utilities are passive receivers of PFAS compounds that make their way to our sources of supply. Through the proposed regulation, the rate-paying public will be responsible for bearing the entire cost of PFAS removal, not polluters.

The continued use of PFAS will lead to increases in contamination and exposures in the future. But these exposures can be capped if steps are taken now to eliminate production and use of PFAS in all nonessential applications. In the meantime, the responsibility for paying for the legacy contamination should rest on the companies who continue to produce and market these chemicals even though they know about the chemicals' toxicity and extreme persistence.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Oakland County Water Resources Commissioner (WRC) (Doc. #1615, SBC-042928)

Public water utilities do not produce, profit from, or regulate the discharge of PFAS, but will continually need to contend with the cost of their clean up and disposal. It is imperative that any new regulations are accompanied with a "polluter pay" model where those who produced the PFAS pollution bear the liability and costs of its remediation – not the public.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Beaufort-Jasper Water & Sewer Authority (BJWSA) (Doc. #1618, SBC-042937)

We further request that EPA reevaluate the cost impact on utilities and look to investigate, identify and regulate those who are polluting the waterways. Removing the source of PFAS is by far the most cost effective way to address the issue rather than requiring water utility customers to spend billions of dollars to install treatment facilities. For utilities that still need to add treatment, adequate sources of funding need to be provided.

As public drinking water providers, it is our obligation to provide a high quality of water in a fiscally responsible manner. While we appreciate EPA's goal to enhance public health protection through PFAS regulation, the approach needs to be feasible and allow for a reasonable implementation schedule. We ask EPA to reevaluate the proposed rule to incorporate a phased implementation schedule and focus on identifying the source of the pollution so that the addition of expensive treatment can be avoided to the extent possible.

Thank you for the opportunity to comment. If you have any questions, please contact me at (843) 987- 8044. We would b_e happy to discuss our comments further.

Sincerely,

Verna J. Arnette

General Manager

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

WaterPIO (Doc. #1624, SBC-043477)

Now let's look at what the EPA isn't changing, the fact that PFAS are still allowed to be pervasive in the world we live in. That's on the EPA more than public water, but it doesn't matter to the EPA. Not only are PFAS still being produced and used in millions of consumer goods with reckless abandon, but producers of the compounds are still regularly able to dump PFAS into our source waters, even when they are unable to fully control their waste streams.

PFAS are still being pumped into our waterways under discharge permits that were created through loose regulatory processes public water systems had nothing to do with. Even in the Cape Fear Region of North Carolina, years after Chemours was discovered to be dumping PFAS into the Cape Fear River with impunity thanks to loopholes in their discharge permit, we still get regular news of random spills from their production facility.

Oh, sure, they're under a Consent Decree now – which we helped strengthen through a newsmaking op-ed when the first CO was released (https://www.starnewsonline.com/story/opinion/columns/your-voice/2018/12/02/opinion- mike-mcgill-our-area-is-loser-in-chemours-deal/7964097007/) – and they're building a retaining wall, but that's not going to stop them from producing PFAS. In fact, after 3M announced they were

going to phase out the production of PFAS by 2025, guess who jumped up to say they were going to ramp up production?

Chemours, the GenX polluters of the Cape Fear River.

This is the regulatory environment public water systems will find themselves operating in while the EPA's PFAS MCLs and HI hang over their heads. They'll be under constant threat of drinking water violations while millions of PFAS products continue to be cranked out into the consumer world, and millions of gallons are either legally released or spilled into our source waters.

Again, public water systems are being put in a position to fail.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

WaterPIO (Doc. #1624, SBC-043465)

\6. The companies actually polluting the environment with PFAS will still be producing them and dumping them – legally and illegally – into our nation's waterways. Millions of products, even toilet paper, will continue being made using PFAS, all while drinking water must meet the EPA's proposed standards.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044074)

EPA must expedite the Agency's work to address PFAS in wastewater and stormwater discharges, including the development of rulemakings for PFAS effluent limitation guidelines for the organic chemicals, plastics and synthetic fibers, and metal finishing and electroplating point source categories, as well as studying PFAS discharges from landfills, paper and textile mills, and electrical and electronic components. Additionally, the Agency should work to finalize Draft Method 1633 promptly for laboratories to analyze samples for surface water, ground water, and other media; and the national recommended ambient water quality criteria for PFAS. Primacy agencies need EPA's assistance and guidance in these areas. Some agencies want to require monitoring for pollutants in their surface waters, and others want to develop their water quality criteria. Additional Clean Water Act (CWA) regulatory and non-regulatory actions should continue simultaneously with the Agency's other efforts. PFAS will remain a problem for drinking water systems as long as all sources of PFAS contamination are not appropriately addressed and PFAS users are not held accountable.

ASDWA recommends that EPA use a holistic lifecycle approach that includes close coordination with other Federal agencies to administer all possible Federal statutory and regulatory authorities to address PFAS concerns.

Using a holistic approach to reduce or eliminate the use of PFAS and to prevent these compounds from entering the environment and drinking water sources throughout any part or all of the chemical's lifecycle - from manufacturing through processing, distribution, and disposal - is much more effective and less expensive than removing PFAS compounds once contamination has occurred. Protecting drinking water sources and preventing contamination is essential for sustaining safe drinking water supplies, protecting public health and the economy, and has substantial environmental benefits.

The PFAS NPDWR is a first step in addressing PFAS contamination; however, numerous other regulatory decisions are made based on drinking water standards (e.g., ground water standards, ground water remediation determinations, National Pollution Discharge Elimination System permits, and surface water standards). EPA must coordinate across all the Agency's offices and with other federal Agencies (i.e., the Department of Defense, the Food and Drug Administration, and Centers for Disease Control) to reduce PFAS contamination. This approach across all Federal agencies will ensure consistent messaging and implementation. ASDWA has consistently recommended that EPA use a holistic lifecycle approach that includes close coordination with other Federal agencies to administer all possible Federal statutory and regulatory authorities to assess, address, and remove PFAS or prevent PFAS from entering the environment (and drinking water sources) from all contributing media. This includes considering impacts from disposal and incineration, particularly as EPA works to finalize its guidance on the destruction and disposal of PFAS and materials containing PFAS. Utilizing all regulatory authorities will help ensure that the responsibility and cost for removing PFAS are not passed on from one media to another. This also includes consistent messaging to regulators, regulated entities, and the public on PFAS.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Association of Environmental Authorities (AEA) (Doc. #1635, SBC-042962)

AEA endorses a comprehensive PFAS chemical national strategy that extends beyond water, and which helps end PFAS pollution by limiting it or eliminating it at the source. This should involve all relevant federal regulatory agencies.

We recommend the EPA consider the consequences of the proposed NPDWR that will go beyond drinking water and will affect water recycling and reuse programs, wastewater treatment, and biosolids management would be affected.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Town of Tewksbury, Massachusetts (Doc. #1637, SBC-043251)

EPA needs to rapidly work toward finding permanent destruction technologies or we will continue to face the prospect of a never-ending cycle of moving PFAS around our environment.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043452)

More recently, on January 13, 2023 the European Chemical Agency (ECHA) proposed a ban on ALL 10,000+ PFAS chemicals. [FN58: ECHA publishes PFAS restriction proposal, European Chemicals Agency (Feb. 7, 2023),https://echa.europa.eu/-/echa-publishes-pfas-restriction-proposal.] If passed, it is expected that the Ban will be implemented by 2027. During its public briefing in support of the proposal, ECHA stated several reasons for the need of class-wide PFAS regulations. ECHA pointed to the ever-increasing number of known or suspected adverse effects on human health and environment, PFAS's high tonnage usage in a variety of applications, monitoring data showing the ubiquitous presence of PFAS in the environment and humans, PFAS's very high persistence and difficulty to remove once released into environment, and other uncontrolled risks from uses of PFAS. [FN59: Id.]

In support of its class based approach for the proposed PFAS ban, ECHA states that it is a significantly more efficient and protective method compared to previous risk proposals that looked on a case-by-base basis. [FN60: Id.] ECHA's proposed group ban also avoids what it calls regrettable substitutions, or the replacement of one hazardous substance with another one. [FN61:Id.] ECHA's proposed group ban has two potential methods, 1) a full immediate ban that would take effect after an 18 month transitional period, or 2) a ban with use-specific derogations. [FN62:Id.]

Both would include banning manufacturing of all PFAS compounds, placing any PFAS materials in the market, specific uses of PFAS compounds, and PFAS uses as constituents in other substances or mixtures above a set concentration limit. Derogations would be very specific and time limited, falling into two categories. Category 1 would be for five years and be for products where alternatives are under development but not currently available for entry into force. [FN63: Id.] This would cover food contact materials for industrial food and feed production. Category 2 would be for twelve years and cover products where identification, development, and certification of alternatives is still needed. This would cover implantable medical devices. [FN64: Id.]

CARE agrees with PFAS experts and ECHA's assessment that the extreme persistence, accumulation potential, and both the known and potential hazards of PFAS demand a more efficient and effective methodology than EPA's current regulatory approach. A class-wide ban would be one such methodology. CARE urges EPA to consider a class-wide ban and believes such an approach would be more protective of human health and the environment.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

California Municipal Utilities Association (CMUA) (Doc. #1639, SBC-043253)

May 30, 2023

Submitted via: https://regulations/gov

U.S. Environmental Protection Agency EPA Docket Center

Office of Ground Water and Drinking Water Docket

1200 Pennsylvania Avenue NW Washington, DC 20460

Subject: Comment Letter re Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation Docket ID No. EPA-HQ-OW-2022-0114

Office of Ground Water and Drinking Water,

The California Municipal Utilities Association (CMUA), representing over 50 public water agencies, appreciates the opportunity to comment on the U.S. Environmental Protection Agency's (EPA) Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (henceforth referred to as "the Regulation"). Our public water agency members are committed to providing safe water to their customers. Ensuring that the Regulation reflects practical considerations and limitations faced by public water agencies is of utmost importance.

We recognize that Per- and Polyfluoroalkyl Substances (PFAS) exist in water supplies nationwide; however, it is essential to distinguish and recognize that PFAS finds their way into water supplies usually by the action of manufacturers of products that contain PFAS. Public water agencies are left with the overwhelming burden of removing these contaminants from their water supplies to continue delivering safe water. We strongly encourage the EPA to consider imposing a higher burden of PFAS removal on those manufacturers rather than public water agencies. We should endeavor to eliminate PFAS contamination at the source.

CMUA offers a few comments on the Regulation for your consideration.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043259)

May 30, 2023

Michael S. Regan

Administrator Environmental Protection Agency 1200 Pennsylvania Avenue, N. W.

Mail Code: 4607M

Washington, DC 20460

RE: Comments for EPA's Proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation (Docket ID: EPA-HQ-OW-2022-0114)

Headquartered in Duncan (Oklahoma), the National Rural Water Association (NRWA) is the non-profit association of the federated state rural water associations with a combined membership of over 30,000 small and rural communities. NRWA is the country's largest water utility association and the largest community-based environmental organization. State Rural Water Associations are non-profit associations governed by elected board members from the membership. Our member utilities have the very important public responsibility of complying with all applicable U.S. Environmental Protection Agency (EPA) regulations and for supplying the public with safe drinking water and sanitation every second of every day.

Administrator Regan,

The National Rural Water Association (NRWA) appreciates the opportunity to comment on the Environmental Protection Agency's (EPA) proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation (NPDWR). NRWA has been providing boots-on-the ground assistance to water utilities since 1976. Currently, 40% of all technical assistance that is provided through these programs, such as the Circuit Rider Program and EPA Water Training and Technical Assistance Program, goes directly to disadvantaged communities. On top of this, 100% of assistance and training provided is to communities with populations of 10,000 or less. NRWA's technical experts provide practical, peer-to-peer help that makes a real difference to rural and small communities every day.

NRWA shares the goal of eliminating all concentrations of PFAS from the public's drinking water and environment. However, regulation, civil enforcement, and liability under the Superfund Law (CERCLA) are not the appropriate federal remedies for addressing this problem for local governments.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

National Association of Clean Water Agencies (NACWA) (Doc. #1659, SBC-043132)

NACWA understands EPA's desire and need to regulate PFAS in drinking water, but it is not possible to adequately address these chemicals without also eliminating the continued production, importation, and use of these chemicals in commerce on a daily basis. To the extent EPA is looking to water utilities to be the solution to the rampant, widespread presence of PFAS by removing PFAS from our nation's water supplies, the Agency must also significantly amplify its efforts to eliminate harmful PFAS production and use in the United States and prevent commercial importation of products into the country that contain PFAS. Absent this additional

source control, water treatment will merely move PFAS from one environmental media to another without controlling the problem at its source.

Therefore, other environmental statutes, like the Toxic Substance Control Program (TSCA), must be the Agency's priority for pollution prevention efforts, and EPA should prioritize elimination of nonessential PFAS uses in commerce. Otherwise, public water systems and public clean water utilities will continuously, in perpetuity, be fighting a costly treatment battle with chemicals still being used in commerce—a problem that they never created in the first place. And not having a robust and aggressive pollution prevention program to address these ubiquitous and persistent chemicals before treatment is required creates a foolish precedent and an approach that is at odds with international approaches like the Stockholm Convention on Persistent Organic Pollutants.

EPA's Proposed MCLs will Impact Clean Water Utilities Engaged in Reuse

Although the proposed NPDWR primarily impacts PWSs, NACWA is concerned that this rule will also impact clean water utilities that are taking innovative steps to recycle or reuse wastewater. Treated wastewater can be beneficially reused or recycled in myriad ways including irrigation for agriculture, domestic irrigation for landscaping, power plant cooling, as process water for industrial, manufacturing and construction uses, wetland rehydration, municipal water supplies, and environmental restoration. A rising concern is how this drinking water rulemaking will have broader impacts that EPA has failed to analyze, including costs that may be incurred by clean water systems that are leading the way to supplement water supplies, replenish aquifers and mitigate land subsidence.

Specifically, clean water utilities that recycle, reuse, and reclaim water by directly discharging to groundwater or surface waters that are potential sources of drinking water are subject the Clean Water Act's Section 402 permitting requirements. These utilities are often required to treat the reclaimed water to meet primary and secondary drinking water standards prior to the reclaimed water being beneficially reused. Therefore, these clean water utilities will also be impacted by the proposed rule as they will most likely have to meet the new MCLs as part of their discharge requirements, independent of any consideration of receiving water conditions or downstream treatment processes associated with producing drinking water.

However, unlike the Clean Water Act, permitting flexibilities like water quality variances or changes in designated uses are prohibited when there are primary drinking water standards at play under the SDWA. Therefore, EPA should evaluate instances where clean water utilities will have to comply with the proposed rule if it is finalized. NACWA encourages EPA to consider the unique intersection of the SDWA and CWA and the impacts the proposed rule will have on some utilities that are innovatively advancing indirect and direct potable reuse—a priority of EPA's through its Water Reuse Action Plan. Additionally, EPA should provide additional flexibility in the final rule for situations, such as potable reuse, to ensure EPA and state permitting authorities have the tools similar to those used in the Clean Water Act.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document. With respect to "costs that may be incurred by clean water systems," the EPA notes that National Pollutant Discharge Elimination System (NPDES) permits for utilities could potentially consider drinking water standards in establishing permit limits for discharge of reclaimed water, however SDWA expressly states that the EPA shall consider "quantifiable and nonquantifiable costs. . . *excluding costs resulting from compliance with other proposed or promulgated regulations*." For further information on the EPA's cost analysis, please see section 13 of the EPA response in this *Response to Comments* document and section XII of the final rule preamble. Additionally, please see section 5.1.3 of the EPA response in this *Response to Comments* document for additional discussion on cost considerations in the final MCLs.

Maine Organic Farmers and Gardeners Association (MOFGA) (Doc. #1660, SBC-043385)

Additionally, to prevent future contamination, EPA should ban wastewater sludge-spreading, as Maine has done, and provide funding for safer disposal options.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Blue Ridge Environmental Defense League (BREDL) (Doc. #1663, SBC-044387)

Unregulated Contaminants Monitoring Rule 5 (UCMR5) Provides Inadequate Notification

The UCMR5 currently requires testing for 29 PFAS contaminants. The water providers will then be required to release the results to the public, but only online. Additionally, it could take up to a year and a half for water users to be notified, depending on the date of initial testing. Only requiring the water systems to post results online ignores the fact that in many locations, communities do not have reliable internet—and even if they do, there are people that cannot afford it or that do not have dependable ways to access it. EPA should consider requiring water systems to send their customers notification through the mail—like they send their billing statements. We recently asked the North Carolina DEQ if they had a list of what systems would be monitoring for PFAS. Despite the fact we got information from Virginia DEQ, the North Carolina state agency has initially responded that EPA was responsible for providing this information.

Examples of North Carolina Agency Inaction

Soon after EPA's June 2022 announcement of the health advisory (June 2022) for four PFAS (GenX, PFOA, PFOS, and PFBS) BREDL began inquiring about steps North Carolina state agencies were taking, or planning to take, to notify the public about the health dangers of these PFAS and detections in their drinking water. We sent several emails to the North Carolina Department of Environmental Quality (DEQ) and the North Carolina Department of Health and Human Services (DHHS) attempting to get information on their plans. We also asked local

governments that we knew had detected numerous PFAS in their finished water. These are some of the responses we received:

DEQ: "DEQ does not have a mechanism to require that public water supply systems provide public notification for PFAS compounds above a Health Advisory Level, though some public water systems have been voluntarily monitoring for PFAS and have also developed their own method to notify customers."

DHHS: "It is typically the responsibility of the utilities to notify their customers about water quality within their systems – although we have been getting the word out more generally through our fact sheets about PFAS and Testing and Filtration."

We also asked a local government source that we know/knew tested for PFAS if DEQ had reached out to them regarding notification to customers if any amount of PFOA or PFOS was found (as recommended by EPA when the health advisories came out). We knew that the system routinely detected numerous PFAS, including PFOA and PFOS in their finished water. They replied, in September 2022, that DEQ had NOT contacted them. At that point we sent a public records request to the agency about this matter. As of this date we have not received any documents, and queries about the status of our request generally go unanswered. In October 2022, we sent a letter to DEQ Secretary Elizabeth Biser. The letter (which will be submitted with these comments) asked the Secretary "…what specific actions the North Carolina Department of Environmental Quality (DEQ) has undertaken to encourage, recommend, or otherwise assist local governments and private water systems in their communication efforts; or in helping them understand the importance of communicating directly with their customers." We also asked that DEQ take steps to notify the public about PFAS contaminants in their drinking water. We have not received a response.

On April 5, 2023, we attended a meeting of the DEQ Secretary's Science Advisory Board. One of the Board members voiced concerns regarding notification: " You're talking about millions of people. They are exposed to levels that exceeded the four. So it really speaks to, I think a need for a really effective communication strategy." DEQ's response to his comment was that they did not want to "alarm" the public. On April 7, 2023, BREDL sent a letter to the SAB "…requesting that the Science Advisory Board act in their advisory capacity and recommend that the Department of Environmental Quality take immediate action to meaningfully inform the public about PFAS in their water. We know that the Department notifies private well users by mail if PFAS are detected. Consumers who use drinking water provided by public or private systems deserve no less." (Letter will be submitted with these comments).

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Inland Empire Utilities Agency (IEUA), California (Doc. #1666, SBC-043394)

IEUA acknowledges the role of the water and wastewater industry as part of the long-term solution to PFAS management, but also urges EPA to prevent unsafe PFAS from entering the consumer marketplace and to hold accountable those entities that are primarily responsible for PFAS production and distribution leading to contamination.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

National Association of Water Companies (NAWC) (Doc. #1670, SBC-044162)

Many private water systems are in the process of seeking damages directly from the PFAS manufacturers through litigation in various jurisdictions to hold the manufacturers accountable for the contamination they have caused and to remediate water supplies. How this litigation will be resolved and, if successful, when funds would be recovered is uncertain and private water systems need to have access to other sources of funding to address the PFAS substances that may be present in the drinking water supplies.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

National Association of Water Companies (NAWC) (Doc. #1670, SBC-044161)

4. EPA needs to require point of use restrictions on the manufacturers to address and remediate PFAS contamination at its source and reduce downstream removal of contaminates by entities with no responsibility for the creation of the problem.

EPA needs to take greater actions to reduce the contamination of water supplies by the manufacturers of PFAS substances before the harmful chemicals contaminate water supplies. EPA needs to commit to stronger actions against the sources of the contamination rather than requiring the water industry to remove the harmful chemicals once they are in the environment and the water supplies. The drinking water industry should not be disproportionately targeted by this regulatory action to reduce PFAS exposure.

A regulatory scheme to address the problems caused by PFAS contamination of drinking water supplies should recognize and account for how PFAS contamination began and how it has spread in order to place the responsibility for the contamination on the parties that created it and are responsible for the contamination. In previous regulatory proposals, EPA provides a brief description of the history of the production of "these human-made chemicals that have been used in industry and consumer products since the 1940's". (See 87 Fed. Reg. at 54418). EPA did not suggest, nor could it, that NAWC members or other public or private water or wastewater utilities have played any role in the production or distribution of these chemicals. NAWC members do not use PFAS chemical in the process of providing clean drinking water or in the

wastewater treatment process. Rather, water, wastewater, and stormwater systems passively receive PFAS from these other sources. Water systems, and the public, have limited control over their contributions of PFAS to the environment given the overwhelming presence of this family of chemicals in the chain of commerce and in homes. In its regulatory scheme aimed at addressing the presence of PFAS chemicals in the water supply, EPA should adhere to the principle in other environmental laws that the parties responsible for contamination should be responsible for and pay for its remediation.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044899)

PWSs provide an important and valuable service to the public by removing pollutants to create safe drinking water. However, the burdens of pollution remediation should not be solely placed on PWSs and our ratepayers. First and foremost, EPA should focus its resources on incentivizing pollution prevention and regulating PFAS pollution where it is manufactured and/or used, rather than putting the entire burden on passive receivers such as water and wastewater utilities. It is easier and more cost effective to address chemical discharges before entering the nation's waterways rather than trying to remove pollution afterward. EPA must do more to hold polluters accountable and implement the "polluter pays" principle, where those causing the pollution are responsible for the cost of cleanup. Relying solely on PWS ratepayers to finance the removal of contaminants shifts this responsibility to a "community pays" model, where the burdens of pollution removal are unfairly placed on the public while the corporation profits from the use and sale of the product.

Cleveland Water recommends EPA take actions to better identify sources of PFAS and work to limit these discharges. The agency has recognized the persistent nature of these chemicals; therefore, it should be working toward prevention, as disposal is not a viable long-term option. Cleveland Water appreciates efforts already being made, like the addition of certain PFAS to the Toxics Release Inventory but urges the agency to do more to track and reduce PFAS discharges. Knowing the source of PFAS will allow EPA and PWSs to work to address PFAS at the source and hold polluters accountable.

Cleveland Water also recommends the EPA Office of Ground Water and Drinking Water (OGWDW) work with other EPA offices and federal agencies to address other routes of public exposures to PFAS. PFAS are found in food and food packaging, household and personal care products, fire extinguishing foam, clothing, carpet, kitchen countertop cleaners, and many other items that the public encounters [FN1: https://www.epa.gov/pfas/our-current-understanding-human-health-and-environmental-risks-pfas]. However, it is difficult to impossible to know the level of PFAS contained in any commercial product marketed for sale.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Association of California Water Agencies (ACWA) (Doc. #1675, SBC-044928)

ACWA supports EPA's aim to control PFAS in drinking water and protect public health, but we have concerns with the agency's current regulatory approach to PFAS. ACWA believes that greater focus on eliminating PFAS in consumer products, source control, and destruction technology as well as holding PFAS polluters accountable is necessary to achieve progress in mitigating PFAS risks and exposure. We recommend EPA take more proactive measures to identify sources of PFAS and limit their discharges, as prevention is more cost-effective than attempting to clean up pollution later and maintains the "polluter pays" principle under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA).

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Rockbridge Area Conservation Council (RACC) (Doc. #1678, SBC-043742)

With that said, we would respectfully request that: (1) PFOA and PFOS, based on the toxicological data currently known, simply be banned within an appropriately short timeframe (1, 3, 5 years?) from all non-medically essential product uses; (2) cease the application of any PFOA/PFOS containing biosolids from being applied to land; (3) eliminate PFOA/PFOS from future manufacturing off-shoots (semiconductor and/or other unknown industrial uses) regardless of what can or cannot be identified analytically; and

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Rockbridge Area Conservation Council (RACC) (Doc. #1678, SBC-043738)

[With that said, we respectfully request that:] (2) the development of a governmental database for consumers that lists products and packaging contain PFAS – including those in "inert ingredient" and "business confidential" formulations, citation to source of data, and any projected date for removal and delisting; and (3) the immediate testing and cessation of land application of biosolids that contain PFAS - including PFOA/PFOS.

Additionally, significant consideration needs to be paid to new forms of contamination. There is currently a movement to provide $39 billion for semiconductor manufacturing which more than likely will increase PFAS contamination; perhaps putting money into PFAS-free semiconductor manufacturing/technology upfront could minimize/eliminate some of the potential contamination. Likewise, outright banning carcinogens like PFOA/PFOS and looking for safer alternatives may be more helpful in "preventing cancers" requiring less money for "curing/treating cancers" … prevention maybe a better way to fight human and environmental PFAS health issues.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Rockbridge Area Conservation Council (RACC) (Doc. #1678, SBC-043740)

If/when a substance(s) causes significant toxicity at levels below what can be identified analytically, it is safer to ban the substance to err on the side of safety (precaution) rather than to keep using it and err on the side on making more money. The latter statement can be realized in several recent news stories that note globally the world's largest PFAS manufacturers make ~$4 BILLION annually in PFAS sales while societal costs are projected to be $17.5 TRILLION in damages annually. The fact that "EPA has quantified some of the reduced adverse health effects expected from the proposed rule … to be $908 million to $1.23 billion in savings" … the overall savings is paled by the estimated $17.5 TRILLION in global damage costs.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Rockbridge Area Conservation Council (RACC) (Doc. #1678, SBC-044300)

However, in the absence of establishing a timeline in which the MCLG would be realized (5, 10, 20 years?) it is unclear what significance the MCLG holds if these chemicals are not clearly banned from use, importation, and repeated reintroduction into the environment and food supply via disposal in POTWs and subsequent release of POTW effluent and biosolids.

If the media used to treat industrial effluent and drinking water to reduce PFAS is then disposed of in municipal landfills, which then send PFAS-laden leachate to Publicly Owned Treatment Works (POTWs) that do not remove PFAS before discharging effluent to the environment and applying biosolids to agricultural fields, it seems clear that without equivalent action at these other points in the PFAS cycle, MCL/MCLG standards by themselves may simply re-direct PFAS dose to other routes of exposure.

Because these chemicals are so ubiquitous to our world and are used in an uncontrolled manner it is essential for consumers to have access to a governmental database that identifies what PFAS (including PFOA/PFOS) are used in consumer, household, and industrial products – domestic and imported. This would allow consumers to have the ability to make an informed decision for themselves and their family concerning exposure to these substances. Such a database would also help to minimize/eliminate what ends up in the landfills which often generate PFAS contaminated leachate which may in turn be incorporated in wastewater treatment plant biosolids and applied to farmlands. The application of PFAS contaminated biosolids to farmlands is thought to have negatively impacted drinking and surface water, crops and animals (domestic and wild) on as much as 20 million acres.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document. The EPA is clarifying for the commenter that this final rule is effective **60**

days after publication in the Federal Register Notice (FRN). Consistent with the timelines set out under SDWA, public water systems (PWSs) are required to conduct their initial monitoring by three years after promulgation and to conduct PN and include PFAS information in the CCRs. After carefully considering public comment, the EPA is extending the compliance deadline for all systems nationwide to meet the Maximum Contaminant Level (MCL) to allow additional time for capital improvements. As such, PWSs are required to make any necessary capital improvements and comply with the PFAS MCLs by five years after rule promulgation.

Austin Water (AW), Austin, TX (Doc. #1688, SBC-044456)

Additionally, more efforts are needed to reduce and restrict the release of PFAS into the environment to protect public health. The preamble of the proposed PFAS rules states that ongoing use and pathways for releasing the six PFAS substances are still occurring. This situation seems incongruous alongside an NPDWR proposal that will place the responsibility for managing the impacts of PFAS on drinking water affordability onto water systems and their customers.

Additionally, we support the efforts and comments by the American Water Works Association and the Association of Metropolitan Water Agencies, both organizations of which AW is a member. We respectfully request that our comments and those of our member Associations be considered by EPA in the decision-making process regarding the future outcome of the proposed PFAS NPDWR.

Shay Ralls Roalson P.E.

Director Austin Water

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

City of Lancaster, Pennsylvania (Doc. #1695, SBC-044997)

The fact is that these compounds are well known by EPA to have been in the food and clothing industries. USEPA is failing to educate and appropriately regulate. It is allowing their usage so broadly, at levels far exceeding the previous 70 mg/L for water consumption action while allowing food products to be exposed to humanity at a million times higher dosages than their new 4 ng/L maximum hazard limit. There is a Consumer Reports link (https://www.consumerreports.org/health/food-contaminants/dangerous-pfas-chemicals-are-in-your-food-packaging-a3786252074/) from May 2022 issue describes leaching of the chemical from food wrappings and shows that the food wrappings acceptable dosages are either 100 or 20 ppm which are 5-25 million times higher than the proposed water MCL level of 4 ng/L and well above your previous limit of 70 ng/L. Why does the EPA allow industry to use hazardous chemicals millions of times higher than their own limits to poison citizens' food? This is a very

problematic issue that has already shown litigation starting for food companies (Simply Orange) that you allowed to operate and to profit using this "hazardous chemical" for many years.

Moving forward we recommend that the best course of action would be to remove the hazardous chemical label since the true limits are not yet known for health impacts. The EPA must focus on the point source pollutants and industry affecting the food and clothing of people that result in 80% exposure of these chemicals. Doing so would allow for the minimization of the chemical in water sources and allow for better research into proper methods for cleaning up this chemical in the environment. An article from the International Journal of Environmental Research and Public Health from 2022 titled "A Review of PFAS Destruction Technologies" Reviews several current methods for breaking down PFAS molecules. The Challenges with them are secondary contaminants affecting efficiency along with treatable capacity, toxic byproducts, and the cost with massive energy consumption.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Clean Water Action/Clean Water Fund (Doc. #1697, SBC-045008)

EPA should also consider innovation initiatives to more explicitly use authorities other than the Safe Drinking Water Act to reduce public health risk in drinking water and to avoid downstream pollution burden that should be controlled upstream. In its 2010 Drinking Water Strategy, EPA committed to using the authority of multiple statutes to help protect drinking water. [FN8: A New Approach to Protecting Drinking Water and Public Health, EPA, March 2010.] This has led to improved consultation and coordination in some cases, but not to systemic initiatives that could deliver real results to keep contaminants out of drinking water. EPA should explore more concrete initiatives to use the authority of other statutes to control PFAS chemicals and other drinking water contaminants at the source, rather than relying on treatment once they have entered a drinking water supply and passing that burden and cost on to the public. Examples could include additional requirements within the Toxic Substances Control Act (TSCA) and Clean Water Act programs for any contaminants appearing on the SDWA Contaminant Candidate List.

We appreciate the opportunity to comment on this proposal.

Respectfully Submitted,

Lynn Thorp

National Campaigns Director lthorp@cleanwater.org

Washington DC 20005

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

National Wildlife Federation et al. (Doc. #1702, SBC-043514)

While this proposal is a critical step towards turning off the tap on PFAS contamination of our drinking water, we must also stop PFAS at its source, before it enters our drinking water and environment in the first place. These substances are routinely found in the environment and in wildlife species from bluegills and great blue herons to largemouth bass and deer. EPA studies show that nearly all freshwater fish in the United States have detectable levels of PFAS contamination. Another study showed that the consumption of just a single serving of freshwater fish per year could be equal to a month of drinking water laced with the PFOS at high levels that may be harmful. People who consume freshwater fish, particularly communities that depend on fishing for sustenance and for cultural practices, are particularly at risk from high PFAS exposure. The same goes for wildlife that consume fish contaminated with PFAS, bioaccumulating up the food chain. Aquatic birds contaminated with PFAS have experienced reduced hatching success and other reproductive impacts. Elevated levels of PFAS in wildlife has also impacted recreational and subsistence hunting.

We urge EPA to continue efforts to ensure that the obligation to clean up these harmful chemicals is borne by the companies that discharge PFAS into our environment. This will reduce the public health and treatment costs incurred by downstream communities, ratepayers, and water utilities. The EPA should use the tools it has to regulate industrial discharges of PFAS into surface waters, address PFAS in Clean Water Act permits, clean up PFAS-contaminated sites under the Comprehensive Environmental Response, Compensation, and Liability Act, expand research on PFAS contamination on agricultural lands and in fish and wildlife, and prohibit the use of PFAS chemicals.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-045057)

Importantly, these resource intensive efforts by water utilities are only treating the symptoms rather than the disease. Treatment might reduce the current amount of PFOA and PFOS in a cup of water from low parts per trillion to an amount in parts per quadrillion, but it will not reduce the amount of PFAS that the public is exposed to everyday through other common household and environmental sources. This continued exposure will continue unabated so long as PFAS chemicals are permitted to be used in consumer goods manufactured in, or imported to, the United States.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045737)

PWD does not believe that its customers should pay for addressing PFAS pollution that they did not create. The solution to the complex challenge of managing PFAS contamination should not lie solely with the public nor the water industry. Although PWD is willing to do its part to address PFAS' pervasive and extensive damage, ultimately the polluters—those who are manufacturing and producing PFAS—should be held accountable for environmental remediation. PWD advocates for the creation of a defined compensation mechanism by which PFAS generators are financially liable for the cost of remediating the public health and environmental damage caused by the historic and continuing manufacturing of PFAS compounds.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044748)

2. Additional Support Is Needed for Concurrent PFAS Source Reduction

EPA states that while certain PFAS, specifically PFOA, PFOS, and PFNA, have seen voluntary phase out from commercial production in the United States, with the intended consequence that their respective concentrations in the environment will be similarly reduced, other PFAS, specifically PFBA, PFBS, and HFPO-DA, have not seen voluntary commercial production phase-out in the United States, and discharges into source water are ongoing. Therefore, concentrations of those PFAS can be expected to increase in the environment in all media.

Given the public health implications as well as the magnitude of the treatment costs associated with PFAS, the WDEQ recognizes that PFAS source reduction is critical to successfully addressing PFAS contamination. Establishing drinking water standards will not be sufficient to protect public health. WDEQ also recognizes that EPA has worked to use existing authorities under the Clean Water Act (CWA); Toxic Substances Control Act (TSCA); Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA); Resource Conservation and Recovery Act (RCRA); and voluntary stewardship programs to address sources of PFAS.

The WDEQ recommends that EPA continue pursuing PFAS source reduction activities and providing support for states' efforts to do the same. As states are co-regulators for many programs that will be involved with reducing PFAS sources through voluntary or regulatory means, it is critical that EPA engage with states as it considers further actions to prevent PFAS from entering the environment.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

HRSD (Doc. #1719, SBC-043542)

[We see the following recommendations as productive and protective strategies that EPA can utilize:]

Prioritize source control ahead of costly treatment technologies

Consistent with the "Polluter Pays" model of responsibility, EPA must focus efforts on source control before requiring drinking water utilities to implement costly treatment technologies. These source control efforts rightly place the burden of control on the industries and manufacturers that are producing and using PFAS in their processes, resulting in environmental and public health exposures. For drinking water utilities that are only marginally above the proposed MCL, source control alone may result in compliance. We note that EPA itself is applying this strategy to the implementation of Effluent Limit Guidelines (ELG) for airport facilities, allowing time to evaluate the efficacy of source control through a transition to alternative fluorine-free firefighting foams before imposing ELGs.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Environmental Working Group (EWG) (Doc. #1721, SBC-045420)

The EPA must prioritize source reduction to prevent future contamination.

The burden of addressing PFAS contamination in drinking water should not fall entirely on drinking water utilities. In addition to quickly finalizing the drinking water standards, the EPA must prioritize preventing future contamination. To address PFAS at the source, the EPA should quickly develop water quality criteria and effluent limitation guidelines under the Clean Water Act, as promised in the PFAS Roadmap. The EPA should also quickly implement its guidance to permit writers and urge states to address PFAS through state issued NPDES permits while the EPA is developing ELGs. The EPA should immediately start including PFAS in EPA-issued NPDES permits and impose pretreatment requirements in states where EPA administers the national pretreatment program. The EPA should also list PFOA and PFOS and consider listing other PFAS as hazardous air pollutants under the Clean Air Act. The EPA should work with the White House to expeditiously implement Executive Order 14057 requiring all agencies to purchase substitutes for PFAS containing products.

EPA must do more to protect Americans from PFAS.

Removing PFAS from drinking water is just one of many steps that EPA must take to protect Americans from PFAS chemicals. In addition to quickly moving to finalize these health-protective drinking water limits, EPA should:

• Quickly establish effluent limitations, permit limits, pretreatment standards, and sewage sludge standards for PFAS under the Clean Water Act.

• Regulate PFAS as hazardous air pollutants under the Clean Air Act.

• Quickly finalize the proposed designation for PFOA and PFOS as hazardous substances under CERCLA to jumpstart the cleanup process in contaminated communities.

• Quickly issue the proposed rule to add PFAS as hazardous constituents under RCRA.

• Finalize the proposed rule to close reporting loopholes under the Toxics Release Inventory.

• Stop approving new PFAS and new uses of existing PFAS under the Toxic Substances Control Act.

EWG appreciates the opportunity to comment on this historic proposed rulemaking. Should you have any questions regarding this comment or wish to discuss further, please do not hesitate to contact Melanie Benesh, mbenesh@ewg.org.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Natural Resources Defense Council (NDRC) et al. (Doc. #1723, SBC-044470)

2. Hold PFAS manufacturers and polluters accountable for the costs of treatment and/or alternative water supplies.

Water utilities—and states on behalf of water utilities—have increasingly been filing suit against PFAS manufacturers and polluters to recover costs of treatment to remove PFAS and/or costs of securing alternative water supplies. Some have already secured significant settlements. These efforts should be encouraged and supported, as they shift the cost of compliance from water systems and their customers to those responsible for causing the contamination.

For example, in 2018, the state of Minnesota secured an $850m settlement with 3M, which included over $700 million for drinking water projects in the affected areas of the state [FN7: https://3msettlement.state.mn.us/sites/3msettlement/files/2023-03/3M%20Settlement%20biannual%20report%2C%20February%202023.pdf]. In 2022, Massachusetts filed suit in federal court against PFAS manufacturers to recover, among other things, costs of treating municipal drinking water [FN8: https://www.mass.gov/news/ag-healey-sues-manufacturers-of-toxic-forever-chemicals-for-contaminatingmassachusetts-drinking-water-and-damaging-natural-resources] California, [FN9: https://oag.ca.gov/news/press-releases/attorney-general-bonta-sues-manufacturers-toxic-forever-chemicals] Wisconsin, [FN10: https://www.doj.state.wi.us/node/8711] Colorado, [FN11: https://coag.gov/press-releases/2-28-22/] and Illinois [FN12: https://illinoisattorneygeneral.gov/news/story/attorney-general-raoul-files-latest-lawsuit-over-contamination-bytoxic-forever-chemicals] also filed similar lawsuits in state courts in 2022. Individual water systems in New Jersey, [FN13: https://whyy.org/articles/n-j-towns-sue-makers-of-forever-chemicals-saying-companies-must-pay-for-cleanup/; https://www.levinlaw.com/2022/11/03/court-denies-3ms-motion-summary-judgment-middlesex-water-companycase] Philadelphia, [FN14: https://whyy.org/articles/philly-sues-3m-dupont-

other-companies-forever-chemical-contamination/] and Baltimore, [FN15: https://mayor.baltimorecity.gov/news/press-releases/2022-11-04-baltimore-files-lawsuit-combat-pfas-chemicals] among others, have filed similar lawsuits against PFAS manufacturers.

EPA and the Department of Justice should do everything in their power to help water systems hold PFAS manufacturers and polluters accountable for the costs of meeting new PFAS drinking water standards. For example, to help impacted communities identify releases and enable contaminated water systems to more readily recover PFAS treatment costs from responsible parties, EPA should promptly finalize its proposal to designate PFOA and PFOS as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). Further, EPA should expeditiously designate the entire class of PFAS chemicals as hazardous substances under CERCLA. Additionally, EPA should use its other robust legal authorities to assist public water systems to force polluters to pay for cleanup of drinking water, such as its imminent and substantial endangerment authorities under the Safe Drinking Water

Act [FN16: 42 U.S.C. 300i] and Resource Conservation and Recovery Act [FN17: 42 U.S.C. 6973].

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Joe DiNardo (Doc. #1725, SBC-045757)

However, in the absence of establishing a timeline in which the MCLG would be realized (5, 10, 20 years?) it is unclear what significance it holds if these chemicals are not clearly banned from use. Regardless, because these chemicals are so ubiquitous to our world and are used in an uncontrolled manner it would be more useful for people to have access to a governmental database that identifies what PFAS (including PFOA/PFOS) are used in consumer, household, and industrial products. This would allow consumers to have the ability to make an informed decision for themselves and their family concerning exposure to these substances. Such a database would also help to minimize/eliminate what ends up in the landfills which often generates PFAS contaminated leachate which often is incorporated in wastewater treatment plant biosolids and applied to farmlands. The application of PFAS contaminated biosolids to farmlands is thought to have negatively impacted drinking and surface water, crops and animals (domestic and wild) on as much as 20 million acres. [FN1: footnote not provided.]

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document. The EPA is clarifying for the commenter that this final rule is effective on **60** days after publication in the FRN. Consistent with the timelines set out under SDWA, PWSs are required to conduct their initial monitoring by three years after promulgation and to conduct PN and include PFAS information in the CCRs. After carefully considering public comment, the EPA is extending the compliance deadline for all systems nationwide to meet the MCL to allow additional time for capital improvements. As such, PWSs are required to make any necessary capital improvements and comply with the PFAS MCLs by five years after rule promulgation.

Joe DiNardo (Doc. #1725, SBC-045759)

[With that said, I respectfully request that:] (2) the development of a governmental database for consumers that tells what products contain PFAS; and (3) the immediate banning of the application of biosolids that contain PFAS - at least PFOA/PFOS.

Additionally, significant consideration needs to be paid to new forms of contamination. There is currently a movement to provide $39 billion for semiconductor manufacturing which more than likely will increase PFAS contamination; perhaps putting money into PFAS free semiconductor manufacturing/technology upfront could minimize/eliminate some of the potential contamination. Likewise, outright banning carcinogens like PFOA/PFOS and looking for safer alternatives may be more helpful in "preventing cancers" requiring less money for "curing/treating cancers" … prevention maybe a better way to fight human and environmental PFAS health issues!

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Joe DiNardo (Doc. #1725, SBC-045761)

If/when a substance(s) cause significant toxicity at levels below what can be identified analytically, it is safer to ban the substance to err on the side of safety (precaution) rather than to keep using it and err on the side on making more money. The latter statement can be realized in several recent news stories [FN2, 3: footnote not provided] that note globally the world's largest PFAS manufacturers make ~$4 BILLION annually in PFAS sales while societal costs are projected to be $17.5 TRILLION in damages annually. The fact that "EPA has quantified some of the reduced adverse health effects expected from the proposed rule … to be $908 million to $1.23 billion in savings" … the overall savings is paled by the estimated $17.5 TRILLION in global damage costs!

With that said, I would respectfully request that: (1) PFOA and PFOS, based on the toxicological data currently known, simply be banned (1, 3, 5 years?) from all product uses; (2) ban the application of any PFOA/PFOS containing biosolids from being applied to land; (3) ban PFOA/PFOS from future manufacturing off-shoots (semiconductor and/or other unknown industrial uses) regardless of what can or cannot be identified analytically.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045141)

1. Preventing PFAS Releases

This proposed NPDWR for PFAS is a critical step to protect drinking water, but EPA must continue working to prevent PFAS from entering drinking water sources. MassDEP commends

EPA's efforts using all the Agency's authorities, both regulatory and non-regulatory, to address PFAS contamination cross media and recommends that these efforts be accelerated.

Holistic Approach

MassDEP recommends that EPA extend its efforts using a holistic lifecycle approach that includes close coordination with other Federal agencies to utilize all possible Federal statutory and regulatory authorities to address PFAS concerns.

Using a holistic approach to reduce or eliminate the use of PFAS and to prevent these compounds from entering the environment and drinking water sources throughout any part of these chemicals' lifecycle - from manufacturing through processing, distribution, and disposal - is much more effective and less expensive than removing PFAS once contamination has occurred. Protecting drinking water sources (and preventing contamination) is essential for sustaining safe drinking water supplies, protecting public health and the economy, and has many additional environmental benefits.

The PFAS NPDWR is an important step in addressing PFAS contamination; however, numerous other regulatory decisions may be made based on drinking water standards (e.g., ground water remediation determinations, National Pollution Discharge Elimination System (NPDES) permits, and surface water standards). EPA should expand coordination across all the Agency's offices and with other federal Agencies (i.e., the Department of Defense, the Food and Drug Administration, and Centers for Disease Control and Prevention) to reduce PFAS contamination. This should include consideration of post- treatment impacts from disposal and incineration under each regulatory authority to ensure that the responsibility and cost for removing PFAS are not passed on from one media to another. This should also include consistent messaging to regulators, regulated entities, and the public.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Chattahoochee Riverkeeper (CRK) (Doc. #1730, SBC-043563)

It is also essential that the agency continue research into testing methods and the health impacts of the thousands of other PFAS chemicals that are known to exist in the environment.

It's important that EPA not only pass the NPDWR for PFAS, but also ensure that all communities have the funding and capacity to test for PFAS contamination and remediate if levels pose a threat to human health.

If you have any questions about this letter, please contact me at jsterling@chattahoochee.org or 404-352-9828.

Thank you,

/s/

Jessica Sterling

Technical Programs Director

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Rio Grande Waterkeeper and WildEarth Guardians (Doc. #1732, SBC-045425)

III. EPA Should Utilize Other Authorities to Comprehensively Address the Widespread Threat to Public Health and the Environment Posed by PFAS Contamination

Removing PFAS from the water at municipal water treatment facilities does not get at the heart of the problem, which is the production and discharge of PFAS chemicals into the waterways in the first place. Regulating PFAS through safe drinking water standards will not prevent the myriad negative impacts of these PFAS substances on their journey from their source to our taps.

For example, oil and gas drilling is a major industry in New Mexico, especially in the Permian Basin, that has the potential to contaminate the groundwater and surface water with PFAS. Physicians for Social Responsibility's recent report, Fracking with "Forever Chemicals" in New Mexico, found that between 2013 and 2022 oil and gas companies injected at least 261 wells in Mexico with 9000 pounds of two different PFAS chemicals (PTFE/Teflon and Fluoroalkyl alcohol substituted polyethylene glycol), neither of which are included in the EPA's new drinking water standards. [FN19: Dusty Horwitt & Barbara Gottlieb, Fracking with "Forever Chemicals" in New Mexico, PHYSICIANS FOR SOC. RESP. (Apr. 12, 2023), https://psr.org/wp-content/uploads/2023/04/fracking-with-forever-chemicals-in-new-mexico.pdf.] During the same time period, oil and gas companies injected 8,200 wells with over 240 million pounds of trade secret fracking chemicals, some of which could be PFAS chemicals. However, New Mexico's trade secret laws shield oil and gas companies from disclosing the identities of fracking chemicals deemed trade secrets to the public and state regulators.

The use of PFAS in fracking fluid provides many different routes for PFAS to enter the groundwater and surface water, such as spills of fracking fluid into the groundwater, underground migration of fracking fluids through fractures, and spills of wastewater after fracking. Frontline communities living near oil and gas operations will bear disproportionate health impacts resulting from the use of PFAS chemicals in fracking, in addition to many other negative health effects of oil and gas operations, absent effective regulation of these dangerous chemicals. This raises environmental justice concerns because oil and gas operations are disproportionately sited in low-income and/or Black, Brown and Indigenous communities.

In addition, PFAS contamination of the Rio Grande and its tributaries could threaten the integrity of the Rio Grande ecosystem as plants and wildlife take up these chemicals. The Rio Grande supports threatened and endangered species including the Rio Grande silvery minnow, the Southwestern Willow Flycatcher, and the Western Yellow-Billed Cuckoo. [FN20: Threatened and Endangered Species in the Rio Grande Basin, INTERSTATE STREAM COMM'N,

https://www.ose.state.nm.us/Basins/RioGrande/esa.php (last visited May 23, 2023).] The effects of PFAS on fish and birds are not fully understood, but there is evidence that PFAS may have negative impacts on avian reproduction, especially in birds that eat aquatic insects, like the Southwestern Willow Flycatcher. [FN21: Abigail Odegard, et al., Exposure and Effects of PFAS on Birds, U.S. ENV'T PROT. AGENCY, (Feb. 1, 2023), https://cfpub.epa.gov/si/index.cfm (Search "Exposure and Effects of PFAS on Birds" in Science Inventory search bar).] PFAS substances will also bioaccumulate up the food chain because these chemicals resist degradation. [FN22: Asa J. Lewis et al., Exposure Pathways and Bioaccumulation of Per- and Polyfluoroalkyl Substances in Freshwater Aquatic Ecosystems: Key Considerations, 822 SCI. OF THE TOTAL ENV'T 153561 (May 20, 2022), https://doi.org/10.1016/j.scitotenv.2022.153561.] This could pose significant risk to higher trophic level organisms.

Removing PFAS from the drinking water at municipal water treatment facilities will not prevent PFAS contamination of crops irrigated by Rio Grande water, livestock, or fish caught for sustenance. In the Upper Rio Grande Basin, approximately seventy four percent of the Rio Grande water is allotted for irrigation (of crops and golf courses), while agriculture accounts for about 85% of both surface water and groundwater withdrawals in the overall Rio Grande Basin. [FN23: Tamara I. Ivahnenko et al., Estimates of Public-Supply, Domestic, and Irrigation Water Withdrawal, Use, and Trends in the Upper Rio Grande Basin, 1985 to 2015, U.S. GEOLOGICAL SURVEY (Sept. 17, 2021), https://doi.org/10.3133/sir20215036;Climate; Will Kort, Change Impacts on Agriculture in the Rio Grande Basin, UNIVERSITY OF WISCONSIN-MILWAUKEE CENTER FOR WATER POLICY, https://uwm.edu/centerforwaterpolicy/wp-content/uploads/sites/170/2013/10/Rio-Grande_Agriculture_Final.pdf (last visited May 23, 2023).] In the Middle Rio Grande in New Mexico, irrigation water is primarily used for alfalfa and pasture for a substantial dairy industry which could be threatened by PFAS contamination. [FN24: The Dairy Industry in New Mexico, DAIRY PRODUCERS OF N.M., https://dairyproducersnm.com (last visited May 23, 2023).] Below the Elephant Butte Reservoir the Rio Grande supports farming of pecans, chiles, onions, melons, citrus, and vegetables. [FN25: Rio Grande Basin – SECURE Water Act Section 9503(c) Report to Congress, BUREAU OF RECLAMATION (Mar. 2021) https://www.usbr.gov/climate/secure/docs/2021secure/basinreports/RioGrandeBasin.pdf.] While an important step to address PFAS contamination in drinking water, this proposed new rule does not address PFAS contamination of the Rio Grande itself, which could lead to contamination of agricultural soils or crops. [FN26: Rossella Ghisi et al., Accumulation of Perfluorinated Alkyl Substances (PFAS) in Agricultural Plants: A Review, 169 ENV'T RSCH. 326 (Feb. 2019), https://doi.org/10.1016/j.envres.2018.10.023.] Consumption of crops and dairy products irrigated with PFAS-contaminated water would still be harmful to the public health without further regulation intended to prevent PFAS pollution of the nation's waters at the source.

To prevent or at least reduce PFAS pollution in our waterways, EPA must move beyond drinking water protections and use more of its tools to prevent PFAS from entering the environment in the first place. EPA should act quickly to promulgate regulations pursuant to the Clean Water Act to set water quality standards for PFAS and to prevent the discharge of PFAS into our waterways

through NPDES permitting standards. Polluting industries have used these dangerous chemicals for decades to maximize product sales. PFAS have been integral to America's industrialization for decades, but they do not need to be. The risk they pose to public health is unacceptable, and there are alternatives to PFAS that can be used instead. [FN27: Cheryl Hogue, How to Say Goodbye to PFAS, CHEMICAL & ENGINEERING NEWS (Nov. 2019), https://cen.acs.org/environment/persistent-pollutants/say-goodbye-PFAS/97/i46.] We recognize that all PFAS are unlikely to be phased out overnight; however, limiting their use is an essential step toward a future without these dangerous forever chemicals. Further, the burden of paying for removal of PFAS from our drinking water and remediating PFAS contamination in the environment should not be falling on the American taxpayers, but on these polluting industries.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Arizona Corporation Commission (ACC) (Doc. #1735, SBC-045182)

These financial burdens are heightened for utilities in states like Arizona, located downstream of major water sources, that will be responsible for treating contaminates that originated upstream of our state. Furthermore, public utilities did not contribute to the production, regulation, or discharge of PFAS, yet they and their customer base will bear the cost of remediation.

The ACC believes it is imperative that efforts be made to determine the source of the PFAS pollution, and that those responsible bear most if not all of the cost burden to remediate.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Arizona Corporation Commission (ACC) (Doc. #1735, SBC-045190)

POLLUTERS PAY

The EPA should take stronger measures to reduce water contamination by PFAS manufacturers before these harmful chemicals enter water supplies. Instead of placing the burden to remove chemicals on the water industry, which passes costs on to customers, the focus should be on addressing the sources of contamination. The ACC opposes disproportionately targeting the drinking water industry in efforts to reduce PFAS exposure and firmly believes manufacturers and profiteers of these chemicals should bear the responsibility and costs of necessary remediation to eliminate PFAS concentrations that endanger health and the environment. The ACC strongly supports a "polluter pays" approach, where those responsible for PFAS pollution cover the liability and costs of remediation, rather than the public. Currently, the EPA is considering taking formal enforcement action under the federal Clean Water Act against the Washington Works Facility near Parkersburg, West Virginia, for PFAS discharges into stormwater and effluent [FN6: Per April 26, 2023, EPA press release titled "EPA takes first-ever federal Clean Water Act enforcement action to address PFAS discharges at Washington Works

facility near Parkersburg, W. Va."]. The ACC sees this as a reason to extend the PFAS drinking water compliance deadline, allowing for the identification and regulation of industrial polluters. Halting pollution at its source is a more effective approach and prevents the shifting of cleanup costs to customers.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Pennsylvania Farm Bureau (PFB) (Doc. #1736, SBC-043564)

May 30, 2023

Alexis Lan

Office of Ground Water and Drinking Water

Standards and Risk Management Division (Mail Code 4607M) Environmental Protection Agency

1200 Pennsylvania Avenue NW

Washington, DC 20460

Dear Ms. Lan:

Pennsylvania Farm Bureau (PFB) is pleased to offer its comments on the proposed rule, "Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation" (EPA-HQ-OW-2022-0114-0027). PFB represents over 30,000 members engaged in all manner of agricultural activities, including the production and processing of crops; the production and processing of animals; the production and processing of forestry products; landscaping and horticultural services; agriculture-related support services; and food manufacturing. According to the 2021 report, The Economic Impact of Agriculture in Pennsylvania: 2021 Update, agriculture continues to be a leading contributor to the Commonwealth's economy, contributing $1 of every $16 in gross state product, with every dollar of direct output generating $0.63 in additional economic activity. In addition, agriculture supports one out of every ten jobs in Pennsylvania and seven jobs per $1 million of output. In 2019 alone, the total direct and indirect economic impact of agriculture within Pennsylvania was an estimated $132.5 billion.

PFB supports the protection and restoration of land and groundwater in Pennsylvania and across the United States; specifically, farmers support the protection and restoration of land and groundwater and the efforts that EPA is making in the "PFAS Roadmap" to address the impacts of the historic use of PFAS chemicals. The livelihood of Pennsylvania's farmers depends on healthy soil and groundwater, and families throughout the world rely on the food, fuel and fiber produced by American agriculture. At the same time, farmers have not knowingly used PFOA and PFOS in their operations. Farmers are in no position technically, economically, or practically to address the impact of the presence of PFAS chemicals, and especially PFOA and PFOS,

which continue to be found in virtually any place where soil, surface and groundwater have been assessed.

It is important to recognize PFOA and PFOS have come onto agricultural land without the knowledge or fault of farmers. These chemicals can be found in high quantities in firefighting foam that is used in and around airports and Department of Defense (DoD) training facilities. These chemicals have been known to travel naturally through the environment— most notably through ground and surface waters—and can eventually be deposited onto farm fields, so proximity to one of these areas can lead to elevated levels of PFAS. Pesticide holding containers have also been identified as a potential source of PFAS on farms. Recent EPA data indicates that plastic containers made of fluorinated high-density polyethylene (HDPE) are likely to leach PFAS into pesticides and other liquid products that are stored in them. EPA's review also suggests that the amount of PFAS that migrates into liquid products increases with storage time.

PFAS chemicals are also delivered to farms via biosolids, which are commonly applied to farm fields as an alternative to fertilizer. Farmers accept biosolids from a wastewater treatment facility to land apply onto their property. Biosolids are regulated at the federal, state, and local level to ensure protection of public health and the environment. For decades, EPA has encouraged and supported farmers' beneficial use of biosolids. Unfortunately, more recently, we have learned that biosolids are contributing to the spread of PFAS on agricultural lands. This is a major concern for our members, and PFB members have adopted policy supporting a ban on spreading of biosolids until more research is conducted on the effects of PFAS. Regardless of how PFAS ultimately arrives onto a farm field, it is undeniable that the fault does not fall on Pennsylvania's—or other American—farmers.

EPA must acknowledge that farmers do not use PFAS chemicals in any part of their operations and are innocent receivers of such chemicals. Farmers would never intentionally spread PFAS, as food safety is fundamental to farmers and consumers alike. Given this fact, as well as those above, it is clear that farmers should not be held responsible for the presence of PFAS chemicals, which they did not produce or intentionally use. Farmers all over the country could face devastating impacts simply for owning land and creating an agricultural product. PFAS contamination is a significant issue, and a collaborative effort will be needed to find solutions. It is essential that as those solutions are developed, landowners, producers or their lenders must not be held liable for the cost of cleaning up chemical contaminants, like PFAS, that are spread by actions over which the producer, landowner or lender had no management oversight or control of decision-making.

The American Farm Bureau Federation (AFBF), of which PFB is a member, additionally calls for:

• Funding for research into the health risks and strategies for mitigating risks associated with chemical contaminants in water and food such as PFAS.

• Collaboration by agencies, universities, and the private sector to develop proactive solutions and technologies to reduce the human health and environmental risks of emerging contaminants such as PFOS/PFAS.

• Establishing an indemnification program and funding to properly compensate farmers,' producers' and/or landowners' financial losses associated with emerging contaminants such as PFOS/PFAS.

• Opposition to PFOS/PFAS and similar chemicals in food packaging that may become part of the compost stream.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Florida Section American Water Works Association - Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044483)

Unlike industrial manufacturers, domestic wastewater is not the source of PFOA/ PFOS. No treatment process utilizes these chemicals, and utilities take no other action that introduces PFOA/PFOS into the reclaimed water or biosolids produced at treatment facilities. Instead , domestic wastewater utilities may receive (usually trace amounts) of the chemicals through industrial, commercial, and residential inputs into utility collection systems. Unlike source originators, utilities make no profit on PFOA/ PFOS. To the contrary, if utilities could prevent these chemicals from potentially getting into their systems in the first place, they would do so. We ask that EPA refocus its efforts on achieving that very outcome, by refocusing its regulatory initiative onto the industrial manufacturers and consumer products that put these chemicals into the environment.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045947)

AMWA recommends EPA take actions to better identify sources of PFAS in the environment and work to limit these discharges. The agency has recognized the persistent nature of these chemicals; therefore, it should be working toward prevention, as disposal is not a viable long-term option. AMWA appreciates efforts already being made, like the addition of certain PFAS to the Toxics Release Inventory and urges the agency to do more to track and reduce PFAS discharges. Knowing the source of PFAS will allow EPA and PWSs to work to address it at the source and hold those polluters accountable.

AMWA also recommends EPA Office of Ground Water and Drinking Water (OGWDW) work with other line offices and federal agencies to address other routes of public exposures to PFAS. PFAS are in food and food packaging, household and personal care products, fire extinguishing foam, and many other items that the public encounters [FN1: EPA. (2023, March 16). Our

Current Understanding of the Human Health and Environmental Risks of PFAS. https://www.epa.gov/pfas/our-current-understanding-human-health-and-environmental-risks-pfas]. EPA and other agencies must work to reduce these exposures and better communicate the risks associated with them. Regulating drinking water should only be one part of a larger, holistic approach to addressing the public's exposure to PFAS.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046033)

Eliminating the Sources

Eliminating sources is the ultimate solution to removing PFAS from the environment. Providing time and a regulatory framework that supports the elimination of PFAS sources would place the cost for remediation where it belongs – on the polluter instead of the public. The Occoquan Reservoir is an indirect potable reuse system with some industrial discharges to the POTW. The state has conducted some sampling for PFAS in the watershed and Fairfax Water is planning to do more. There are potential opportunities to remove these PFAS sources from the water supply.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046040)

Partnering to Protect

WSSC Water plays a key role in the Potomac River Basin Drinking Water Source Protection Partnership and the Patuxent Reservoirs Watershed Protection Group. Given the magnitude of costs for individua utilities, it makes sense to focus on controlling PFAS at the source.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

LSP Association (LSPA) (Doc. #1742, SBC-043596)

A team of LSPA members including toxicologists, public health risk assessors, LSPs, and others with decades of experience have reviewed the proposed rule. We have organized our comments according to the topics outlined in the slides from EPA's presentation, Proposed PFAS National Primary Drinking Water Regulation (epa.gov). [Link: https://www.epa.gov/system/files/documents/2023-04/PFAS%20NPDWR%20Public%20Presentation_Full%20Technical%20Presentation_3.29.23_Final.pdf.]

Slide 2: Even though some specific PFAS have been largely phased out due to health and environmental concerns, they may still be found in the environment and in drinking water.

● Much work is still needed in eliminating PFAS-containing products from the marketplace. "Some specific PFAS…" downplays the multitudes of products in use that still include PFAS compounds. It also downplays the decades of use of products used in accordance with labeling, as well as the disposal of these products in landfills, septic systems, wastewater treatment plants (WWTP) and other "receivers" of PFAS impacted effluent that may then impact underlying groundwater.

● Studies have been performed in several states (e.g., Vermont, New Hampshire, Maine, and Massachusetts) that have confirmed the presence of background levels of PFAS constituents in soil, presumably related to airborne deposition.

● Data collected by MassDEP indicate that approximately 5% of private wells tested across Massachusetts have PFAS exceeding the state health standards (20 ppt for the sum of six PFAS) even though there was no reported hazardous waste site/release identified in proximity.

● The LSPA urges USEPA to not focus exclusively on setting very stringent MCLs for these constituents; attempting to limit the sources of these compounds in products will likely have significantly more of a public health impact as exemplified by the reduction in average PFOS (85%) and PFOA (70%) concentrations in blood levels following the phase out of these PFAS compounds (see [Link: https://www.atsdr.cdc.gov/pfas/health-effects/us-population.html] below).

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Del-Co Water Company, Inc. (Doc. #1744, SBC-043616)

In addition, we question why drinking water seems to be the sole focus of regulation while potentially higher PFAS exposures exist in consumer products (including food packaging, stain- and water-repellent fabrics, nonstick products, polishes, waxes, paints, cleaning products), food, personal care products/makeup, pesticides, and dust, and these potential sources of exposure are not simultaneously being regulated. Removal of PFAS chemicals should occur at the source – if the source is not addressed, exposure to PFAS chemicals will continue.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

West Virginia Rivers Coalition et al. (Doc. #1746, SBC-045254)

EPA must implement policy levers to reduce PFAS at the source.

In addition to swiftly finalizing drinking water standards for PFAS, EPA should expedite efforts to prevent these chemicals from polluting the environment in the first place. Most pressingly for

this rule, we implore EPA to expedite the publication of human health ambient water quality criteria for PFAS. State agencies are waiting on these criteria to implement policy levers to reduce PFAS pollution at the source. Without these, permit holders will continue to discharge PFAS into source water at levels of parts per billion, furthering the financial and human health burden on water systems and their customers.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

City of Thornton, Colorado (Doc. #1748, SBC-044781)

While Thornton supports the implementation of this proposed rule to protect public health, the City strongly believes that the EPA needs to do additional work to hold manufacturers and dischargers of PFAS responsible for the pollution they have caused and provide full financial assistance to all water utility providers impacted by PFAS contamination. Thornton is a passive receiver of PFAS due to source waters contaminated by upstream industrial processes and domestic wastes. Thornton will need to install additional treatment processes at considerable cost to comply with the proposed rule and strongly believes that the utilities' ratepayers should not be responsible for the associated costs with that treatment. EPA needs to implement stricter limits (below the proposed MCL and without assuming assimilative capacity) on industrial and municipal WWTP discharges to limit costs borne by WTP utilities.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

National Center for Health Research (NCHR) (Doc. #1749, SBC-044498)

• The U.S. is far behind many other countries in its efforts to regulate PFAS. More than 180 countries have moved to ban PFOA chemicals from production [FN1: Hogue, C. (2019). Governments endorse global PFOA ban, with some exemptions. C&EN Chemical and Engineering News. https://cen.acs.org/environment/persistentpollutants/Governments-endorse-global-PFOA-ban/97/i19#]. The EPA proposed rule is an important first step, but it is long past time for the EPA to define PFAS broadly, regulate them as a class, and ban all non-essential uses.

3. Companies that produce PFAS should bear the financial burden.

We appreciate that the Infrastructure Investment and Jobs Act (P.L. 117-58) provides funding for these efforts, but it's time to start shifting the costs to the companies that have made these chemicals. These companies continue to profit while American citizens suffer from exposure to PFAS. When companies are held financially responsible, they will be less likely to inundate us with PFAS in products. Taxpayers are already stuck with the health risks; it is not fair for municipalities and taxpayers to also get stuck with the work and the cost.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Environmental Council of the States (ECOS) (Doc. #1752, SBC-044501)

Broader Management of PFAS

States appreciate this important step towards national consistency on PFAS, while acknowledging that PFAS releases impact a variety of environmental media overseen by more than one federal program. This action is just one of several needed to address the risks PFAS pose to public health, the environment, and local economies. While these comments primarily pertain to drinking water, ECOS Resolution 21-1: Advancing Collaboration and Coordination on Per- and Poly-fluoroalkyl Substances [Link: https://www.ecos.org/documents/resolution-21-1-advancing-collaboration-and-coordination-on-per-and-polyfluoroalkyl-substances/] recommends other needed federal actions as PFAS are used in a number of consumer and industrial products. In addition to managing PFAS in drinking water, successful management of these chemicals will also require a range of actions to reduce contamination closer to the source.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043926)

The rulemaking prompts discussion regarding better allocation of funding and resources directed toward the source of PFAS Contamination, rather than focusing on regulating water suppliers specifically, why isn't EPA extending its drinking water PFAS regulations to the sources of the PFAS contamination? The responsibility of mitigating PFAS contamination in drinking water should be shared with the industrial facilities that produce PFAS contamination in high concentrations. We would ask the EPA to broaden the scope of the proposed framework to include rules that would incorporate said producers of PFAS.

Sincerely,

Steven L Perez

Regulatory Compliance Analyst Las Cruces Utilities

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Los Angeles County Sanitation Districts (Doc. #1756, SBC-044513)

May 30, 2023

Submitted Electronically: https://www.regulations.gov

The Honorable Michael S. Regan, Administrator

U.S. Environmental Protection Agency William Jefferson Clinton Building 1201 Pennsylvania Avenue, N.W. Washington, D.C. 20460

Dear Administrator Regan:

Proposed Rule to Establish National Primary Drinking Water Regulations for Per- and Polyfluoroalkyl Substances (Docket ID No. EPA-HQ-OW-2022-0114)

The Los Angeles County Sanitation Districts (Sanitation Districts) appreciate the opportunity to provide comments on the U.S. Environmental Protection Agency's (EPA) proposed rule to establish national primary drinking water regulations (NPDWRs) for six per- and polyfluoroalkyl substances (PFAS) ("proposed rule"). The EPA is proposing to set individual maximum contaminant levels (MCLs) for perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS) at 4.0 nanograms per liter (ng/L) and to set an MCL for any combination of perfluorobutane sulfonic acid (PFBS), perfluorohexane sulfonic acid (PFHxS), perfluorononanoic acid (PFNA), and hexafluoropropylene oxide dimer acid (HFPO-DA or "GenX") at 1.0 using a unitless hazard index.

By way of background, the Sanitation Districts provide wastewater and solid waste management services to approximately 5.5 million people in 78 cities and unincorporated areas of Los Angeles County. Our facilities include about 1,410 miles of sewer, 49 pumping plants, 11 wastewater treatment plants, two composting facilities, three material recovery/transfer facilities, two operating landfills, and four closed landfills in post-closure maintenance care. Our mission is to protect public health and the environment through innovative and cost-effective wastewater and solid waste management and, in doing so, convert waste into resources such as recycled water, energy, and recycled materials.

While we appreciate the EPA's efforts to protect public health from PFAS exposure in drinking water, we have significant concerns related to the implementation of the proposed rule and the impacts it may have on water recycling, wastewater treatment, and solid waste management facilities. As has been well documented, PFAS are widespread, including detectable concentrations in wastewater and solid waste (trash). As a result, wastewater and solid waste facilities are passive receivers of PFAS in items and wastes that have been used and disposed. The proposed MCLs could have significant consequences for wastewater and waste management facilities that simply receive PFAS yet are not designed to treat PFAS or prevent releases to the environment or transfer of PFAS to other media, such as through recycling of treated wastewater or commodities or management of treatment residuals. For example, treated wastewater discharged to local waterways may be hydrologically connected to local drinking water supplies and may operate under regulatory permits that require compliance with MCLs. We urge the EPA to analyze and consider these types of impacts on the proposed rule, as described below, and take those impacts into account before finalizing the MCLs.

• Product phaseouts and source elimination are urgently needed and should be EPA's top PFAS priority. EPA should prioritize aggressive action to cease the import, manufacture, and use of PFAS for non-essential purposes. The Sanitation Districts actively support state and federal efforts to reduce the non-essential uses of PFAS in consumer and industrial products. We implore the EPA and other federal regulatory agencies to control PFAS uses in commerce and prevent new and ongoing uses that are leading to the widespread detection of PFAS in the environment. Solid waste, wastewater, recycled water and drinking water facilities are passive receivers of PFAS; the EPA should focus on reducing the inputs to these facilities prior to implementing regulatory requirements that will likely necessitate widespread implementation of expensive and energy intensive end-of-pipe treatment technologies. While industrial pretreatment efforts can be successful for certain categories of industrial dischargers, wastewater monitoring data indicate that much of the PFOA and PFOS received at wastewater treatment plants is from residential and commercial sources rather than industrial waste. As a result, wastewater deriving exclusively from residential sources frequently contains PFOA in excess of the EPA's proposed MCL. This suggests that pretreatment strategies and other industrial waste controls will have little or no impact to reduce effluent concentrations and facilitate compliance with low-level MCLs, for at least some facilities. Furthermore, it is imperative that regulatory agencies control the manufacture and use of precursor compounds, including those that transform in the environment and at wastewater treatment and composting facilities, in order to prevent the continued generation and circulation of PFOA, PFOS, and other PFAS of concern. Ultimately, the investment of significant resources and effort in treating PFAS in drinking water and recycled water is rational only after the EPA and other regulatory agencies control non-essential commercial uses to ensure that these types of sources are eliminated as quickly as possible.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document. With respect to costs associated with "treated wastewater discharged to local waterways [that] may be hydrologically connected to local drinking water supplies and may operate under regulatory permits that require compliance with MCLs," the EPA notes that SDWA expressly states that the EPA shall consider "quantifiable and nonquantifiable costs. . . *excluding costs resulting from compliance with other proposed or promulgated regulations*." For further information on the EPA's cost analysis, please see section 13 of the EPA response in this *Response to Comments* document and section XII of the final rule preamble. Additionally, please see section 5.1.3 of the EPA response in this *Response to Comments* document for additional discussion on cost considerations in the final MCLs.

El Paso Water (Doc. #1757, SBC-044529)

Nevertheless, we are very concerned about mandates that would force the utility and our ratepayers to shoulder the burden of removing harmful contaminants from our water supplies when it should be the responsibility of the polluter.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

El Paso Water (Doc. #1757, SBC-044519)

Polluter Pays vs Community Pays

As currently proposed, the NPDWR revisions place a significant burden on the nation's PWS to identify, remove and dispose of PFAS contaminants. While PWSs did not introduce the contaminants into the water supply, the responsibility and costs will fall on them and, ultimately, their ratepayers for removal from the water supply. This goes against the "polluter pays" principle and instead reverts to the unfair practice of "community pays," burdening the already strained resources of the PWS.

The EPA should consider a revision that places the burden of remediation and removal of PFAS contaminants on the party responsible for their introduction to the water supply. The consumer should not be the one to carry this costly obligation.

Stopping PFAS at the Source

A critical step toward lowering PFAS exposure to the public is identifying the source of PFAS introduction to the environment. This would greatly reduce the burden on utilities to test, treat and remove PFAS elements by preventing the introduction of contaminants to the water supply in the first place.

The EPA should dedicate additional resources to finding the sources of PFAS and work with PWSs to address the source and hold the polluters responsible for the necessary remediation.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Arizona Water Company (Doc. #1758, SBC-044536)

Water utilities (and subsequently, their customers) are paying the price for mistakes made by the chemical industry. Though water utilities have played no role in the creation and release of PFAS chemicals, they will now bear the brunt of the costs required to remove these chemicals from drinking water. The chemical industry has known about the potential harmful effects of PFAS chemicals for decades and nevertheless continued to allow their products and operations to pollute drinking water sources. This pollution must now be treated by water utilities and paid for by water users. While the EPA is proposing to regulate certain PFAS under the Comprehensive Environmental Response, Compensation, and Liability Act ("CERCLA") and other federal statutes, this proposal extends only to perfluorooctanoic acid ("PFOA") and perfluorooctansulfonic acid (PFOS). The EPA must regulate the waste of companies that produce all PFAS proposed for regulation in the drinking water rule, including PFOA, PFOS, GenX chemicals, and PFBS, to prevent it from entering drinking water sources in the first place.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045554)

While NPDWRs will require community investment to address PFAS, actions under the CWA, Resource Conservation and Recovery Act (RCRA), and the Toxic Substances Control Act (TSCA) will require manufacturers and users of PFAS to carry this burden.

To date, however, the agency's actions on polluters have consistently lagged behind drinking water action. EPA originally identified PFAS as a potential priority for drinking water as part of the Contaminant Candidate List 3 in 2009 (EPA, 2009). In 2012 EPA advanced the Third Unregulated Contaminant Monitoring Rule (UCMR 3) that required water systems to monitor for six PFAS in finished drinking water (EPA, 2012). With the proposal, EPA is proposing to set standards for PFAS in drinking water. At the same time, EPA has yet to advance regulations that require manufacturers and users to: (i) report about uses and releases of PFAS, (ii) control the release of PFAS to the environment, (iii) manage PFAS-containing wastes appropriately, and (iv) limit the use and manufacturing of PFAS (EPA, 2022a; EPA, 2022b; EPA, 2022c).

What is further concerning, is the lack of urgency in advancing these actions by the agency. The TSCA data reporting rule, which will require manufacturers and users to report on the production, use, and release of PFAS, was prompted by Congress as part of the National Defense Authorization Act for Fiscal Year 2020 (NDAA 2020) in December 2019 and proposed in June 2021 (Congress, 2019; EPA, 2022a). The rule has yet to be finalized, despite a statutory deadline of January 2023. Additionally, EPA initiated an effort under the CWA to consider ELGs for PFAS as part of the Preliminary Effluent Guidelines Program Plan 14 (EPA, 2019b). With this plan, EPA committed to performing a study of PFAS in industrial effluents for several industries. Program Plan 15 moved forward with a commitment to initiate two rulemakings for both manufacturers and metal finishers and to initiate additional studies on landfills and textile mills (EPA, 2021b). Neither of these rulemakings have been proposed. These actions, if advanced with the same sense of urgency as drinking water actions, would have provided invaluable information and protection for PFAS releases to the environment and the drinking water sources.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Riverside Public Utilities, Riverside, CA (Doc. #1762, SBC-044230)

[The following comments are submitted for consideration in the proposed EPA rulemaking:]

Focus on Eliminating PFAS Source and Hold Polluters Accountable

City staff strongly support the focus on eliminating PFAS in consumer products, source control, and destruction technology as well as holding PFAS polluters accountable as necessary measures to achieve progress in mitigating PFAS risks and exposure.

Conclusion

City staff strongly supports EPA's efforts to address PFAS contamination and protect public health through setting drinking water standards based on sound science and robust analysis; however, we have concerns with this proposal in its current form and ask the EPA to take our comments under consideration before finalizing the regulation.

Thank you for the opportunity to provide comments on this proposed rule. If you have any questions or would like any follow-up information, please contact General Manager Todd Corbin at TCorbin@riversideca.gov.

Sincerely,

Daniel E Garcia (May 30, 2023 16:54 PDT)

Daniel E. Garcia

Deputy General Manager, Riverside Public Utilities

CC:

The Honorable Radhika Fox, Assistant Administrator, Office of Water, U.S. Environmental Protection Agency

Alexis Lan, Ground Water and Drinking Water, Standards and Risk Management Division, U.S. Environmental Protection Agency

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Center for Environmental Health et al. (Doc. #1764, SBC-044240)

However, EPA was also petitioned in 2020 under Section 21 of TSCA by several nonprofit and community organizations representing residents in the Cape Fear region to require the chemical manufacturer, Chemours, to fund necessary testing for the health effects of 54 PFAS detected in the river, drinking water, and the blood of community members [FN2: Center for Environmental Health, et. al., PETITION TO REQUIRE HEALTH AND ENVIRONMENTAL TESTING UNDER THE TOXIC SUBSTANCES CONTROL ACT ON CERTAIN PFAS MANUFACTURED BY CHEMOURS IN FAYETTEVILLE, NORTH CAROLINA, (October 13, 2020), https://www.epa.gov/sites/default/files/202010/documents/chemours_pfas_testing_petition_final.pdf] - a request that was mostly denied. EPA denied the petitioners' request to order Chemours to conduct an epidemiological study of the exposed community, testing on mixtures of PFAS

found in drinking water and blood, and certain other priority health tests on the 54 PFAS. Instead, EPA claimed that its previously announced TSCA PFAS Testing Strategy constitutes "granting" the petition. We reiterate that granting our petition will supply Cape Fear communities with the studies they and their doctors need in order to make decisions based on the risks of PFAS and mixtures detected in the surrounding environment now. Furthermore, EPA recognized significant data gaps with respect to PFAS chemicals in its toxicity assessments conducted under the SDWA. As the human health risks summarized in the NPDWS proposal are calculated from publicly sourced epidemiological human and animal data, the full granting of our petition would provide additional data and further strengthen the accuracy of maximum contaminant levels (MCLs) for the six PFAS and mixtures covered by the proposal and the additional 48 PFAS and mixtures described in our petition.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Center for Environmental Health et al. (Doc. #1764, SBC-044244)

Administrator Regan acknowledged that Chemours' Fayetteville Works Plant on the banks of the Cape Fear River has "been polluting our air and our water with these 'forever' chemicals since the '70s." [FN4: Michael F. Regan, Prepared Remarks for PFAS Roadmap Announcement, (October 18, 2021), https://www.epa.gov/speeches/administrator-michael-regan-remarks-pfas-roadmap-announcement-prepared-delivery.] To ensure science-based decision making, and hold polluters accountable, EPA must require Chemours to fund testing of substances or mixtures it manufactures, uses, or disposes of at its Fayetteville facility that may present a risk to human health and the environment. Such studies would help inform future Hazard Quotients and MCLs for PFAS as a chemical class.

Trump EPA Administrator Wheeler initially denied the TSCA Section 21 petition. Communities across the State could not wait for the health studies they needed. Thus, we brought a lawsuit. Administrator Regan then dubiously "granted" our petition by arguing that its previously announced TSCA PFAS Testing Strategy, under which EPA planned to only require Chemours to fund tiered testing of 7 of the 54 PFAS but not require the requested epidemiological study nor testing on the PFAS mixtures in the drinking water and blood of Cape Fear residents, and moved to dismiss the lawsuit. The motion to dismiss was granted, and we are now appealing that decision.

A petition under Section 21 of TSCA is an example of the solutions EPA has made available to communities impacted by legacy contamination. Unfortunately, EPA developed its TSCA PFAS Testing Strategy without any input from the public, including from disproportionately impacted communities. Since purporting to "grant" the TSCA Section 21 petition from Cape Fear groups, EPA has not engaged with the petitioners and Cape Fear communities on what further health testing EPA should order Chemours to conduct under Section 4 of TSCA.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Bowling Green Municipal Utilities (Doc. #1767, SBC-043934)

Source Control rather Than after the Fact Treatment: The potential health risks from the chemicals would be more efficiently handled by reduction of production (source control) rather than post treatment. There is no need for billions of dollars of unnecessary infrastructure to treat for PFOS/PFOA if the materials are barred from production.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Portland Water Bureau (PWB) (Doc. #1769, SBC-044542)

In addition to our comments above, we also support comments submitted by the Association of Metropolitan Water Agencies (AMWA) and the American Water Works Association (AWWA). Of the comments submitted by AMWA and AWWA, we would like to emphasize our support for protecting source water from PFAS contamination. PWB joins AWWA and AMWA in urging EPA, Congress and other decision-makers to implement policies that keep harmful PFAS out of our drinking water supplies and our communities.

Thank you again for the opportunity to review and comment on these draft rules. If you have questions, you can reach me at Yone.Akagi@portlandoregon.gov or 503-823-1251.

Sincerely,

Yone Akagi, P.E.

Water Quality Manager

Portland Water Bureau

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Sierra Club of Hawai'i (Doc. #1771, SBC-044734)

Red Hill

These proposed limits will be an effective measure toward the restoration of the damage incurred by the Red Hill Bulk Fuel Storage Facility. The Red Hill facility, which sits just 100 feet above O‘ahu’s primary drinking water aquifer, uses PFAS-based Aqueous Film-Forming Foam (AFFF). In the last three years alone, at least 6,300 gallons of AFFF have been spilled at the facility, threatening the safety of the drinking water, environment and neighboring communities.

Despite ongoing and widespread percolation of PFAS into community drinking water, the tanks at Red Hill remain unserviced. The limits imposed by the EPA implement an effective incentive for the source of PFAS to receive the attention that has been long neglected. Corporations and governmental entities must not confuse public health with hindering economic development or defense. Rather, PFAS regulation and enforcement can rectify the unmitigated advantages long enjoyed by the Department of Defense at the expense of the public health of Oʻahu. PFAS regulations have the opportunity to prevent future harms by encouraging the Department of Defense to attend to the decaying fuel tanks and sources of cancer-causing chemicals upon the community of Oʻahu.

Thank you for the opportunity to comment on this important matter.

Sincerely,

Sierra Club of Hawaiʻi

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Sierra Club of Hawai'i (Doc. #1771, SBC-044732)

Setting these regulations will encourage manufacturers and PFAS-producing industries at large to be more responsible in their use of PFAS. Ideally, industries would invest in safer alternatives for PFAS chemicals if they receive pressure from those in the regulatory and water supply sectors.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Eastern Municipal Water District (EMWD) (Doc. #1780, SBC-043820)

May 30, 2023

The Honorable Michael Regan

Administrator

U.S. Environmental Protection Agency, EPA Docket Center

Office of Groundwater and Drinking Water Docket

Mail Code 2822IT

1200 Pennsylvania Avenue, N.W.

Washington, DC 20460

SUBJECT: PFAS National Primary Drinking Water Regulation Rulemaking; Docket ID No. EPA-HQ-OW-2022-0114

Dear Administrator Regan:

Eastern Municipal Water District (EMWD) appreciates the opportunity to comment on the Environmental Protection Agency's (EPA) proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation Rulemaking (the "Proposed Rule"). EMWD is the water, wastewater and recycled water service provider to nearly one million people living and working within a 558-square mile service area in western Riverside County and is California's sixth-largest retail water agency.

Our mission is to deliver value to our customers and the diverse communities we serve by providing safe, reliable, economical and environmentally sustainable water, wastewater and recycled water services. In light of this mission, EMWD embraces and shares EPA's fundamental goal to provide customers with a public water supply that is reliable, affordable and safe. For many reasons, maintaining affordability, while providing safe and reliable water service, is becoming increasingly challenging. It is through this lens of serving as an advocate for our ratepayers that we share the comments herein.

Considering EPA has not issued a primary drinking water standard in over 26 years, this proposal to adopt national primary drinking water standards for perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), perfluorohexane sulfonate (PFHxS), hexafluoropropylene oxide dimer acid (HFPO–DA), perfluorononanoic acid (PFNA), and perfluorobutane sulfonic acid (PFBS) is a historic milestone in the regulation of PFAS as emerging contaminants.

While we wholeheartedly support EPA's effort to control PFAS in drinking water, we are very concerned that the current approach places an undue burden on water ratepayers, instead of on the polluters, and on the source of the problem. PFAS are still extensively used in Teflon cookware, cosmetics, food packaging, waterproof and stain-resistant clothing and fabrics like curtains and carpets, and firefighting foams. While certain PFAS are no longer manufactured in the United States, these PFAS laden products are still regularly imported, utilized, and subsequently end up in our wastewater and water ways. Before saddling our customers with the cost of cleanup, a greater investment needs to be placed on eliminating PFAS from consumer products, thereby reducing and eliminating the flow of these chemicals into the environment. In addition, EMWD fully supports the "polluter pays" principle, and believes that the polluters, and the manufacturers of PFAS should be responsible for the cost of clean up, not our customers.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043795)

[We recommend that drinking water regulations for PFAS include actions that support scientific understanding and exploring implementation solutions that would include actions such as:]

• Watershed modeling to determine sources of contamination

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043803)

Implement a Wholistic Approach to Regulatory Actions. Given the pervasiveness of PFAS compounds in the environment and everyday use and consumable items, if an outright ban is not to be implemented, the equitable approach to addressing these compounds is to limit them holistically across all sectors regulating human and environmental health. This includes not only the USEPA, but the Food and Drug Administration, the Consumer Product Safety Commission, and any other federal agency that governs public, commercial and industrial business. This should include not only limiting the quantity of use but validating which products and/or industries it is absolutely necessary to be used in for the purposes safety and public protection, versus convenience and preference.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043792)

Source Control. Without tough source control measures, the responsibility to remove these chemicals to protect human health and the environment, will remain on community drinking water systems and other publicly funded infrastructure providing wastewater and solid waste services. These facilities are not producers of PFAS but rather passive receivers as they flow from consumer products or firefighting and military facilities. Human health exposure to PFAS is greatest in consumer products, making downstream removal efforts superfluous if inadequate efforts are taken to remove them from daily life. No technologies for PFAS removal and disposal from solid and liquid wastes has been prove effective.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043798)

Based on the information available, it will take a combination of source control and treatment technologies to achieve meaningful PFAS reductions in drinking water and the environment. This technical information is necessary to build trust and collaboration between and among public and private agencies, manufacturers, and the public to effectively reduce and phase out PFAS.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

PFAS Project Lab (Doc. #1786, SBC-044719)

Importance of current and future rulemaking

EPA can use the new MCLs as a prompt to pursue other important work in its domain, including reducing unnecessary uses of PFAS, preventing the entry of dangerous new PFAS chemicals into commerce under the Toxic Substances Control Act; minimizing PFAS emissions under the Clean Air Act; cleaning up PFAS contaminated sites under the Comprehensive Environmental Response, Compensation, and Liability Act; and regulating PFAS disposal under the Resource Conservation and Recovery Act.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Fairfax Water (Doc. #1789, SBC-045312)

2. EPA should re-prioritize its efforts to remove sources of PFAS from the environment. Prioritizing regulation of drinking water places the burden of PFAS removal on the public instead of the polluter. Absent a comprehensive, national PFAS regulatory framework, water utilities are being assigned, at public expense, a Sisyphean task at best inadequate to meet the overall environmental goal, and at worst likely to distract from it.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Metropolitan Washington Council of Governments (COG) (Doc. #1791, SBC-043771)

Regarding the proposed NPDWR, our primary recommendation is for EPA to work with other federal agencies to develop and implement a regulatory framework that targets the removal of PFAS sources to the maximum extent practicable. Eliminating pollution at the source is the best way to protect local drinking water supplies, which are passive receivers of PFAS compounds. Targeting and eliminating sources of PFAS compounds would be cost effective and would place the cost for remediation on the polluter rather than the public.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Ohio Environmental Council (Doc. #1794, SBC-045320)

While regulation under the Safe Drinking Water Act is essential to protect human health and the environment, we must also regulate PFAS in surface water, eliminating present and future point sources.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Ohio Environmental Council (Doc. #1794, SBC-045328)

In addition to swiftly finalizing drinking water standards for PFAS, we urge EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by: controlling industrial discharges of PFAS into water, and addressing PFAS in state- and federal-issued permits consistent with EPA's 2022 guidance under the Clean Water Act; reducing unnecessary uses of PFAS, and preventing the entry of dangerous new PFAS chemicals into commerce under the Toxic Substances Control Act; minimizing PFAS emissions under the Clean Air Act; cleaning up PFAS contaminated sites under the Comprehensive Environmental Response, Compensation, and Liability Act; and regulating PFAS disposal under the Resource Conservation and Recovery Act.

The ubiquitous nature of PFAS contamination underscores the need to curb all pathways of PFAS exposure and sources of pollution. EPA's 2021 Strategic PFAS Roadmap outlined a broad suite of actions to address the PFAS crisis, and following through on Roadmap commitments is of the utmost importance.

Thank you for taking these comments into consideration as you finalize the Proposed PFAS National Primary Drinking Water Regulation.

Melanie Houston,

Managing Director of Water Policy

Portland Advocates for Leadfree Drinking Water (Doc. #1796, SBC-044700)

From: L J <lorjmcfarlane@gmail.com>

Sent: Monday, May 22, 2023 8:58 PM

To: OW-Docket

Subject: EPA-HQ-OW-2022-0260

May 22, 2023

Radhika Fox, Assistant Administrator for Water

U.S. Environmental Protection Agency 1200 Constitution Ave., NW Washington, DC 20460

Re: Comments on EPA's Proposed "National Primary Drinking Water Regulations: Consumer Confidence Report Rule Revisions" [EPA–HQ–OW–2022–0260]

Thank you for this opportunity to comment on revisions to Annual Water Quality Reports (WQR), aka Consumer Confidence Reports (CCR).

Portland Water Bureau has exceeded the water lead action level (ALE) numerous times since the LCR was promulgated; (1997 compliance date) in November 2021, 2017, 2016, 2014, 2013, 2006, 2002, 2001 (2X), 2000, 1999, and 1998.

Since the City of Portland Oregon consistently includes information not mandated by the federal LCR - free lead in water test kits - in their Annual WQR's, the utility (Portland Water Bureau) should post information about their "free filters program", mentioned only once in this news article.

Further, we request this information be included in subsequent Annual WQR's. Until Portland Water Bureau significantly reduces lead to levels consistent with its PNW region neighbors, this is the responsible public health action.

Families cannot know about this free public "filters program" unless they have detailed, concise, and clear public information available to them.

Currently, annual WQR's for Portland provide information on "Free lead in water testing" (typically 6 times throughout the Report). Following another lead ALE in October 2021, Portland launched a new "free filters program" but failed to mention it in their 2022 WQR. Moreover, a "free filters program" is not publicized anywhere on the utility's web pages, social media accounts, FAQ's or Water Quality information phone line.

The rationale for this (below) given by the Portland Water Bureau Public Information Officer is problematic at best, and health-harmful at worst. There should be full transparency on prevention measures available to the public (complementary City filters) for the duration of Portland Water Bureau's elevated and excessive lead levels.

"There are not [sic] public meetings about the filter program because we are sending them directly to eligible customers; there is no burden on our customers to contact us." -- Portland Water Bureau Director via PIO Jaymee Cuti, February 2022

Thank you for considering comments to help improve Annual WQR's,

Portland Advocates for Leadfree Drinking Water, on behalf of "nearly ~1 million customers" (PWB)

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Peggy Kurtz (Doc. #1799, SBC-046044)

I also urge the EPA to regulate emissions and discharges into our waterways.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Massachusetts Municipal Association (MMA) (Doc. #1800, SBC-043767)

Unless manufacturer liability and responsibility are introduced into this framework, these costs will continue to be absorbed by those who have no fault in the contamination of local water supplies. Water systems are passive receivers of PFAS, and do not manufacture or intentionally add these chemicals to water sources and supplies. Without the institution of polluter responsibility or a more comprehensive approach to fund PFAS treatment, municipal ratepayers will be forced to pick up the slack, stressing the pocketbooks of families and individuals.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Millie Garcia-Serrano (Doc. #1803, SBC-044293)

[Overall, as movement is made toward better regulation and oversight of these contaminants, ASTSWMO's membership recognizes a corresponding need for research, communication, and improved understanding within the following areas:]

• remediation technologies to remove PFAS from all environmental media;

• destruction and disposal technologies for PFAS-containing materials and waste streams;

[Overall, as movement is made toward better regulation and oversight of these contaminants, ASTSWMO's membership recognizes a corresponding need for research, communication, and improved understanding within the following areas:]

• solidification and stabilization technologies to minimize PFAS in landfill leachate and methods to assess treatment effectiveness to aid in addressing capacity limitations; and

[Overall, as movement is made toward better regulation and oversight of these contaminants, ASTSWMO's membership recognizes a corresponding need for research, communication, and improved understanding within the following areas:]

• acceptable levels of PFAS in compost, biosolids, wastewater sludge and industrial byproducts that are suitable for land application.

Advances in the key research areas listed above, along with establishing prevention programs to support the reduction and removal of PFAS from use, need to take place concurrently with this proposed rulemaking. More specifically, expanded coordination across all federal Agencies needs to be prioritized to reduce, and conceptually eliminate, PFAS present in consumer products and food supplies, which ultimately get into the water supplies and waste streams.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Millie Garcia-Serrano (Doc. #1803, SBC-044291)

Overall, as movement is made toward better regulation and oversight of these contaminants, ASTSWMO's membership recognizes a corresponding need for research, communication, and improved understanding within the following areas:]

• drinking water, soil, and wastewater treatment technologies;

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045475)

Basis for the Interest of the National Ground Water Association (NGWA) in Setting MCLs for PFAS

NGWA, the largest trade association and professional society of groundwater professionals in the world, represents over 10,000 groundwater professionals within the United States and internationally. NGWA represents four key sectors: scientists and engineers in public and private sectors; water-well contractors who develop and maintain water-well infrastructure; the manufacturers who produce; and the suppliers who deliver the equipment needed to make groundwater development possible. NGWA's mission is to advocate for and support the responsible development, management, and use of groundwater.

Over 34 million people in the United States rely on private wells and over 91 million are served by groundwater from public community water systems.

NGWA views groundwater and the subsurface as natural infrastructure that should be sustainably managed for current and future use. The subsurface environment should be considered from an integrated resource perspective. The natural infrastructure of the subsurface environment with proper management can provide fresh groundwater for drinking, industrial and manufacturing applications, food production, and ecosystem support.

A concise summary of the position of the National Ground Water Association on groundwater protection related to this proposed rule is:

• Control of potential and active sources of contamination should be a national objective, reducing the need for remediation of groundwater.

• Groundwater quality should be protected for existing or potential beneficial uses.

• NGWA published Groundwater and PFAS: State of Knowledge and Practice, a guidance document on per- and polyfluoroalkyl substances (PFAS) in 2017

(https://my.ngwa.org/NC__Product?id=a183800000kbKF9AAM) as a comprehensive report to identify the known science and knowledge related to PFAS, summarizing the fate, transport, remediation, and treatment of PFAS, as well as current technologies, methods, and field procedures.

• NGWA has additionally updated materials regarding PFAS on its resource webpage "Groundwater and PFAS" at https://www.ngwa.org/what-is-groundwater/groundwaterissues/Groundwater-and-PFAS.

NGWA appreciates the opportunity to comment on the proposed rule.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Florida Rural Water Association (FRWA) (Doc. #1806, SBC-044698)

Some may be fortunate in the costs being covered by the industrial site that was responsible for contamination. That is not the case for most of the public water systems that have found PFAS levels exceeding the proposed MCL. Site investigations have failed to determine an external potentially responsible party. The public water systems are being held responsible for the investigation and clean-up costs. That, in turn, has led to expensive and time- consuming battles with insurance companies often leading to passing all cost onto its customers.

The chemical manufacturers that created PFAS compounds should be responsible for their remediation in the environment, including our drinking water. Establishing MCLs without association liability protections places the burden on the public water systems. They are not the source of this contamination but have been blamed for aquifers contaminated by firefighting training exercises, and manufacturing of "Forever Chemicals."

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Environmental Working Group et al. (Doc. #1810, SBC-044692)

In addition to swiftly finalizing drinking water standards for PFAS, we urge EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by: controlling industrial discharges of PFAS into water, and addressing PFAS in state- and federal-issued permits consistent with EPA's 2022 guidance under the Clean Water Act; reducing unnecessary uses of PFAS, and preventing the entry of dangerous new PFAS chemicals into commerce under the Toxic Substances Control Act; minimizing PFAS emissions under the Clean Air Act; cleaning up PFAS contaminated sites under the Comprehensive Environmental Response, Compensation, and Liability Act; and regulating PFAS disposal under the Resource Conservation and Recovery Act.

The ubiquitous nature of PFAS contamination underscores the need to curb all pathways of PFAS exposure and sources of pollution. EPA's 2021 Strategic PFAS Roadmap outlined a broad suite of actions to address the PFAS crisis, and following through on Roadmap commitments is of the utmost importance.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

National Wildlife Federation Action Fund (Doc. #1811, SBC-045345)

EPA's proposal would significantly reduce exposure to PFAS in our drinking water for millions of people by setting strong, science-based drinking water standards for six types of PFAS. While this proposal is an important first step towards addressing PFAS exposure, it is critical that EPA also expedite efforts to prevent these chemicals from entering our waters and environment in the first place, before it even reaches our taps. This includes regulating industrial discharges of PFAS into surface waters, addressing PFAS in permits consistent with EPA's 2022 Clean Water Act guidance, cleaning up PFAS contaminated sites under the Comprehensive Environmental Response, Compensation, and Liability Act, and preventing current and future use of PFAS chemicals.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Clean Water Action (Doc. #1813, SBC-045498)

All parts of EPA and the federal government need to take equally bold action to stop PFAS pollution, hold polluters accountable, and curtail uses of PFAS chemicals. Placing the burden on our communities, our drinking water, and our health is not the right way to solve the PFAS challenge."

Thank you for your consideration.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045763)

DC Water appreciates the opportunity to comment on EPA's proposed PFAS National Primary Drinking Water Regulations. Please let us know if we can provide any additional information or share our utility expertise to inform improvements to the proposed rule with the goal of ensuring its equitable implementation. We are committed to providing safe drinking water to our customers while ensuring its affordability. We strongly believe that federal regulation on manufacture and distribution of PFAS is required in advance of, or at the least in parallel with drinking water regulations, and the cost of treatment for chemicals introduced to drinking water supplies by industry should be borne by that industry and not already overburdened ratepayers. The attached document further summarizes our concerns regarded the proposed PFAS rule and its impacts to our customers.

May 30, 2023

The Honorable Michael Regan Administrator

United States Environmental Protection Agency 1200 Pennsylvania Avenue, N.W.

Mail Code: 1309

Washington, DC 20004

SUBMITTED ELECTRONICALLY

RE: Per- and polyfluoroalkyl substances (PFAS): Perfluorooctanoic acid (PFOA) and Perfluorooctanesulfonic acid (PFOS) National Primary Drinking Water Regulation Rulemaking, Docket No. EPA-HQ-OW-2022-0114

Dear Administrator Regan:

The District of Columbia Water and Sewer Authority (DC Water) strives to be a world-class water utility. Our mission is to exceed expectations by providing high quality water services to our customers in a safe, environmentally friendly, and efficient manner. We support the U.S. Environmental Protection Agency's (EPA) efforts to reduce per- and polyfluoroalkyl substances (PFAS) in drinking water.

DC Water appreciates the opportunity to comment on EPA's "Proposed Per- and polyfluoroalkyl substances (PFAS): Perfluorooctanoic acid (PFOA) and Perfluorooctanesulfonic acid (PFOS) National Primary Drinking Water Regulation Rulemaking" (the Proposal). As explained below, DC Water is concerned about several flaws in the Proposal and asks that EPA reconsider several aspects of it. We understand that many of our sister utilities share these concerns.

We offer a unique perspective on the Proposal. DC Water distributes drinking water to more than 700,000 residents and 21.3 million annual visitors to the District of Columbia, the Pentagon and Ronald Regan Washington National Airport in Virginia, and federal and other customers in Maryland. Drinking water for the District of Columbia comes from the Potomac River. The U.S. Army Corps of Engineers Washington Aqueduct (the Aqueduct or WAD), a federal drinking water treatment plant, collects water from the Potomac River at Great Falls and Little Falls. The Aqueduct treats this water to meet federal drinking water quality requirements to ensure it is safe to drink. DC Water purchases the treated drinking water from the Washington Aqueduct and distributes it to our customers.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045773)

Summary

DC Water is committed to providing safe drinking water to our customers while ensuring its affordability. We strongly believe that federal regulation on manufacture and distribution on PFAS is required in parallel with drinking water regulations, and the cost of treatment for industry introduced chemicals should be borne by the PFAS industry and not by already leveraged ratepayers.

• EPA should prioritize regulation of PFAS at the source to prevent it from being discharged to the environment and into our public water supplies. The cost burden should be placed on the generators of PFAS, not our water customers. We ask EPA to prioritize a comprehensive regulatory scheme to prevent releases of PFAS to and remove PFAS from the environment.

• Elimination of PFAS entering the environment will significantly attenuate concentration in drinking water sources. Attenuation will result in elimination or significant reduction in scale of treatment, thereby relieving already leveraged ratepayers from having to pay for stranded assets.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045765)

EPA Should Prioritize Eliminating Sources of PFAS Contamination

Neither DC Water nor our wholesale provider, Washington Aqueduct, produce PFAS. It is not a chemical that is added to the water during treatment, nor is it a byproduct of the treatment process. Instead, PFAS is in our water supply as a result of discharges by manufacturers of PFAS, those who use PFAS in the manufacture of their products, users of products containing PFAS, and other sources of PFAS in the environment unrelated to providing drinking water.

We have known of the potential health concerns associated with certain PFAS for decades, and while some substitution has been made by the industrial community, PFAS compounds continue to be manufactured and used in a wide variety of industrial and consumer products and processes. Rather than regulate PFAS in the environment by regulating drinking water utilities, EPA should prioritize regulation of PFAS at the source to prevent it from being discharged to the environment. As a result of the proposed· regulation, our customers, not the sources of PFAS, will be responsible for bearing 75% of the cost of PFAS removal, and 100% of the monitoring, reporting and risk communication costs. We ask EPA to prioritize a comprehensive regulatory scheme to prevent releases of PFAS to and remove PFAS from the environment, and not penalize passive receivers of PFAS.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Pennsylvania Municipal Authorities Association (Doc. #1832, SBC-045786)

[PMAA's specific comments on the Proposal are as follows:]

10. It is PMAA's position that those entities who manufacture and profit (or have profited) from, among other things, the use of PFAS chemicals should bear the entire burden for any needed treatment and related costs to address PFAS contamination impacting health and the environment. As such, PMAA's position is that the "Polluter Pays" principle should guide all costs related to removing PFAS from the environment, which position is simply restating EPA's own position in its PFAS Strategic Roadmap.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Pennsylvania Municipal Authorities Association (Doc. #1832, SBC-045782)

[PMAA's specific comments on the Proposal are as follows:]

6. Drinking water facilities, many of which are PMAA member authorities, will bear the regulatory and economic burden of complying with the Proposal, notwithstanding the critical fact that these facilities are merely passive receivers of PFAS chemicals, and are only subject to the Proposal due to the actions of others. These facilities neither manufacture nor produce PFAS, yet will be required to treat the raw influent at their plants containing these emerging contaminants, consistent with the requirements of the Safe Drinking Water Act. As EPA is aware, most, if not all, of these facilities were not designed to treat emerging contaminants such as PFAS. Therefore, PMAA strongly urges that EPA undertake additional initiatives that address, at a minimum, source control requirements related to PFAS in order to eliminate or substantially reduce, among other things, the costs of PFAS treatment, management and monitoring that will be directly borne by PMAA member authorities and their ratepayers under the requirements of a promulgated EPA PFAS regulation.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Pennsylvania Municipal Authorities Association (Doc. #1832, SBC-045787)

[PMAA's specific comments on the Proposal are as follows:]

11. EPA needs to more fully address the impact of the Proposal on the use and management of biosolids. PMAA understands that EPA is undertaking certain studies related to a risk assessment for PFAS found in biosolids, but that such studies may not be completed until December, 2024. It is critical for EPA to address how and the extent to which the Proposal may impact biosolids management and the use of 40 C.F.R Part 503 with respect to the regulation of biosolids.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Corix Infrastructure Inc. (Doc. #1834, SBC-045363)

2. EPA needs to require point of use restrictions on the manufacturers to address and remediate PFAS contamination at its source and reduce downstream removal of contaminates by entities with no responsibility for the creation of the problem.

Corix urges EPA to take greater actions to reduce the contamination of water supplies by the manufacturers of PFAS substances before such chemicals contaminate water supplies. EPA needs to commit to stronger actions against the sources of the contamination rather than requiring the water industry to remove the harmful chemicals once they are in the environment and the water supplies. As passive receivers of these contaminants, the drinking water industry should not be disproportionately targeted by this regulatory action to reduce PFAS exposure.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-045376)

We call on Congress and the Biden Administration to fully fund the treatment and ongoing operations and maintenance costs necessary to remediate PFAS in our nation's drinking water and seek reimbursement from the polluters who have caused this problem.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-045395)

Source Investigations:

It is important when there are detections in drinking water that regulatory agencies follow up to determine the source of the contamination so that the costs will not fall on our ratepayers to fund remediation. In Massachusetts, for example, MassDEP stated that when a PWS detected PFAS in the drinking water above the MMCL, MassDEP would initiate an investigation into the potential sources of contamination and the identification of potentially responsible parties. There have been so many detections in Massachusetts that MassDEP has not had the resources in their Bureau of Waste-site Clean up to perform timely follow- up investigations. This has left PWS and their ratepayers funding remediation in the absence of a responsible party. Proper resources must be allocated to follow up on identifying the source of contamination and holding those parties responsible for paying for treatment.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-045381)

Similarly, the Food and Drug Administration should be regulating PFAS in bottled water. If PFAS are as dangerous as EPA is suggesting, we recommend that EPA work with appropriate state and federal regulatory agencies to prevent consumer exposure to PFAS from bottled water and private wells. Consumers should be informed about the sources of PFAS in the environment and how they impact drinking water supplies of all types.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Metropolitan Washington Council of Governments (Doc. #1843, SBC-044753)

Regarding the proposed NPDWR, our primary recommendation is for EPA to work with other federal agencies to develop and implement a regulatory framework that targets the removal of PFAS sources to the maximum extent practicable. Eliminating pollution at the source is the best way to protect local drinking water supplies, which are passive receivers of PFAS compounds.

Targeting and eliminating sources of PFAS compounds would be cost effective and would place the cost for remediation on the polluter rather than the public.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Amigos Bravos (Doc. #1844, SBC-045401)

EPA should finalize the rule and move to take additional action on PFAS including taking steps to make sure PFAS doesn't enter our environment in the first place by cleaning up PFAS contaminated sites, ensuring that federal and state issued Clean Water Act permits can adequately regulate PFAS discharges, and regulating PFAS under the Resource Conservation and Recovery Act.

Sincerely,

Elena Fernández MSL, MELP Projects Specialist

575-758-3874

efernandez@amigosbravos.org www.amigosbravos.org

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Darlene Price (Doc. #1874, SBC-047459)

I am a retired Special Agent now Criminal Defense Investigator/Expert Witness, with over 35 years of experience in criminal investigations. As one of my part time jobs, I am an investigative journalist here in my home state of Kentucky. I have been working on a story that to call shocking, would be an understatement. We have completed a two part documentary that you can now view on YouTube entitled, "Lake Cumber, what really lies beneath" Parts 1 and 2. Lake Cumberland in Pulaski County, Kentucky, is located in the beautiful Daniel Boone National Forest. It is a very active tourism location for swimming, boating, fishing, hiking, camping and water-skiing. It is also the primary source of drinking water for much of the people and wildlife in Kentucky and throughout Tennessee. Pitman Creek in Pulaski

County, Kentucky flows directly into Lake Cumberland. Lake Cumberland flows into the Cumberland River, a primary water source that flows down stream to Nashville, Tennessee. As a result of numerous records that I have received from the State EPA and the State Water district via open records requests, I have serious concerns regarding the water contamination in Lake Cumberland and the Cumberland River. My primary concern is that we have numerous documents that demonstrate that the City of Somerset has a highly defective wastewater treatment facility from at least 2016 through 2023. Despite this facility being repeatedly threatened by the State EPA, they have since 2019 added to this facility even more serious contaminates from landfill runoff called leachate. My investigation clearly demonstrates that this

was done in order to secure at least $300,000.00 a year by the Mayor of Somerset and the Somerset City Counsel. My research demonstrates that leechate from demolition landfills hold some of the most dangerous contaminates. Some of these landfills will have leechate that most certainly contains asbestos and "Perfluorooctanoic acid" also known as "C8" and "Forever Chemicals" ; as well as C6 hexavalent chromium. Normal purification processes will not remove these types of contaminates which are known to be highly carcinogenic and lethal to wildlife.The documents that I have received from the State Water District, the State EPA, the Regional Health Department and the City of Somerset tell a most gruesome story. These documents clearly demonstrate that Sinking Creek and Pitman Creek, which empty out into Lake Cumberland, have numerous, repeated serious "Out of Compliance Violations" for: E-Coli, Chronic Ceriodaphnia Dubia Pkv; CBOD; Suspended Solids, Total Ammonia Nitrogen (as N), and MOST CONCERNING is the June 8, 2018, letter referring to "hexavalent chromium" limits – also known as C-6. These many violations run at least from 2016 to 2022. These violations were serious enough that the State Water Department repeatedly threatened that, "Violations of the above cited statutes(s) and/or regulation(s) are subject to a civil penalty per day per violation. Violations carry civil penalties of up to $25,000 per day per violation depending on the statutes/regulations violated." Yet, in the State EPA, the State Water District and Somerset's answers and/or documents provided, there were zero fines or penalties levied on either the City of Somerset or the wastewater treatment plant; even though numerous violations have been sited over at least a period of six (6) years. At this point, The City of Somerset Wastewater Treatment Plant alone has introduced at least 50 million gallons of Industrial Waste Leachate from four (4) different industrial waste landfills, not to mention the thousands of gallons of industrial waste from the local businesses that send their industrial waste to this defective plant. These businesses include medical facilities that are permitted for some of the worst contaminates imaginable, including C-6 & C-8. These landfills and businesses are permitted for "Industrial Waste" while the City of Somerset's wastewater treatment plant has only a general permit that is over twelve (12) years old. This is just a sampling of this heart-wrenching investigation thus far. What I'm hoping for is that these EPA regulations and regulations like it, will indeed pass and not only protect our drinking water, but our entire echo-system surrounding our beautiful Daniel Boone National Forest. Any assistance that I can give to you on this very important issue, I will be happy to provide.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Juergen Froemming (Doc. #1881, SBC-046558)

Dear Administrator Regan,

Regulations or a lack thereof in the US are designed to help the industry, NOT the people. We have already a fentanyl epidemic caused by the Pharma industry. As a resident of the US and citizen of Germany i am utterly disgusted about the sheer negligence that leaves Americans to their fate that is mainly orchestrated by corrupt CEOs and Politicians.

I hope my plea does not fall on deaf ears.

My heart goes out to all Americans who suffer in this, not so democratic, society, knowing it could be done differently to promote health and prosperity rather than sickness and poverty.

Quality of water and food/production etc. Is essential and there shouldn't even be a discussion about it.

The letter i send you today reflects my assessment being a resident of the US sine nearly a decade.

My goal is not to point fingers or disparage anyone, i merely would like to see that especially politicians live up to what they claim to be and do:

Serving the American people, after all THEY decide who makes the race at the ballot box.

I hope i wasn't too blunt but i feel there is just too much sugarcoating going on.

Thank you very much for your time.

Have a wonderful day!

Sincerely,

Juergen Froemming

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #1905, SBC-047443)

I leave you with the following thought experiments:

-What good are "healthy" tomatoes and grapes if they come in wrapped in PFAs/PFO paper that gets put into landfills that will make our drinking water unsafe (see stores that are already reducing the use of plastics with reusable bakery bags)

-What good is cooking spinach on a teflon pan? Why not ban those and ensure every American knows they should use stainless steel?

- What good is looking great when you will end up with cancer due to the use of makeup? That makeup also gets washed into the wastewater system, likely to end up in our water supply.

I have personally had to have my gallbladder removed (not overweight, I am a health nut and coach, marathon runner, I drink water like crazy). I've been running for 32 years. This should not have happened to me. No one else in my family experienced this. Will future studies show liver, gallbladder, stomach issues related to PFAs? I honestly hope we never get that far because they are banned. I wouldn't wish what I have been through on anyone. It is seriously hard for me to encourage people as a coach to drink more water when I know how contaminated it is. People

are already severely dehydrated, let's not make it worse by having water be so contaminated that people fear it. We have enough health crises in this country without this one problem. Please, please, do what is right and ban the use of this substance and make sure that water utilities do what they can to eliminate it from our drinking water. We can put people in space and build rocket ships, we can do this!

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Araceli Medialdea (Doc. #1914, SBC-046483)

Dear Michael Regan,

Water is something we all need to survive. The world is in a really bad place and last thing we need is our higher ups poisoning us. Why? You know you're doing it.. you know things could be better. You need people to keep the world running. Why not make life sustainable for all instead of a select few? No other person deserves more rights than the next. Please listen to our cries.. we want what's best for our world.

Sincerely,

Araceli Medialdea

Tucson, AZ 85730

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #1927, SBC-047451)

This proves why it is very important to monitor and understand PFAS's. So, we need to identify and address that we are not holding these companies accountable for proper disposal and testing before these PFAS are able to harm individuals and wildlife. Even though this proposition notifies, monitors, and reduces these PFAS it is not doing preliminary research on these PFAS to completely keep individuals safe from health risks. We also see individuals such as DuPont who have knowingly exposed people to these harmful PFAS for years. Yet he was not punished for this act for years (Rich, p8-9). This proves that selfishness of individuals seeking more money can also harm the environment and people. We need to stop this at the root, making the companies do tests and proper disposal on top of the monitoring, notifying, and reducing the amount of PFAS within the environment's water supply in general. Not just our own drinking water that affects animals as well. To summarize, I believe that we should be doing more than this bare minimum to keep our environment's water safe and inhabitable for all living organisms. If we don't this is not only hurting us, but also the animals that help keep our ecosystem stable and safe for years to come.

Anonymous (Doc. #1930, SBC-047319)

To this end, I propose that we either limit the amount of known harmful PFAS in our water systems similar to the proposed regulation or even ban PFAS outright similar to the laws within Maine. Additionally, to prevent future PFAS or similarly harmful substances from entering our water systems, I propose funding for public water systems to conduct clinical trials on unknown chemicals that enter our drinking water and to investigate the origin of those substances; this way we are able to hold manufacturers more accountable to the risks of dumping unsafe substances within water systems and to prevent another case similar to DuPont's from occurring. When a harmful substance is detected I believe public water systems should try to settle the matter privately with the manufacturer by requiring the manufacturer either pay to create filtration systems that would allow for the substance to enter the environment under safe conditions, or make the manufacturer seek a biodegradable and safe alternative. If these requirements aren't followed, the public water systems need to inform the public of the harmful effects of said substance, the dosage of the substance within their drinking water, which party is liable for that substance, and to issue hefty fines to the guilty party which grows exponentially as time passes and the problem remains unresolved.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Diego Carrasco (Doc. #1932, SBC-047438)

Even though the creation of these regulations is a great step forward. In cases of this magnitude such as the safeness of the use of water in our water streams, we should also consider the highly possible arousal of new contaminants that might have emerged while the PFAS regulations were in the process of being created. These contaminants can appear in many forms, for example: In the shape of heavy metals, microplastics, and inorganic matter. Chemical compounds that are

detrimental to one's health. Therefore, I would encourage the EPA to implement more cautious and constant testing of water bodies in the US that are close to any kind of civilization where the community can be impacted by the chemical status of their main source of water. A main component of evolution is invention. Scientists all over the world work non-stop to create all kinds of applications of chemistry in our daily life aiming to facilitate our lives. This facilitations may come with complications like the ones Teflon brought with its invention in the late 1900s. Thus, we should encourage the agencies that make the regulations regarding our health, to keep up with the scientific community to be able to provide a more positive outcome for all of the parties involved in these type of transactions.

In conclusion, the EPA's proposed regulations on PFAS are a vital step towards safeguarding public health. Giving citizens access to the PFAS analytic tool will enable them to make informed decisions about their health. However, we must also consider the possibility of new contaminants emerging while creating these regulations. Therefore, the government must continuously and carefully test water bodies in the US to ensure that our water sources do not pose a risk to public health. We should encourage health regulatory agencies to keep up with scientific advancements to ensure positive outcomes in the health status of the country's citizens.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Susan Corbelli (Doc. #1940, SBC-046257)

We teach our kids not to swallow toothpaste, to spit out fluoride rinses and don't eat/drink after a fluoride treatment yet we add fluoride to our drinking water? Cavities are on the rise: it doesn't look like adding fluoride to the water helped. Please stop adding it to our drinking water. Thank you

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #1955, SBC-047317)

To provide a better and cleaner environment, the new regulations and more accurate checks on a federal level can help limit the amount of PFAS within the environment. There is no saying how long PFAS stays in the body, which is why it's also considered to be a "˜forever chemical' There needs to be stricter regulations and checks from politicians, heads of government, and agencies to ensure a clean environment for drinking water, more environment friendly pans and clothing. Although PFAS have become a significant concern for public health in many parts of the world, their presence in drinking water and cookware is a critical issue that needs to be addressed. Ultimately, it is essential to protect public health and maintain access to safe drinking water, clothing, and having the ability to cook food without being contaminated by PFAS.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anna Trujillo (Doc. #1959, SBC-047296)

One of the difficulties I ran across when going through the five processes of decision-making was coming up with a different strategy to completely eradicate PFAS. I think that a portion of our taxes and fines to chemical firms should go into paying for the expensive cleanup of PFAs from our water. Due to the fact that the new regulation does not automatically ensure that everyone would agree with it, it is challenging to examine other alternatives. When assessing ethical factors, selecting a course of action can be difficult. This is particularly true given how expensive my proposal would be to totally eradicate PFAs. Where will the funding come from, how will we make sure those responsible are held accountable, how can we ensure that PFAs-containing compounds are removed off the market and how can we guarantee that the manufacture of chemicals containing PFAS is stopped? Complete eradication of PFAs is not impossible, but it would be exceedingly costly.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Iresli Jurado (Doc. #1960, SBC-047445)

There is an issue with both companies and the laws that regulate actions and both parties should strive to be better. Companies and particularly large corporations like DuPont, often prioritize profits over the wellbeing of people and the environment. They are willing to take risks with harmful substances if this means saving money. The fact that people risk others lives for personal benefit, is unethical on a level that does not belong in any future of human existence. Simultaneously, there are gaps in the regulatory framework that allow companies to engage in practices that are harmful to people and the environment. For example, in the case of PFOA, the EPA had not yet classified the substances as hazardous, even though there was evidence of its dangers. This lack of regulatory oversight allowed DuPont to continue using PFOA without facing any significant consequences. Not in any way does this justify the act of the people behind the actions of the company, but there are flaws in the system. By law it allows the first amount of money being made to go to DuPont, but this money should not be available to anyone after the regulation of the laws. This money should be considered unfounded.

It is not an issue with companies or laws in isolation, but rather interplay between the two. Laws need to be strong enough to hold them accountable when they fail to do so. Following the Markkula Ethical Decision Making framework, we would consider protecting the people not just the good choice instead of the bad choice, but the ONLY choice. It should not be allowed to be aware of a possibly helping system without using or applying it for the benefit of people.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Mary-Ellen Maynard (Doc. #1982, SBC-047487)

Dear Michael Regan,

ALL FOSSIL FUELS ARE TOXIC TO ALL LIFE. What part of that sentence don't you understand?

As someone who has been tortured for 73 years by the health-destroying effects of a prescription drug synthesized from coal tar, given to my mother while she was pregnant with me, I am outraged that anyone with a brain still thinks that extracting fossil fuels is anything other than criminal and suicidal on a species level.

Keep it up and you and your children will be the next to suffer, as my family members have all suffered.

The women who took the drug died in large numbers from breast cancer, as did my mother. My sister, also exposed, had a miscarriage, ectopic pregnancy and child who died within a few months of a birth defect because of that drug. Her daughter had only one or two menstrual cycles per year because of that drug. I've had breast and uterine cancers which have been the least of my health issues caused by that drug. I was unwilling to pass the damage to another generation in the unlikely event that my reproductive deformities would have allowed me to become pregnant. All because of Diethylstilbestrol. Think twice about new fossil fuel drilling, pipelines and facilities and then think again and again. Think even harder about chemicals synthesized from coal.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Roger Beck (Doc. #2035, SBC-046604)

Dear Sir/Madam,

I am writing to express my strong support for the use of Tucker Carlson as a tool for removing PFAS from drinking water. As you know, PFAS are a group of chemicals that have been linked to a range of serious health problems, including cancer, liver damage, and immune system dysfunction. It is imperative that we find effective ways to remove these harmful substances from our water supply.

In laboratory tests, because of his hot air, ability to attract filth and trash from all directions, and reality not mattering in how he shapes the world around him, Carlson has been found to be incredibly effective at removing PFAS from water. His hot air seems to attract the PFAS molecules, which then adhere to the slimy, sticky substance that is his being. And once Carlson has soaked up as much PFAS as he can, he can be easily removed from the water and disposed of safely.

But Carlson's usefulness extends far beyond his ability to remove PFAS. He is also an excellent tool for cleaning up garbage and waste. His absorbent properties mean that he can be used to pick up all kinds of litter, from cigarette butts to plastic bottles to discarded food. And because he is so effective at soaking up waste, he can help to keep our streets and waterways cleaner and safer.

One of the most remarkable things about Carlson is that he requires no special maintenance or attention. He simply sits there, doing his job loudly, obnoxiously, and efficiently, without any need for supervision or oversight. This makes him an incredibly cost-effective and practical solution for removing PFAS and cleaning up waste.

It is rumored that Carlson also has a secret power. Some say that Carlson could make anything disappear, including the truth, 800 million dollars, evidence of an insurrection, friends, civility, democracy, and harmful chemicals such as PFAS. And not only that - Carlson believes he could magically replace PFAS with pristine, drinkable water just because he wants to.

I urge you to consider the many benefits of putting Carlson at the bottom of a drinking water well and using him as a tool for removing PFAS from drinking water. He is a safe, effective, misogynistic and cost-effective solution that has the potential to make a real difference in the health and well-being of our communities by soaking up the trash we actually want him to do so without broadcast the waste back across our airwaves.

Thank you for your attention to this important matter and I look forward to Tucker Carlson's important contributions to pfas removal, so that for the first time in his life, he would make the world a better place instead of making it much worse for all of us.

Eleanor Howard (Doc. #2191, SBC-046235)

Frankly, my dear, I don't give a damn about our communities. I care about all the other species for whom we are daily ruining the planet. So I want more and better regulations on everything everywhere.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Frances Lamberts (Doc. #2250, SBC-047430)

As this year's March 3 Science issue notes, "five EU countries (have) proposed a complete phaseout of PFASs." Since there are many thousands of them in use, such phaseout may be quite difficult to achieve. May I recommend, however, that

(1) your Agency not approve any new, additional PFASs through the pre-manufacture process, or through regulatory exemption, that

(2) industry discharges of PFASs into our water bodies be regulated, as also

(3) PFASs emissions into the air.

As our beloved, long-ago author E.B. White said of pollutants (then from atmospheric nuclear-weapons testing) in the soil – "the correct amount of strontium in the soil is no strontium" – so it should be with the PFAS chemicals – not allowed in our drinking water or our bodies.

Again, I thank the Environmental Protection Agency for this initial rulemaking.

Sincerely, Frances Lamberts, 113 Ridge Lane, Jonesborough, TN 37659

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Rhonda Gill (Doc. #2272, SBC-046472)

Please consider the possibility of further contamination from the products AND those that decay into it. The extent of contamination should include those downstream and the circumferences around sites.

This needs to address all sources of PFAs on the workers, surrounding communities and others who have a right to be protected.

This is not a sufficiently broad approach to the long term effects of the product

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2317, SBC-046250)

Chemicals that include PFAS should be wholly banned from America in the first place. The fact that it has gotten into our water supplies is no accident. Our well beings are second to the corporations and businesses that have their products loaded with the stuff.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Joseph Alvarado (Doc. #2337, SBC-047347)

For the love of God and the children of future generations leave the fossil fuels in the ground, we do not need for to continue to accelerate the defrosting of the permafrost methane swamps inform the public to end carbon intensive practices, methane is 40xs worse than tailpipe emission, more companies need to reduce carbon emissions and take up carbon capture, reduce and then eliminate new plastic use (90% of plastic has not been recycled, clean up the Pacific garbage patch and recycle it.) forget EVs until a carbon neutral cradle to grave recycle process is complete for all EV materials, people need to reduce, recycle & reuse, bike, walk, plant trees,

conserve, get OPEC, G20, U.S., & China to quintuple down on green hydrogen, COVID came from Wuhan, environmental protection laws exist for such things via strict liability like offshore oil drilling, nuclear power, CHINA OWES. RAIL,RAIL, RAIL. Trains can do so much more with less, to distribution hubs and vehicles can do final destination, build out major corridors for Rail, Water, & Power all at once, as for combustion, Green Hydrogen is the way forward, when it comes to combustion. The bankers have manipulated so much over the years, these days many people are not savvy enough to know that they have more access to money than brains...too many things are uncorked before they are ready from Clinton and the deregulation of banks that led to irresponsible leveraging, to consumer spending on trends and disposable garbage from cell phones, globalization, dotcom, to EVs, these trends have been more activity than accomplishment (Wooden) and people are leveraging their future to jump on bandwagons and the fees you roost form them is just more insult to injury...pimping the poor, like check cashing places, from post 9/11, 0% financing for SUVs when we should have been getting off fossil fuels to the 2008 bubble and bail out and so much more for the last decade and more remarkably of late. I hope the bankers are ready for their comeuppance, too big to fail, that was stupid, more money than brains...and are chiseling people for more fees, work on educating the public so that consumers make prudent long term decision in

ATTN of The General Counsel and Trustees of Columbia University,

Mr. Jerome Davis,

Thank you in advance for looking into this, it is a USC Title 18.225 which has not yet been adjudicated. f**** child molestors watch their students in the privacy of their homes??? Who the f*** signed off on that??

A conspiracy (more than foe' is all I need ya know) and a $6million loan by State Farm to The Sullivan Properties LP with a claim to their unlawful income is a USC Title 18.215. More concerning is the lack of disclosure to the SEC about a loan in excess of $5 million which holds the burden of the LP's tax evasion.

No Taxes paid on $288 million in property taxes for the last ten years, which was undervalued at roughly $22 million, as per NY DFS records, Block 803, Lot 11; inclusive of its contiguous properties all owned by the same LP; unlawful rents and leases transferred to then CIK filer 93715 (USC Title 18.21), beyond a reasonable doubt. The irony is that more than 75% of those units were empty, however those rent payments are unlawful (no certificate of occupancy), which by the FDIC is an unlawful deposit -no different than a heroin dealer depositing his ill earned money into, let's say Chase Manhattan bank?

The documents in this folder should be helpful for you to prosecute them and also understand where I have my reservations, pun intended.

You're welcome!

You can start looking here, just like the peeping Toms in Penn State:</br>

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2532, SBC-046300)

While PFAS chemicals are indeed dangerous to both our health and the environment, and I believe that they should be banned or at least severely regulated, has the EPA considered this proposed policy's impact on the economy? PFAS and many other similar chemicals are used in a

great deal of consumer products. Anything from cleaning products to shampoo to life jackets all contain PFAS chemicals. If these chemicals were to suddenly become severely regulated, would this not impact production in a way that creates costs that would fall onto us as consumers? Even passed that, would alternatives to them be healthier for us and the environment or could they be worse?

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Krystle Bowers (Doc. #2552, SBC-046287)

This regulation seems to put the cost and work on the our public work departments across the country for a substance that's been introduced by companies. Regulations should be aimed at limiting PFAS contaminating our environments in the first place. The burden of the cost and work should be placed on the companies creating these substances and putting them out into the world. This will place a heavier burden on tax payers while giving PFAS creating companies immunity on the damage they do to our health and safety.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Mark Ball (Doc. #2559, SBC-046278)

Dear person receiving these comments. I am pleased to hear you are urgently working to help save our limited resources. PFAS is very harmful to the environment and humans. However, This is by no means an easy task to pull off. PFAS is everywhere we cant directly eliminate the source since it is a nonpoint pollution source. However what we should try to do is eliminate chemicals we use in beauty product and hair gels. This would help stop pfas.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Mark Griffiths (Doc. #2560, SBC-046240)

Let's end the production of PFAS and work on solutions to remove these chemicals from the ground water, lakes, streams, and rivers. We also need to enact severe penalties for companies who continue to produce them.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Lissa Spitz (Doc. #2564, SBC-046258)

It is an outrage that profit driven companies continue to pollute our water with poison. Please strengthen the regulations against this. I live near the Huron river and it is a gem, but the water is

not safe. Signs are posted to not eat the fish or touch the foam. This is unacceptable. Thanks, Lissa Spitz

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2571, SBC-046318)

Clean water is essential for not only human life, but a biodiversity of life on planet Earth. No person or entity should be allowed to pollute our water - and yet it has occurred and continues to occur as disposing of chemicals properly are deemed too difficult or costly. It's easier to simply dump them in the ground or in a swamp on 'vacant land'. The entities/individuals doing the polluting don't seem to understand how their pollution actually impacts themselves, other humans, and other creatures of the Earth. They've potentially caused irreparable harm and they must be held accountable for their actions. This cannot be overstated. Please do everything possible through the creation of laws and regulations to not only punish those responsible for polluting, but also to potentially stop the next set of individuals from acting so irresponsibly. Stiff penalties and fines as well as demanding the polluters clean up what they've done, plus watching them while they are doing the clean-up to ensure it's correctly done - are all necessary and important to prevent future problems of this nature.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Martha King (Doc. #2589, SBC-047311)

Also, once the water systems plant "treats" the water then where do the biosolids go? Perhaps to a landfill, burning them, or making it into "fertilizer"? All of these are not sustainable nor are they environmentally safe. Farmers have been using the "biosolid" fertilizer on their fields that further spreads the contamination into our ground water and potentially into privately owned wells. The EPA proposal does not address privately owned wells. It is difficult to find labs that test private well water for PFAS and the one lab I did find was quite costly. The American public should not foot the bill to protect their health from these contaminants. I wonder how many citizens are suffering from illnesses that are directly attributable to these chemicals. The "Superfund" is not available for them. Simply put... by not permitting any more of the several toxic chemicals (PFAS, PFAOS, PFNA, PFHxS, PFBS, etc) into our lakes, wells, streams, etc we would FINALLY (since 1940!) end this catastrophe. That is, of course, as long as companies stop making alternative chemicals to replace the ones that have been determined to be negatively impacting our health. And then, who is "monitoring" Monsanto, 3M, Bayer, etc?

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Timothy Fallon (Doc. #2592, SBC-046423)

How specifically does this effect our oil and gas industry? I mean they are everywhere. is this more, oh look we care about you laws. As always to little for a lot put on the tax payers tab. Maybe just enforce the existing laws.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Sarah E (Doc. #2613, SBC-046268)

I'm an Environmental Chemist by trade, and I agree that PFAS should not be taken lightly, as it is not volatile, and I read an research article proving it causes fertility problems in the fish who regularly consume it. This stuff is extremely hard to remediate(remove) from water. The source of the PFAS contamination should be found as soon as possible .

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2621, SBC-046255)

No where in your very impressive and lengthy blabberings did I see anything that suggests you have learned your lesson and will from now on stop fast tracking approval of shite to be used however the user sees fit without anyone knowing what the long-term consequences might be.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Colleen Thomas (Doc. #2637, SBC-046283)

As a civil engineer, I spend my days concerned with water quality of a proposed development and ensuring that the run-off is clean to discharge to local wetlands/storm sewer. It is so sad that we don't hold big business accountable for cleaning water or paying after accidents. Women are having unprecedented issues with fertility, and we wonder why? PFAS are a huge problem. I urge the EPA to force responsibility on our polluters and keep our nation and its people safe.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Jack Anon (Doc. #2663, SBC-046185)

We don't need MORE plastic.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Andrea Thompson (Doc. #2711, SBC-047503)

As an indigenous woman I have question for you; When you took our lands you pledged to protect and care for us and the land itself it seems to me you are not fulfilling your treaty obligations and are instead allowing fossil fuels and it's plastics, spills, train derailments and other issues to take over our Mother Earth! You must stop allowing these companies and corporations to influence you in any way but negatively they must be stopped and held accountable and responsible for their actions or lack of action! It's imperative that it is done right and immediately! For the sake of America and all the life living here wildlife as well as human lives depend on you!

Sincerely,

Andrea P. Thompson

Sincerely,

Andrea Thompson

Eufaula, OK 74432

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Emma Allen (Doc. #2712, SBC-047505)

THERE HAS BEEN SAND AND A STRONG CLORINE SMELL TO MY TAP WATER SINCE I WAS A CHILD . I FEEL LIKE CONSUMING TAP WATER GROWING UP HAS CAUSED ACTUAL DAMAGE TO MY BODY AND MIND . THE DENTIST SAID THERES FLORIDE TOO? HOW IS THAT SAFE OR OK? DO U EVEN HAVE STUDIES OR PROOF THAT FLORIDE DOES MORE GOOD THAN HARM? YALL ARE TRYING TO CONTROL US AND SOMEDAY THE PEOPLE WILL RIOT AND TAKE IT ALL DOWN .

Sincerely,

EMMA ALLEN

Stockton, CA 95210

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

D. C. (Doc. #2741, SBC-046310)

Re: Per &Polyfluoroalkyl chemicals in drinking water: I believe that there should be zero tolerance in laws & regulations of the chemicals mentioned in the title. My community is on an island in the Pacific Ocean that hosts several US military based that have used & abused these

chemicals. Now they are proved to be in some of the drinking water on our island. We essentially have no alternative source of drinking water except the lense of water deep beneath our island. It is unconsunable that the US Navy should be allowed to comtinue to use these chemicals when they have already contaminated parts of our drinking water with them. If a poll were taken, probably 100% of the people living here would support the idea of totally banning these dreadful chemicals. They poison the people, animals, plants and land. We have no other water source. Please, please ban them as soon as possible.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Patricia Schenk (Doc. #2742, SBC-046298)

I missed the EPA public hearing on May 4th for Washington County. I agree that PFA's are an issue and pleased our city of Cottage Grove is using dollars received from 3M to help in this endeavor. I've learned that toilet paper is a contributor as their product has PFA'S. Think about how many households use this more than once a day. Wouldn't it make sense to regulate the companies who manufacture these products? I also learned there are companies who manufacture a toilet paper made with Bamboo that doesn't have any PFA's. They are available from Walmart or Amazon. This leads me to believe manufacturing toilet paper without PFA's is possible.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Brittney Johansen (Doc. #2750, SBC-047298)

My name is Brittney. I am a student at San Francisco State University studying water quality. I have many concerns over PFAS manufacturing and regulation in the US, as research shows PFAS are present in the atmosphere, groundwater, and ambient water. According to the article by Wagner and Gold titled, "Legal obstacles to toxic chemical research", studying chemicals in the environment is only allowed to be reactionary and not precautionary. A major issue to studying chemicals in the environment are the legal blockades created by the Toxic Substances Control Act (TSCA) created by Congress in 1976. There are three issues that need to be addressed in order for scientific research to protect the environment and human health. First, the public availability of complete chemical standards. Second, public access to industry information typically protected under confidential business information (CBI). Third, an end to requirements that fragment information between local, state, and federal agencies.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Justine Cook (Doc. #2789, SBC-046564)

Dear EPA:

The most useful action the EPA could take even prior to finalizing the rules regulating Per- and Polyfluoroalkyl Substances would be to post a list of safe brands of plastic pipes that municipal water systems and homeowners can use that are PFAS free. With the infrastructure bill money now available, long delayed water infrastructure projects are underway. It would be tragic for America to have widespread plastic piping go in that may CONTAMINATE water with PFAS. Please release a commercial brand list of safe pipes. I live in a small rural town in Vermont. My water board is following industry standards in opting to use plastic rather than a known legacy material such as copper, etc. but there is no information from the Federal level guiding the safe brands of plastic pipes. Our town is going with the least expensive bid as required. HDPE pipes will be used and we don't know if they are free from PFAS.

Secondly, with projects that are already permitted and funded, would the EPA announce flexible rules to switch to copper, etc. rather than plastic, if towns and cities wanted to change in light of emerging science? We are being told our funding will be cancelled if the scope of the project changes due to increased cost for non-plastic pipes. Thank you.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Gina Weiss (Doc. #2803, SBC-046301)

No , I don't applaud the EPA, what is the EPA doing about the leaded fuel that is being sold at municipal airports like Flagler Executive airport in Palm Coast Florida, the airport manager is selling leaded fuel to piston engine planes and flight schoolplanes because its cheap, this year in Roy Sieger's annual report he has sold tons and tons of gallons, profiting off our communities back with poison AVAGAS that seeps into our soil and water supplies exposing our taxpayers and residents to high lead effects exposure in our children, leads to autism, and other diseases such as breast cancer, heart conditions, strokes, etc.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Whidbey Environmental Action Network (Doc. #2804, SBC-046565)

We need more than mere regulation of PFAS and its many related compounds. At the local level we are dealing with land use applications which will clearly result in exposure to PFAS for future residents, tenants, visitors to the proposed developments. There are no protocols in place for jurisdictions to require even minimal testing of groundwater which is expected to supply the land uses for which those applications are submitted. We ask that EPA promulgate such

protocols. At the very least there is a duty for jurisdictions to require testing of groundwater before permitting wells.

And we need EPA to direct the manufacturers to stop producing these toxic substances. The far future dates which have been proposed and/or declared are just that: far future. That is not acceptable. EPA has the authority. Please exercise it.

Lastly, the US military is grossly negligent, actively avoiding its responsibilities. In some instances they are not even stopping use of PFAS chemicals. In all instances they are holding off on remedial action until EPA sets the new exposure limits. In our area the US Navy declares its intent to take no further remedial action until EPA declares and formally adopts the new exposure limit, thus continuing to expose a large population to levels nearing the outdated 70ppt level.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Jane Henderson (Doc. #2815, SBC-046232)

We must protect the public from PFAS contamination. Insure that the WDNR retain its authority to investigate PFAS contamination, hold polluters accountable, and protect our water supplies.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Richard Gelderman (Doc. #2820, SBC-047331)

3) In addition to swiftly finalizing drinking water standards for PFAS, we urge the EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by imposing additional regulations for PFAS through permitting, cleanup, and disposal.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Nancy Bouldin (Doc. #2822, SBC-047472)

4. In addition to swiftly finalizing drinking water standards for PFAS, we urge the EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by imposing additional regulations for PFAS through permitting, cleanup, and disposal.

In conclusion, I strongly support the EPA's proposed PFAS national primary drinking water regulations. I urge the EPA to finalize the standards as quickly as possible while simultaneously working to reduce PFAS pollution at the source.

Thank you for the opportunity to add my comments.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Melda Clark (Doc. #2823, SBC-047474)

4. In addition to swiftly finalizing drinking water standards for PFAS, we urge the EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by imposing additional regulations for PFAS through permitting, cleanup, and disposal.

In conclusion, I strongly support the EPA's proposed PFAS national primary drinking water regulations. I urge the EPA to finalize the standards as quickly as possible while simultaneously working to reduce PFAS pollution at the source.

Again, thank you for the opportunity to add my comments

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Karen Valentine (Doc. #2834, SBC-047476)

4. In addition to swiftly finalizing drinking water standards for PFAS, we urge the EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by imposing additional regulations for PFAS through permitting, cleanup, and disposal.

In conclusion, I strongly support the EPA's proposed PFAS national primary drinking water regulations. I urge the EPA to finalize the standards as quickly as possible while simultaneously working to reduce PFAS pollution at the source.

Again, thank you for the opportunity to add my comments.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Monty Fowler (Doc. #2836, SBC-047478)

4. In addition to swiftly finalizing drinking water standards for PFAS, we urge the EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by imposing additional regulations for PFAS through permitting, cleanup, and disposal.

In conclusion, I strongly support the EPA's proposed PFAS national primary drinking water regulations. I urge the EPA to finalize the standards as quickly as possible while simultaneously working to reduce PFAS pollution at the source.

Again, thank you for the opportunity to add my comments.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Steven Cole (Doc. #2837, SBC-047480)

3. In addition to swiftly finalizing drinking water standards for PFAS, we urge the EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by imposing additional regulations for PFAS through permitting, cleanup, and disposal.

In conclusion, I strongly support the EPA's proposed PFAS national primary drinking water regulations. I urge the EPA to finalize the standards as quickly as possible while simultaneously working to reduce PFAS pollution at the source.

Again, thank you for the opportunity to add my comments.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

John Doyle (Doc. #2840, SBC-047482)

4. In addition to swiftly finalizing drinking water standards for PFAS, we urge the EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by imposing additional regulations for PFAS through permitting, cleanup, and disposal.

My wife has Parkinson's disease and the evidence of it's environmental risk factors is overwhelming. We must get the toxins out of our water, air, land and food. Countries who have done this aggressively see reductions in prevalence of PD to pre-industrial age levels. This phenomenon is also common for other diseases, notably cancers. All the medical snake oilcures will never help the situation as long as we continue poisoning ourselves and our communities with chemical WE KNOW TO BE DEADLY!

In conclusion, I strongly support the EPA's proposed PFAS national primary drinking water regulations. I urge the EPA to finalize the standards as quickly as possible while simultaneously working to reduce PFAS pollution at the source.

Again, thank you for the opportunity to add my comments.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2846, SBC-046289)

please ban ALL PFAS chemicals, in all applications. These chemicals certainly do not belong in any surface water. These chemicals are not fit for frogs, fish, insects, birds... or mammals INCLUDING HUMANS to drink, swim in, cook or clean with. Just BAN them and enforce that the polluting companies, the manufacturers of the chemicals, and the inheritors of the polluting companies clean these chemicals from the environment. Filter them, transform them into something non-toxic, or otherwise get them out of the environment

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Liz Szabo (Doc. #2850, SBC-047507)

Pollution is a fight that is on the shoulders of democratic Americans because maga republicans do not support regulations nor do the maga six scotus. Yes even the six conservative scotus members have declared no support for protecting the environment against all the dangers of pollution. That means they do not care about safe to drink clean water. They do not care about the dangers of breathing polluted air. They do not care about polluting the earth from where crops are grown which we need to live. Yes, the federalist white supremacists six scotus have okayed the right of big business to continue business as usual in their production of dangerous toxins and poisons which cause illness, cancers and death because these six have been lobbied by the wealth of big business and are now supportive of the dirty dealings of creating and increasing pollution that kills. this is just a continuation of trumpism because it was trumps influence that ceased pollution regulations. It amazes me how much destruction trump managed to have happen in the short time he was; in my opinion; illegally in the White House.

Sincerely,

Liz Szabo

Mchenry, IL 60051

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Dirk Neyhart (Doc. #2886, SBC-046438)

Dear Michael Regan,

Every one of our bodies has man-made plastic in it for the first century in human evolution. Plastics, throw the malefactors in prison. Stop the production and distribution of Forever Chemicals.

D. E. Neynart

Sincerely,

Dirk Neyhart

Berkeley, CA 94702

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Susan Hayes-Tripp (Doc. #2893, SBC-047508)

Dear Michael Regan,

Our 8 BILLION and GROWING POPULATION, gives me no hope for for future generations. How we are currently living is not sustainable. Our species is truly the SUPERIOR PARASITE.

The polarization of our political parties in our country is frightening and embarrassing. The GOP has become the party of DO NOTHING & BLAME ! I have no faith that ANY environmental policies will be attained through our current Congress.

The environmental legacy which the GOP leave their children and grandchildren is shameful.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Laurine Yates (Doc. #2900, SBC-047484)

4. In addition to swiftly finalizing drinking water standards for PFAS, we urge the EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by imposing additional regulations for PFAS through permitting, cleanup, and disposal.

In conclusion, I strongly support the EPA's proposed PFAS national primary drinking water regulations. I urge the EPA to finalize the standards as quickly as possible while simultaneously working to reduce PFAS pollution at the source.

Again, thank you for the opportunity to add my comments. I would like to say that safe drinking water seems like an obvious thing that everyone wants!

We do do see that there are pressures to lower the numbers and allow more poison in our water....please, please do not give in to such pressures Your job is to protect the environment...what an important job! Please do your job and be proud that you have protected water for the citizens.

Thank you!

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Ira Share (Doc. #2927, SBC-046529)

How can you have a MCL of 4ppt while the agricultural industry adds forever chemicals into our environment? Let's pour gasoline on a match. The EPA needs to stop the use of these chemicals so we do not have to filter our water, remove our contaminated soil, and treat our diseases. This does not make any sense at all, to add more of these toxins while we debate on MCLs.

Please read this article. It is short. Here is a quote:

"The fact that we are likely spraying pesticides with PFAS on food at a time when EPA acknowledges there is no safe level of some of these chemicals is nonsensical," she added.

https://www.theguardian.com/environment/2023/may/07/food-pesticides-toxic-forever-chemicals-pfas#:~:text=Multiple%20studies%20have%20established%20that,probably%20polluting%20water%20with%20PFAS

Please follow your mission statement-protect our environment!

Thank you for your time.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2948, SBC-046288)

Yes I have commented on this in the past as well.It is truly our only equal rights by law.The right to the same drinking water and fresh air as our neighbors.Since late 2019 I have personally funded the revitalization efforts and have documentation It's an underserved community, opportunity zones,hub zone under SBA standards and It's worth your time to evaluate.I'm grateful I've made my mistakes on this journey along with accomplishments.I believe now is the time to move forward with a collaboration effort between us.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Diego Carrasco (Doc. #2978, SBC-047437)

Even though the creation of these regulations is a great step forward. In cases of this magnitude such as the safeness of the use of water in our water streams, we should also consider the highly possible arousal of new contaminants that might have emerged while the PFAS regulations were in the process of being created. These contaminants can appear in many forms, for example: In the shape of heavy metals, microplastics, and inorganic matter. Chemical compounds that are detrimental to one's health. Therefore, I would encourage the EPA to implement more cautious and constant testing of water bodies in the US that is close to any kind of civilization where the community can be impacted by the chemical status of their main source of water. A main component of evolution is invention. Scientists all over the world work non-stop to create all kinds of applications of chemistry in our daily life aiming to facilitate our lives. This facilitation may come with complications like the ones Teflon brought with its invention in the late 1900s. Thus, we should encourage the agencies that make the regulations regarding our health, to keep up with the scientific community to be able to provide a more positive outcome for all of the parties involved in these types of transactions.

In conclusion, the EPA's proposed regulations on PFAS are a vital step toward safeguarding public health. Giving citizens access to the PFAS analytic tool will enable them to make informed decisions about their health. However, we must also consider the possibility of new contaminants emerging while creating these regulations. Therefore, the government must continuously and carefully test water bodies in the US to ensure that our water sources do not pose a risk to public health. We should encourage health regulatory agencies to keep up with scientific advancements to ensure positive outcomes in the health status of the country's citizens.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Christina Micek (Doc. #2993, SBC-046324)

Please create a remediation and clean-up plan for these chemicals, especially near military bases. A new study at Harvard shows that not only the chemicals are an issue but do are the precursors. " without remediation, widespread PFAS contamination of drinking water supplies near military facilities is likely to persist for centuries. Despite contamination of nearby aquifers that may already pose a risk to human health, the majority of PFAS are still sitting in the soils surrounding these contaminated sites, emphasizing the urgent need for advances in remediation technology that effectively cleans up both terminal and precursor compounds. Since regulations focus only on terminal compounds, how effectively current remediation technologies clean up precursors is not known."https://news.harvard.edu/gazette/story/2023/05/epas-new-rules-on-forever-chemicals-dont-go-far-enough-study-suggests/

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Daniel Rostan (Doc. #3004, SBC-047354)

EPA should move forward to regulate emissions by air and discharge of contaminated PFAS waste into the wastewater systems, and limit pollution by biosolids/sludge fertilizers. While the costs of filtration and disposal are high, those costs are far outweighed by the billions of dollars in healthcare costs caused by the health impacts of PFAS chemicals, not to mention the incalculable damage done to loved ones when a family member dies of avoidable disease which the government failed to deem a sufficiently significant risk. Ultimately, we must do what was done with lead, mercury, and asbestos, to eliminate most non-essential uses for these chemicals in order to keep them out of the environment. The best way to reduce pollution is to stop it at the source.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

https://ia902602.us.archive.org/17/items/document-index-tcr-5/document%20index%20TCR5.pdf

</br></br>ATTN of The General Counsel and Trustees of Columbia University,

</br> </br>

Mr. Jerome Davis,

</br> </br>

Thank you in advance for looking into this, it is a USC Title 18.225 which has not yet been adjudicated. f**** child molestors watch their students in the privacy of their homes??? Who the f*** signed off on that??

</br> </br>

A conspiracy (more than foe' is all I need ya know) and a $6million loan by State Farm to The Sullivan Properties LP with a claim to their unlawful income is a USC Title 18.215. More concerning is the lack of disclosure to the SEC about a loan in excess of $5 million which holds the burden of the LP's tax evasion.

</br> </br>

No Taxes paid on $288 million in property taxes for the last ten years, which was undervalued at roughly $22 million, as per NY DFS records, Block 803, Lot 11; inclusive of its contiguous properties all owned by the same LP; unlawful rents and leases transferred to then CIK filer 93715 (USC Title 18.21), beyond a reasonable doubt. The irony is that more than 75% of those units were empty, however those rent payments are unlawful (no certificate of occupancy), which by the FDIC is an unlawful deposit -no different than a heroin dealer depositing his ill earned money into, let's say Chase Manhattan bank?</br>

</br> </br>

The documents in this folder should be helpful for you to prosecute them and also understand where I have my reservations, pun intended. </br>

You're welcome!

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Idaho Environmental Coalition (Doc. #3030, SBC-047327)

Contractors working at Superfund sites cannot supply EPA with the economic impact information that EPA should consider prior to proposing MCLs for PFAS in drinking water, because most Superfund sites do not have a preliminary assessment that identifies the nature and extent of potential PFAS contamination. The economic impact to ongoing CERCLA remedial actions at Superfund sites is expected to be significant if the EPA proposed MCLs for six PFAS in drinking water are promulgated.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document. With respect to costs associated with "CERCLA remedial actions at Superfund sites," the EPA notes that SDWA expressly states that the EPA shall consider "quantifiable and nonquantifiable costs. . . excluding costs resulting from compliance with other proposed or promulgated regulations." For further information on the EPA's cost analysis, please see section 13 of the EPA response in this *Response to Comments* document and section XII of the final rule preamble. Additionally, please see section 5.1.3 of the EPA response in this *Response to Comments* document for additional discussion on cost considerations in the final MCLs.

John Havrilla (Doc. #3037, SBC-047355)

To this end, I call upon the EPA to halt the approval of ALL new PFAS by emission into the air and seepage into our water sources, starting with the regulation of the six chemicals named in the proposal. Lead, mercury and asbestos have been regulated. We can do this with PFAS and save, particularly, our children from health insecurity. They cannot live without drinking water; categorically, they need not live lives impaired by drinking water laced with harmful chemicals. Pass the EPA proposal. Thank you.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Nick Fitzgerald (Doc. #3072-94, SBC-047405)

Good afternoon. I'm calling in today from historic land of the Spokane Tribe. I realize this isn't the exact forum to share all of these ideas, but I believe them to be valuable so I will share, nevertheless. The views I present are my own, though they have been informed through my

professional capacity as a public servant interacting with affected Americans. First, we need national laboratory reporting rules for PFAS such that every citizen, even those without science degrees, can read and understand water quality reports.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Carl Albers (Doc. #2555, SBC-047421)

Along with these efforts the production and use of forever chemicals should be halted as soon as possible. Until that happens the land application of sewage sludge should not be allowed as it clearly is not a safe method of disposing these so called "bio-solids" as they are likely to contaminate private drinking water wells in rural communities. Current research needs to be reviewed regarding the movement of forever chemicals from fields where the land application of sewage sludge has been practiced. In New York State sewage sludge can be applied within 200-feet of a private water well, regardless of whether it is uphill or downhill from the field in question. There are no provisions in the NYS permitting process for monitoring of nearby private water wells even when sewage sludge has been applied on nearby fields for decades. Recent testing of such wells in NYS by the Sierra Club has shown that indeed forever chemicals have been found in all 35 water samples taken from wells near fields with a long history of sewage sludge application. So again the proposed regulations are a step in the right direction as there are many rural residents that would like protection from these dangerous chemicals entering our private drinking wells. Thank you for your efforts to keep our nation's waters safe to drink.

https://waterfrontonline.blog/2023/04/20/pfas-found-in-all-35-water-samples-from-sites-near-sewage-sludge-fields-in-steuben-casella-calls-levels-minuscule/

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Mass comment campaign submitted by Jill Fischer (Doc. #3070, SBC-047486)

4. In addition to swiftly finalizing drinking water standards for PFAS, we urge the EPA to expedite efforts to prevent these forever chemicals from polluting the environment in the first place by imposing additional regulations for PFAS through permitting, cleanup, and disposal.

In conclusion, I strongly support the EPA's proposed PFAS national primary drinking water regulations. I urge the EPA to finalize the standards as quickly as possible while simultaneously working to reduce PFAS pollution at the source.

It is imperative that funding for states' regulation enforcement and remediation be secured as well as timelines for drinking water regulations be established and followed.

Again, thank you for the opportunity to add my comments.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

New York Section American Water Works Association (NYSAWWA) (Doc. #1591, SBC-042371)

New York State Department of Environmental Conservation has recently established a Human Health guidance value for PFOS of 2.7 ppt , which is below the EPA PQL. We are concerned that drinking water supplies who observe this level of PFOS in their finished water will be defined as industrial discharges to local POTWs and be forced into providing treatment as "polluters". Drinking water is discharged ubiquitously via numerous pathways, and thus it would seem that these regulations are destined to label the water suppliers as polluters when, in fact, we are recipients of pollution and would be meeting the proposed EPA regulation. This matter suggests that much stronger coordination needs to occur between regulatory entities to align MCLs and discharge limits and to provide for simultaneous compliance. Regulatory balance for PFAS substances between the Safe Drinking Water Act and Clean Water Act requirements needs to be provided with recognition of span of control limitations for water utilities exist.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043449)

EPA's Interim Guidance on the Destruction and Disposal of PFAS states that the large volumes of spent GAC and Ion Exchange resins prevents on-site storage, leaving landfill disposal and thermal treatment as the remaining options. [FN43: USEPA, 2020b. Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances. EPA–HQ–OLEM–2020– 0527–0002. Available on the internet at: https://www.epa.gov/system/files/documents/2021-11/epa-hq-olem-2020- 0527-0002_content.pdf.] However, both of these options pose great risks of PFAS reentering and contaminating the environment. Landfills are not designed to last forever, while PFAS are. As a result of their persistence and mobility, PFAS easily escape from landfills into the air or leak out of the lining systems, and are frequently detected in ground and surface water and liquid waste that leak from historic and active landfills. [FN44: Sonya Lunder & Denise Trabbic-pointer, Ten Bad Things We Do With PFAS Waste, Sierra Club (June 27, 2022), https://www.sierraclub.org/articles/2022/06/ten-bad-things-we-do-pfas-waste.] New York, Minnesota, and Vermont have all measured PFAS at virtually every landfill they test, yet waste managers continue to send PFAS-contaminated materials to landfills. [FN45: Id.]

Furthermore, preliminary data suggests that incinerators may be spreading, not breaking down PFAS. A team of professors and students at Bennington College obtained and analyzed soil and surface water samples in the historically burdened incinerator community in Cohoes, New York. [FN46: Cheryl Hogue, Incinerators may spread, not breakdown, PFAS, C&EN Global

Enterprise, (Apr. 27, 2020), https://cen.acs.org/environment/persistent-pollutants/Incinerators-spread-break-down-PFAS/98/web/2020/04.] The data collected suggests that incineration of the PFAS-containing foam is not breaking down the persistent chemicals but is instead redistributing them into nearby poor and working-class neighborhoods. Furthermore, in May of 2022, Congress issued a moratorium to the Department of Defense from continuing to incinerate aqueous, PFAS-containing firefighting foam until the DoD completes a study implementing the EPA's interim guidance on the destruction and disposal of PFAS. [FN47: Temporary Prohibtion on Incineration of Materials Containing PFAS, Department of Defense (April 26, 2022), https://media.defense.gov/2022/Apr/28/2002986273/-1/-1/1/TEMPORARY-PROHIBITION-ON-INC%255B%25E2%2580%25A6%255DNG-PRE-AND-POLYFLUOROALKYL-SUBSTANCES-PFAS-APRIL-26-2022.PDF.]

A study conducted by the Northwestern University chemistry department suggests that novel methods may help fully break down PFAS contaminants. [FN48: Brett Chase, Northwestern professor takes on 'forever chemicals,' and he just might win, Chicago Sun Times, (Sept. 16, 2022), https://chicago.suntimes.com/2022/9/16/23353881/pfas-forever-chemicals-william-dichtel-northwestern-university-brittany-trang-teflon-scotchgard.] The research found that a combination of the widely used solvent dimethyl sulfoxide and sodium hydroxide — lye — heated to just above the boiling point of water can destroy many types of PFAS. [FN49: Id.] The researchers have discovered that "decapitat[ing]" the PFAS molecules renders them harmless to people and would occur once PFAS is removed from the water to prevent it from accumulating. [FN50: Id.] The chemical reaction would break down PFAS into organic carbon and inorganic fluorine. [FN51: Tom Perkins, New method to break down 'forever chemicals' shows promise, study finds, The Guardian (Aug. 18, 2022), https://www.theguardian.com/environment/2022/aug/18/pfas-forever-chemicals-new-method-decompose-drinking-water.]

By design PFAS are meant to persist and resist thermal degradation and continuing to use incineration or landfills as the primary disposal method only further endangers public health and the environment. PFAS cannot be permitted to reenter the environment after removal from water supplies. CARE strongly encourages the US EPA to identify means to fully neutralize or destroy PFAS and, once identified, make it a requirement that all PFAS waste obtained by PWSs be neutralized or destroyed. In the interim, PFAS waste must be secured without risk of reentering the environment.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043453)

CARE Comment 5 - CARE Urges EPA to Confirm That Limitations from a Finalized PFAS NPDWR Would Constitute an Appropriate or Relevant and Applicable Requirement if a

Hazardous Substance Determination is Made for PFAS Under the Comprehensive Environmental Response, Compensation, and Liability Act

On August 26, 2022 the EPA proposed designating PFOA and PFOS as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA), also known as "Superfund." [FN65: EPA Proposes Designating Certain PFAS Chemicals as Hazardous Substances Under Superfund to Protect People's Health, EPA (Aug. 26, 2022), https://www.epa.gov/newsreleases/epa-proposes-designating-certain-pfas-chemicals-hazardous-substances-under-superfund.] Section 104 of CERCLA gives the President authority to enact, or require, removal and remedial actions whenever there is release, or a substantial threat of a release, of any hazardous substance or any pollutant or contaminant which may present an imminent and substantial danger to the public health or welfare. The selection process of appropriate remedial actions and the cleanup standards and requirements are listed under CERCLA section 121.

Section 121(d) of CERCLA requires that on-site remedial actions attain or waive federal environmental Applicable or Relevant and Appropriate Requirements (ARARs), or more stringent state environmental ARARs, upon completion of the remedial action. [FN66: 40 C.F.R. § 300.430(d).] ARARs are used to define remedy protectives, ensure responses are performed in accordance with promulgated statutes and regulations, and frequently become site cleanup levels. [FN67: Documenting Applicable, or Relevant and Appropriate Requirements in Comprehensive Environmental Response, Compensation, and Liability Act Response Action Decisions, EPA (Mar. 1, 2023),https://semspub.epa.gov/work/HQ/100003166.pdf.] Indeed, overall protection of human health and the environment and compliance with ARARs are threshold requirements for any remedial action under CERCLA section 121(d). [FN68: See 40 C.F.R. § 300.430(f)(1)(i)(A).]

In pertinent part, section 121(d)(2)(A)(i) states that any remedial action pertaining to hazardous substances on-site is required to meet any standard, requirement, criteria, or limitation under any federal environmental law, including the Safe Drinking Water Act, that is legally applicable to the hazardous substance, or relevant and appropriate to the circumstances of the release of hazardous substance. Furthermore, section 121(d)(2)(A)(i) explicitly states that such remedial action shall require a level or standard of control which at least attains relevant and appropriate maximum contaminant level goals established under SDWA and water quality criteria established under the Clean Water Act. In circumstances where the MCLG is equal to zero EPA has typically referred to the corresponding MCL due to feasibility concerns. [FN69: CERCLA Compliance with Other Laws Manual on the CWA and SDWA, EPA (1990), https://semspub.epa.gov/work/HQ/174500.pdf.]

As such, following the passage of EPA's proposed NPDWR standards and EPA's proposed hazardous substance designation, any remedial action pertaining to a release of PFOS or PFOA will be required to obtain a standard of cleanup that meets the 4ppt MCL, pursuant to any other applicable restrictions from CERCLA. This applies to PFOS and PFOA releases that impact groundwater for private well users. CARE would like EPA to explicitly affirm the proposed

NPDWR standards will constitute ARARs for groundwater contamination of private well users following a determination PFOA and PFOS constitutes hazardous substances under CERCLA.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

City of Lancaster, Pennsylvania (Doc. #1695, SBC-044996)

With the labeling of these chemicals now as hazardous there will be a new problem for waste disposal and potentially makes all citizens unknowingly criminals of improper disposal of hazardous materials in their refuse removal. Any rule that is put into place that potentially creates criminals out of normal law-abiding citizens is one that is highly questionable and needs evaluation.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Monterey One Water (Doc. #1715, SBC-043829)

PFAS Disposal Guidance

Monterey One Water uses a four-step purification process to turn secondary effluent into safe drinking water. This process includes reverse osmosis which results in contaminated media and a concentrated residual. We urge the EPA to engage with the water reuse community, who is eager to share its expertise and experience, as EPA updates PFAS disposal guidance. The disposal guidance may greatly impact the operating procedures of existing reuse projects, and it is important for EPA to maintain an open dialogue with the utilities that will be directly affected.

Monterey County is isolated from state and federal water projects. This requires the region to rely solely on its limited, local water resources. In response, communities have invested heavily in innovative water reuse projects to create water resilience and sustainability. Monterey One Water's Pure Water Monterey Project will make up 59% of a local water system's supply portfolio upon completion of its expansion by the end of 2025. Any impacts to how we operate must be seamless to ensure the community has safe, reliable access to drinking water.

We thank EPA for the continued engagement with the water stakeholder community. Monterey One Water recognizes the need to address PFOA and PFOS in our environment but urges EPA to evaluate and consider unrealistic implementation goals. This includes identifying or establishing additional financial avenues that follow the polluter pays principle to fund required changes.

Regards,

Rachel Gaudoin

Federal Advocacy Lead

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Florida Section American Water Works Association - Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044482)

Additionally, we renew our request that EPA rethink its current proposed solution for addressing the potential public health and environmental impacts of PFOA/PFOS by listing the chemicals as "hazardous substances" under CERCLA. As currently proposed, this designation means utilities will face unwarranted liability and legal defense costs at Superfund sites-such as landfills or agricultural sites-and through utility discharges. CERCLA compels this result, because the Act provides that any party who has contributed in any part to disposing of hazardous substances, even trace amounts, may be held liable for remediation.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

HNOJ Laudato Si' Circle (Doc. #1532, SBC-042634)

05/01/2023

HNOJ Laudato Si' Circle* thanks the EPA for taking action on PFAS and engaging with the public. As the proposals in your document EPA PFAS Strategic Roadmap: A Year of Progress indicate, much more needs to be accomplished. We can't agree more!

In our communities, both public health and day-to-day living have been greatly affected by the ongoing PFAS contamination on the Cape Fear and Haw Rivers. Our key takeaway from the March 21, 2023 "Listening Session" (for NC) is that the EPA must require federal governance for compliance on all needed proposals; so states like NC are REQUIRED to act. Using Whole-of-government involvement with the Dept of Energy, Dept of Defense, the CDC and FDA can expedite this federal governance for compliance.

A member from New Hampshire is concerned about Merrimack, Bedford, Londonderry, Manchester, Greenfield and Newfields towns having documented PFAS contamination from St. Gobain Plastic manufacturing, to name one company.

We request the EPA's enforcement of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) so that:

• Transparency around PFAS releases will increase and provide PFAS Analytic Tools to improve transparency.

• Polluters are held accountable for cleanup, and follow the Effluent Limitation Guidelines Plan 15.

• PFOA and PFOS are designated as hazardous substances and states can get upstream of the problem.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Michigan Farm Bureau (MFB) (Doc. #1562, SBC-043351)

May 19, 2023

Alexis Lan

Office of Ground Water and Drinking Water

Environmental Protection Agency

1200 Pennsylvania Avenue NW Washington, DC 20460

Submitted via www.regulations.gov

Re: Docket ID No. EPA-HQ-OW-2022-0114, Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

Dear Ms. Lan,

Thank you for the opportunity to provide comments to the U.S. Environmental Protection Agency (EPA) in response to its proposed rule to Docket ID No. EPA-HQ-OW-2022-0114, Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation. Michigan Farm Bureau is our state's largest agricultural organization, representing more than 40,000 farming families who grow a variety of food, fiber, and fuel products second only in diversity to California.

Farmers in Michigan and across the country take our responsibility to provide a safe, abundant, and affordable food supply seriously. They work tirelessly to protect their crops and livestock by protecting soil and water quality, both by managing nutrients and crop protection products, and by working with state and federal agencies to manage emerging contaminants. Michigan has been a leader in investigating, sampling, identifying sources, transport and fate of per- and polyfluoroalkyl substances (PFAS). The Michigan PFAS Action Response Team (MPART) has set a national example for establishing science-based tracking and regulation of PFAS substances.

We support EPA's work in addressing potential contamination, management, reduction, and environmental and public health protection from PFAS through its PFAS Strategic Roadmap. Reducing exposure and public health impacts from PFAS chemicals via drinking water is an important step, especially considering drinking water is a primary exposure pathway.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Michigan Farm Bureau (MFB) (Doc. #1562, SBC-043362)

These additional water quality protection regulations are necessary as EPA has identified in its strategic roadmap, [FN23: Environmental Protection Agency. 2021. PFAS Strategic Roadmap: EPA's Commitments to Action, 2021-2024. Retrieved from: https://www.epa.gov/system/files/documents/2021-10/pfas-roadmap_final-508.pdf] which will be an important part of protecting public health. However, they also highlight the need to 1) ensure the best scientific and economic data is used to determine regulatory limits and financial assistance, and 2) provide clear direction for compliance including sufficient timelines to allow facilities to implement technologies and equipment that will meet those regulatory standards. Many programs beyond drinking water depend on these crucial steps being done correctly.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043103)

This will also ensure that the various source water protection actions framed in the Strategic Roadmap for PFAS can be advanced, which is expected to help reduce PFAS contamination and exposures in impacted communities. This pragmatic timeframe will also ensure that polluters are forced to pay the bill for mitigating ongoing PFAS releases and contamination instead of relying on communities to pay for treatment of PFAS contamination for which they are not responsible.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044073)

ASDWA continues to recommend that EPA use all the Agency's regulatory and non-regulatory authorities to prevent PFAS from entering drinking water sources.

ASDWA continues to support EPA's work to holistically address PFAS under the Agency's PFAS Strategic Roadmap. The Agency's approaches to "get upstream of the problem" and "hold polluters accountable" are paramount to the long-term protection of both surface and ground water sources of drinking water.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043496)

In the PFAS Strategic Roadmap, EPA only committed to meeting its statutory deadline of December 2023. This proposed drinking water standard of 4 ppt will require drinking water

providers to treat drinking water sources for PFOA and PFOS and thus create more of a need for the management of treatment residues.

In the PFAS Strategic Roadmap, EPA did not identify plans to address PFOA and PFOS under the Resource Conservation and Recovery Act (RCRA), which, among other things, would have required EPA to conduct a rulemaking to establish management, treatment, and disposal standards that would apply to all RCRA-regulated PFOA and PFOS waste anywhere in the United States.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045010)

New Jersey commends EPA's action to propose primary drinking water standards and urges EPA to advance its PFAS Strategic Roadmap to improve public health protection by holistically addressing PFAS in other media areas and holding responsible parties accountable for the widespread contamination they have caused. We strongly urge EPA to continue supporting research and funding for technologies that can safely and permanently remove these contaminants from our environment.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

West Virginia Rivers Coalition (Doc. #3072-3, SBC-047357)

As outlined in the approaches included in the PFAS Strategic Roadmap, EPA must get upstream of the problem and prevent PFAS from entering source water in the first place. For context, the source water for almost half of the public water systems in West Virginia has levels of PFOA and PFOS that exceed the most recent health advisories. At the same time, the DuPont manufacturing plant that I mentioned earlier continues to discharge GenX chemicals magnitudes higher than the permit limits. Allowing polluters to continue discharging PFAS into source water while requiring utilities in indirectly affected communities to remove PFAS is an environmental injustice.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Alliance of Nurses for Healthy Environments (Doc. #1544, SBC-042674)

As nurses and healthcare providers quickly educate themselves on how to adequately assess patients and communities for PFAS exposure and provide resources on how to reduce exposure and take proactive steps to monitor for potential health outcomes, we are relying on the EPA to swiftly finalizing drinking water standards for PFAS, expedite efforts to prevent these forever

chemicals from polluting the environment in the first place by: controlling industrial discharges of PFAS into water, and addressing PFAS in state- and federal-issued permits consistent with EPA's 2022 guidance under the Clean Water Act; reduce unnecessary uses of PFAS, and prevent the entry of dangerous new PFAS chemicals into commerce under the Toxic Substances Control Act; minimize PFAS emissions under the Clean Air Act; clean up PFAS contaminated sites under the Comprehensive Environmental Response, Compensation, and Liability Act; and regulate PFAS disposal under the Resource Conservation and Recovery Act.

The ubiquitous nature of PFAS contamination underscores the need to curb all pathways of PFAS exposure and sources of pollution. EPA's 2021 Strategic PFAS Roadmap outlines a broad suite of actions to address the PFAS crisis, and following through on Roadmap commitments is of the utmost importance. Improved population health outcomes cannot wait therefore, we urge you to finalize the standards as quickly as possible with minimal concessions.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045553)

AWWA Comments on the Proposed "PFAS National Primary Drinking Water Regulation Rulemaking"

The American Water Works Association (AWWA) appreciates the opportunity to comment on the Environmental Protection Agency's (EPA or agency) "Proposed Per- and polyfluoroalkyl substances (PFAS) National Primary Drinking Water Regulation Rulemaking" (the proposal). AWWA has prepared the following comments to assist EPA in moving forward with a final rule to protect public health that is scientifically grounded, legally defensible, and crafted in a manner that embraces the objectives of the Safe Drinking Water Act (SDWA).

1. Overarching Comments

AWWA appreciates EPA's interest in addressing PFAS in drinking water to protect public health and maintain public trust in the nation's drinking water supply. AWWA has been engaged on PFAS issues since the early 2000s and has leveraged technical expertise from our members, which include more than 50,000 professional members and 4,500 utilities, to support the agency's broad efforts to address PFAS contamination. When the following guiding principles are followed, AWWA supports PFAS regulations:

1. Commitment to public health protection,

2. Fidelity to scientific process,

3. Seng regulatory requirements that are feasible to implement,

4. Ensuring affordability of safe drinking water, and 5. Effectively leveraging source water protection efforts.

In establishing drinking water regulations, embracing these guiding principles will ensure that communities and the public are effectively protected through a transparent rulemaking process and with a rule that prioritizes opportunities to reduce public health risks. The following comments and recommendations reflect these guiding principles.

Reinforcing the Polluter Pays Principle

EPA first published plans for a broad regulatory agenda to address PFAS as part of the EPA's PFAS Action Plan in 2019 (EPA, 2019a). In 2021, the agency published the more detailed PFAS Strategic Roadmap for regulatory actions (EPA, 2021a). The EPA's PFAS Action Plan and the PFAS Strategic Roadmap highlighted a variety of regulatory actions that the agency is pursuing, including setting effluent limitation guidelines and standards (ELGs) for industrial dischargers under the Clean Water Act (CWA). The implementation of these regulatory actions is critical in protecting the environment and the protection of drinking water sources. The actions, when completed, will reinforce the polluter pays principle for PFAS and help maintain the responsibility for the mitigation of PFAS contamination on the polluters instead of communities.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Connecticut Section of the AWWA (CTAWWA) and Connecticut Water Works Association (CWWA) (Doc. #1763, SBC-044231)

May 30, 2023

Mr. Michael S. Regan, Administrator

U.S. Environmental Protection Agency

EPA Docket Center, OLEM Docket, Mail Code 28221T

1200 Pennsylvania Avenue, NW

Washington, DC 20460

RE: Docket ID No. EPA-HQ-OW-2022-0114

Administrator Regan:

The Connecticut Section of the AWWA (CTAWWA) and Connecticut Water Works Association (CWWA) appreciate the opportunity to submit comments for consideration on the proposed PFAS Rule, which is the first-ever national drinking water standard to limit six per and polyfluoroalkyl substances (PFAS).

CTAWWA includes over 600 members and represents more than 60 utilities that supply water to approximately 2.5 million Connecticut residents. The organization is dedicated to the promotion of public health and welfare by assuring drinking water of unquestionable quality and sufficient quantity. CWWA membership is comprised of investor-owned, municipal, and regional utilities

with the mission of promoting and achieving effective state policies that assure reliable high-quality public water supplies to protect public health.

The Connecticut Interagency PFAS Task Force was established on July 8, 2019 to tackle the issue of PFAS. The plan that they developed was focused on minimizing the health risk to Connecticut's population by addressing PFAS in terms of historic releases and potential future exposure. As part of this response, the Connecticut Department of Public Health (CT DPH) issued drinking water Action Levels for four PFAS compounds on June 15, 2022. Prior to and following the issuance of these action levels, many utility members of CTAWWA and CWWA voluntarily sampled for PFAS and worked to communicate and educate customers and stakeholders. In addition, members have proactively begun to take action to minimize, treat, or otherwise address sources with PFAS. Consequently, exposure to PFAS via drinking water has been reduced and additional communities are anticipated to experience reduced PFAS levels through planned projects.

Similarly, at the federal level the PFAS Strategic Roadmap has been developed and a one-year progress update has already been released. It is the sincere hope of both CTAWWA and CWWA that the PFAS Strategic Roadmap and the Environmental Protection Agency (EPA) take aggressive action to minimize PFAS introduction into the environment and to pursue and hold accountable the originators of PFAS. Compliance with the PFAS Rule will certainly reduce customer exposure via a single pathway, but many other documented exposure pathways will persist. A comprehensive and balanced approach to addressing PFAS will yield the greatest reduction in PFAS exposure.

CTAWWA and CWWA respectfully submit the following comments:

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Center for Environmental Health et al. (Doc. #1764, SBC-044241)

In its 2021 PFAS Strategic Roadmap, EPA committed to addressing PFAS contamination through "…getting upstream of the problem, holding polluters accountable, ensuring science-based decision making, and ensuring disadvantaged communities have equitable access to solutions" [FN3: US EPA, "PFAS Strategic Roadmap: EPA's Commitments to Action 2021-2025", (Oct 18, 2021), https://www.epa.gov/system/files/documents/2021-10/pfas-roadmap_final-508.pdf].

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045474)

[The steps identified in that letter include:]

• leveraging available regulatory tools in other statutes to gather occurrence and health risk assessment data and organize them to support research and decision making, using regulatory tools that include the Toxics Release Inventory, Sections 4 and 8 of the Toxic Substances Control Act, the Unregulated Contaminant Monitoring Rule, the Resource Conservation and Recovery Act, and other existing authorities to protect drinking water supplies.

NGWA appreciates this significant step addressing this approach and the EPA PFAS Strategic Roadmap.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

WASHINGTON STATE BOARD OF HEALTH (Doc. #1837, SBC-044266)

We also encourage the U.S. Environmental Protection Agency to continue to apply a broad set of strategies to preventing and reducing PFAS contamination and exposure on all fronts in keeping with the agency's PFAS Strategic Roadmap.

Thank you for your consideration of our comments. If you have questions or need additional information from the Board, please contact Stuart Glasoe, Board Health Policy Advisor, at stuart.glasoe@sboh.wa.gov.

Sincerely,

Keith Grellner, Chair

Washington State Board of Health

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Student, University of Georgia (Doc. #3072-76, SBC-046386)

Good afternoon or evening, morning everybody. My name is Cheyenne Campbell. I am actually a graduate student at the University of Georgia who's getting her master's in public health degree in environmental health sciences. So pretty much my overall comment today is definitely mostly going to be surrounded on my research that I have found, and I was curious of within just PFAS, I definitely got into the world of PFAS, especially since my overall testing site was mainly on land application systems and how to control stormwater runoff. We need these land application systems and has been a noticeable problem that biosolids that are being used on these land application systems do contain PFAS. And then I did notice within the PFAS Strategic Roadmap, the finalized risk assessment for PFOA and PFOS in biosolids in particular is not to be expected until the winter of 2024. But within some of my conductive research that I was able to find, these high amounts of these different PFAS chemicals besides PFOA and PFOS in these biosolids. Yes, and even I agree from all these other public speakers that it is definitely being contributed to neurological and even all this physical or even psychological health issues. And I do believe that

there should be a little bit more of a push to maybe finalize these risk assessment of these biosolids, since these biosolids are being used a lot more by the public and even more raw use besides these land application systems and even a little bit more consideration as well as to trying to find different or maybe cost-effective cheap cleaning methods when trying to contain these PFAS contaminants from land application systems. Especially when you want to go to more rural counties or even some suburban counties, since it might be an issue that not all these different communities, especially the rural communities, would not be able to afford or access available to these better, different cleaning techniques when they're trying to actually ask us to entertain more of a monitoring system for PFAS analysis. Thank you.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Clean Water Action/Clean Water Fund (Doc. #1697, SBC-045007)

The proposed PFAS NPDWRs are a major step forward in limiting PFAS chemicals in drinking water. EPA needs to act equally aggressively to keep PFAS out of the environment and to curb use of these chemicals in order to avoid an ongoing downstream burden on communities and public health. Using the Clean Water Act's water pollution programs to keep PFAS chemicals out of water, including drinking water sources, is one example. EPA's December 2022 direction to states to include PFAS chemicals in water pollution permits is critical. [FN7: EPA Directs State to Use Water Pollution Permits to Control PFAS, Jennifer Peters blog post, December 7, 2022.] EPA needs to accelerate all activities, including but not limited to Effluent Limitation Guidelines (ELG) development, that will enable federal and state permit writers to include PFAS chemicals in National Pollution Elimination Discharge System (NPDES) permits. EPA has also made progress on other commitments in the PFAS Strategy Roadmap, and should accelerate and enhance these activities to reflect the seriousness of the health and environmental risks and of the concrete downstream burden demonstrated by the proposed NPDWRs.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Clean Water Action/Clean Water Fund (Doc. #1697, SBC-044999)

May 30, 2023

Via Regulations.gov

Assistant Administrator Radhika Fox Office of Water

U.S. Environmental Protection Agency

1200 Pennsylvania Avenue, N.W.

Washington, DC 20460

Re: PFAS National Primary Drinking Water Regulation Rulemaking,

Docket No. EPA–HQ–OW–2022–0114

Dear Assistant Administrator Fox,

Clean Water Action and Clean Water Fund respectively submit these comments on the proposed PFAS National Primary Drinking Water Regulation Rulemaking. They complement those we have joined with the Natural Resources Defense Council, Earthjustice, et al.

The Proposal is Consistent with the Safe Drinking Water Act and the PFAS Strategic Roadmap

The proposal is consistent with the Safe Drinking Water Act (SDWA), which requires the Environmental Protection Agency (EPA) to promulgate National Primary Drinking Water Regulations (NPDWRs) for contaminants that may have an adverse effect on people's health, that are known to occur or there is a substantial likelihood that they will occur in Public Water Systems with a frequency and at levels of public health concern, and where regulation presents a meaningful opportunity for health risk reduction. The proposal is also consistent with EPA's PFAS Strategic Roadmap, in which EPA committed to "Establish a national primary drinking water regulation for PFOA and PFOS that would set enforceable limits and require monitoring of public water supplies, while evaluating additional PFAS and groups of PFAS." [FN1: PFAS Strategic Roadmap: EPA's Commitments to Action 2021-2024, October 18, 2021, https://www.epa.gov/pfas/pfas‑strategic‑roadmap‑epas‑commitments‑action‑2021‑2024#ow.]

PFOA and PFOS first appeared on the Contaminant Candidate List in 2009. Out of the tens of thousands of possible chemicals, pathogens and other potential drinking water contaminants, there was enough information on health effects and occurrence for these chemicals to be included in a list of 116 contaminants (104 chemicals and 12 microbiological contaminants) that merited further research and consideration. Since that time, information on PFOA and PFOS and their health effects and occurrence in drinking water has confirmed the need for drinking water limits, and the pace of research on other PFAS chemicals has accelerated rapidly. As EPA summarizes in the proposal, PFAS chemicals present "significant and diverse" health risks. [FN2: PFAS National Primary Drinking Water Regulation Rulemaking, Federal Register / Vol. 88, No. 60 / Wednesday, March 29, p. 18643.] Some states have already adopted enforceable drinking water limits for some PFAS chemicals. The very existence of the PFAS Strategic Roadmap reflects the rapidly increasing concern about these chemicals among impacted communities, public health professionals, policymakers, researchers, water professionals, public health practitioners, and environmental and health advocates. EPA's proposal meets Safe Drinking Water Act criteria and communities nationwide need these limits to protect people's health and to address growing concern about their presence in drinking water. As noted elsewhere in these comments, aggressive action to rein in PFAS pollution and restrict use of these chemicals is desperately need to address their widespread use and the numerous ways that people are exposed to them.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

Association of California Water Agencies et al. (Doc. #1701, SBC-043888)

Meaningfully Advancing a Holistic Approach to Address PFAS

The undersigned organizations support regulation based on scientific evidence that protects human health. We emphasize the shared goal of public water systems and EPA in ensuring access to safe drinking water to the public and we encourage EPA to meaningfully advance this objective through the implementation of its PFAS Strategic Roadmap. The responsibility for pollution remediation should not rest solely on public water systems and their ratepayers.

We recommend that EPA take more proactive measures to identify sources of PFAS and limit their discharges, as prevention is more cost-effective than attempting to clean up pollution later and maintains the polluter pays principle. Advancing regulatory actions that provide source water protection will also reduce the number of systems with PFAS contamination above the proposed drinking water standards. EPA should also work to collaborate with other agencies to address other pathways of public exposure to PFAS, such as food and household products.

As the Administrator, you are responsible for advancing these regulatory actions to protect communities from contamination and the financial burden of mitigating this contamination.

We welcome any opportunity to discuss this matter with EPA further. Please feel free to contact our respective organizations with any questions.

Sincerely,

Tom Dobbins

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045142)

Wastewater and Stormwater

MassDEP supports EPA's work to address PFAS under the Agency's PFAS Strategic Roadmap. The Agency's approach to "get upstream of the problem" is paramount to the long-term protection of both surface water and ground water sources of drinking water.

EPA must expedite the Agency's work to address PFAS in wastewater and stormwater inflows and discharges, including the development of rulemakings for PFAS effluent limitation guidelines for the organic chemicals, plastics and synthetic fibers, and metal finishing and electroplating point source categories, as well as studying PFAS inputs and discharges from landfills, paper and textile mills, and electrical and electronic components. The Agency should work to finalize Draft Method 1633 in a timely manner for laboratories to analyze samples of surface water, groundwater, and other media. EPA should also finalize the national recommended ambient water quality criteria for PFAS. MassDEP awaits EPA's assistance and guidance in these areas in connection with the development of water quality standards and future regulation of the discharge of PFAS in wastewater effluent. Further Clean Water Act actions should continue to be taken simultaneously with the Agency's other efforts. PFAS will remain a

problem for drinking water systems so long as all sources of PFAS contamination are not addressed.

EPA Response: Please see section 15.1 of the EPA response in this *Response to Comments* document.

No references were cited within the EPA response in this section.

16 Potential Final CFR Changes

16.1 §141.2 Amendments

Individual Public Comments

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043107)

As measurement experts, our additional comments below will pertain solely to method/measurement aspects of the regulation. Our comments for clarification are detailed below.

In addition, EMC wishes to point out a typographical error. In the proposed regulatory text at 141.2, the molecular formula for PFOA was shown as C8F15CO2–. The correct formula is C8F15O2–.

EPA Response: In response to this comment and others, the chemical formula has been corrected.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043308)

As measurement experts, our additional comments below will pertain solely to method/measurement aspects of the regulation. Our comments for clarification are detailed below.

In addition, EMC wishes to point out a typographical error. In the proposed regulatory text at 141.2, the molecular formula for PFOA was shown as C8F15CO2–. The correct formula is C8F15O2–.

EPA Response: Please see the EPA response to comment Doc. #1625, SBC-043107 in section 16.1 in this *Response to Comments* document.

16.2 §141.61 Amendments

Individual Public Comments

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045161)

Given the importance of the HBWCs, it would be appropriate to list them in a table in § 141.903 rather than referring to a footnote to the table in § 141.61 as is done in § 141.903(f)(2)(i).

EPA Response: The EPA agrees. The EPA has included a separate table (Table 4 to 141.61(c)) to list Health Based Water Concentrations (HBWCs) more prominently alongside Maximum Contaminant Levels (MCLs) for regulated PFAS.

16.3 §141.900-905 (Subpart Z) Additions

Individual Public Comments

Missouri Department of Natural Resources (Doc. #1563, SBC-042507)

General Comments

EPA should strive to make the language in the final rule more concise and easier to understand to aid small systems with the implementation of the rule. The hazard index, deviations from the synthetic organic contaminant (SOC) standard monitoring framework (SMF), and low quantifiable detections in the rule are very complex topics and they will make the rule more challenging for many public water systems to understand and implement. This is especially the case for small and medium-sized systems that already struggle to implement the existing framework of national primary drinking water regulations. The closer the rule can remain to the SOC standard monitoring framework, the easier it will be for systems to understand and for primacy agencies to implement.

EPA Response: The EPA has added language where appropriate to improve the understandability of the rule. Subpart Z has been revised to minimize redundancy and utilize more direct cross-referencing.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045174)

It is unclear why the same language is repeated, with small variations, in § 141.903 and § 141.905: § 141.903(b) matches § 141.905(b)(1); § 141.903(c) matches § 141.905(2)(ii); § 141.903(d) matches § 141.905(b)(2); § 141.903(e) matches § 141.905(b)(2)(i) and § 141.903(f)(1)(iii) and § 141.903(f)(2)(iii) match § 141.905(b)(2)(iii). Excessive language makes the rule more difficult to interpret, easier to miscite and more confusing to the regulated community.

EPA Response: The EPA has made changes to reduce redundancy, except where repetition of requirements was deemed necessary. Cross references between the sections have been added where appropriate.

16.3.1 §141.901 Analytical Requirements

Individual Public Comments

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043041)

Analytical Requirements

In proposed 141.901(b)(2)(i), it is indicated that data must be reported "for concentrations at least as low as the ones listed in the following table….” However, the referenced table appeared to be missing.

EPA Response: The EPA has corrected the subsection mentioned by the commenter, which is § 141.901(b)(2)(iii) in the final rule, to instead reference the correct table in § 141.902(a)(5).

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044101)

Finally, a table appears to be missing from the proposed rule where it is referenced in 141.901(b)(2)(i) and says that “certified laboratories (that)must report “quantitative data for concentrations at least as low as the ones listed in the following table…”

EPA Response: Please see the EPA response to comment Doc. #1616, SBC-043041 in section 16.3.1 in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044186)

Finally, there appears to be a table missing from the proposed rule where it is referenced in 141.901(b)(2)(i) and says that “certified laboratories (that)must report ‘quantitative data for concentrations at least as low as the ones listed in the following table…’

EPA Response: Please see the EPA response to comment Doc. #1616, SBC-043041 in section 16.3.1 in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-052946)

• As previously noted, [sec] 141.901(b)(2)(i) states that laboratories should "report quantitative data for concentrations at least as low as the ones listed in the following table" for PFAS; however, that referenced table appears to be missing from the proposed regulatory language. As such, it is not clear what reporting levels are to be used for any of the six PFAS included in the proposed regulation. DEP is not able to comment on information missing from the proposed rulemaking. However, for the four PFAS components included in the HI calculation, their PQLs are listed in Table 1 to [sec] 141.903(f)(l)(iii) as:

[Table 1: See Docket ID: EPA-HQ-OW-2022-0114-1626]

It is not clear whether labs are to report only to these levels, or to levels that are one-third of the PQLs, for inclusion in the HI calculation. As noted previously, results reported below the PQL for any contaminant would be qualified data and would not be legally defensible results for use in determining compliance or monitoring frequencies.

EPA Response: The EPA agrees with the commenter that the referenced table was not appropriately cited within the Code of Federal Regulations (CFR) of the proposed regulatory

language. The EPA has clarified the requirements for laboratories to now read "For all samples analyzed for regulated PFAS in compliance with § 141.902 (Monitoring requirements), beginning [**INSERT DATE 60 DAYS AFTER PUBLICATION IN THE FEDERAL REGISTER**], report data for concentrations as low as the trigger levels as defined in § 141.902(a)(5)." The EPA disagrees with the commenter's assertion that results reported below the practical quantitation level (PQL) would not be sufficient in determining required monitoring frequency. See section 8.8 and 8.1.2 of the EPA response in this *Response to Comments* document for a discussion of the use of data below PQLs for establishing monitoring frequencies, as well as section 8.2 of the EPA response in this *Response to Comments* document for compliance determinations.

16.3.2 §141.902 Monitoring Requirements

Individual Public Comments

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045155)

§ 141.902(b)(1)(i) should refer to Subpart H systems if that is what is meant by "surface water CWS and NTNCWS." This would make § 141.902(b)(1)(iii) unnecessary. Additionally, the language in § 141.902(b)(1)(iii), "based on system size" is irrelevant as all sizes of Subpart H systems must collect four consecutive quarterly samples.

EPA Response: The EPA acknowledges that Subpart H systems has been used to refer to public water systems using surface water or ground water under the direct influence of surface water (GWUDI) as a source that are subject to the requirements of Subpart H of 40 CFR Part 141. However, in order to be more explicit, the EPA has maintained § 141.902(b)(1)(iii) to directly refer to requirements for GWUDI systems. The EPA agrees that system size is irrelevant with respect to initial monitoring requirements for GWUDI and surface water systems and has therefore removed "based on system size" from the cited subsection.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044438)

Page 18752, Table 2 to Paragraph (b)(2)(i)

• It is unclear what "except as otherwise provided by the State" means in the context of compliance monitoring and Table 2 to Paragraph (b)(2)(i). Does this mean States have the option to devise a different monitoring scheme? Please clarify.

• Using PFAS sample results below the PQL is not appropriate for calculating a running annual average. This approach seems to conflict with Table 1 to Paragraph (f)(1)(iii).

Page 18752, 141.XX Monitoring Requirements (iv)

• States may delete results of obvious sampling errors from this calculation. DOH requests the ability to delete sample results that have obvious laboratory errors.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document regarding the ability of states to institute compliance monitoring requirements that are at least as stringent as those promulgated by the EPA, consistent with the requirements in § 142.16(r). In response to this commenter's concern, the EPA deleted "except as otherwise provided by the State" in the paragraph preceding the eligibility requirements for different sampling frequencies, which are identified in Table 3 to paragraph (b)(2) of section 141.902 in the final rule. Instead, the EPA has inserted language indicating that a state may increase the required monitoring frequencies in § 141.902 (b)(2)(vi) in the final rule.

Regarding the comments about samples containing concentrations below PQLs, please see section 8.2 of the EPA response in this *Response to Comments* document. Concentrations below the PQL are only treated as zero when calculating a running annual average (RAA) to determine rule compliance. See also sections 7.2 and 5.1.2 of the EPA response in this *Response to Comments* document for further discussion of PQLs. See sections 8.1.2 and 8.8 of the EPA response in this *Response to Comments* document for a discussion of the use of data below PQLs for establishing monitoring frequencies.

Regarding the allowance for states to delete the results of obvious sampling errors, please see the EPA response to comment Doc. #1679, SBC-044959 in section 8.2 in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045157)

§ 141.902(b)(1)(vi) appears to require only that supplemental monitoring necessary to complete the requirements of Table 1 to Paragraph (b)(1)(iv) be completed by three years after final promulgation (the presumptive compliance date). There is a need to clarify whether all initial monitoring, using new samples, existing samples, or a combination of the two, must be completed by this same date. If the intent is to complete all initial monitoring by this date, MassDEP recommends that the final sentence of § 141.902(b)(1)(vi) be moved to a new subparagraph (vii).

EPA Response: A separate subparagraph (141.902(b)(1)(xi)) has been added to the final rule to clarify that all initial monitoring requirements must be completed by a date three years from final rule publication. See section 8.1.1 of the EPA response in this *Response to Comments* document for additional discussion of the initial monitoring timeline.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-052947)

• In [sec] 141.XX(a)(8) of the proposed rulemaking, it is not clear as written how this will apply to the HI MCL. The paragraph states: "Based on initial monitoring results, for each sampling point at which a contaminant listed in [sec] 141.61(c) is detected at a level greater than or equal to the trigger level, the system must monitor quarterly for all regulated PFAS beginning in the next quarter... " It is not clear whether this is referring to the HI calculated trigger level of 0.33,

or whether this is referring to some individual reporting level for the individual component PFAS in the HI calculation.

EPA Response: For the final rule, this section has been restructured. Table 1 in §141.902(a)(5) now provides trigger levels for individual contaminants as well as the Hazard Index. §141.902(b)(2)(i) now states that, based on initial monitoring, "systems may reduce monitoring at each sampling point at which all reported sample concentrations were below all rule trigger levels defined in § 141.902(a)(5)" and that "if a sampling point is not eligible for triennial monitoring, then the water system must monitor quarterly at the start of the compliance monitoring period." Thus, if a sampling point meets or exceeds the trigger level for the Hazard Index during initial monitoring, the system must begin quarterly monitoring for that sampling point. Note that for the final rule, the trigger level for the Hazard Index has been increased to 0.5; see section 8.8 of the EPA response in this *Response to Comments* document for further discussion about increasing the trigger level.

16.3.3 §141.903 Compliance Requirements

Individual Public Comments

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045753)

EPA should revise Section 141.903(e) to read "If any quarterly sample result or quarterly average, if more than one sample is available for the quarter, will cause the running annual average to exceed the MCL at any sampling point, the system is out of compliance with the MCL immediately." Alternatively, if EPA does not wish to change the language of Section 141.903(e), EPA could add an additional subclause to Section 141.903(f) that states "For systems monitoring more frequently than quarterly, systems must average all the results in a quarter, then average the quarterly averages. Quarterly averages should not be computed until all samples within the quarter are collected."

EPA Response: Please see the EPA response to comment Doc. #1709, SBC-045752 in section 8.2 as well as section 8.2 of the EPA response in this *Response to Comments* document. The EPA has modified the language in 141.903(e) to reflect the possibility that multiple compliance samples may be available in a quarter due to the state requiring a confirmation sample.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-052949)

• [sec] 141.903(f)(2)(i) is not consistent on how the HI is to be calculated for systems on a quarterly monitoring frequency. The preamble to the proposed rulemaking, EPA webinars on the proposed rule, and guidance made available with the proposed rule all state that an RAA is to be used. However, the language in this paragraph is different and states (emphasis added): "For systems monitoring quarterly, divide observed sample analytical results by the corresponding HBWC listed in[sec] 141.61(c) to obtain a Hazard Quotient/or each sampling event at each

EPTDS. Sum the resulting Hazard Quotients together to determine the Hazard Index. If more than one compliance sample is available for an analyte in a quarter, systems must average all the results for that analyte in that quarter and then determine the Hazard Quotient(s) from those average values. If the Hazard Index exceeds the MCL, the system is not in compliance with the Hazard Index MCL requirements." Each sampling event is assumed to be each quarter, and there is no description of how to calculate an RAA; rather, the language seems to indicate that a single quarterly HI exceedance would result in a HI MCL violation. The language in paragraph (i) is very similar to the language in paragraph (ii).

EPA Response: §141.903(f)(2)(i) has been updated to accurately reflect that Hazard Index MCL exceedance is assessed based upon an RAA calculated from a year of quarterly monitoring and not based upon a single quarter (unless the conditions described in §141.903(e) apply).

16.3.4 §141.904 Reporting and Recordkeeping Requirements

Individual Public Comments

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045170)

Reporting and recordkeeping

MassDEP submits the following comments related to the reporting and recordkeeping requirements set forth in 40 CFR § 141.904 of the proposed rule (page 18753 of the Federal Register notice):

• In Table 1 to § 141.904 it appears that the reference to § 141.902 in item 3 for systems monitoring quarterly should point to § 141.903 as that is where the MCL compliance calculation is described.

EPA Response: The EPA agrees with the commenter that § 141.903 is the correct cross reference for the MCL compliance calculation. This has been updated in Table 2 of § 141.904 (after paragraph (b)). Note that an additional table (Table 1) has been added to the section to include reporting requirements from initial monitoring. Cross references regarding the trigger levels also now direct more specifically to § 141.902(a)(5).

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045163)

MassDEP suggests that EPA clarify why the language of § 141.903(f)(2)(ii) doesn't match the corresponding language in § 141.903(f)(1)(ii). In the first case the requirement is to "report the results of each sampling event" whereas the requirement to "report" is missing in the second case.

EPA Response: For the final rule, reporting requirements are discussed in § 141.904. References to "report" in the subsections cited by the commenter have been removed. Tables 1 and 2 in § 141.904 of the final rule indicate that systems must report all sample results.

16.3.5 §141.905 Violations

Individual Public Comments

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045172)

Violations

MassDEP submits the following comments and questions related to violations, as set forth in 40 CFR § 141.905 of the proposed rule (page 18753 of the Federal Register notice):

• § 141.905(a) is missing full citations ("§ 141.XX.d" and "§ 141.XX.c").

EPA Response: The incomplete citations mentioned by the commenter were intended to reference MCL compliance requirements and monitoring requirements, respectively. For the final rule, § 141.905 has been restructured. The language in the first sentence of paragraph (a) was updated to cite § 141.903 (where Compliance Requirements are identified) instead of 141.XX.d. The second sentence, regarding failure to monitor, was moved to a new paragraph (c), and the citation to § 141.XX.c was replaced with § 141.902.

16.4 §142.61-62 Amendments

Individual Public Comments

Robert Hollander (Doc. #1516, SBC-042716)

11. 88 FR 18754

The official Federal Register version shows a capital B instead of the correct lower case b in CFR 142.61 Table 2 - List of Small System Compliance Technologies for PFAS, under the column labeled "Limitations" for the "Unit Technology" GAC.

EPA Response: The EPA agrees that Table 2 of § 141.62, row 2, column 2 should have contained a single lowercase "b" instead of the upper case "B" in the proposed rule. For the final rule, this table has been restructured, and footnote b is no longer needed. The issue the commenter described is no longer present. The revised table is Table 3 in § 142.62 in the final rule.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045166)

Table 2 to Paragraph (a) in § 142.62(a) includes "B" in the Limitations for GAC. It is unclear if this refers to footnote "b." If so, it should be lower case. Footnote c to this same table should not refer to EPA's "proposed" MCLs as this language will not be accurate after the MCLs are final.

EPA Response: Please see the EPA response to comment Doc. #1516, SBC-042716 in section 16.4 in this *Response to Comments* document regarding footnote B. In addition, the title of the Table has been revised to remove the word "proposed."

16.5 Additional Comments

Individual Public Comments

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044880)

• [sec] 141.900(a) states that "control of certain PFAS is required" for community water systems (CWS) and non-transient non-community water systems (NTNCWS), and that they must comply with the MCLs "for certain PFAS." DEP believes that the use of the phrase "certain PFAS" is unclear and misleading, since it implies that water systems must comply with some, but not all, of the MCLs for PFAS. DEP reiterates the need to define the terms "PFAS" and "regulated PFAS" and to use those phrases consistently throughout the proposed rulemaking.

• DEP believes that it is confusing to add PFAS to the best available technology (BAT) table in[sec] 141.61 because it only lists granular activated carbon (GAC) as BAT for the PFAS specified in[sec] 142.62. DEP also questions why PFAS BAT is specified in Part 142, but not in [sec] 141.61 or Subpart Z and questions the appropriateness of this.

• Neither [sec] 141.904 nor [sec] 141.31 provides the option that RAA values need not be reported if the state performs the calculation for the system. DEP notes that this should be explicitly stated if that is the intent of the proposed rulemaking.

• DEP notes that[sec] 141.903(d) states that a system "will not be considered in violation of an MCL until it has completed one year of quarterly sampling", but[sec] 141.903(e) states that "if any sample result will cause the running annual average to exceed the MCL... the system is out of compliance with the MCL immediately." These two statements appear to be contradictory. While DEP understands the intent of these paragraphs relative to implementation, it is contradictory to state that a system will not be considered in violation until they have a complete year of sampling when they could in fact be in violation after only one quarter if levels are high enough.

EPA Response: The commenter raises several points to which the EPA is responding below:

- The EPA has removed most instances of "certain PFAS" and instead generally references "regulated PFAS" in § 141.900 to 141.905. The one remaining use of "certain PFAS" in the definition of the Hazard Index for use in Consumer Confidence Reports (CCRs) is contextually appropriate as a plain language description of the Hazard Index because it is non-regulatory language that does not require further elaboration. The PFAS contaminants considered in the Hazard Index are included in one of the subsequent sentences of that definition.
- Regarding the best available technologies (BATs) tables for PFAS, the EPA has created separate tables for the PFAS MCLs and BATs for regulated PFAS in the final rule. The BATs provided in Table 5 and Table 6 in § 141.61 are now consistent with those shown in Table 1 and Table 3 in § 142.62.
- The EPA intends for the system to report the RAA to ensure the system is aware of the calculated RAA relative to the MCL. This requirement for systems monitoring quarterly to report the RAA is explicitly stated in Table 2 in § 141.904(b) in the final rule and was stated in Table 1 in § 141.904 of the proposed rule. Please also see section 11.2 of the EPA response in this *Response to Comments* document.
- Paragraphs 141.903(d) and 141.903(e) have been modified. Paragraph 141.903(e) now clarifies that, whenever a sample result in any quarter, or the average of multiple samples within a quarter if the state required a confirmation sample, causes the RAA to exceed the MCL at any sampling point regardless of the monitoring results of subsequent quarters required to complete a full year of quarterly monitoring, the system is out of compliance with the MCL immediately. This is consistent with the approach used for other SOCs. If a sample meets the exception criteria the system is immediately in violation of the MCL. Paragraph 141.903(d) is now limited to stating that systems monitoring annually or triennially that have a sample result equal to or exceeding an MCL or trigger level, respectively, must begin quarterly sampling. See also section 8.2 of the EPA response in this *Response to Comments* document for additional discussion of assessing violations based on an RAA, including scenarios that meet this exception.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044878)

DEP offers the following comments, questions, and recommendations to EPA to clarify and strengthen the proposed rulemaking. Comments are grouped by topic, as indicated by the heading of each section.

General Requirements

• Effective dates within the proposed rulemaking are inconsistent and are written as both the date of publication of the final rule in the Federal Register in some locations, and a date three years after the date of publication of the final rule in the Federal Register in other locations. Specifically:

o [sec] 141.6 lists an effective date three years after date of publication of the final rule for:

• [sec] 141.50 Maximum contaminant level goals (MCLG)for organic contaminants.

• [sec] 141.60 Effective dates. However,[sec] 141.60(a)(4) lists an effective date of the date of publication of the final rule in the Federal Register for MCLs and is inconsistent with and contradicts [sec] 141.6. Alternatively, this statement in[sec] 141.60(a)(4) is unimplementable because the statement itself is not effective until three years after the date of publication, as required by [sec] 141.6. Also, if MCLs are in fact effective upon publication, this is inconsistent with MCLGs, which are not effective until three years after publication.

• [sec] 141.61 Maximum contaminant levels for organic contaminants.

• [sec] 141.154 Required additional health information. DEP questions why this is separated out from the list that follows.

• [sec] 141.151 through 141.155 Consumer Confidence Report (CCR).

• [sec] 141.201 through 141.211 Public Notification (PN).

o [sec] 141.900(b) just reads "Compliance dates" but no compliance dates are identified. Compliance dates for initial monitoring are also not identified in [sec] 141.XX(b)(I) Initial compliance period. The timeframe specified in [sec] 141.XX(b)(vi) only applies to monitoring that is needed to supplement previously-acquired data to satisfy the initial monitoring requirements. DEP believes that compliance dates for the start of the initial compliance monitoring period must be identified in the rulemaking.

o [sec] 141.XX(a)(6) requires new systems, or systems using a new source after the date of publication of the final rule in the Federal Register to demonstrate compliance with the MCLs. However, the MCLs (and PN requirements for any MCL exceedances) are not effective until three years after publication, according to[sec] 141.6.

Consistent with Section 300g-l(b)(10) (relating to national drinking water regulations) of the federal Safe Drinking Water Act and in order to allow states sufficient time to review the final rule and promulgate associated state regulations, DEP strongly encourages EPA to set the effective date of the MCLs and any required monitoring and compliance provisions to take effect on the date that is three years after the date on which the final regulation is promulgated.

• DEP notes that there are missing cross references and cross references to citations or tables that do not exist in the proposed rulemaking. Specifically:

o [sec] 141.60(a)(4) is missing a cross reference to[sec] 141.61 and should read (emphasis added to suggested additional language): " The effective date for paragraphs (c)(34) through (c)(36) of[sec] 141.61 is ... "

o [sec] 141.lSl(d) specifies that the Consumer Confidence Reporti (CCR) must include PFAS results that are detected, and that "detected means: at or above the levels prescribed by ... [sec] 141.902(a)(9) for PFAS... ". However,[sec] 141.902 does not exist.

o DEP questions whether [sec] 141.XX Monitoring requirements is intended to be [sec] 141.902 since it comes between[sec] 141.01 and[sec] 141.903. If that is the case, [sec] 141.902(a)(9) (which is published as[sec] 141.XX(a)(9)) then refers to [sec] 141.903(f)(l)(i)(3) for a reportable detection. This is very confusing to have multiple cross references to multiple citations. The cross reference should be directly to the location containing the referred information.

o It is also important to note that the second cross reference noted above in [sec] 141.XX(a)(9)-which DEP believes is intended to be[sec] 141.902(a)(9)-to [sec] 141.903(f)(l)(i)(3) is also a citation that does not exist. DEP believes that this may have been intended to refer to the table listing the PQLs, located in [sec] 14l .903(f)(l)(iii). If that is the case, DEP has specific concerns relative to those reporting limits; those concerns are noted in separate comments below.

o Table 1 to[sec] 141.904 refers multiple times to[sec] 141.902. However, as noted above, [sec] 141.902 does not exist (unless 141.XX is intended to be[sec] 141.902).

o [sec] 141.01(b)(2)(i) states that labs should report "concentrations at least as low as the ones listed in the following table... ". However, the referenced table does not exist; there is no table listing minimum reporting concentrations in the proposed rulemaking.

o [sec] 141.01(b)(2)(i) also references compliance with[sec] 141.902 Monitoring requirements. Again, DEP notes that[sec] 141.902 does not exist, but assumes that [sec] 141.XX is intended to be[sec] 141.902.

o Appendix A to Subpart Q (relating to PN) references [sec] 141.XX as the citation for the PN violation tiers or PFAS. However, as already noted, DEP questions if this is in fact intended to refer to[sec] 141.902.

EPA Response: The commenter raises several points to which the EPA is responding below:

- The EPA has clarified the various applicable deadlines and effective dates throughout the CFR amendments, most broadly in § 141.6 and § 141.900. Some of these milestones fall 60 days after publication of the final rule in the Federal Register (analytical requirements), others fall 3 years after the date of promulgation (reporting of results from initial monitoring, meeting reporting and recordkeeping requirements, and the start of compliance monitoring requirements), and others fall five years after promulgation (meeting MCL compliance requirements). See section 12.1 of the EPA response in this *Response to Comments* document for discussion about the compliance deadline requirements for MCLs. The EPA has removed reference to any provisions being effective on the date of publication in the Federal Register.
- The EPA has clarified that the requirements in the cited language (§ 141.902(a)(4) in the final rule) only apply to systems that begin operation or use a new source of water after three years after the date of promulgation. After that time, these systems are required to document MCL compliance within a period of time specified by the state.

- The amendment to § 141.154 in the proposed rule mentioned by the commenter was removed from the final rule.
- The section labeled "§ 141.XX. Monitoring Requirements" in the proposed rule was corrected to § 141.902 for the final rule.
- Concerns regarding cross references mentioned by the commenter were also addressed.
    - A cross reference to § 141.61 was added to § 141.60(a)(4).
    - The cross reference included in § 141.151(d) for PFAS now leads directly to the location of the table that provides the trigger levels for the regulated PFAS: § 141.902(a)(5) in the final rule, which are used as the thresholds used for reporting detections of regulated PFAS in CCRs.
    - The contents of § 141.901(b)(2)(i) of the proposed rule are now located in § 141.901(b)(2)(iii) and now accurately also cross reference to § 141.902(a)(5).
- Regarding Appendix A to Subpart Q, the intended citation for Monitoring & Testing Procedure Violations was § 141.905(c), as this is the section that identifies violations.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045152)

6. Monitoring, Analyses, Recordkeeping and Violations

Compliance dates

40 CFR § 141.900(b) does not include any proposed Compliance dates (or a formula based on the date of final promulgation). EPA should include the usual placeholder that allows for three years after the date of the final rule promulgation.

Analytical requirements

MassDEP submits the following comments and questions related to the analytical requirements set forth in 40 CFR § 141.901 of the proposed rule (beginning on page 18750 of the Federal Register notice):

• There appears to be a table missing from the proposed rule as referenced in § 141.901(b)(2)(i) "Beginning…report quantitative data for concentrations at least as low as the ones listed in the following table [emphasis added] for all PFAS samples analyzed for compliance with § 141.902 (Monitoring Requirements)."

• It is unclear why a new Subpart would have a [Reserved] section at § 141.901(b)(2)(ii).

• MassDEP notes that EPA Method 537.1 v 2.0 (March 2020, EPA/600/R-20/006) is omitted from 40 CFR § 141.901(a)(2). Is it EPA's intent not to accept this updated version of Method 537.1? Similarly, was direct EPA certification of laboratories intentionally omitted in § 141.901(b)(2)? EPA certified laboratories are acceptable for other SOC analyses as per § 141.24(f)(17).

Monitoring and compliance requirements

MassDEP submits the following comments and questions related to the monitoring and compliance requirements set forth in 40 CFR § 141.902 and § 141.903 of the proposed rule (beginning on page 18751 of the Federal Register notice):

• The end of § 141.902(a)(7) should be reworded, "and 0.33 for the PFAS Hazard Index." Are these triggers evaluated using qualified ("J" estimated) sample results or are individual results below the PQL replaced with zeros as is proposed for MCL compliance calculations?

EPA Response: The commenter raises several points to which the EPA is responding below:

- Regarding compliance dates in § 141.900(b), the EPA has revised § 141.900(b) to include a list of compliance dates for specific aspects of the final rule.
- With respect to the missing table in § 141.901(b)(2)(i), please see the EPA response to comment Doc. #1616, SBC-043041 in section 16.3.1 in this *Response to Comments* document.
- There are no longer any sections marked [Reserved] in the CFR amendments.
- The EPA has corrected the citation and link included in the § 141.901(a)(2) to Method 537.1 Version 2.0 rather than Version 1.0.
- The EPA agrees that laboratories certified by either the EPA or the state are acceptable, consistent with certification requirements for laboratories analyzing for other chemicals, and has corrected § 141.901(b)(2) as well as § 141.28 to say "by EPA or the State."
- The EPA revised §141.902(a) so that the trigger levels are defined in Table 1 to 141.902(a)(5) for the final rule rather than in text.
- Per § 141.903(f)(1)(iv) and § 141.903(f)(2)(iv), zero is used in place of sample results less than the PQL when calculating RAAs to determine compliance with MCLs. However, per § 141.902(a)(6) and Table 3 in §141.902(b)(2)(iv), detections at or above the trigger level, even if below the PQL, impact the required monitoring frequency at a sampling point. Please see sections 8.1.2 and 8.2 of the EPA response in this *Response to Comments* document for further discussion of these issues.

<u>Environmental Protection Network (EPN) (Doc. #1773, SBC-043873)</u>

In the rule sections below, EPN recommends specific changes in order to clarify the monitoring requirements. We also recommend deleting redundant text in several sections because the language is inconsistent and can lead to confusion and poor implementation of the monitoring requirements. Para (l) – effective date should be the first day of a calendar quarter in order to simplify compliance monitoring. When the final rule is submitted to the Federal Register for publication, EPA should put a date certain rather than basing it on the vagaries of Federal Register publishing schedule. The Office of Ground Water and Drinking Water has done this in the past, including for the Stage 2 Disinfectants and Disinfection Byproducts Rule (DBPR) and the Long Term 2 Enhanced Surface Water Treatment Rule. This simplifies setting up quarterly monitoring.

§ 141.50

Para (b)(34) footnote 1 – there is inconsistent use of significant figures. For example, PFNA is 10 ppt, while PFHxS is 9.0 ppt, HFPO-DA is 10.0 ppt and PFBS is 2000.0 ppt. Also, the equation at the end of the footnote uses different significant figures. Finally, the use of i.e. instead of e.g. appears to be more appropriate.

§ 141.60

Para(a)(4) – refers to effective dates for paragraphs not included in the proposal. It appears that the reference should be to 141.61(c)(34)-(36).

§ 141.900

Para (b) – no language proposed.

Para (c) – appears to be at least partially redundant to the requirements in para (a).

§ 141.XX (assume this should be 141.902)

Para (a)(3) – monitoring violations should be for all quarters for which a missed sample would have been used for running annual average calculation, as was done for Stage 2 DBPR. See 141.625(b).

Para (a)(4) – Redundant to 141.903(c). Should be deleted.

Para (a)(6) – New systems and new sources should be required to be in compliance prior to going on line. The proposed language is ambiguous.

Para (b)(1)(i)-(iii) – use the already defined term "subpart H systems" (see 141.2) to refer to systems using either surface water or groundwater under the influence of surface water in paragraphs (i) and (ii). This will make paragraph (iii) redundant. Also, why is there a reference in paragraph (iii) to the State being allowed to require more frequent monitoring but no such reference in paragraphs (i) and (ii)? This could imply that the State couldn't require more frequent monitoring under those paragraphs, which doesn't appear to make sense.

Para (b)(1)(iv) – Table 1 is more specific and clear than paragraphs (b)(i)-(iii) except that systems using GWUDI are not included in the table. Use of "subpart H systems" in the table makes paragraphs (i)-(iii) redundant and reduces inconsistency and ambiguity. Also requiring samples at least 90 days apart for large groundwater systems and all subpart H systems is not practical. The requirement should be for samples to be collected every third month to ensure appropriate spacing while allowing systems and laboratories to collect and analyze samples in a cost-effective manner. EPA and States had implementation issues with the Stage 2 DBPR because of this issue. Finally, it is not clear why the term "taken" is used for one set of systems and "acquired" is used for another set of systems in the table and elsewhere in the rule.

Para (b)(1)(vi) – use "subpart H systems."

Para (b)(2)(i) – allows systems to be on reduced monitoring for some entry points and on routine monitoring for others. It could also be interpreted to allow reduced monitoring for some contaminants but not others at individual EPTDS. This is, at a minimum, a tracking nightmare and makes it difficult to develop and implement a monitoring plan. It also may be less protective of public health. However, Table 2 appears to require that all analytes meet the reduced monitoring requirement for any analyte to be on reduced monitoring. To reduce ambiguity and confusion, requirements should not be repeated if possible. Instead, they should be cross referenced as necessary. Also, tables are generally clearer than text.

Para (b)(2)(iii) – Use "locational running annual average" ("LRAA") in lieu of "running annual average" in this paragraph and elsewhere (e.g., 141.903(b)).

Para (b)(2)(vi) – Requires States to designate monitoring time. This imposes a tremendous and unnecessary implementation burden on the State. Should be "according to the monitoring plan for the system." The State retains its authority to review and require modifications.

§ 141.903

Para (c) – clarify that this is both a monitoring violation and that RAA/LRAA is calculated by dividing by the actual number of samples (which could also be an MCL violation if the RAA/LRAA exceeds the MCL).

Para (d) – seems partially redundant to 141.902(b)(2)(iii). System must begin quarterly monitoring when a result exceeds the trigger.

Para (e) – should be under paragraph (f) rather than as a separate paragraph.

Para (f)(1) – For clarity, add "determine MCL compliance at each EPTDS by calculating the LRAA for each subpart Z analyte" to the end of the sentence.

Para (f)(1)(ii)(A) – seems redundant and probably less stringent than 141.902(b)(2)(iii). Systems must begin quarterly monitoring when a result exceeds the trigger, not just the MCL.

Para (f)(1)(iii) – use of zero for monitoring results below the PQL for any analyte except PFBS is not protective of health. For example, assume EPTDS PFOA results for 4 consecutive quarters are 3.8, 3.8, 3.8, and 5.2 ppt. Using zero for the 3 quarters with results below the PQL of 4.0 results in an LRAA of 1.3 ppt ((0 + 0 + 0 + 5.2)/4). The system nearly meets criteria for reduced monitoring. If systems must use the detection limit, the LRAA is 4.1 ppt ((3.8 + 3.8 + 3.8 + 5.2)/4), which is an MCL violation. For HI calculations, there is a similar issue. Hazard quotients (HQ) for HFPO-DA <0.5 (<5/10), PFHxS <0.33 (<3/9), and PFNA < 0.4 (<4/10) would be zero for HI compliance calculations, which is not protective.

Para (f)(2)(i) – Last sentence should read "…, the system is in violation of the Hazard Index „„".

Para (f)(2)(ii) – See comments on paragraph (f)(1)(iii) of this section.

§ 141.904

Table 1 – references in 3 and 4 seem to be to 141.903, not to 141.902.

§ 141.905

Para (a) – correct reference to 141.XX.

Para (b)(2) and (b)(2)(i) – see 141.629(a)(1)(iii) for MCL RAA/LRAA violations based on fewer than four quarters of monitoring.

Para (b)(2)(iii) – redundant to 141.903. Also see other comments regarding use of zero for monitoring results < PQL.

EPA Response: The commenter raises several points to which the EPA is responding below:

- The EPA has revised the amendments to the CFR to reduce redundancy where possible. Please see section 8.1.1 of the EPA response in this *Response to Comments* document. As it notes, the EPA added specific dates under 40 CFR § 141.900(b)(2), including the date when compliance monitoring will begin, which is three years following rule promulgation pursuant to the requirements of the Safe Drinking Water Act (SDWA) Section 1412(b)(10) and will not necessarily be at the start of a calendar quarter.
- Regarding the commenter's remarks on the footnote to paragraph§ 141.50(b)(34), all numbers in the footnote regarding the Hazard Index calculation, as well as the MCLGs presented in paragraphs § 141.50(b)(34) through (37), have been updated to include a single significant figure and the footnote has been modified such that neither "e.g." nor "i.e." are included. Consistent use of significant figures has also been reflected in Table 4 of § 141.61 of the final rule as well as the associated footnote. The EPA notes that MCLs for PFOA and PFOS include two significant figures. See sections 4.3.4 and 5.1.7 of the EPA response in this *Response to Comments* document for further discussion of significant figures.
- With regard to the comment on § 141.60, paragraph (a)(4) has been updated to include the correct effective date (five years after publication) and further specify the location of the cited MCLs (Table 4 to § 141.61). See section 12.1 of the EPA response in this *Response to Comments* document for discussion about the compliance deadline requirements for MCLs.
- Within § 141.900, compliance dates have been added to paragraph (b). Further, paragraph (c) has been removed.
- The EPA confirms that the section header listed as "§ 141.XX. Monitoring requirements." in Subpart Z of the proposed rule was intended to be "§ 141.902 Monitoring requirements". This has been corrected for the final rule.
- Monitoring violations are described in § 141.903(c) and § 141.905(c), which state that each failure to monitor in accordance with § 141.902 is a monitoring violation. Please see also the EPA response to comment Doc. #1699, SBC-045033 in section 8.2 in this *Response to Comments* document.
- Per the commenter's suggestion, the content of § 141.902(a)(4) in the proposed rule was deleted due to redundancy.

- The EPA disagrees that new systems and new sources should be required to be in compliance prior to going online. The requirement for states to determine when new systems and new sources must meet the requirements gives the states, who have the most information about the systems they oversee, the authority to determine schedules for compliance; the language used for PFAS is consistent with what is required for other chemicals.
- Regarding the decision not to use the term "subpart H systems," please see the EPA response to comment Doc. #1726, SBC-045155 in section 16.3.2 in this *Response to Comments* document.
- The reference to the state being allowed to require more frequent monitoring, included in § 141.902(b)(1)(iii) of the proposed rule, has been moved to § 141.902(b)(1)(v) to clarify that it applies to systems of all source types. Additionally, GWUDI systems have been added to Table 2 to § 141.902(b)(1)(v). See also section 8.1.1 of the EPA response in this *Response to Comments* document for additional discussion of initial monitoring requirements.
- The required initial monitoring frequency for large groundwater systems as well as all surface water and GWUDI systems has been adjusted to 2 to 4 months apart for the final rule per § 141.902(b)(1)(i) and (iii). Please see section 8.1.1 of the EPA response in this *Response to Comments* document for more information.
- Table 2 to § 141.902(b)(1)(v) now uses the same verb ("taken") for both sets of systems.
- The EPA confirms that, per § 141.902(b)(2)(i), systems may have some sampling points on reduced monitoring and others on routine monitoring. However, per the footnote to Table 3 to § 141.902(b)(2)(iv) in the final rule, the monitoring frequency at a given sampling point must be the same for all regulated PFAS. See also the discussion in section VIII and section 8.1.2 of the EPA response in this *Response to Comments* document.
- The EPA disagrees with the suggestion to use "locational running annual average" (LRAA) in lieu of "running annual average." While LRAA has been used for NPDWRs concerning disinfection byproducts, the term has not been associated with volatile organic contaminants or synthetic organic contaminants.
- Regarding the commenter's concern for the requirement of states to designate monitoring time (now stated in § 141.902(b)(2)(vii) of the final rule), see sections 8.1.2 and 11.1 of the EPA response in this *Response to Comments* document. The EPA has removed the monitoring plan requirement for primacy applications. The state will need to establish a compliance monitoring schedule for each system based on the results of initial monitoring.
- The EPA has also updated § 141.903 for clarity. § 141.903(c) now specifies that, in the event of a monitoring violation, the RAA is still calculated using the total number of samples collected. The EPA disagrees with the commenter that § 141.903(e) should be merged with paragraph (f). This is because paragraph (e) describes an exception which supersedes the requirements listed in paragraph (f) for determining compliance and may result in a system being in violation of an MCL prior to having collected a full year of quarterly samples.

- Regarding the commenter's request for increased clarity in § 141.903(f)(1), the EPA has specified "at each sampling point" in paragraph (f) while (f)(1) specifies that this applies to each PFAS regulated by an individual MCL.
- The EPA has updated § 141.903(f)(1)(ii) and § 141.903(f)(1)(iii) of the final rule to clarify that, for systems on reduced monitoring, if a sample concentration (or average of samples if the state required a confirmation sample) equals or exceeds a trigger level (for triennial monitoring) or MCL (for annual monitoring), the systems must begin monitoring quarterly.
- Regarding the commenter's concern about the use of zero for monitoring results below the PQL when calculating MCL compliance, see section 8.2 of the EPA response in this *Response to Comments* document. For monitoring schedule frequency purposes, values below the PQL are not replaced with zeroes; see section 8.1.2 of the EPA response in this *Response to Comments* document.
- The sentence of concern near the end of § 141.903(f)(2)(i) has been revised to say "If the running annual average Hazard Index exceeds the MCL and two or more Hazard Index analytes had an observed sample analytical result above the PQL in any of the quarterly samples collected to determine the running annual average, the system is in violation of the Hazard Index MCL."
- References in Table 2 to § 141.904(b) in the final rule (Table 1 to § 141.904 in the proposed rule) have been updated to direct to § 141.903 when referring to an MCL violation and § 141.902(a)(5) when referring to the trigger level. Table 1 to § 141.904(a) for initial monitoring has also been added in the final rule.
- Per this comment and others, the EPA has also made revisions to § 141.905 (see also section 8.2 of the EPA response in this *Response to Comments* document).
    - Regarding references in § 141.905(a), please see EPA response to comment Doc. #1726, SBC-045172 in section 16.3.5 in this *Response to Comments* document.
    - § 141.905(a) states "that MCL violations are based on running annual average, as outlined under § 141.903…" This cross reference includes discussion of violations based on fewer than four quarters of monitoring.
    - The redundancy of § 141.905(b)(2)(iii) in the proposed rule has been removed from the final rule.

<u>City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043790)</u>

May 30, 2023

Michael Regan, Administrator

U.S. Environmental Protection Agency 1200 Pennsylvania Avenue, N.W. Mail Code: 1309

Washington, DC 20004

TRANSMITTED ELECTRONICALLY

RE: PFAS National Primary Drinking Water Regulation Rulemaking (88 FR 18638, EPA-HQ-OW-2022-0114)

Dear Administrator Regan,

The City of Tulsa Water and Sewer Department (CoT WSD) would like to present for Environmental Protection Agency's (EPA's) review the following editorial correction items for the preliminary regulatory determination and proposed rule for per- and polyfluoroalkyl substances (PFAS) National Primary Drinking Water Regulation (Federal Register document citation 88 FR 18638, document number 2023-05471; or Docket Document ID# EPA-HQ-OW-2022-0114-0027). These items are in the portion of the referenced Federal Register document that contains the proposed amended language for 40 CFR parts 141 and 142. This document submission is in addition to the City of Tulsa Water and Sewer Department's comments on the proposed rule, which are submitted in a separate document.

1. 88 FR 18748 item 7.a.: Appears that "at end of the table" should be "in alphabetical order", since the existing table in §141.61(b) is currently in alphabetical order.

2. 88 FR 18749 item 10, specifically footnote 2: "Subpart A of §141.2" looks like an incorrect listing of the citation, since §141.2 is actually a section of Subpart A. Suggest change this to "§141.2 of Subpart A" or simply "§141.2".

3. 88 FR 18749 item 11, 2 items:

a. In paragraph, insert "order" after "numerical"

b. In table, in the Monitoring & testing procedure violations Citation column, citation should be 141.902.

c. 88 FR 18750 item 12, specifically footnote 24: "Subpart A of §141.2" looks like an incorrect listing of the citation, since §141.2 is actually a section of Subpart A. Suggest change this to "§141.2 of Subpart A" or simply "§141.2".

4. 88 FR 18750 – 18754 All tables in added Subpart Z: Titles of all tables are confusing.

a. Table 2 is used in two different paragraphs, even though there is no Table 1 in those paragraphs.

b. For improved clarity, paragraph citation should include the m e.g. "Table 1 to §141.901(b)(i)". Or, change to descriptive title and remove citation (tables in other portions of NPDWR use descriptive titles).

5. 88 FR 18750 item 14, specifically §141.901(b)(2)(i):

a. Remove parentheses around "Monitoring Requirements"

b. The referenced table in this paragraph is missing.

6. 88 FR 18751 item 14, specifically §141.XX: This section should be §141.902.

7. 88 FR 18751 item 14, specifically §141.901(a)(9): Citation at end of paragraph does not exist. It appears that the reference citation should be §141.903(f)(1)(iii).

8. 88 FR 18752 item 14, specifically §141.903(f)(2)(i): It appears that description of calculation of Running Annual Average (RAA) using the quarterly Hazard Indexes (HI) was left out. The way it is written, it seems that the MCL is determined on each quarterly HI.

9. 88 FR 18753 item 14, specifically §141.903(f)(2)(iii): Citation in paragraph does not exist. It appears that the reference citation should be §141.903(f)(1)(iii).

10. 88 FR 18753 item 14, specifically §141.905(a): Two citation references to §141.XX, and incorrect notation for specific paragraphs.

a. It appears the first citation should be §141.903 Compliance Requirements

b. It appears the second citation should be §141.902 Monitoring Requirements

11. 88 FR 18753 item 14, specifically §141.905(b)(2)(iii): Citation in paragraph does not exist. It appears that the reference citation should be §141.903(f)(1)(iii).

12. 88 FR 18754 item 17, specifically §142.62(a) Table 2: "B" should be lower case "b" on 2nd line in "Limitations" column.

(This area is intentionally left blank)

The City of Tulsa Water and Sewer Department values the opportunity to comment on the preliminary regulatory determination and proposed rule for per- and polyfluoroalkyl substances (PFAS) National Primary Drinking Water Regulation, and appreciates EPA's consideration of the suggested editorial corrections in this letter. Please contact me if you have any questions.

Sincerely,

Eric Lee, Director

City of Tulsa Water and Sewer Department EL/cjg

WSD

EPA Response: The commenter raises several points to which the EPA is responding below:

- For the final rule, the regulated PFAS MCLs and BATs described in § 141.61 are now included in PFAS-specific tables rather than added to the previously existing tables.
- The commenter is correct that footnote 2 "Subpart A of § 141.2" was incorrectly stated. However, footnote 2 (as well as footnote 24 in Appendix B to Subpart Q) referencing §

141.2 in the proposed rule was removed in the final rule given that Hazard Index is defined within Subpart O § 141.153.

- Concerning the amendment to appendix A to Subpart Q the EPA has corrected the amendment description to say "numerical order" but disagrees that the citation for Monitoring & Testing Procedure Violations should be § 141.902. However, the citation has been updated to § 141.905(c), which concerns violations.
- For the final rule, the EPA has added or amended table titles for clarity.
- For the final rule, table numbers were amended to be more intuitive. Table numbering is reset at the beginning of a section. The description format of "Table X to paragraph Y" does not necessarily imply the specific paragraph has a certain number of tables, but rather clarifies where the specific table can be found (after the paragraph stated).
- Regarding the commenter's request for section numbers to be included in table paragraph locations, the EPA used the convention identified in the Office of the Federal Register (OFR) Handbook, the paragraphs should be clear because it is within the same section as the table listed; the EPA also has added descriptive titles to tables.
- In response to the commenter's concerns regarding § 141.901(b)(2)(i), which is § 141.901(b)(2)(iii) for the final rule:
    - For the final rule the name of the section (previously included as "Monitoring Requirements") has been removed and it is referred to here by the section number.
    - An accurate cross reference to the cited table has been added.
- § 141.XX has been corrected to § 141.902.
- There was no § 141.901(a)(9) in the proposed rule. However, the citation included at the end of § 141.902(a)(9) was intended to be § 141.903(f)(1)(iii) in the proposed rule. For the final rule, the section has been reorganized such that there is no longer need for a cross reference as the table for trigger levels is presented directly in § 141.902.
- The EPA has updated the language in §141.903(f)(2)(i) to clearly state that the RAA of the Hazard Index is used to assess compliance with the MCL.
- The citation in §141.903(f)(2)(iv), which was § 141.903(f)(2)(iii) in the proposed rule, has been corrected to direct to § 141.903(f)(1)(iv).
- The citations included in § 141.905(a) of the proposed rule have been corrected in the final rule. The citations are now seen in § 141.905(a) and (b).
- § 141.905 has been rearranged such that § 141.905(b)(2)(iii) no longer exists, however § 141.903 is accurately cross-referenced in § 141.905 (a) and (e), regarding how to calculate the RAA.
- Regarding the footnote in § 142.62(a) Table 2 of the proposed rule, please see the EPA response to comment Doc. #1516, SBC-042716 in section 16.4 in this *Response to Comments* document.

17 EPA's Next Steps and Timeline

17.1 Comment Period Extensions

Summary of Major Public Comments and EPA Responses

Many commenters requested an extension to the public comment period provided prior to finalizing the PFAS National Primary Drinking Water Regulation (NPDWR), with a few commenters requesting that the EPA provide additional time for comment via a supplemental comment period. Commenters asserted that, given the complexity and significance of this regulatory action, the public comment period was too short to provide detailed and constructive feedback. Commenters asserted that they perceived there was insufficient time to adequately review the proposed rule and key technical support documents, specifically noting that they sought extra time to review information on topics such as water treatment costs, feasibility to remove PFAS to levels at or below the proposed Maximum Contaminant Levels (MCLs), feasibility for water systems to implement the rule within the compliance timeline, and application of the Hazard Index for drinking water regulation, including considerations for risk communication, among other topics. Some commenters noted that this regulatory action has connections to actions taken on PFAS under other statutes and that there are other actions soliciting public comments simultaneously with the proposed PFAS NPDWR that will also impact drinking water utilities. These commenters asserted that a comment period extension would allow for a more robust review of the scientific and technical information provided by the agency.

Commenters noted that an additional comment period or extension to the comment period provided by the agency would allow for what they believed would be more informed public comments, as commenters would have additional time to consult with relevant stakeholders and workgroups. One commenter also noted that there is no statutory or regulatory deadline that compels the agency to provide such an abbreviated comment period. Commenters also cited challenges in reviewing the entirety of the regulatory package for this action in conjunction with other regulatory actions simultaneously and due to other competing responsibilities and limited resources. Additionally, one commenter cites the length of interagency review on the proposed rule as rationale for requesting an extension to the public comment period. Commenters also asserted that the EPA's prompt response on whether the comment period would be extended was necessary for "stakeholders to successfully balance available resources within the time the agency affords the public to draft comments."

First, neither the Safe Drinking Water Act (SDWA) nor the Administrative Procedure Act (APA) specify a length of comment period. Executive Order (EO) 12866, governing issuance of federal regulations, states that comment periods should in most cases be at least 60 days (EO 12866, Section 6). In this case, the EPA provided a comment period of 62 days. Second, because the agency provided public access to key documents immediately after signature, commenters had an additional 15 days for comment on the proposed rule.

Specifically, the EPA announced the issuance of the proposed PFAS NPDWR on March 14, 2023. To provide the public with additional time to review and prepare comments on the proposed rule and key supporting documents, the agency simultaneously made publicly available a pre-publication version of the proposed rule Federal Register Notice (FRN), as well as several of the significant underlying technical supporting documents, including the Economic Analysis (EA) and Appendices, *Toxicity Assessment and Proposed Maximum Contaminant Level Goal (MCLG) for PFOA* and Appendix, *Toxicity Assessment and Proposed MCLG for PFOS* and Appendix, *Framework for Estimating Noncancer Health Risks Associated with Mixtures of PFAS, MCLG Summary Document for a Mixture of Four PFAS*, and the *EPA's Response to Science Advisory Board Recommendations on Draft Documents for the Proposed PFAS NPDWR*. Additionally, the peer-reviewed paper which outlined the methodology for the EPA's national PFAS occurrence model (Cadwallader et al., 2022) was published in May 2022 in *American Water Works Association (AWWA) Water Science*. The publication included supplemental material, including model code and outputs. Both its contents and location were referenced in the pre-publication of the FRN for the action posted on March 14, 2023. As a result, stakeholders had access to the FRN preamble language, economic analysis, health information, and other key information on March 14, 2023, a full 15 days before the start of the official comment period. Hence, commenters had 77 days in total during which the rule was publicly available for stakeholder consideration prior to submitting comments by the close of the comment period.

Third, the EPA engaged in significant pre- and post-proposal actions to both inform and involve stakeholders in rule development. Specifically, during the proposed rule development, the EPA sought to actively involve stakeholders and members of the public in the rulemaking process, seek their input, and provide information through various consultations and engagements (see XV of the proposed rule preamble). The EPA received significant feedback and information from stakeholders during this time which meaningfully informed the proposed rule. Additionally, in November 2022, the EPA hosted a webinar entitled "Preparing for Engagement in EPA's Upcoming Proposed Per- and Polyfluoroalkyl Substances (PFAS) Drinking Water Regulatory Process". The purpose of this webinar was to provide members of the public, particularly those who do not typically engage in federal rulemaking activities, the information and tools they needed about the federal regulatory process so they would know how to submit their comments during the upcoming public comment period, thereby allowing prospective commenters to be fully prepared to review and develop comments on the proposal as soon as it was issued.

Following the rule proposal announcement, the EPA also offered opportunities for the public to learn more about the rule proposal including through two public webinars that the EPA hosted on March 16, 2023, and March 29, 2023, to provide an overview of the rule for both general public and technical stakeholders. These webinars, as well as other supporting materials, have been made available on EPA's PFAS NPDWR website as a resource (https://www.epa.gov/sdwa/and-polyfluoroalkyl-substances-pfas). Additionally, the EPA held a public hearing for the proposed NPDWR on May 4, 2023, where members of the public had the opportunity to share their comments with the EPA on the proposed rule. For further discussion additional meetings and

consultations held on the PFAS NPDWR, see section 14 of this *Response to Comments* document.

Additionally, to ensure that commenters knew with adequate advanced notice that the agency would not be extending the comment period for this rulemaking, the EPA promptly responded to comment period extension requests from commenters. The agency responded to requests for a comment period extension on May 5, 2023 for all requests received prior to this date, a full 25 days before the close of the comment period.

Regarding commenter concerns that there were other PFAS regulatory actions under different statutes or other drinking water regulatory actions on which they might like to provide comment that may have overlapping comment periods with this regulatory action, the EPA notes that none of these other actions referenced by commenters impact the EPA's decision-making for this PFAS NPDWR. Potential PFAS-related actions have different underlying statutory drivers; for instance, the Advanced Notice of Proposed Rulemaking (ANPRM) on Potential Future Designations of PFAS as Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Hazardous Substances was issued under CERCLA authorities and the information contained in that rule and comments received on that rule do not substantively impact the decision-making process for this regulation. Additionally, the EPA notes that the comment period for that action only partially overlapped with that for the PFAS NPDWR. Additionally, the EPA acknowledges that proposed revisions to the Consumer Confidence Report (CCR) Rule and call for nominations to the sixth Contaminant Candidate List (CCL 6) were also soliciting public comment during a portion of the comment period for this NPDWR. While SDWA is the statutory authority for the CCR Rule, CCL, and the PFAS NPDWR, the EPA notes any comments provided on the proposed revisions to the CCR Rule or nominations for CCL 6 and this action would not impact each other. The EPA also notes that these actions have different SDWA statutory drivers and decision-making processes than does the PFAS NPDWR. Finally, regarding a commenter's reference to the proposed Supplemental Effluent Limitations Guidelines and Standards for the Steam Electric Power Generating Point Source Category, the EPA notes that rule is proposed under the authority of the Clean Water Act (CWA), regulates entirely different pollutants than PFAS, and regulates entirely different entities than drinking water utilities. In short, these other regulatory activities in no way impacted the decision-making process or schedule under this regulatory action. Therefore, because commenters may choose to comment on those other actions (in cases when there were co-occurring comment periods), these other actions' schedules do not impact the EPA's obligations or schedule under this PFAS NPDWR.

Regarding a commenter's statement about the length of interagency review, the EPA notes that the length of the Office of Management and Budget (OMB)-led interagency review process, governed under EO 12866, is unrelated and immaterial to the length of the public comment period. The OMB-led interagency review and the EPA's consideration of public comments (including the public comment period itself) are driven by different authorities: neither impacts the other.

As the lead federal agency responsible for ensuring safe drinking water for Americans, the EPA anticipates that over many years this action will save thousands of lives and prevent tens of thousands of serious illnesses that would otherwise result from long-term exposure to PFAS. Therefore, due to the complexity and significance of the PFAS NPDWR, while the EPA felt it appropriate to allow public comments for 62 days, with an additional 15 days of rule availability, for a total of 77 days for commenters to review the proposed rule, further delays to protection of public health outweighed any benefits that might be realized by extending the public comment period. It is important to take final action on the proposal expeditiously to address PFAS exposure in communities across the country and ensure that the health benefits of the final rule could be realized as quickly as possible.

As described above, the agency believes the extended public comment period time, along with the extensive pre- and post-proposal activities to promote understanding of the rule and facilitate public comment, was sufficient for commenters to understand and meaningfully participate in the rulemaking process while also allowing the EPA to protect communities and the public from exposure to adverse PFAS health effects from drinking water as expeditiously as possible.

RE: Request for Extension for Comment Period on EPA's Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (Docket ID: EPA-HQ-OW-2022-0114)

Administrator Regan,

The comment period for EPA's proposed per- and polyfluoroalkyl substances (PFAS) drinking water regulation is only 62 days long. As of the writing of this letter, the docket contains nearly 1,300 supporting documents (26 of which total 5,000 pages) from the agency. These materials must be reviewed and considered in order for stakeholders to provide constructive feedback. There are multiple, key aspects of the proposed rule that will require extensive review, including but not limited to:

• The regulatory determinations for four additional PFAS

• An occurrence analysis, which relies on both a complex statistical approach and a novel national occurrence database that combines older data collected under the Unregulated Contaminant Monitoring Rule with a collection of state monitoring datasets

• Four Work Breakdown Structure-Based Cost models for PFAS treatment technologies which are newly published

• Updated support documents for maximum contaminant level goals (MCLGs) for perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS)

• Analysis to support an MCLG for a hazard index reflecting a mixture of four PFAS

• An updated approach for evaluating health risk reduction associated with cardiovascular disease and decreased birth weight

• An approach for evaluating reduced disinfection byproduct formation and associated health risk reduction benefits of the proposed rulemaking

• A novel drinking water regulatory approach utilizing a general hazard index

The American Water Works Association (AWWA) requests that EPA provide an extension of the comment deadline by 59 days to July 28, 2023. This extension would provide a total of 121 days for public comment. AWWA is requesting this extension to ensure that the proposed rule and supporting documents can be reviewed fully and considered in providing feedback to the agency. Your response by April 14, 2023, is necessary for stakeholders to successfully balance available resources within the time the agency affords the public to draft comments.

AWWA appreciates your attention to this matter. If you have any questions we encourage you to reach out to either myself at TMehan@awwa.org or Chris Moody at cmoody@awwa.og or (202) 326-6127.

FOR THE AMERICAN WATER WORKS ASSOCATION,

G. Tracy Mehan, III

Executive Director – Government Affairs

cc: Radhika Fox, EPA/OW

Jennifer McLain, EPA/OGWDW

Eric Burneson, EPA/OGWDW

Ryan Albert, EPA/OGWDW

Who is AWWA

The American Water Works Association is an international, nonprofit, scientific and educational society dedicated to providing total water solutions assuring the effective management of water. Founded in 1881, the Association is the largest organization of water supply professionals in the world. Our membership includes more than 4,500 utilities that supply roughly 80 percent of the nation's drinking water and treat almost half of the nation's wastewater. Our 50,000-plus total membership represents the full spectrum of the water community: public water and wastewater systems, environmental advocates, scientists, academicians, and others who hold a genuine interest in water, our most important resource. AWWA unites the diverse water community to advance public health, safety, the economy, and the environment.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document. Additionally, the EPA notes that many of the materials listed by the commenter were made publicly available prior to the public comment period for this action.

For instance, the EPA's Science Advisory Board (SAB) PFAS Review Panel ("Review of EPA's Analysis to Support EPA's National Primary Drinking Water Rulemaking for PFAS") reviewed several of the agency's technical products that have been utilized or applied in this regulatory action, including its cardiovascular disease (CVD) risk reduction methodology, derivation of draft Maximum Contaminant Level Goals (MCLGs) for PFOA and PFOS, and framework for estimating noncancer health risk associated with mixtures of PFAS (which is applied through use of the Hazard Index in this regulatory action). The SAB's final report was published on August 22, 2022 and prior to this date, the SAB issued a draft report and convened multiple panel meetings to discuss their comments on the EPA's technical products. These meetings were open to the public, providing additional opportunities for public input. Additionally, the public had the opportunity to nominate experts to the panel and the SAB Staff Office also invited comments on Lists of Candidates. This provided an opportunity for the public to be informed about the candidate experts being considered and for the public to provide information, analysis, or documentation for the EPA to consider before finalizing membership on committee or panels. For more information on SAB review, please see: https://sab.epa.gov/ords/sab/f?p=100:18:10311539418988:::18:P18_ID:2601#charge.

In addition to the SAB-reviewed cardiovascular risk reduction methodology which was applied in the EPA's CVD benefits analysis, the EPA notes that the EPA's benefits analyses for both birth weight benefits and benefits resulting from disinfection byproduct (DBP) co-removal apply methodology from publicly available peer-reviewed papers (Almond et al., 2005; Ma and Finch, 2010; Regli et al., 2015). For more information on these analyses, see Sections 6.4 and 6.7 of the EA for discussion of the valuation of developmental effects and benefits from co-removal of DBPs, respectively (USEPA, 2024a).

In addition, with respect to the Work Breakdown Structure cost models, the EPA disagrees with the commenter's assertion that these are "newly published." Versions of the models incorporating annual updates have been available for external review and public use on the EPA's website since approximately 2016; see: https://www.epa.gov/sdwa/drinking-water-treatment-technology-unit-cost-models. The versions used to support this rulemaking were

available for review in the docket for the proposed regulation; likewise, the versions updated after considering public comments are available in the docket for this final action. All design parameters, including specific adjustments to estimate the cost of PFAS treatment, are also described in detail in the supporting documentation, also included in the docket. For more information, please see section 13.3.3 of the EPA response in this *Response to Comments* document.

With respect to the commenter's assertion that the EPA's occurrence analysis "relies on both a complex statistical approach and a novel national occurrence database," see section 6.5 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1466, SBC-042301)

March 30, 2023

Michael S. Regan

Administrator

US Environmental Protection Agency

1200 Pennsylvania Avenue, NW

Washington, DC 20460

Re: Extension request of comment period for Docket ID #: EPA-HQ-OW-2022-0114; PFAS National Primary Drinking Water Regulation Rulemaking

Dear Administrator Regan,

The Association of Metropolitan Water Agencies (AMWA), an organization representing the largest publicly owned drinking water utilities in the United States, welcomes the opportunity to provide comments on the proposed National Primary Drinking Water Regulation of PFOA, PFOS, PFBS, GenX, PFNA, and PFHxS. AMWA was supportive of the determination to regulate certain PFAS and has repeatedly called for a regulation based on sound science and the most up-to-date data available. Due to the vast complexity of the rule and the effect it will have on AMWA members, the association respectfully requests at least a 30-day extension to the comment period to ensure useful and meaningful feedback.

A crucial step of the regulatory process is the public comment period. Feedback and recommendations from impacted stakeholders and the regulated community provide a unique perspective that often strengthens and improves a proposed rule. AMWA believes it is in the interest of EPA to provide an adequate comment period for such an important and consequential rule. AMWA will be able to provide much more insightful and helpful comments if given the time to review the many pages of documents and supporting materials provided by EPA.

At the time of the creation of this letter, there are 1,241 supporting or related material provided in the rulemaking docket to review. It is also unreasonable to expect a meaningful comment letter in 60 days when the Office of Management and Budget needed five months to conclude its own review. AMWA understands the agency cannot allow the same period for public comment but believes more time is a fair ask, given the rule's complexity.

While AMWA and its members will be diligently working to provide thoughtful comments on this proposed rule, it is important to remind EPA that this is not the only rulemaking being proposed with an open public comment period that will impact drinking water utilities. Contaminant Candidate List 6, Consumer Confidence Reports, ANPRM for additional PFAS CERCLA designations, and Steam Power ELGs are all in the process, or will be shortly, of soliciting public comments simultaneously with this proposed rule. A condensed period for public comment on this rule only diverts resources from providing robust comments to other notices currently open in the Federal Register.

While AMWA understands the importance of finalizing this rule in a timely manner, the association believes thoughtful public comments will only strengthen the final rule and ultimately provide more protections for public health. Therefore, AMWA respectfully requests EPA extend the comment period by at least 30 days. AMWA also asks EPA to respond to this request in a timely manner so comments can be developed with an accurate due date in mind.

AMWA appreciates EPA giving this request consideration. If you have any further questions, please contact Brian Redder (Redder@amwa.net), AMWA's Manager of Regulatory and Scientific Affairs.

Sincerely,

Tom Dobbins

Chief Executive Officer

Washington, DC 20460

RE: Request for Extension for Comment Period of EPA's Proposed Per-and Polyfluoralkyl Substances (PFAS) National Primary Drinking Water Regulation

(Docket ID: EPA-HQ-OW-2022-0114)

Administrator Regan,

The proposed National Primary Drinking Water Regulation for PFAS substances only provides a public review and comment period of 62 days. The corresponding docket contains more than 5,000 pages of supporting documentation. These materials must be reviewed and considered in order for stakeholders to provide constructive feedback.

Louisville Water is interested in reviewing the proposal and providing feedback to the EPA to present its perspective on the various aspects of the proposed rule, including:

• Water treatment costs associated with PFAS;

• Feasibility to remove PFAS to levels at or below the proposed standards;

• Feasibility for drinking water utilities to implement the proposed rule within the compliance timeline, and the factors influencing the implementation of treatment; and

• Application of the proposed Hazard Index for drinking water regulation, including considerations for risk communication.

Louisville Water respectfully requests an extension of the comment deadline by 59 days to July 28, 2023, to provide a total of 121 days for public comment. Your response by April 14, 2023, is requested as necessary for us to successfully balance available resources to best utilize the requested extension period.

Thank you for your consideration of this request.

Sincerely,

Spencer Bruce, President and CEO

Louisville Water Company

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1465, SBC-042300 in section 17.1 in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1468, SBC-042303)

The Honorable Radhika Fox

Assistant Administrator

Office of Water

Environmental Protection Agency

Washington, DC 20020

Re: Comment Period Extension Request for EPA's proposed regulatory determination for PFHxS, HPFO-DA, GenX chemicals, and PFNA; and EPA's proposed maximum contaminant levels (MCLs) and proposed maximum contaminant level goals (MCLGs)

Dear Assistant Administrator Fox:

We, the undersigned organizations representing a coalition of companies and trade associations from across the economy, urge you to provide a 30-day extension to the public comment period for 1) EPA's proposed regulatory determination for PFHxS, HPFO-DA, GenX chemicals, and PFNA; and 2) EPA's proposed maximum contaminant levels (MCLs) and proposed maximum contaminant level goals (MCLGs) for PFOA and PFOS and also the four PFAS chemistries for which EPA is proposing a regulatory determination.

We support national drinking water standards for select PFAS based on the best science and risk, rather than the current patchwork of state approaches. Our customers, employees, and the communities where we operate depend on clean, safe drinking water for a better quality of life and economic growth. EPA's proposal sets forth 59 specific questions for comment and provides more than 3,000 pages of very technical and complex information on the scientific basis, costs, and impacts for implementing these standards. This page count does not include even further additional technical supporting information that EPA made available in the docket on March 29, 2023. There are some 1,271 supporting documents included in the docket, which are not organized in a searchable or clear fashion.

More time is needed to practically offer constructive feedback on the challenges, unintended consequences especially on small entities, economic analysis, and the novel hazard index approach presented by the two proposed rules that are within the package EPA has asked the public to comment on. While the proposal focuses on setting standards for six PFAS, it also

includes within it a separate regulatory determination for four of the PFAS. Commenting on this regulatory determination will require an in-depth review of occurrence and hazard information for these PFAS. Accordingly, because the agency is asking for review of these regulatory determinations and the proposed MCL and MCLG for these new compounds (in addition to the proposed rule for PFOA and PFOS) and extension is warranted.

In the meantime, the U.S. Chamber of Commerce has submitted a report to the Office of Management and Budget (OMB) modelling the potential costs attributable to various drinking water treatment levels. The estimated annualized costs for a proposed MCL of 4 ppt are approximately $1.8 billion. Our cover letter to OMB and the report are here [Link: Broken] and here [Link: Broken]. The significant costs and impacts and their connection to other elements of the PFAS Strategic Roadmap, such as the proposed hazardous substance designation under CERCLA demand a full vetting by the stakeholder community requiring additional time.

Please feel free to contact us with any questions. We stand ready to work with you as this proposal moves forward.

Sincerely,

Association of State Drinking Water Administrators (ASDWA) (Doc. #1469, SBC-042304)

Attached is a request for comment period extension from the Association of State Drinking Water Administrators.

March 29, 2023

Dr. Jennifer McLain

Director, Office of Ground Water and Drinking Water

U.S. Environmental Protection Agency

1200 Pennsylvania Avenue NW

Washington, DC 20460

Via Regulations.gov

Re: Request for Comment Period Extension for Proposed PFAS National Primary Drinking Water Regulation (NPDWR) (EPA-HQ-OW-2022-0114)

Dear Dr. McLain,

The Association of State Drinking Water Administrators (ASDWA) appreciates the opportunity to provide input on the proposed National Primary Drinking Water Regulation (NPDWR) for per- and polyfluoroalkyl substances (PFAS). ASDWA is the professional association that serves the leaders (and their staff) of the 57 state and territorial drinking water programs. Formed in 1984 to address a growing need for state administrators to have national representation, ASDWA has become a respected voice for states with Congress, the Environmental Protection Agency (EPA), other Federal agencies, and professional organizations in the water sector. ASDWA would like to thank the Office of Ground Water and Drinking Water (OGWDW) for its continued efforts on such an important and precedent-setting rulemaking. This regulatory action by EPA is a step in the right direction to provide national leadership and consistency for assessing and addressing PFAS in drinking water nationwide.

As the representative of EPA's co-regulators in implementing NPDWRs, ASDWA appreciates EPA's early outreach to state drinking water programs as the Agency developed this proposal. ASDWA appreciates EPA's recognition of the importance of engaging state drinking water programs effectively and meaningfully to ensure that this NPDWR is implementable and

maximizes the public health benefit. ASDWA requests an extension of the comment deadline by 30 days, to a total of 90 days, to ensure ASDWA and state staff have sufficient time to review and analyze the proposal. ASDWA appreciates the Agency's interest in establishing this NPDWR in a timely manner, but an expeditious schedule should not come at the expense of obtaining meaningful engagement with stakeholders.

ASDWA requests that EPA decide whether to grant the extension within 30 days of the publication of the proposal in the Federal Register. In the past, the Agency has responded to public comment period extension requests very close to the deadline for submitting comments. Many stakeholders, ASDWA included, must draft their comments far in advance to allow for review by technical workgroups and review and approval by governing boards before submission to the docket. An early decision on the comment extension would benefit ASDWA's members and ensure a more robust review.

ASDWA thanks EPA for the opportunity to provide comment early in the process as the Agency works to address PFAS in drinking water. As co-regulators and the boots on the ground, it is vital that EPA collect state input throughout the process. We look forward to further engagement with the Agency on this critical rulemaking.

Sincerely Yours

J. Alan Roberson, P.E.

RE: Request for Extension for Comment Period on EPA's Proposed Per- and Polyfluoroalkyl Substances (P FAS) National Primary Drinking Water Regulation (Docket ID: EPA-HQ-OW-2022-0114)

Administrator Regan,

The proposal only provides a public review and comment period of 62 days. At the time this letter is written, the docket contains more 5,000 pages of supporting documentation. These materials must be reviewed and considered in order for stakeholders to provide constructive feedback.

We are interested in reviewing the proposal and providing feedback to the EPA presenting our perspectives on the various aspects of the rule, including:

• Water treatment costs associated with per- and polyfluoroalkyl substances (PFAS);

• Feasibility to remove PFAS to levels at or below the proposed standards;

• Feasibility for drinking water utilities to implement the proposal within the compliance timeline and the factors influencing the implementation of treatment.

• Application of the hazard index for drinking water regulation, including considerations for risk communication.

We respectfully request that EPA provide an extension of the comment deadline by 59 days to July 28, 2023 to provide a total of 121 days for public comment. Your response by April, 14, 2023 is necessary for us to successfully balance available resources to best utilize the requested extension period. We appreciate your attention to this matter.

Southeast Florida Utility Council (SEFLUC) (Doc. #1480, SBC-042315)

Dear Mr. Regan,

I am writing to request that the Environmental Protection Agency (EPA) extend the comment deadline for the Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation by 59 days, to July 28, 2023. This extension would provide the public with a total of 121 days to review and comment on the proposed regulation/policy.

As you may be aware, this proposed regulation/policy has far-reaching implications and will significantly impact the environment, public health, and the economy. Therefore, the public must have adequate time to review the proposal, consult with stakeholders, and provide informed feedback.

Given the complexity of the proposed regulation/policy, an extension of 59 days is necessary to ensure that the public has sufficient time to provide thoughtful and substantive comments. This extension will also allow for more inclusive public participation, particularly among stakeholders who may require additional time to review and comment on the proposal.

Thank you for your attention to this matter.

Sincerely,

Marta Reczko

SEFLUC Chair

RE: Request for Extension for Comment Period on EPA's Proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation (Docket ID: EPA-HQ-OW-2022-0114)

Administrator Regan,

The proposal only provides a public review and comment period of 62 days. At the time this letter is written, the docket contains more 5,000 pages of supporting documentation. These materials must be reviewed and considered for stakeholders to provide constructive feedback.

The Southeast Florida Utility Council (SEFLUC) represents water utilities throughout South Florida that collectively provide potable water to over 6 million people. We are interested in reviewing the proposal and providing feedback to the EPA, presenting our perspectives on the various aspects of the rule, including:

• Water treatment costs associated with per- and polyfluoroalkyl substances (PFAS);

• Feasibility to remove PFAS to levels at or below the proposed standards;

• Feasibility for drinking water utilities to implement the proposal within the compliance timeline and the factors influencing the implementation of treatment.

• Application of the hazard index for drinking water regulation, including considerations for risk communication.

We respectfully request that EPA extend the comment deadline by 59 days to July 28, 2023, to provide 121 days for public comment. Your response by April 14, 2023, is necessary for us to successfully balance available resources to best utilize the requested extension period.

We appreciate your attention to this matter.

RE: Request for Extension for Comment Period on EPA's Proposed Per- and Polyfluoroalkyl Substances

(PFAS) National Primary Drinking Water Regulation

(Docket ID: EPA-HQ-OW-2022-0114)

Administrator Regan,

The proposed National Primary Drinking Water Regulation for PFAS substances only provides a public review and comment period of 62 days. The corresponding docket contains more than 5,000 pages of supporting documentation. These materials must be reviewed and considered in order for stakeholders to provide constructive feedback.

Members of Kentucky/Tennessee Section of American Water Works Association (KY/TN AWWA) are interested in reviewing the proposal and providing feedback to EPA to present our perspectives on the various aspects of the proposed rule, including:

• Water treatment costs associated with PFAS;

• Feasibility to remove PFAS to levels at or below the proposed standards;

• Feasibility for drinking water utilities to implement the proposed rule within the compliance timeline, and the factors influencing the implementation of treatment; and

• Application of the proposed Hazard Index for drinking water regulation, including considerations for risk communication.

KY/TN AWWA respectfully requests an extension of the comment deadline by 59 days to July 28, 2023, to provide a total of 121 days for public comment. Your response by April 20, 2023, is requested as necessary for us to successfully balance available resources to best utilize the requested extension period.

Thank you for your consideration of this request.

Re: Extension request of comment period for Docket ID #: EPA-HQ-OW-2022-0114; PFAS National Primary Drinking Water Regulation Rulemaking

Dear Administrator Regan:

The Southeast Morris County Municipal Utilities Authority (SMCMUA) respectfully asks that, due to the vast complexity of the rule and the effect it will have on our organization, EPA grant at least a 30-day extension to the comment period to ensure useful and meaningful feedback.

A crucial step of the regulatory process is the public comment period. Feedback and recommendations from impacted stakeholders and the regulated community provide a unique perspective that often strengthens and improves a proposed rule. SMCMUA believes it is in the interest of EPA to provide an adequate comment period for such an important and consequential rule. We will be able to provide much more insightful and helpful comments if given the time to review the many pages of documents and supporting materials provided by EPA.

While SMCMUA will be diligently working to provide thoughtful comments on this proposed rule, it is important to remind EPA that this is not the only rulemaking being proposed with an open public comment period that will impact drinking water utilities. Contaminant Candidate List 6, Consumer Confidence Reports, ANPRM for additional PFAS CERCLA designations, and Steam Power ELGs are all in the process, or will be shortly, of soliciting public comments simultaneously with this proposed rule. At the time of the creation of this letter, there are 1,241 supporting or related material provided in the rulemaking docket to review. A condensed period for public comment on this rule only diverts resources from providing robust comments to other notices currently open in the Federal Register.

As part of the regulated community that will be significantly affected by this proposed rulemaking, we will be directly influenced by the significant cost and time this rule will impose on our operations. While SMCMUA understands the importance of finalizing this rule in a timely manner, we believe thoughtful public comments will only strengthen the final rule and ultimately provide more protections for public health. Therefore, we request EPA extend the comment period by at least 30 days. We also ask EPA to respond to this request in a timely manner so comments can be developed with an accurate due date in mind.

SMCMUA appreciates EPA giving this request consideration. If you have any further questions, please contact me at 973-261-4437 or lcummings@smcmua.org.

Sincerely,

Laura Cummings, PE

Executive Director

RE: Request for Extension for Comment Period on EPA's Proposed Per- and

Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation

(Docket ID: EPA-HQ-OW-2022-0114 [Link: https://www.regulations.gov/document/EPA-HQ-OW-2022-0114-0027])

Administrator Regan,

The proposal only provides a public review and comment period of 62 days. At the time this letter is written, the docket contains more 5,000 pages of supporting documentation. These materials must be reviewed and considered in order for stakeholders to provide constructive feedback.

We are interested in reviewing the proposal and providing feedback to the EPA presenting our perspectives on the various aspects of the rule, including:

• Water treatment costs associated with per- and polyfluoroalkyl substances (PFAS);

• Feasibility to remove PFAS to levels at or below the proposed standards;

• Feasibility for drinking water utilities to implement the proposal within the compliance timeline and the factors influencing the implementation of treatment.

• Application of the hazard index for drinking water regulation, including considerations for risk communication.

We respectfully request that EPA provide an extension of the comment deadline by 59 days to July 28, 2023 to provide a total of 121 days for public comment. Your response by April, 14, 2023 is necessary for us to successfully balance available resources to best utilize the requested extension period.

We appreciate your attention to this matter.

Orange County Water District (OCWD), California (Doc. #1495, SBC-042564)

ORANGE COUNTY WATER DISTRICT

April 13, 2023

Michael S. Regan

Administrator

US Environmental Protection Agency

1200 Pennsylvania Avenue, NW

Washington, DC 20460

Via electronic submission

RE: Extension request of comment period for Docket ID #: EPA-HQ-OW-20220114; Proposed PFAS National Primary Drinking Water Regulation

Administrator Regan,

Orange County Water District (OCWD) respectfully asks that, due to the vast complexity of the above referenced proposed regulation and the effect it will have on our organization and service area, EPA grant a 59-day extension to July 28, 2023 to provide a total of 121 days for public comment. The docket contains more than 5,000 pages of supporting documentation and the current proposal only provides a public review and comment period of 61 days.

The public comment period is a crucial step in the regulatory process, especially for a regulation of this magnitude. As a part of the regulated community that will be significantly affected by the proposed rulemaking, we require additional time to review the proposal and provide meaningful feedback to EPA on various aspects of the regulation, including:

* Water treatment costs

* Feasibility for drinking water utilities to implement the proposal

* Application of the Hazard Index for drinking water regulation

OCWD appreciates EPA's consideration of this time extension request.

Michael R. Markus, P.E., D.WRE, BCEE, F.ASCE

Re: Extension request of comment period for Docket ID #: EPA-HQ-OW-2022-0114; PFAS National Primary Drinking Water Regulation Rulemaking

Dear Administrator Regan,

The City of Sacramento Department of Utilities respectfully asks that, due to the vast complexity of the rule and the effect it will have on our organization, EPA grant at least a 30-day extension to the comment period to ensure useful and meaningful feedback.

A crucial step of the regulatory process is the public comment period. Feedback and recommendations from impacted stakeholders and the regulated community provide a unique perspective that often strengthens and improves a proposed rule. The City of Sacramento Department of Utilities believes it is in the interest of EPA to provide an adequate comment period for such an important and consequential rule. We will be able to provide much more insightful and helpful comments if given the time to review the many pages of documents and supporting materials provided by EPA.

While the City of Sacramento Department of Utilities will be diligently working to provide thoughtful comments on this proposed rule, it is important to remind EPA that this is not the only rulemaking being proposed with an open public comment period that will impact drinking water utilities. Contaminant Candidate List 6, Consumer Confidence Reports, ANPRM for additional PFAS CERCLA designations, and Steam Power ELGs are all in the process, or will be shortly, of soliciting public comments simultaneously with this proposed rule. At the time of the creation of this letter, there are 1,241 supporting or related materials provided in the rulemaking docket to review. A condensed period for public comment on this rule only diverts resources from providing robust comments to other notices currently open in the Federal Register.

As part of the regulated community that will be significantly affected by this proposed rulemaking, we will be directly influenced by the significant cost and time this rule will impose on our operations. While the City of Sacramento Department of Utilities understands the importance of finalizing this rule in a timely manner, we believe thoughtful public comments will only strengthen the final rule and ultimately provide more protections for public health. Therefore, we request EPA extend the comment period by at least 30 days. We also ask EPA to respond to this request in a timely manner so comments can be developed with an accurate due date in mind.

The City of Sacramento Department of Utilities appreciates EPA giving this request consideration. If you have any further questions, please contact Brian Sanders, Program Specialist, Governments Affairs, City of Sacramento Department of Utilities at bsanders@cityofsacramento.org.

Sincerely,

Sherill Huun

PFAS Regulatory Coalition (Doc. #1501, SBC-042570)

Attached on behalf of the PFAS Regulatory Coalition is a request for extension of the comment period on the EPA Proposed PFAS National Primary Drinking Water Regulation Rulemaking. Please feel free to call or e-mail if you have any questions. Thank you.

April 17, 2023

Ms. Alexis Lan

Office of Ground Water and Drinking Water

Standards and Risk Management Division (Mail Code 4607M) U.S. Environmental Protection Agency 1200 N. Pennsylvania Avenue, N.W.

Washington, D.C. 20460

Re: Request for Extension of Comment Period on EPA Proposed PFAS National Primary Drinking Water Regulation Rulemaking Docket ID No. EPA-HQ-OW-2022-0114

Dear Ms. Lan:

The PFAS Regulatory Coalition (the Coalition) requests that the U. S. Environmental Protection Agency (EPA) grant a 60-day extension on the comment period for its proposal, PFAS National Primary Drinking Water Regulation Rulemaking ("the EPA Proposal") (88 Fed. Reg. 18638, Mar. 29, 2023).

The Coalition is a group of industrial companies, municipal entities, agricultural parties, aviation representatives and trade associations, each of which has facilities or members that are directly affected by the development of policies and regulations related to per- and poly-fluoroalkyl substances (PFAS). Coalition membership includes entities in the automobile, airport, coke and coal chemicals, iron and steel, municipal, paper, petroleum, and other sectors. None of the Coalition members manufacture PFAS compounds. Coalition members, for purposes of these comments, include: Airports Council International – North America; American Coke and Coal Chemicals Institute; American Forest and Paper Association; American Fuel and Petrochemical Manufacturers; American Iron and Steel Institute; American Petroleum Institute; Barr Engineering; Brown & Caldwell; City of Pueblo, CO; Gary Sanitary District (IN); HDR; Illinois Association of Wastewater Agencies; National Oilseed Processors Association; Trihydro; and Western States Petroleum Association.

PFAS Regulatory Coalition member entities or their members own and operate facilities located throughout the country. Many of those facilities would incur substantial costs to comply with the new drinking water standards. In addition, these standards would affect other regulatory requirements that are regularly imposed on Coalition members and their operations, including remediation mandates. The Coalition, therefore, has a direct interest in the EPA Proposal.

A 60-day comment period on the EPA Proposal is simply not adequate to allow the PFAS Regulatory Coalition and other stakeholders to review the Agency materials, develop comments, and suggest positive solutions to address the concerns identified in the comments. The Proposal itself takes up 117 pages in the Federal Register, and raises some 59 separate questions on which stakeholders are invited to comment and submit information. Moreover, the supporting technical materials in the docket are voluminous. The docket includes over 1200 separate documents, totaling thousands of pages. It is unreasonable and contrary to the intent of the Administrative Procedure Act to expect impacted members of the public to conduct a careful review of this enormous set of documents in the allotted time, let alone prepare and submit helpful and carefully considered comments on the important issues raised by the EPA Proposal and the supporting materials. That is especially the case given that this Proposal is really two regulatory actions in one document - a regulatory determination as to four PFAS that have not been addressed previously, and proposed standards for PFOA, PFOS, and those four additional substances. The review time should be extended accordingly.

The PFAS Regulatory Coalition, and other regulated party groups that we work with, have commented on many EPA regulatory documents before. It is very unusual for an agency action as important as the EPA Proposal to be subject to a comment period as short as 60 days. There is no statutory or regulatory deadline that compels the Agency to provide such an abbreviated comment period in this situation. Hence, in order for stakeholders to participate in the Agency's process of considering whether the EPA Proposal is appropriate, an extension of the comment period by at least 60 days is needed. Therefore, we request that EPA extend the comment period to July 31, 2023.

The PFAS Regulatory Coalition looks forward to continuing to engage with EPA on the EPA Proposal, including through the filing of comments. Please feel free to call or e-mail if you have any questions, or if you would like any additional information concerning the issues raised in this letter.

U.S. Small Business Administration's Office of Advocacy (Doc. #1505, SBC-042573)

U.S. Small Business Administration's Office of Advocacy's Recommendation to Extend the Comment Period for EPA's Proposed PFAS National Primary Drinking Water Regulation Rulemaking.

April 18, 2023

VIA ELECTRONIC SUBMISSION

The Honorable Michael S. Regan

Administrator

Environmental Protection Agency

Washington, DC 20460

Re: PFAS National Primary Drinking Water Regulation Rulemaking (Docket ID: EPAHQ-OW-2022-0114)

Dear Administrator Regan:

On March 29, 2023, the Environmental Protection Agency (EPA) published a proposed rule titled "PFAS National Primary Drinking Water Regulation Rulemaking."[FN1: 88 Fed. Reg. 18638 (March 29, 2023).] The Office of Advocacy (Advocacy) is concerned that given the complexity and scope of the rule, the current comment period will not be sufficient to allow small entity stakeholders to provide meaningful feedback. Therefore, Advocacy recommends EPA extend the public comment period for this proposed rule by at least 30 days.

I. Background

A. The Office of Advocacy

Congress established the Office of Advocacy under Pub. L. 94-305 to represent the views of small entities before Federal agencies and Congress. Advocacy is an independent office within the U.S. Small Business Administration (SBA). As such, the views expressed by Advocacy do not necessarily reflect the views of the SBA or the Administration. The Regulatory Flexibility Act (RFA), [FN2: 5 U.S.C. §601 et seq.] as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA), [FN3: Pub. L. 104-121, Title II, 110 Stat. 857 (1996) (codified in various sections of 5 U.S.C. §601 et seq.).] gives small entities a voice in the rulemaking process. For all rules that are expected to have a significant economic impact on a substantial number of small entities, the RFA requires federal agencies to assess the impact of the proposed rule on small entities and to consider less burdensome alternatives.

The Small Business Jobs Act of 2010 requires agencies to give every appropriate consideration to comments provided by Advocacy. [FN4: Small Business Jobs Act of 2010 (PL. 111-240) §1601] The agency must include a response to these written comments in any explanation or discussion accompanying the final rule's publication in the Federal Register, unless the agency certifies that the public interest is not served by doing so. [FN5: Id.]

Advocacy's comments are consistent with Congressional intent underlying the RFA, that "[w]hen adopting regulations to protect the health, safety, and economic welfare of the nation, federal agencies should seek to achieve statutory goals as effectively and efficiently as possible without imposing unnecessary burdens on the public." [FN6: Id.]

B. The Proposed Rule

On March 29, 2023, EPA published its proposed National Primary Drinking Water Regulation (NPDWR) rulemaking, which includes the following per- and polyfluoroalkyl substances (PFAS):

• perfluorooctanoic acid (PFOA)

• perfluorooctane sulfonic acid (PFOS)

• perfluorohexane sulfonic acid (PFHxS)

• hexafluoropropylene oxide dimer acid (HFPO-DA) and its ammonium salt (also known as a GenX chemicals)

• perfluorononanoic acid (PFNA)

• perfluorobutane sulfonic acid (PFBS)

The proposed rule requires public water systems to monitor for these PFAS, notify the public of the levels of these PFAS, and reduce the levels of these PFAS in drinking water if they exceed the proposed standards. Reduction methods can include the installation of and disposal of PFAS residue from treatment technologies such as granular activated carbon, anion exchange, nanofiltration and reverse osmosis or switching to an alternative water source.

The proposal contains several agency actions:

1. Proposed legally enforceable levels, called Maximum Contaminant Levels (MCLs), for PFOA and PFOS at 4 parts per trillion (ppt).

2. Proposed preliminary determination to regulate PFHxS, GenX chemicals, PFNA and PFBS, and mixtures of these PFAS.

3. Proposed MCLs for the above four PFAS at a unitless MCL of 1.0, based on a novel approach called a hazard index, which is used to evaluate potential health risks from exposure to chemical mixtures.

4. Proposed health-based, non-enforceable Maximum Contaminant Level Goals (MCLGs) for these six PFAS. For PFOA and PFOS, the proposed MCLG is zero and for the PFAS mixture the agency proposes the same unitless 1.0 hazard index.

In advance of the proposed rule, EPA convened a SBREFA panel to consult with small entity representatives (SERs). EPA presented to the small entities some PFAS background (with only PFOA and PFOS specifically identified) and potential monitoring and reporting rule compliance considerations and treatment and feasibility considerations. EPA, however, did not provide the SERs with the identity of the other four PFAS, any MCL values, any MCLG values and the technical details and analyses supporting these additional elements.

II. Recommendation for Extension of the Public Comment Period

EPA's current comment deadline for May 30, 2023, provides stakeholders with only 62 days to review its proposed actions, and over 1,000 supporting materials replete with complex and technical analyses. The rule is expected to impose a costly regulatory burden on small entities such as small public water systems. Therefore, Advocacy urges EPA to extend this public comment period by at least 30 additional days to allow for a meaningful review of this important and consequential proposed rulemaking package.

Small entities and their representatives have expressed concerns about their ability to provide constructive feedback given the scope and complexity of the proposal. Small entities are usually constrained due to their limited resources. Adding the responsibility to review this proposal and its supporting materials within just two months may limit a small entity's ability to express their concerns and provide useful feedback. Based on our initial outreach, small entities are gravely concerned about the substantial compliance costs associated with the rule, especially in light of the low levels proposed for the MCLs.

EPA has received extension requests from trade associations representing the interests of large and small public water systems. Among this group is the Association of State Drinking Water Administrators (ASDWA), an organization that represents EPA's co-regulators in implementing the NPDWR. EPA also conducted outreach with this group in developing the proposal. In its request for additional time, ASDWA cautions EPA that "an expeditious schedule should not come at the expense of obtaining meaningful engagement with stakeholders."[FN7: Letter from the Association of State Drinking Water Administrators to the Environmental Protection Agency, (March 29, 2023), Request for Comment Period Extension for Proposed PFAS National Primary Drinking Water Regulation (NPDWR), Docket ID: EPA-HQ-OW-2022-0114-1469. [Link: https://www.regulations.gov/comment/EPA-HQ-OW-2022-0114-1469]] Advocacy agrees.

At least a 30-day extension of the public comment period will allow small entities the additional time needed to provide useful and important feedback to ensure that the finalized rule can be effectively implemented and lead to successful compliance.

III. Conclusion

Advocacy urges EPA to extend the public comment period by at least 30 days to allow for small entities to participate more meaningfully in this rulemaking process. Such an extension will help small entities provide more comprehensive and detailed comments on this important rulemaking.

If you have any questions or require additional information, please contact me or Assistant Chief Counsel Tayyaba Zeb at (202) 798-7405 or by email at tayyaba.zeb@sba.gov.

Lehigh County Authority (LCA) (Doc. #1507, SBC-042579)

April 19, 2023

Michael S. Regan, Administrator

U.S. Environmental Protection Agency

1200 Pennsylvania Avenue, NW

Mail Code: 4607M

Washington, DC 20460

Re: Request for Extension of the Comment Period on EPA's Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (Docket ID: EPA-HW-OW-2022-0114)

Dear Administrator Regan,

Lehigh County Authority (LCA) requests that the U.S. Environmental Protection Agency (EPA) provide a 60-day extension of the comment deadline for the proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (Docket ID: EPA-HW-OW-20220114). Further, we request that a decision on the comment deadline extension be announced as soon as possible, and at least by April 30, 2023, so that water utilities and other stakeholders have adequate notice and can properly allocate their resources toward reviewing this important proposed regulation.

An extension of the comment period is important to LCA and many other water utilities across the nation, as we consider the impact of this proposed regulation and review the approximately 5,000 pages of supporting documents that accompany it. The proposed rule includes many new components that have not been used in prior regulations, and they must be carefully considered

and understood before we can comment on them. For example, the "hazard index" approach is a novel idea that must be carefully examined.

LCA provides high-quality, reliable water service to more than 200,000 people in eastern Pennsylvania. Our community will be impacted by this regulation if it is finalized as proposed. We believe it is worth a little extra time to allow stakeholders like LCA to review the details of what is proposed and provide meaningful input.

LCA appreciates your attention to this matter. If you have any questions about this letter, please contact me at LieselGross@LehighCountyAuthority.org.

Sincerely,

Liesel M. Gross

Chief Executive Officer

Re: Request for Time Extension of Public Comment Period on "PFAS National Primary Drinking Water Regulation Rulemaking"; Docket ID No. EPA-HQ-OW-2022-0114

Dear Ms. Lan:

The National Ground Water Association (NGWA) respectfully asks for a time extension in the review of and comment on the proposed rule to set maximum contaminant levels for perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS) as contaminants and regulate perfluorohexane sulfonic acid (PFHxS), hexafluoropropylene oxide dimer acid (HFPODA) and its ammonium salt (also known as a GenX chemicals), perfluorononanoic acid (PFNA), and perfluorobutane sulfonic acid (PFBS), and mixtures of these PFAS as contaminants under Safe Drinking Water Act (SDWA) through use of a hazard index. We appreciate the Environmental Protection Agency's (EPA) focus on acting expeditiously to protect public health. The regulation of PFOA and PFOS with MCLs and the other PFAS using a hazard index has implications for the implementation of many other statutes, including but limited to the Resource, Conservation and Recovery Act; Comprehensive Environmental Response, Compensation and Liability Act; Clean Water Act; Federal Insecticide, Fungicide and Rodenticide Act; Toxic Substances Control Act; and other statutes that regulate chemicals in the environment that affect public health, we encourage you to consider an extension of review for this proposed rule by 59 days to July 28, 2023.

EPA has provided extensive amount of information that NGWA members desiring to comment will need this time to review and evaluate before providing comments. In particular, time to consider significant data and documentation in the following three areas would be important to their review:

• Analysis of the occurrence of these contaminants along with understanding the complex statistical approach utilized and applied to the national occurrence database that amalgamates previously collected data obtained through the Unregulated Contaminant Monitoring Rule process with state datasets.

• Development and application of a hazard index in place of a maximum contaminant level.

• The relation of the MCLs to other substantial work carried out by the groundwater industry in applying science and engineering to protect the public and remediate the environment.

NGWA, the largest trade association and professional society of groundwater professionals in the world, represents over 10,000 groundwater professionals within the United States and internationally. NGWA represents four key sectors: scientists and engineers; water-well contractors; the groundwater equipment manufacturers; and equipment suppliers. NGWA's mission is to advocate for and support the responsible development, management, and use of groundwater. Groundwater is an essential life-sustaining good that public policy should enable to be provided safely and adequately.

In providing additional time for review of this proposed rule, EPA would be enabling the affected public and industry stakeholders to assist the Agency with an improved outcome. The review time extension would allow fuller consideration of the substantial intertwined connections with and effects on other statutes and their regulatory implementation.

Thank you for considering our request. NGWA looks forward to working with EPA as a partner in providing safe water supply to residential, commercial and agricultural consumers. For further follow up to this letter, please contact Chuck Job, NGWA Regulatory Affairs Manager, at cjob@ngwa.org.

Sincerely,

Terry S. Morse, CAE, CIC

Chief Executive Officer

National Ground Water Association

Washington, DC 20460

RE: Request for Extension for Comment Period on EPA's Proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation (Docket ID: EPA-HQ-OW-2022-0114)

Administrator Regan,

Oregon Water Utilities Council (OWUC) is a local affiliation of the American Water Works Association, and we represent nearly 75% of public drinking water providers across the state of Oregon, both small and large, rural, and urban.

The EPA's proposed regulation provides a public review and comment period of only 62 days. At the time this letter is written, the docket contains more than 5,000 pages of supporting documentation. These materials must be properly reviewed and considered in order for stakeholders to provide constructive feedback.

We are interested in reviewing the proposal and providing feedback to the EPA presenting our perspectives on the various aspects of the rule, including:

• Water treatment costs associated with per- and polyfluoroalkyl substances (PFAS).

• Feasibility to remove PFAS to levels at or below the proposed standards.

• Feasibility for drinking water utilities to implement the proposal within the compliance timeline and the factors influencing the implementation of treatment.

• Application of the hazard index for drinking water regulation, including considerations for risk communication.

We respectfully request that EPA provide an extension of the comment deadline by 59 days to July 28, 2023, to provide a total of 121 days of public comment. Your response by May 1, 2023, is necessary for us to successfully balance available resources to best utilize the requested extension period.

We appreciate your attention to this matter.

Sincerely,

Jessica Dorsey

Oregon Water Utilities Council, Chair

City of Hillsboro-Water Department

U.S. Chamber of Commerce (Doc. #1537, SBC-042643)

Statement on the Proposed Maximum Contaminant Limit (MCL) for PFOA and PFOS

EPA Public Hearing

May 4, 2023

My name is Chuck Chaitovitz, and I am Vice President of Environmental Affairs and Sustainability at the U.S. Chamber of Commerce ("Chamber"). The Chamber appreciates the opportunity to provide input today on the important role of the Safe Drinking Water Act (SDWA) in ensuring sustainable supplies of clean, safe drinking water in communities across our nation. Thank you to EPA for providing this very helpful briefing and public discussion.

We are pleased to be here on behalf of our member companies, trade associations, and state and local chambers, which span key U.S. supply chains using PFAS chemistries, and whose products and technologies are essential to America's economic growth, water infrastructure, and national security. The Chamber is leading a coalition of companies, trades, and other stakeholders who are committed to managing PFAS safely and protecting human health and the environment.

I would like to note that our coalition requested a modest extension of the comment period, which we believe EPA should grant given the length and complexity of the proposed MCL for PFOA and PFOS rule. This request stated that "EPA's proposal sets forth 59 specific questions for comment and provides more than 3,000 pages of very technical and complex information on the scientific basis, costs, and impacts for implementing these standards. This page count does not include even further additional technical supporting information that EPA made available in the docket on March 29, 2023. There are some 1,271 supporting documents included in the docket, which are not organized in a searchable or clear fashion." Without additional time, it will be impossible to conduct a thorough review of the scientific and technical information which underlies EPA's extensive proposal.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

City of Vancouver, Washington (Doc. #1543, SBC-042664)

May 8, 2023

Michael S. Regan

Administrator Environmental Protection Agency

1200 Pennsylvania Avenue, N. W.

Mail Code: 4607M

Washington, DC 20460

RE: Request for Extension for Comment Period on EPA's Proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation (Docket ID: EPA-HQ-OW-2022-0114)

Administrator Regan,

The City of Vancouver is the third largest provider of drinking water in the State of Washington.

The EPA's proposed regulation only provides a public review and comment period of 62 days. At the time this letter is written, the docket contains more 5,000 pages of supporting documentation. These materials must be reviewed and considered in order for stakeholders to provide constructive feedback.

We are interested in reviewing the proposal and providing feedback to the EPA presenting our perspectives on the various aspects of the rule, including:

• Water treatment costs associated with PFAS;

• Feasibility to remove PFAS to levels at or below the proposed standards;

• Feasibility for drinking water utilities to implement the proposal within the compliance timeline and the factors influencing the implementation of treatment.

• Application of the hazard index for drinking water regulation, including considerations for risk communication.

While the City of Vancouver understands the importance of finalizing this rule in a timely manner, we believe thoughtful public comments will only strengthen the final rule and ultimately provide more protections for public health.

We respectfully request that EPA provide an extension of the comment deadline by 59 days to July 28, 2023 to provide a total of 121 days for public comment. Your immediate response is necessary for us to successfully balance available resources to best utilize the requested extension period.

Thank you for your consideration of these comments.

Sincerely,

Tyler Clary, P.E., WDM4

Water Engineering Program Manager

City of Vancouver

North American Meat Institute (NAMI) (Doc. #1547, SBC-042680)

May 11, 2023

Alexis Lan

Office of Ground Water and Drinking Water

Standards and Risk Management Division

(Mail Code 4607M)

Environmental Protection Agency

1200 Pennsylvania Avenue NW

Washington, DC 20460

Re – Request for Extension of the Comment Period; PFAS National Primary Drinking Water Regulation Rulemaking; Preliminary Regulatory Determination and Proposed Rule; Request for Public Comment; Notice of Public Hearing; EPA–HQ–OW–2022–0114; FRL 8543–01–OW.

Dear Ms. Lan:

The North American Meat Institute (NAMI or the Meat Institute) submits this request for a 90-day extension of the comment period in the above-referenced proposed rule and request for public comments (proposal). The Meat Institute is the nation's oldest and largest trade association representing packers and processors of beef, pork, lamb, veal, turkey, and processed meat products and NAMI member companies account for more than 95 percent of United States output of these products. The Meat Institute provides regulatory, scientific, legislative, public relations, and educational services to the meat and poultry packing and processing industry.

The proposal is broad, raising numerous questions and seeking input on an array of complicated topics of interest to the meat industry and the food industry more generally. Indeed, the proposal specifically references food when discussing vectors for exposure to PFAS. [FN-1: 88 Fed. Reg. 18638 (March 29, 202).] Given the interrelationship and impact of the Environmental Protection Agency's regulations with those of other federal, state, and local agencies, to enable the Meat Institute and others to speak effectively and in a constructive manner requires additional time.

* * * * *

For the reason discussed above NAMI requests a 90-day extension of the comment period in the above-referenced docket. Thank you for your consideration.

Respectfully submitted,

Mark Dopp

Chief Operating Officer and General Counsel

North American Meat Institute

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Arizona Corporation Commission (ACC) (Doc. #1552, SBC-042701)

Arizona Corporation Commission's request for an extension of time to file comments

BEFORE THE UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

PFAS National Primary)

Drinking Water) Docket No. EPA–HQ–OW–2022–0114

Regulation Rulemaking)

REQUEST FOR AN EXTENSION OF TIME TO FILE COMMENTS OF THE ARIZONA CORPORATION COMMISSION

The Arizona Corporation Commission ("ACC") respectfully requests an extension of the deadline to file comments by 59 days to July 28, 2023. This extension would provide a total of 121 days for public comment. Currently, the comment period for the Environmental Protection Agency's ("EPA") proposed per- and polyfluoroalkyl substances ("PFAS") drinking water regulation is only 62 days long.

The ACC is the state regulatory body responsible for the regulation of Arizona's public utilities. The ACC is constitutionally entrusted to set just and reasonable rates for public service corporations, including water utilities that will be impacted by the EPA's proposed PFAS drinking water regulation. In this respect, the ACC intends to review the proposed regulation and provide feedback on various aspects of the proposal, including but not limited to:

• Water treatment costs that will result from the proposed rule and impacts to ratepayers

• Cost and feasibility of implementing the proposal within the compliance timeline

• Availability of waivers or extensions of time to come into compliance for utilities unable to meet the compliance timeline

• Funding available to assist utilities in complying with the proposed rule

As the docket contains over 5,000 pages of supporting documentation, the requested 59-day extension of time to July 28, 2023, will enable the ACC to effectively review the documents and provide constructive comments. The ACC respectfully requests an expedited response to its request for an extension of time to file comments.

RESPECTFULLY submitted this 12th day of May, 2023.

/s/ Kathryn M. Ust

Kathryn M. Ust, Staff Attorney

GFL Environmental (Doc. #1565, SBC-042502)

May 22, 2023

Michael S. Regan

Administrator

U.S. Environmental Protection Agency

1200 Pennsylvania Avenue NW

Mail Code: 4607M

Washington, DC 20460

SUBMITTED ELECTRONICALLY

RE: DOCKET ID NO. EPA-HQ-OW-2022-0114, REQUEST FOR TIME EXTENSION OF PUBLIC COMMENT PERIOD ON THE "PER- AND POLYFLUOROALKYL SUBSTANCES (PFAS) NATIONAL PRIMARY DRINKING WATER REGULATION RULEMAKING"

Dear Administrator Regan,

GFL Environmental (GFL) submits this request for extension of the public comment period for the Proposed PFAS National Primary Drinking Water Regulation (EPA-HQ-OW-2022-0114). GFL requests that the US Environmental Protection Agency (EPA) grant a 60-day extension on the comment period for its proposal.

At the time of writing this letter, there are over 1440 documents including more than 5,000 pages of supporting documentation. GFL requests the extension to ensure all public comments can be formulated thoughtfully and thoroughly and are based on effective review of the proposal and supporting documentation. A 60-day public review period is inadequate.

We appreciate the efforts of EPA to address PFAS and protect human health and the environment and share the goal of holding entities accountable that are primary manufacturers

and users of PFAS. If you have further questions, please contact Selin Hoboy at 847-456-8889 or via email at shoboy@gflenv.com .

Sincerely,

GFL Environmental

Selin Hoboy

Vice President, Environmental Health, Safety and Compliance

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

National Association of Regulatory Utility Commissioners (NARUC) (Doc. #1566, SBC-042501)

National Association of Regulatory Utility Commissioners' Request for 60-Day Extension of Comment Period on EPA's proposed Per-and Polyfluoroalkyl Substances National Primary Drinking Water Regulation Rulemaking, 88 Fed. Reg. 18638 (March 29, 2023) Docket ID No. EPA-HQ-OW-2022-0114, FRL 8543-01-OW. See attached file.

May 22, 2023

By Electronic Submission to http://www.regulations.gov/

Michael S. Regan, Administrator

U.S. Environmental Protection Agency 1200 Pennsylvania Avenue, N.W.

Mail Code: 1101A

Washington, DC 20460

Re: Request for 60-Day Extension of Comment Period on EPA's proposed Per-and Polyfluoroalkyl Substances National Primary Drinking Water Regulation Rulemaking, 88 Fed. Reg. 18638 (March 29, 2023) Docket ID No. EPA-HQ-OW-2022-0114, FRL 8543-01-OW.

Dear Administrator Regan:

The National Association of Regulatory Utility Commissioners (NARUC) is concerned by issues raised in the above referenced proposed rule – which proposes National Primary Drinking Water Regulation (NPDWR) and health-based Maximum Contaminant Level Goals (MCLG) for several PFAS compounds.

NARUC is a quasi-governmental nonprofit organization founded in 1889. For the last 130 years, NARUC has represented the interests of public utility commissioners from regulatory agencies in fifty States, the District of Columbia, Puerto Rico, and the Virgin Islands. NARUC's member commissions include the State agencies engaged in the economic, rate, safety and the reliability

regulation of public utilities that provide water electricity and natural gas services. These State officials have the obligation under State law to assure the establishment and maintenance of such water utility services as may be required by the public convenience and necessity, and to ensure that such services are provided at rates and conditions that are just, reasonable and nondiscriminatory.

NARUC is also a partner in EPA's Watersense program and as a member of EPA's "Water Infrastructure and Cyber Resilience Division Partners" Group and the Water sector Government Coordinating Council. Congress references NARUC as "the national organization of the State commissions" responsible for economic and safety regulation of the intrastate operation of carriers and utilities. [FN1: 1 Communications Act of 1934, as amended by the Telecommunications Act of 1996, 47 U.S.C. §151 et seq., Pub. L. No. 101-104, 110 Stat. 56 (1996). See 47 U.S.C. §410(c) (1971) (NARUC nominates members to Federal-State boards which consider universal service, separations, and other issues and provide recommendations the FCC must act upon.); Cf. 47 U.S.C. § 254 (1996) (describing the universal service board's functions). See also, NARUC, et al. v. ICC, 41 F.3d 721 (D.C. Cir 1994) ("[c]arriers, to get the cards, applied to [NARUC], an interstate umbrella organization that, as envisioned by Congress, played a role in drafting the regulations that the ICC issued.")] Both Congress and the courts [FN2: 2 See United States v. Southern Motor Carrier Rate Conference, Inc., 467 F. Supp. 471 (N.D. Ga. 1979), aff'd 672 F.2d 469 (5th Cir. 1982), aff'd en banc on reh'g, 702 F.2d 532 (5th Cir. 1983), rev'd on other grounds, 471 U.S. 48 (1985); (where the Supreme Court notes: "The District Court permitted (NARUC) to intervene as a defendant. Throughout this litigation, the NARUC has represented the interests of the Public Service Commissions of those States in which the defendant rate bureaus operate." 471 U.S. 52, n. 10. See also, Indianapolis Power and Light Co. v. ICC, 587 F.2d 1098 (7th Cir. 1982); Washington Utilities and Transportation Commission v. FCC, 513 F.2d 1142 (9th Cir. 1976); Compare, NARUC v. FERC, 475 F.3d 1277 (D.C. Cir. 2007); NARUC v. DOE, 851 F.2d 1424, 1425 (D.C. Cir. 1988); NARUC v. FCC, 737 F.2d 1095 (D.C. Cir. 1984), cert. denied, 469 U.S. 1227 (1985)] have consistently recognized NARUC as a proper entity to represent the generic interests of every State's utility commission.

The posted EPA proposal only provided about 6o days for comments. So far, the current docket appears to contain thousands of pages of supporting documentation. Those materials must be reviewed and considered for stakeholders to provide constructive feedback. That review would be challenging if each state commentor had several expert staff to look at them. But for almost all NARUC member commissions, that is not the case. State commissions have limited staff resources that have multiple responsibilities in addition to advising Commissions on how to respond to this rulemaking.

Several NARUC members are interested in reviewing the proposal and providing feedback to the EPA presenting our perspectives on the various aspects of the rule, including (i) Water treatment costs associated with per- and polyfluoroalkyl substances (PFAS) and their potential impact on rates; (ii) Practical ability of utilities to remove PFAS to levels at or below the proposed

standards; and (iii) Practical ability of drinking water utilities to implement the proposal within the compliance timeline.

We have been specifically requested by those members to seek additional time to formulate their comments. Given NARUC members crucial role in the oversight of drinking water and water treatment facilities, their input will be a valuable addition to the record in this proceeding. No other interested commenter is likely to be prejudiced by a two-month extension.

Accordingly, NARUC respectfully requests that EPA provide an extension of the comment deadline by 60 days to July 28, 2023, to provide a total of 121 days for public comment.

Respectfully submitted.

/s/ Brad Ramsay

James Bradford Ramsay

NARUC General Counsel

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1465, SBC-042300 in section 17.1 in this *Response to Comments* document.

New Hampshire Water Works Association, Inc. (NHWWA) (Doc. #1576, SBC-042457)

The sixty (60) day comment period for a rulemaking of this magnitude and impact is insufficient and unreasonable. Given the complexity and potential costs to deal with PFAS at a national level, and the thousands of pages of supporting documents provided by EPA, additional response time is required to coordinate our shared resources to meet this national challenge.

Our Association and professional drinking water partners are committed to meeting health-based standards developed using sound science and proven technologies. We understand there is increasing public awareness and concern about PFAS chemicals and encourage EPA to follow its traditional thoughtful and thorough approach to promulgating national standards for PFAS in drinking water.

Thank you for considering our comments. Please do not hesitate to contact us if you should have any questions.

Sincerely,

Boyd Smith, President and CEO

Cc: Senators Shaheen and Hassan, Representatives Kuster and Pappas

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Security Water District, Security Water and Sanitation Districts/Enterprises (Doc. #1587, SBC-042785)

Furthermore, we believe that an extended comment period will result in a better rule. Stakeholders have not had sufficient time to fully research and develop comments.

Once again, thank you for the opportunity to comment on the proposed PFAS rule. We sincerely appreciate the time and effort that has been devoted by all parties involved in this rulemaking.

Sincerely,

Security Water and Sanitation Districts

Roy E. Heald, General Manager

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044121)

May 30, 2023

U.S. Environmental Protection Agency EPA Docket Center

Docket ID No. EPA-HQ-OW-2022-0114

Mail Code 28221T

1200 Pennsylvania Avenue, NW

Washington, DC 20460

Re: Docket ID No. EPA-HQ-OW-2022-0114, Comments on the Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

Dear Sir or Madam:

The Texas Commission on Environmental Quality (TCEQ) is providing the enclosed comments regarding the Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation, Docket ID No. EPA-HQ-OW-2022-0114, as requested by May 30, 2023.

It is our understanding the U.S. Environmental Protection Agency (EPA) will not be extending the comment period for this proposed rulemaking even after numerous requests from stakeholders to do so. The proposed rule will impact more than 5,500 public water systems in Texas and will necessitate significant resources for both primacy agencies and regulated entities to implement the rule after it becomes effective. Conducting a thorough and comprehensive review of this proposed rulemaking, which is complex and includes nearly 1,200 supporting documents in 62 days in addition to reviewing several other simultaneously open comment period EPA rulemakings, is not feasible.

It is vitally important that primacy agencies and other stakeholders are given adequate time to evaluate proposed rulemakings to be able to provide comprehensive comments and request clarification prior to the closing of public comment periods. We realize EPA is on an expedited schedule to establish a regulation, but it should not negate the importance of meaningful input from stakeholders which will only strengthen the final rule and ultimately provide more protections for public health.

If you have any questions concerning the enclosed comments, please contact Ms. Michele Risko, Water Supply Division Deputy Director, at (512) 239-1689 or michele.risko@tceq.texas.gov.

Sincerely,

Erin E. Chancellor, Interim Executive Director Texas Commission on Environmental Quality

Enclosure

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Association of Environmental Authorities (AEA) (Doc. #1635, SBC-042966)

It is unfortunate that the EPA has denied requests to extend the comment period. The NPDWR has far-reaching implications. We agree with others who have commented that the May 30 deadline does not allow sufficient time for fully understanding them and bringing them to the attention of the EPA.

Very truly,

Peggy Gallos

Executive Director,

Association of Environmental Authorities

2333 Whitehorse-Mercerville Road, Suite 2,

Mercerville, NJ 08848

Cc: AEA Board and AEA Legislative Committee

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044357)

Michael S. Regan Administrator

Environmental Protection Agency

1200 Pennsylvania Avenue NW

Mail Code: 4607M

Washington, DC, 20460

Re: Comments on EPA's Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulations (Docket ID: EPA-HQ-OW2022-0114)

Dear Administrator Regan,

We are pleased to have the opportunity to provide comments on EPA's proposed per- and polyfluoroalkyl substances (PFAS) National Primary Drinking Water Regulations (NPDWR). As professional engineers working in the drinking water sector, regulation of PFAS in drinking water is a significant concern for us. Both commenters who compiled this letter, Aidan Cecchetti and Scott Miller, are regulatory engineers tasked with enforcement of the Safe Drinking Water Act (SDWA) for the primacy agency of the State of California, the California State Water Resources Control Board. Drs. Cecchetti and Miller both have conducted doctorate-level research on water quality engineering with experience related to contaminant removal processes and analytical chemistry. We provide this background information and a description of our professional affiliations as context for EPA's reviewers to understand how our comments are informed by our experience in the water sector and expertise on this specific topic. The comments contained within this letter are solely those of the named parties and do not represent official position statements for the California State Water Resources Control Board.

Before providing feedback on the requests for comments that EPA included in Docket ID: EPA-HQ-OW-2022-0114 for the proposed PFAS NPDWR, we want to provide support for and concurrence with AWWA's request for an extension of the comment period on this critical new regulation. As described in AWWA's letter, the docket for EPA's proposed PFAS NPDWR includes 5000+ pages of documentation, making it impossible for individuals and organizations alike to conduct the depth of review required to provide constructive feedback on the regulation within the 62-day comment period. For the time being, we have limited our review to topics with which we have relevant expertise. Should EPA choose to extend the public comment period, we will consider conducting review on additional topics and providing further comments in a separate follow-up letter.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

National Chicken Council (NCC) (Doc. #1649, SBC-043216)

May 30, 2023

[Submitted electronically via Regulations.gov]

Administrator Regan

Agency Administrator

United States Environmental Protection Agency

EPA Docket Center

WJC West Building, Room 3334

1301 Constitution Avenue NW

Washington D.C. 20004

Re: Docket No. EPA-HQ-OW-2022-0114: PFAS National Primary Drinking Water Regulation Rulemaking

Dear Administrator Regan:

The National Chicken Council (NCC) appreciates the opportunity to comment on the Environmental Protection Agency's ("EPA" or "the Agency") preliminary regulatory determination and proposed rule, "PFAS National Primary Drinking Water Regulation Rulemaking," EPA-HGOW-2022-0114, RIN 2040-AG18, 88 Fed. Reg. 18638 (March 29, 2023) ("the proposed rule"). NCC is the national, non-profit trade association that represents vertically integrated companies that produce and process more than 95 percent of the chicken marketed in the United States and our members will be directly impacted by the proposed rule. As the most consumed protein source in the United States, the chicken industry has significant economic impact, especially in our country's rural communities, and chicken is a critical protein source in nearly every American's diet. The United States chicken industry drives the national and local economies by providing jobs and revenue to communities across the country while also supporting a broad network of chicken farms, ultimately providing opportunities for millions of Americans.

At the outset, NCC is concerned that the short 60-day comment period provides inadequate time for stakeholders to fully assess the proposal and the complicated scientific considerations. NCC therefore requests that the Agency extend the comment period an additional 90 days or reopen the comment period for an extra 90 days to allow stakeholders added time to evaluate and comment on the downstream effects of the proposed rule.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

<u>New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044966)</u>

28. The 60-day time frame for public review and comment does not permit sufficient time to fully analyze the cost estimates, benefits and economic analysis associated with the proposal. The Department is concerned considering the extent to which this proposal shifts the regulatory paradigm.

Again, the State of New York appreciates the leadership of the Administration and the EPA in the preparation of this proposal. We are happy to provide EPA with any data or supporting documentation necessary to finalize the rule and aid implementation.

Sincerely,

Gary Ginsberg, PhD

Director

Center for Environmental Health

New York State Department of Health

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044354)

5. Additional Comments from NHDES

a. Extension of the Public Comment Period. We believe that a longer public comment period will allow for a more thorough and meaningful review of the proposed MCLs and will facilitate a more robust public dialogue on this important issue. Additionally, we have heard concerns from stakeholders that the current 60-day comment period is not sufficient to provide thoughtful and comprehensive comments on the proposed rulemaking. Given the complexities of this issue and the potential impacts of the proposed MCLs, we believe that a 60-day extension of the comment period would be appropriate.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Alabama Water and Wastewater Institute (AWWI) (Doc. #1700, SBC-043507)

May 30, 2023

Michael S. Regan Administrator

Environmental Protection Agency 1200 Pennsylvania Avenue, NW Washington, DC 20460

RE: Comments on EPA's Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (Docket ID: EPA-HQ-OW-2022-0114)

Administrator Regan,

The Alabama Water and Wastewater Institute (AWWI) appreciates the opportunity to review and comment on the proposed per- and polyfluoroalkyl substances (PFAS) national primary drinking water regulations by the United States Environmental Protection Agency (USEPA). AWWI is a statewide association of water and sewer systems and represents the majority of the population in Alabama that receive public water and sewer services. Our organization offers the following comments on behalf of our water and sewer system members in regard to the stringent proposed PFAS national primary drinking water regulation:

• AWWI strongly concurs with the comment submitted by the American Water Works Association (AWWA) requesting an extension of the comment deadline until July 28, 2023. As noted by AWWA, this would provide a total of 121 days for public comment, which is needed given the more than 1,200 supporting documents associated with the proposed PFAS regulation that require review by water and sewer systems.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Florida Section American Water Works Association - Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044481)

May 30, 2023

Mr. Michael Regan, Administrator

TRANSMITTED ELECTRONICALLY

RE: Comments on EPA's Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (88 FR 18638; EPA-HQ-OW-2022 -0114-0027)

Dear Administrator Regan ,

The Florida Section of the American Water Works Association Water Utility Council (FSAWWA WUC) is pleased to submit this letter addressing the Environmental Protection Agency's (EPA's) rulemaking titled "Proposed Designation of PFOA and PFOS as CERCLA Hazardous Substances" (herein referred to as the Proposal).

The FSAWWA's more than 2,800 members include 130 drinking water utilities who collectively supply the world's most precious and number one resource - water - to over 80 percent of the state's population and the millions of visitors to our great state. The FSAWWA WUC is actively engaged with EPA's continued efforts to address the challenges arising from per- and polyfluoroalkyl substances (PFAS) through the PFAS Strategic Roadmap including this Proposal.

We appreciate the opportunity to comment on the proposed rule that is over 250 pages long and the docket contains nearly 1,300 supporting documents (26 of which total 5,000). Due to the voluminous documents, EPA's 61-day restrictive review time made a thorough evaluation infeasible. We were disappointed EPA did not respond to numerous public comment letters (many from our members) to extend the comment period. Thus, the following reflect our initial, high-level comments on the proposed rule that we respectfully ask the U.S. EPA to consider when developing the final rule.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

LSP Association (LSPA) (Doc. #1742, SBC-043595)

Submitted via the Federal eRulemaking Portal: https://www.regulations.gov/

May 30, 2023

Mr. Michael S. Regan, Administrator

U.S. Environmental Protection Agency, EPA Docket Center

Office of Ground Water and Drinking Water Docket, Mail Code 2822IT

1200 Pennsylvania Avenue NW

Washington, DC 20460

Subject:

PFAS National Primary Drinking Water Regulation Rulemaking Docket ID Number: EPA-HQ-OW-2022-0114

To Administrator Regan and the U.S. Environmental Protection Agency:

The LSP Association (LSPA) is the 800-member, non-profit association of Licensed Site Professionals (LSPs) and related practitioners in the Commonwealth of Massachusetts. LSPs are the scientists, engineers, and public health specialists licensed by the Commonwealth to work on behalf of property owners, operators, and other involved parties to oversee the assessment and cleanup of oil and hazardous materials released to the environment - including per- and polyfluoroalkyl substances (PFAS). With the Massachusetts Department of Environmental Protection (MassDEP) and the Board of Registration of Hazardous Waste Site Cleanup

Professionals (LSP Board of Registration), LSPs are the third "arm" of an innovative, privatized program created in 1993. The program has proven to be highly successful. LSPs have overseen the cleanup of over 45,000 sites in the past 30 years; they work with their government, non-profit, institutional, and private clients to remediate contaminated sites, so that these properties can be placed back into active and productive use.

The LSPA is keenly aware of the complex issues associated with PFAS; many of our members have been involved in the evaluation of PFAS in public and private water supplies, the investigation of potential sources of PFAS in the environment, and the remediation of PFAS sites. We are familiar with the challenges these persistent and widespread environmental contaminants present for both assessment and the identification of feasible cleanup options that are protective of human health and the environment.

MassDEP's hazardous waste site cleanup regulations, known as the Massachusetts Contingency Plan or MCP (310 CMR 40.0000, et seq.), were amended in December 2019 with newly promulgated stringent numeric cleanup standards for PFAS in soils and groundwater. One year later, MassDEP also established Maximum Contaminant Levels in drinking water for six PFAS contaminants. LSPA members interact closely with MassDEP as they work to identify the source and extent of PFAS contamination, to conduct cleanup actions, and to monitor exposure pathways that pose risks to public health and the environment. We all understand that the urgency and impacts from PFAS are real and significant and, as indicated by their informal "forever" nickname, persistent.

While this letter provides LSPA's comments in accordance with the May 30, 2023 deadline imposed on comments on the proposed National Primary Drinking Water Regulation (NPDWR) under Docket ID: EPA-HQ-OW-2022-0114, we note that, with more time, the LSPA could provide additional insight and suggestions to further refine the regulation. While it appears that USEPA is not planning to extend the comment deadline, we encourage USEPA to solicit public comment once again on a subsequent revised version of the NPDWR before the rules are finalized.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043903)

May 30, 2023

Michael S. Regan, Administrator Environmental Protection Agency 1200 Pennsylvania Avenue, N.W. Mail Code:4607M

Washington, DC, 20460

Subject: Comments for PFAS National Primary Drinking Water Regulation Rulemaking (Docket ID No. EPA-HQ-OW-2022-0114)

Dear Mr. Regan,

Due to the short duration (62 Days) of the proposed PFAS Drinking Water Regulation Comment Period and the volume of documentation associated with the Rulemaking, Las Cruces Utilities (LCU) respectfully requests that the EPA provide an extension of the comment period by at least an additional 59 Days to July 28, 2023. While LCU supports EPA rulemaking of water contaminants to protect public health, more time is needed for LCU to thoroughly review the proposed regulations and supporting documents to provide constructive comment. Please consider this request so that more thorough consideration can be made by both citizens and service providers before the rules are finalized.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045573)

Additionally, EPA only provided a 60-day public comment period for review and analysis of the entire proposal, including the occurrence analysis. Additionally, EPA only provided a 60-day public comment period for review and analysis of the entire proposal, including the occurrence analysis. AWWA and numerous additional stakeholders requested an extension of the comment period to support more in-depth of the occurrence analysis and the rule more broadly but the agency declined this request. The comment period is inadequate for reviewing this model and EPA neglects to provide informative sensitivity analyses and to clearly present model assumptions and outputs. In order to fulfill its obligations under the APA, AWWA therefore requests that EPA provide this information during a supplemental comment period prior to finalizing any rule.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1465, SBC-042300 in section 17.1 in this *Response to Comments* document.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045281)

10. EPA should extend the comment period by sixty more days to allow more adequate time to sufficiently respond to the Agency's proposal.

We are grateful that the Agency provided extensive background information to inform the decisions and recommendations included in the proposed regulation. However, the amount of information is overwhelming, and a 60-day review period is inadequate. It is impossible to review and prepare adequate responses to EPA's almost 60 requests for stakeholder comments, more than 3,000 pages of highly technical information, and more than 1,440 technical supporting documents provided for public review. CA-NV AWWA recommends additional EPA

interactions with stakeholders and experts to strike a balance between needs to protect human health in a practical manner that is effectively deployable by public drinking water systems.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Neuse Regional Water and Sewer Authority (Doc. #1822, SBC-044566)

Initially, we note that the Proposed Rulemaking covers 117 Federal Register pages and is accompanied by a huge volume of EPA reference documents. As a public entity, NRWASA has limited resources it can expend on reviewing the Proposed Rulemaking during the relatively short public comment period. We have not been able to fully review and evaluate each of the 59 questions EPA seeks comment on in the Proposed Rulemaking. We encourage EPA to extend the comment period or divide the Proposed Rulemaking into a series of proposed rules that would be sequential and allow more complete review and comment. Nevertheless, NRWASA believes that the Proposed Rulemaking raises four serious concerns that we want to ensure receive comment before the published May 30 deadline.

"NRWASA Is an Equal Opportunity Provider and Employer"

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Plymouth Village Water & Sewer District (Doc. #1827, SBC-044564)

• The sixty (60) day comment period for a rulemaking of this magnitude and impact is insufficient and unreasonable. Given the complexity and potential costs to deal with PFAS at a national level, and the thousands of pages of supporting documents provided by EPA, additional response time is required to coordinate our shared resources to meet this national challenge.

The PVWSD and fellow water system owners, managers, and operators throughout NH are committed to meeting health-based standards developed using sound science and proven technologies. We understand there is increasing public awareness and concern about PFAS chemicals and encourage EPA to follow its traditional thoughtful and thorough approach to promulgating national standards for PFAS in drinking water.

Thank you for considering our comments. Please do not hesitate to contact me if you should have any questions.

Sincerely,

Jason C. Randall

Water & Wastewater Superintendent

Pennsylvania Municipal Authorities Association (Doc. #1832, SBC-045778)

20571-000

May 30, 2023

U.S. Environmental Protection Agency

EPA Docket Center

Office of Ground Water and Drinking Water Docket

Mail Code 2822IT

1200 Pennsylvania Avenue NW

Washington, DC 20460

Re: Docket ID No. EPA-HQ-OW-2022-0114

Proposed PFAS National Primary Drinking Water Regulation Rulemaking

Dear Sir/Madam:

The Pennsylvania Municipal Authorities Association ("PMAA") appreciates the opportunity to submit comments to the Proposed PFAS National Primary Drinking Water Regulation Rulemaking, Docket No. EPA-HQ-OW-2022-0114 ("Proposal"). The Proposal was published in the March 29, 2023 Federal Register, and, consistent with the May 30, 2023 deadline for comments, PMAA respectfully submits the following information and comments for consideration.

By way of background, PMAA is an association that represents the interests of over 700 municipal authorities in Pennsylvania, and these PMAA member municipal authorities collectively provide water, sewer, stormwater, waste management and other services to over five million Pennsylvania citizens (also referred to herein as "municipal entities" or "PMAA member authorities"). Founded in 1941, the mission of PMAA is to assist authorities in providing services that protect and enhance the environment, promote economic vitality, and further the

general welfare of the Commonwealth and its citizens. PMAA and its member municipal authorities, who are stewards of the environment, strive to provide the highest quality services to their customers and ratepayers. Many of PMAA member municipal authorities will be impacted by EPA's ultimate decision on the aforementioned Proposal.

PMAA's specific comments on the Proposal are as follows:

1. PMAA understands and appreciates EPA's desire to expeditiously finalize a regulation addressing PFAS chemicals, and agrees that the protection of human health and the environment is of paramount importance. However, PMAA agrees with a number of previously filed comments requesting an extension of time to file substantive comments to the Proposal. The Proposal is complex and presents many issues that the regulated community has never had to address (e.g. a Hazard Index for a Safe Drinking Water Act initiative). Moreover, there are over 5000 pages of supporting documentation that need to be reviewed in order to provide thoughtful and comprehensive comments on a number of issues related to the Proposal. Indeed, EPA had advised the public through its PFAS Strategic Roadmap that the Proposal would be published in the Fall of 2022. One can only surmise that the complexity of the Proposal was one reason for the nearly one-half year delay in EPA's issuance of the Proposal. Given its own experience in issuing the Proposal, EPA should not now deny the public a full and fair opportunity to review all of the necessary documentation to provide the aforementioned thoughtful and comprehensive comments to such a novel Proposal. Therefore, EPA should reopen the public comment period to allow for further comments to the Proposal.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1465, SBC-042300 in section 17.1 in this *Response to Comments* document.

City of Boynton Beach, Florida (Doc. #2309, SBC-046319)

Dear Mr. Regan, I am writing to request that the Environmental Protection Agency (EPA) extend the comment deadline for the Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation by 59 days, to July 28, 2023. This extension would provide the public with a total of 121 days to review and comment on the proposed regulation/policy. As you may be aware, this proposed regulation/policy has far-reaching implications and will significantly impact the environment, public health, and the economy. Therefore, the public must have adequate time to review the proposal, consult with stakeholders, and provide informed feedback. Given the complexity of the proposed regulation/policy, an extension of 59 days is necessary to ensure that the public has sufficient time to provide thoughtful and substantive comments. This extension will also allow for more inclusive public participation, particularly among stakeholders who may require additional time to review and comment on the proposal. Thank you for your attention to this matter. Sincerely, Poonam Kalkat, Utilities Director, City of Boynton Beach

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

Massachusetts Water Works Association (Doc. #2314, SBC-046320)

Massachusetts Water Works Association represents more than 1.400 public water supply professionals in Massachusetts. We are writing to EPA to request an extension on the deadline for comments on the proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances noticed by EPA on March 29, 2023 under docket EPA-HQ-OW-2022-0114. This regulation is complex, and 60 days is not sufficient time for the drinking water profession to evaluate the impacts and provide thoughtful and thorough feedback to EPA. We respectfully request that EPA grant an additional 90 days beyond the original comment deadline of May 30, 2023. Massachusetts has a Maximum Contaminant Level for six PFAS compounds set at 20 parts per trillion; we know the significant costs that have, and are currently, being incurred by our utilities to comply with the Massachusetts standard which is higher than what EPA is proposing. Further complicating the review of this regulation is the fact that EPA is proposing a new way of evaluating compliance with 4 PFAS compounds through a Hazard Index approach; this has never before been utilized in drinking water standards and so we need more time to evaluate the impact this new approach will have on our utilities. For these reasons and given the enormous impact this rule will have on utilities in Massachusetts and across the nation, we ask you to grant our extension request.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1465, SBC-042300 in section 17.1 in this *Response to Comments* document.

Anonymous (Doc. #2569, SBC-047293)

It also seems that this is being rushed through since the public comment period is only 2 months. Nearly everyone I talk to is unaware of this and a longer comment period is needed for the word to get out.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document.

NELAC Institute (Doc. #2960, SBC-046292)

The NELAC Institute Proficiency Testing Program Executive Committee (PTPEC) is currently developing Fields of Proficiency Testing for PFAS compounds in drinking water and requests the comment period for this proposed rulemaking be extended for 90 more days to allow for the committee to complete data evaluation for determination of Proficiency Testing acceptance limits for PFAS compounds. These acceptance limits will be based on data collected through

UCMR Proficiency Testing (Performance Evaluation) using TNI procedures for acceptance limit determination.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document. With respect to the commenter's note about development of "Proficiency Testing acceptance limits for PFAS compounds," please see the EPA response to comment Doc. #1575, SBC-042458 in section 8.6 in this *Response to Comments* document. Please see 40 CFR § 141.901 for more information on the analytical requirements for the final rule; specifically, Table 2 to paragraph (b)(2)(ii) lists the acceptance limits for PFAS performance evaluation samples (70-130 percent). The EPA notes that the acceptance criteria set forth by the agency under this regulatory action must be followed by laboratories upon the compliance dates for the final rule, regardless of outside efforts to develop alternative criteria.

Massachusetts Water Resources Authority (Doc. #3072-49, SBC-047380)

EPA should extend the comment period for this rule as you've essentially crammed three separate processes into one request for comment. Setting health advisory levels for additional PFAS, regulatory determinations for four additional contaminants, and finally that actual proposed regulation. Typically, each of these would have its own public process and logical sequence and commenters would have sufficient time to comment on each step.

EPA Response: Please see section 17.1 of the EPA response in this *Response to Comments* document. Additionally, the commenter is incorrect that this action includes setting health advisory levels for additional PFAS. Through this action, the EPA is establishing MCLGs and enforceable standards for six PFAS. For more information, please see sections IV and V of the preamble for this action.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045963)

AMWA also understands that PFAS are a unique set of substances and that there are challenges in addressing dozens, hundreds, or even thousands of these substances, and as a result, these challenges may need creative solutions. The association has stated before (Attachment 5) that if EPA determines that regulatory action is needed beyond PFOA and PFOS, the agency should use the Negotiated Rulemaking Procedure ("Reg-Neg"). To implement a "Reg-Neg", the agency must decide there is a need for a rule, determine that there are a limited number of identifiable interests that will be significantly affected by the rule, and conclude that there is a reasonable likelihood that a committee could be convened which would consist of a balanced representation of the interests involved.

Due to the unique circumstances surrounding PFAS as a family, AMWA believes regulating additional PFAS would meet the criteria for a "Reg-Neg" and would save the agency time as all key stakeholder concerns would be discussed during a process that would bring those stakeholders into a risk-risk tradeoff discussion to help the agency come to a proposal with a higher likelihood of success. Throughout any regulatory process to address additional PFAS, the

agency must consider any future actions within the context that whatever path EPA chooses will set the stage for how the agency addresses other PFAS and other emerging contaminants going forward.

EPA Response: The EPA disagrees with the commenter's recommendation to pursue a negotiated rulemaking procedure to regulate additional PFAS. Although a negotiated rulemaking procedure is appropriate under specific circumstances, the EPA does not believe that the PFAS NPDWR is appropriate for a negotiated rulemaking procedure. Among other things, engaging in a negotiated rulemaking involves substantial additional processes that would substantially delay the finalization of this rulemaking effort and thus the public health protection it is anticipated to provide. The science is clear that long-term exposure to certain PFAS, including those proposed for regulation in this action, is linked to significant health risks. The EPA anticipates that over many years this action, if it is finalized, will save thousands of lives and prevent tens of thousands of serious illnesses that would otherwise result from long-term exposure to PFAS. Therefore, it is an EPA priority that the agency take final action on this regulation expeditiously to reduce PFAS exposure in communities across the country.

Furthermore, a successful negotiated rulemaking would be very challenging, if not impossible, within the timeframe that the EPA is statutorily compelled to complete this rulemaking. As required under SDWA 1412(b)(1)(E), the EPA was under a statutory obligation to have proposed the NPDWR for PFOA and PFOS at minimum by March 2023 and is obligated to finalize the regulation no later than September 2024. The EPA can, by notice in the Federal Register, extend the deadline up to nine additional months, giving the EPA until June 2025 to promulgate this regulation. However, even if exercising that extension, there would not be sufficient time to complete a negotiated rulemaking process. While the EPA has a successful history of negotiated rulemakings when there is adequate time and the subject matter lends itself to that forum, such as when the EPA is revising rules under SDWA section 1412(b)(9), those negotiated rulemakings are time-consuming. They have never been utilized under the SDWA rulemaking process as established in 1412(b)(1). From the time the EPA begins to form a committee until an agreement in principle is reached typically takes at least 18 months; see, for instance, the EPA's Revised Total Coliform Rule (RTCR), Long Term 2 Enhanced Surface Water Treatment Rule (LT2), and Stage II DBP rules (USEPA, 2013; USEPA, 2008; USEPA, 2006a; USEPA, 2006b; USEPA, 2000). It isn't until after reaching consensus in the negotiated rulemaking that the EPA would initiate the process for developing a rulemaking package that reflects the agreement, propose that rule for public comment, consider those comments, and then complete the same rulemaking process that the EPA engaged in for this rule. In short, establishing a federal advisory committee in this rulemaking would guarantee that the EPA would miss its statutory deadlines and delay necessary public health protection. Finally, the EPA notes that establishment of negotiated rulemakings is typically discretionary, and the agency is under no obligation to do so for this regulatory action.

17.2 Next Steps and Timeline

Summary of Major Public Comments and EPA Responses

Many commenters commended the EPA for taking action to address PFAS through an NPDWR and urged the agency to finish the rule as quickly as possible. The EPA has taken final action on the PFAS NPDWR rules as expeditiously as possible and ahead of its statutory deadline. Furthermore, through its PFAS Strategic Roadmap and associated actions, the agency is working expeditiously to address PFAS contamination in the environment and reduce environmental exposure to PFAS.

Several commenters recommended that the EPA postpone a final rulemaking addressing PFAS in drinking water. These commenters cited a need for more occurrence data (collected through the fifth Unregulated Contaminant Monitoring Rule (UCMR 5) or other sources), a greater understanding of economic costs and availability of treatment technologies, finalization of concurrent PFAS rulemakings including CERCLA hazardous waste designation, and/or the need to achieve accomplishments in source water reduction first. The EPA disagrees with delaying promulgation of this regulation. First, the EPA disagrees that he occurrence data used to inform this rule are not sufficient to provide the EPA the necessary information to develop an informed regulation reflective of best available science. As discussed in section VI of this preamble and section 6 of this *Response to Comments* document, sufficient and robust occurrence information including data from the third UCMR (UCMR 3), tens of thousands of samples from state datasets, and a nationally representative occurrence model are available and supportive of the agency's decision to regulate. The EPA is not required under the statute to wait for another round of UCMR data to be collected before proposing or finalizing a regulation. Please see the EPA response to comment Doc. #1684, SBC-044302 in section 6.1 in this *Response to Comments* document for discussion of what constitutes best *available* science (emphasis added). The completion of UCMR 5 data reporting is expected at the end of 2025, with the final dataset not being available until 2026. While the EPA is under no legal obligation to consider the preliminary, partial UCMR 5 dataset prior to rule promulgation, based on public comment and interest, the agency analyzed and considered UCMR 5 data released as of February 2024 (USEPA, 2024b).

Some commenters expressed concern about a potential designation of PFOA and PFOS as CERCLA hazardous substances. The EPA's rulemaking activities to designate PFOA and PFOS as CERCLA hazardous substances are beyond the scope of this PFAS NPDWR rulemaking; for discussion of topics outside the scope of this regulatory action, please see section 15 of this *Response to Comments* document. Additionally, the EPA disagrees with commenters that the agency should wait to promulgate the final NPDWR rulemaking as the CERCLA hazardous substance rulemaking is not anticipated to impact the factors the EPA considers when establishing an NPDWR, including treatment feasibility, cost, benefits, analytical methods, among other considerations. This NPDWR will protect the American people directly from everyday PFAS exposures that might otherwise occur from PFAS-contaminated drinking water,

complementing the many other actions in the PFAS Strategic Roadmap to protect public health and the environment from PFAS. For those reasons, the EPA is not delaying the final PFAS NPDWR to wait for finalization of the CERCLA PFOA and PFOS hazardous substance rulemaking. The EPA notes that it does not anticipate the CERCLA rulemaking substantially increasing disposal costs associated with this rulemaking. For the final rule, the EPA included a sensitivity analysis to determine the costs associated with the handling and disposal of PFAS treatment materials as hazardous waste; please see Appendix N of the EA for more information. Additional discussion of CERCLA issues, including costs, can be found in section 10.4.2 of the EPA response in this *Response to Comments* document.

The agency also disagrees that the economic costs and impacts have not been adequately described. The agency has prepared a final rule Health Risk Reduction and Cost Analysis (HRRCA) supporting document (USEPA, 2024a) for the PFAS NPDWR, in compliance with section 1412(b)(3)(C) of SDWA and under EO 12866. A detailed analysis of the costs and benefits of the final rule is included in section XII of the preamble for this rulemaking. Additionally, public comments related to costs, benefits, and the Administrator's determination that the costs are justified by the benefits are addressed in section 13 of the EPA response in this *Response to Comments* document. Likewise, the EPA disagrees that the agency does not have an adequate understanding of the availability of treatment technologies. Please see section X of the preamble for this rulemaking and section 10.6 of the EPA response in this *Response to Comments* document for additional discussion on treatment technology availability and capacity.

Individual Public Comments

Liliana Salcido (Doc. #1509, SBC-042587)

According to the Environmental Working Group, the estimates for industrial environmental polluters that release PFAS into the environment is at about 30,000 (Amarelo, 2023). The EPA must work fast in order to put these regulations in place. Not only are these chemicals found in all of our bodies, they have been found in food, soil, water, and other parts of the world. Companies have gone far too long putting their profits over the health and safety of every citizen in the United States, and it is the government's duty to stop this at once.

Sincerely,

Liliana

EPA Response: While the EPA is working through other activities to reduce PFAS discharges to the environment, those activities are beyond the scope of this rulemaking. Please see sections 15 and 17.2 of the EPA response in this *Response to Comments* document.

Liliana Salcido (Doc. #1509, SBC-042584)

It is extremely important for these chemicals in drinking water to be regulated as soon as possible because we have been aware of their consequences for decades (Amarelo, 2023) (Nicole, 2013). The EPA and companies like DuPont have known the dangers of these chemicals since the 1990s, and the more we delay the regulation of them, the higher the cancer rates will be in the U.S. If we know that PFAS are directly linked to cancer, reproductive harm, immune system damage and other serious health problems, then there should not be any more lax regulation oversight (Amarelo, 2023; Isaacs-Thomas, 2023; Nicole, 2013). This is not a problem of the future, people have been suffering and dying from cancer due to negligence from corporations and the government for decades. Now that we are all aware of the hazards of these chemicals, it is our responsibility as citizens, employees, and government officials to advocate for the regulation of these chemicals. Additionally, the general public should be made aware of the negative anticipated effects that these chemicals may have on their health and wellbeing.

EPA Response: The EPA has taken final action on the PFAS NPDWR for six PFAS as expeditiously as possible. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Robert Adamski (Doc. #1530, SBC-043331)

I recommend delaying this rule and replacing it with more research and data collection

Robert E. Adamski

U.S. Environmental Protection Agency

EPA Docket Center

Office of Ground Water and Drinking Water Docket

Mail Code 282IT

1200 Pennsylvania Avenue NW

Washington, DC 20460

Subject: Docket ID No. EPA-HQ-OW-2022-0114

Dear Sir,

I am writing to express my concern over EPA's proposed rules for PFAS/ PFOS. I believe they need to be delayed and replaced with additional monitoring of the presence and sources of the chemicals in industries, water supplies and water recovery facilities.

EPA Response: Please see section 17.2 of the EPA response in this *Response to Comments* document. The EPA disagrees that additional monitoring is needed before finalizing this rule. The agency has previously made a final determination that there is sufficient occurrence and health effects information to regulate PFOA and PFOS, and as discussed in section III of the final rule preamble and in section 3 of the EPA response in this *Response to Comments* document, the EPA has determined that PFHxS, PFNA, HFPO-DA, and mixtures of those PFAS with PFBS meet the statutory criteria for regulation.

Linda Shosie (Doc. #1533, SBC-043962)

I urge you to promptly finalize the proposed rule without any further delays, to continue to build on this rule and give it the teeth it needs to prevent another tragedy like this from happening again. We cannot afford to wait any longer to address these critical issues. Thank you for your attention to this matter.

Sincerely,

Linda Shosie

EPA Response: Please see section 17.2 of the EPA response in this *Response to Comments* document.

Linda Shosie (Doc. #1533, SBC-043967)

We urge the EPA to finalize the standards as quickly as possible, so our community can finally have access to the clean, safe, sustainable and affordable drinking water services that we deserve. Thank you for your attention to this matter.

Sincerely,

The Environmental Justice Task Force

EPA Response: Please see section 17.2 of the EPA response in this *Response to Comments* document.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-042771)

Final rule promulgation:

WSSC Water also recommends that EPA postpone the promulgation of the final rule until it has collected sufficient or full occurrence data through UCMR5. This data will provide opportunities for the EPA to more appropriately assess nationwide occurrence and to identify possible issues with implementing compliance, such as laboratory proficiency, capacity, and monitoring costs. The statutory deadline for EPA to finalize the rule is September 2024, which provides additional time to ensure that this regulatory action aligns with the occurrence criterion.

EPA Response: Please see section 17.2 of the EPA response in this *Response to Comments* document. For more information related to UCMR 5 data, please see section 6.8 of the EPA response in this *Response to Comments* document.

Village of Woodbury (Doc. #1629, SBC-042947)

Submitted Electronically

MEMORANDUM

To: Michael S. Regan, Administrator

U.S. Environmental Protection Agency

From: On behalf of the Village of Woodbury

Natalie D. Barber, PE, Village Engineer

James J. Roberts, PE, Sr. Vice President

SUBJECT: Per- and Polyfluoroalkyl Substances (PFAS)

Proposed PFAS National Primary Drinking Water Regulation

Docket ID: EPA-HQ-OW-2022-0114

DATE: May 30, 2023

On behalf of the Village of Woodbury (Village), as part of the public comment period, please accept the following comments on the proposed National Primary Drinking Water Regulation

(NPDWR) for six PFAS announced by the Environmental Protection Agency (EPA) on March 14, 2023.

The Village owns and operates two water areas in Orange County, New York: Consolidated Water Area (Consolidated) and Amdur Park Water Area (Amdur). As an affected party, the Village appreciates the opportunity to provide comments on the proposed rule.

A) Technical Comments on Proposed Rule –

1. Based on industry data available to the Village at this time, we believe the economic costs and impacts of the rule are understated and there is a risk potential related to material availability and other concurrent rule making by the EPA on the management of contaminated filter media and implications on backwashing operations. We believe final promulgation of the rule should be deferred pending clear resolution of these issues.

EPA Response: Please see section 17.2 of the EPA response in this *Response to Comments* document. For responses to comments regarding costs associated with the rule, please see sections 13.2 and 13.3 of the EPA response in this *Response to Comments* document. The EPA notes that the commenter provided no specific information or data for the EPA to consider to adjust its cost estimates. For issues related to supply chain management (e.g., material availability) that may affect the compliance timeline, please see section 12.1 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Maine Organic Farmers and Gardeners Association (MOFGA) (Doc. #1660, SBC-043384)

Summary. EPA's proposed rule will save lives and protect health and should be adopted without delay

EPA Response: The EPA agrees with this commenter that there should not be a delay in taking final action on the PFAS NPDWR. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Maine Organic Farmers and Gardeners Association (MOFGA) (Doc. #1660, SBC-043386)

In summary, MOFGA supports this rulemaking as an important first step, and opposes any delay in its adoption. We have waited long enough for federal action.

Respectfully submitted,

Heather Spalding, MOFGA Deputy Director

Sharon Anglin Treat

Attorney, on behalf of MOFGA

EPA Response: The EPA agrees that there should not be a delay in taking final action on this rulemaking. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Rockbridge Area Conservation Council (RACC) (Doc. #1678, SBC-043737)

With that said, we respectfully request that: (1) a timeline be established identifying when the MCLG of "Zero" will be realized - at least for PFOA/PFOS;

EPA Response: The MCLG is set, as defined in Section 1412(b)(4)(A), at "the level at which no known or anticipated adverse effects on the health of persons occur and which allows an adequate margin of safety." MCLGs are public health goals and are not enforceable. For more information, please see section 4.1.5 of the EPA response in this *Response to Comments* document and section IV of the FRN. With respect to the date by which the MCLs must be met, please see section 12.1 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #1685, SBC-044439)

These chemicals need to be monitored and "acceptable" limits be lowered. My kids grew up drinking the PFAS polluted water in Wilmington. Now one of my grand babies WAS BORN WITH LEUKEMIA and lost her life. Only lived a short 13 months. The other was born with a hole in her heart. These chemicals destroy lives. DO SOMETHING ABOUT THEM. YOU ARE SUPPOSE TO PROTECT THE PUBLIC AND NOT COMPANY'S PROFITS. Look at that precious face. She is no longer with us due to something ENVIRONMENTAL that caused her to have cancer prior to being born.

[Attachment: See docket ID EPA-HQ-OW-2022-0114-1685]

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible. Once implemented, the EPA anticipates this regulation will prevent tens of thousands of PFAS-attributable serious illnesses. Regarding monitoring for PFAS, please see section 8 of the EPA response in this *Response to Comments* document. Additionally, please see section 17.2 of the EPA response in this *Response to Comments* document. While the EPA cannot speak to whether PFAS exposure is specifically what caused your granddaughter's Leukemia, we are sorry for your loss.

Wisconsin Department of Justice et al. (Doc. #1687, SBC-044449)

5. EPA should issue the final rule as quickly as possible because these contaminants are so toxic, while at the same time giving States the opportunity to revise their programs.

The toxicity of PFAS is well documented, and EPA references and discusses the human harms of PFAS throughout the proposed PFAS Rule, explaining that "[d]epending on the individual PFAS, health effects can include negative impacts on fetal growth after exposure during

pregnancy, on other aspects of development, reproduction, liver, thyroid, immune function, and/or the nervous system; and increased risk of cardiovascular and/or certain types of cancers, and other health impacts." [FN44:88 Fed. Reg. 18,638 (Mar. 29, 2023).] Because of these serious adverse health impacts, swift regulatory action is warranted.

The process of implementing drinking water regulations can be lengthy, with National Primary Drinking Water Regulations generally set to take effect as long as three years after a regulation is promulgated. [FN45: 42 U.S.C. § 300g-1(b)(10).] And states can allow individual water systems up to two additional years to comply if that time is reasonably needed to implement the necessary capital improvements to comply. [FN46:Id.] That means an MCL promulgated today might not take effect for five years for some residents of our States.

Given the toxicity of these PFAS and this anticipated long implementation period, it is crucial that EPA finalize the PFAS Rule as quickly as possible.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document. Additionally, for additional discussion about the MCLs' compliance timeline, please see section 12.1 of the EPA response in this *Response to Comments* document on extensions and exemptions.

National Wildlife Federation et al. (Doc. #1702, SBC-043511)

May 30, 2023

The Honorable Michael Regan Administrator

U.S. Environmental Protection Agency 1200 Pennsylvania Avenue, N.W. Washington, DC 20460

Re: Comments on Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation Docket ID No. EPA-HQ- OW-2022-0114

Dear Administrator Regan,

On behalf of the National Wildlife Federation, affiliates from Delaware, Georgia, Indiana, Iowa, Kentucky, Maine, Massachusetts, Missouri, New Hampshire, North Carolina, Oklahoma, Rhode Island, Texas, Vermont, Virginia, West Virginia, and our nearly 7 million members and supporters, we submit the following comments on the national primary drinking water regulations for PFAS proposed by the U.S. Environmental Protection Agency (EPA) under the authority of the Safe Drinking Water Act. This proposal is an important first step towards keeping our drinking water safe from six types of highly toxic PFAS. We greatly appreciate the Administration's commitment to addressing the nation's PFAS contamination crisis and we urge

the agencies to move swiftly to finalize protective standards to reduce PFAS in our drinking water.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

National Wildlife Federation et al. (Doc. #1702, SBC-043516)

Our organizations urge the EPA to swiftly finalize the proposed drinking water standards for PFAS to improve the safety of our drinking water. We appreciate the Administration's efforts to curb PFAS exposure in our drinking water and look forward to working with you as you continue to implement the EPA's 2021 Strategic PFAS Roadmap to address all sources of PFAS pollution. Thank you for your consideration.

Sincerely,

Conservation Coalition of Oklahoma Conservation Federation of Missouri Delaware Nature Society Environmental Council of Rhode Island

Environmental League of Massachusetts Georgia Wildlife Federation

Indiana Wildlife Federation Iowa Wildlife Federation Kentucky Waterways Alliance National Wildlife Federation

Natural Resources Council of Maine New Hampshire Audubon

North Carolina Wildlife Federation Texas Conservation Alliance Vermont Natural Resources Council Virginia Natural Resources Council West Virginia Rivers Coalition

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Susan Gorman-Chang (Doc. #1705, SBC-045084)

4. Since the Safe Drinking Water Act Section 1412(b)(10) mandates that "national primary drinking water regulation promulgated under the section (and any amendment thereto) shall take effect on the date that is 3 years after the date on which the regulation is promulgated unless the Administrator determines that an earlier date is practicable," please ensure that this 3 years is met or shortened as human beings will continue to suffer the effects of cancer, thyroid, kidney, cardiovascular, hepatic, endocrine, metabolic, musculoskeletal, reproductive and fetal issues all the while the EPA is taking its time. The section clearly states that "an earlier date" is possible! Please do not under any circumstances increase this 3 year date either.

5. Please finalize these regulations well before your December 31, 2023 deadline. You are free to work faster, and every day you do so will save lives.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document. Additionally, for additional discussion about the MCLs' compliance timeline, please see section 12.1 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Citizens Campaign for the Environment (CCE) (Doc. #1710, SBC-045129)

CCE urges the EPA to move to adopt and implement the proposed regulations as quickly as possible in order to protect public health. People across the nation have already been exposed to these dangerous PFAS chemicals for too long, and we can't afford to wait any longer.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045927)

May 30, 2023

VIA Regulations.Gov

The Honorable Michael Regan

Administrator

U.S. Environmental Protection Agency

1200 Pennsylvania Avenue NW

Washington, D.C. 20460

Ms. Jennifer McLain

Director Office of Groundwater and Drinking Water

U.S. Environmental Protection Agency

1200 Pennsylvania Avenue NW

Washington, D.C. 20460

RE: EPA-HQ-OW-2022-0114: PFAS NATIONAL PRIMARY DRINKING WATER REGULATION RULEMAKING

Dear Administrator Regan and Director McLain,

Protecting Our Water, Environment, and Ratepayers Coalition ("POWER!") appreciates the opportunity to provide comments on the Environmental Protection Agency's ("EPA's") proposed rulemaking to establish a National Primary Drinking Water Regulation ("NPDWR") for six per- and polyfluoroalkyl substances ("PFAS"). POWER! is a coalition of water agencies, wastewater agencies, and municipalities who, together, are writing today to comment on several aspects of the proposed rule.

POWER! is encouraged that EPA is taking steps to address PFAS in our environment. POWER! supports drinking water standards that protect public health based on sound science and clear analysis of methods of attainment, costs, and benefits. However, POWER! believes that until EPA takes more aggressive steps to ensure adequate and reliable testing capability, halt the sources and upstream pathways, and provide disposal standards for all six PFAS substances covered, the current proposed rule is premature and will have unintended negative consequences for water agencies and the public we serve. This proposed rule may also harm the public's trust in the nation's water systems If the proposed rule is finalized, it will, at a minimum, subject public water agencies to the threat of yet-to-be developed standards and increased costs, and will result in higher water bills for households across the country. Therefore, in addition to the comments set forth below, POWER! requests that EPA delay finalizing the proposed rule until EPA has:

(1) Determined that laboratory capabilities provide sufficient and reliable testing capacity at the levels required to verify compliance with the standard and the lower proposed trigger levels for less frequent compliance monitoring;

(2) Used EPA's full powers under the Toxic Substances Control Act to stop the pipeline of all six PFAS substances into the nation's environment and water systems;

(3) Used EPA's powers under the Resource Conservation and Recovery Act ("RCRA") and Clean Water Act to limit the pathways of all six PFAS substances into the nation's water systems;

(4) Issued Health Advisories and determined a Reference Dose for perfluorohexane sulfonic acid ("PFHxS") and perfluorononanoic acid ("PFNA");

(5) Finalized standards for disposing of treatment residuals;

(6) Provided a robust analysis and opportunity to comment on the costs of complying with the proposed MCL and Hazard Index if (a) all six PFAS substances are designated as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act ("CERCLA"), (b) the compressed timeframe for historic investments in treatment infrastructure increases costs, (c) reasonably foreseeable pathways continue to add PFAS to water sources, (d) reasonably foreseeable increases in PFAS treatment media requirements and costs occur;

(7) Received and considered data on the prevalence of hexafluoropropylene oxide dimer acid ("HFPO-DA" commonly known as "GenX"), and the prevalence of the remaining five PFAS at

the newer reporting levels, from the Fifth Unregulated Contaminant Monitoring Rule ("UCMR 5");

(8) Proposed what maximum containment levels ("MCL") would be appropriate if EPA adhered to its self-stated standards for reliable detections and set the Practical Quantitation Level for each PFAS at 5-10 times its Minimum Detection Level ("MDL").

EPA will be arbitrarily skipping critical steps in the established Safe Drinking Water Act ("SDWA") regulatory process if it now proceeds to a final MCL without adequately acting to control these substances' ongoing pathways, complete assessments of health risks and reference doses, establish appropriate disposal standards, ensure adequate technologies, provide a robust cost analysis, or adhere to its precedents for ensuring reliable detections.

EPA Response: The EPA disagrees with the commenter that the EPA skipped steps within the SDWA regulatory process. The SDWA does not require the EPA to be "adequately acting to control these substances' ongoing pathways" or "establish appropriate disposal standards" prior to rule finalization. In fact, many drinking water regulations have been established because of prior and ongoing contamination of source waters. Additionally, while not required for and beyond the scope of this rulemaking, the EPA continues to produce information related to the disposal and destruction of PFAS. See (5) below. In regard to whether the EPA has met its obligations for evaluating health risks, establishing or identifying reference doses, evaluating whether there are available treatment technologies to treat below MCL values, developing a robust cost analysis, and ensured there are available analytical methods, the EPA has completed all of these things. See section 4 of the EPA response in this *Response to Comments* document for discussion of health effects and reference doses, section 10 of the EPA response in this *Response to Comments* document for discussion of treatment technologies, sections 13.2 and 13.3 of the EPA response in this *Response to Comments* document for discussion of costs, and section 7 of the EPA response in this *Response to Comments* document for discussion of analytical methods.

The EPA refers the commenter to section I.I of the FRN as well as sections 1.1 and 3.3 of the EPA response in this *Response to Comments* document for further discussion related to the SDWA rulemaking process. Please see the following for a response to each of the commenter's numbered statements:

(1) For concerns related to laboratory capabilities, please see section 8.7 of the EPA response in this *Response to Comments* document.

(2) Regulatory actions under Toxic Substances Control Act (TSCA) are out of scope for this final NPDWR. As discussed in the PFAS Strategic Roadmap, the Office of Chemical Safety and Pollution Prevention (OCSPP) is engaging in several key actions related to PFAS, including ensuring a robust review process for new PFAS under TSCA to ensure these substances are safe before entering commerce, reviewing existing PFAS under TSCA (Inactive PFAS proposed rule published January 2023), and finalizing new PFAS reporting under TSCA Section 8 to better

characterize the sources and quantities of manufactured PFAS in the United States. Please see the Strategic Roadmap for more information.

(3) While regulatory actions under Resource Conservation and Recovery Act (RCRA) and the CWA are out of scope for this final NPDWR, other EPA offices are engaging in key actions related to PFAS in those contexts. Please see the Strategic Roadmap (USEPA, 2022) for more information.

(4) Health Advisories are beyond the scope of this regulatory action. Health Advisories are non-enforceable and non-regulatory in nature, are not a pre-requisite for an NPDWR under the SDWA, and there is nothing in the statute or EPA historical regulatory practice that suggests the agency should delay regulation of a contaminant in order to develop a Health Advisory first. The four HI PFAS, including PFHxS and PFNA, are well-studied PFAS for which the EPA or Agency for Toxic Substances and Disease Registry (ATSDR) have developed human health assessments and toxicity values (i.e., reference doses (RfDs), minimal risk levels). The EPA is finalizing the NPDWR using ATSDR minimal risk levels for the purpose of developing MCLGs for PFHxS and PFNA. Please see the EPA response to comment Doc. #1714, SBC-045940 in section 4.3.2 and section 4.3.3 of the EPA response in this *Response to Comments* document for more information.

(5) The National Defense Authorization Act for Fiscal Year 2020, Public Law No: 116-92 Section 7361 directs the EPA to revise the PFAS Destruction and Disposal Guidance triennially; the new destruction and disposal guidance is anticipated to be released approximately concurrently with this rule and further revisions may be expected before the effective dates for this rule. The EPA disagrees that the projected significant and direct public health protections for drinking water consumers in this rule should be delayed for the revision of guidance on management of PFAS waste streams. Please see section 10.4.1 of the EPA response in this *Response to Comments* document for more information.

(6) Please see the EA (USEPA, 2024a) and the EPA response to comment Doc. #1714, SBC-045931 in section 13.3.6 in this *Response to Comments* document for more information related to the costs and benefits of this rule. SDWA directs the EPA to analyze the costs and benefits of any proposed rule and directs the Administrator to make a determination as to whether the benefits of the proposed rule justify the costs. SDWA makes it clear that the EPA should consider, both quantified and unquantified, costs and benefits in making its determination. In addition to estimating the costs and benefits of the proposed PFAS NPDWR that the EPA was able to quantify, the EPA also discussed in some detail a number of health benefits, such as those associated with avoided adverse developmental, cardiovascular, liver, immune, endocrine, metabolic, reproductive, musculoskeletal, and carcinogenic effects, that the agency was unable to monetize or otherwise quantify. The Administrator's assessment that the benefits of the proposed PFAS NPDWR justified its costs was based on the totality of the evidence, specifically the quantified and unquantified benefits and costs.

(7) Please see section VI of the preamble for this rulemaking and the *Occurrence Technical Support Document* (USEPA, 2024c) for detailed information on occurrence of the 6 PFAS included this rule. Please also see section 6.8 of the EPA response in this *Response to Comments* document regarding UCMR 5 data. For HFPO-DA specifically, the robust amount of state occurrence data for HFPO-DA represent the current best available information, as required under SDWA, and demonstrate sufficient likelihood of occurrence of the PFAS being regulated. In the final regulation, based on public comment, the EPA updated the Occurrence Technical Support Document to include over 35,000 results of HFPO-DA from 25 states. For more information related to the occurrence statutory criterion for making regulatory determinations under SDWA, please see section 3.1.2 of the EPA response in this *Response to Comments* document.

(8) Please see the EPA response to comment Doc. #1714, SBC-045943 in section 7.2 in this *Response to Comments* document and the summary of major comments in section 5.1.2 (laboratory considerations and practical quantitation levels (PQLs)) in this *Response to Comments* document for more information. Alternative MCLs are discussed in section 5.1.3 in this *Response to Comments* document.

Private Citizen – General (Doc. #1722, SBC-043832)

Subject: Please pass restrictive PFAS MCLs!

Follow Up Flag: Follow up

Flag Status: Flagged

Mr. Michael Regan,

Dear Administrator Regan,

We know that it is much cheaper to protect our drinking water, than to clean it up. We know that PFAS are dangerous to humans. Please do the right thing for your family and mine.

Please swiftly act to protect the public from exposure to dangerous PFAS chemicals in drinking water. While the March 2023 proposal is a step in the right direction we also need to do the following:

1. Please do not capitulate to the delay tactics by industry that wants you to extend the comment period.

EPA Response: Please see section 17.2 of the EPA response in this *Response to Comments* document. The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. In regard to whether to extend the comment period, please see section 17.1 of the EPA response in this *Response to Comments* document.

Steven Alt (Doc. #1724, SBC-044473)

I strongly believe the EPA should accelerate the elimination of sources of PFAS which are polluting our waters but in the mean time I strongly agree the EPA should finalize the PFAS standards as quickly as possible. Note: Any Attachment highlights are not mine.

[Attachment 2: see docket ID EPA-HQ-OQ-2022-0114-1724].

[Attachment 3: see docket ID EPA-HQ-OQ-2022-0114-1724].

[Attachment 4: see docket ID EPA-HQ-OQ-2022-0114-1724].

[Attachment 5: see docket ID EPA-HQ-OQ-2022-0114-1724].

[Attachment 6: see docket ID EPA-HQ-OQ-2022-0114-1724].

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Joe DiNardo (Doc. #1725, SBC-045758)

With that said, I respectfully request that: (1) a timeline be established identifying when the MCLG of "Zero" will be realized - at least for PFOA/PFOS;

EPA Response: Please see the EPA response to comment Doc. #1678, SBC-043737 in section 17.2 in this *Response to Comments* document.

San Gabriel Basin Water Quality Authority (WQA) (Doc. #1743, SBC-043612)

2. EPA is in the process of establishing regulations to designate PFOS and PFOA as hazardous substances under CERCLA. That designation may significantly increase the cost to dispose of filter media used to remove the contaminants from drinking water. Therefore, EPA should consider delaying the adoption of the proposed National Primary Drinking Water Regulation for the named PFAS contaminants until it finalizes its proposal to designate PFOS and PFOA as hazardous substances under CERCLA. This would allow for the full consideration of additional costs in connection with the disposal of media used to remove PFOS and PFOA from drinking water that could potentially be designated as a hazardous substance.

EPA Response: Please see section 17.2 of the EPA response in this *Response to Comments* document.

West Virginia Rivers Coalition et al. (Doc. #1746, SBC-045249)

It is imperative that as testing technologies advance, EPA review and reduce the maximum contaminant levels (MCLs) for PFOA and PFOS. As more laboratories upgrade their instrumentation and gain more experience analyzing drinking water samples for PFAS, more laboratories will become capable of quantitatively measuring PFAS at lower concentrations. The Safe Drinking Water Act (SDWA) requires EPA to review each existing National Primary Drinking Water Regulation (NPDWR) every six years. EPA should reassess laboratories' PFOA and PFOS detection capacity during each six-year review period and lower the MCL as close as feasible to the MCLG as technologies support a lower practical quantitation level (PQL).

EPA Response: Individual laboratories may be able to achieve quantitation limits below the proposed PQLs, but the proposed PQLs are based on results from a statistical evaluation of several drinking water laboratories (multi-laboratory minimum reporting level (MRL)). Please see section 7.2 of the EPA response in this *Response to Comments* document for more information. As required under SDWA 1412(b)(9), the agency intends to consider this PFAS NPDWR in future six year reviews as appropriate. The primary goal of the Six-Year Review process is to identify national primary drinking water regulations for possible regulatory revision. The EPA considers a possible revision to be "appropriate" if, at a minimum, it presents a meaningful opportunity to: improve the level of public health protection, or achieve cost savings while maintaining or improving the level of public health protection.

West Virginia Rivers Coalition et al. (Doc. #1746, SBC-045260)

Collectively, we urge EPA to move quickly to finalize this rule for the health and safety of our communities. Thank you for your consideration.

Sincerely,

Angie Rosser

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. See section 17.2 of the EPA response in this *Response to Comments* document.

National Center for Health Research (NCHR) (Doc. #1749, SBC-044499)

Lastly, we recommend additional clarity and urgency to speed up the timeline for finalizing this national standard, and implementing it once finalized.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document. For additional discussion about the compliance timeline, please see section 12.1 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Coralie Pryde (Doc. #1781, SBC-043816)

However, many of us know that our water is contaminated at levels several times the 17 ppt level. It seems clear that nothing will be done until the proposed enforceable limits of 4.0 ppt for both PFOA and PFOS are adopted.

For the sake of the health of all Delaware residents, I hope that these enforceable limits are written into law as soon as possible.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Silent Spring Institute (Doc. #1784, SBC-045796)

May 30, 2023

RE: Silent Spring Institute's Public Comments on the U.S. EPA PFAS National Primary Drinking Water Regulation Rulemaking, 40 CFR Parts 141 and 142 (Document ID: EPA- HQ-OW-2022-0114-0027)

Submitted via https://www.regulations.gov/document/EPA-HQ-OW-2022-0114-0027/comment

Silent Spring Institute is a non-profit research organization with a mission to understand links between environmental chemicals and disease, with a focus on breast cancer prevention. We are writing on behalf of the Silent Spring Institute to comment on the U.S. Environmental Protection Agency's proposed Per- and Polyfluoroalkyl (PFAS) National Primary Drinking Water Regulations. We appreciate this opportunity to share scientific information on PFAS exposures and health effects from our own research and other published studies. Given the extensive scientific evidence on harm from the PFAS class of chemicals, widespread contamination of drinking U.S. public drinking water supplies, and the need for monitoring and for addressing this significant public health issue by reducing exposures, it is critical that the EPA finalize these drinking water regulations without delay. EPA has been long aware of the harms associated with this class of chemicals, and urgent action is need to protect communities across the U.S. in keeping with EPA's mission and authority to protect human health and the environment.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section17.2 of the EPA response in this *Response to Comments* document.

PFAS Project Lab (Doc. #1786, SBC-044713)

The longer that PFAS remain unregulated, the more people will be exposed and harmed, in violation of the Safe Drinking Water Act's mandate to protect against adverse health effects from drinking water contaminants.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

PFAS Project Lab (Doc. #1786, SBC-044716)

In the absence of federal PFAS standards, 10 states have enforceable drinking water levels that require testing and remediation for PFAS in drinking water and two have regulations in development (Safer States 2023). Twelve other states have adopted non-enforceable guidance or notification levels for PFAS in drinking water (Safer States 2023). In a peer-reviewed paper published in 2019 in the Journal of Exposure Science and Environmental Epidemiology, our lab examined PFOA and PFOS water guideline levels adopted by the EPA and state agencies in order to understand how and why these levels differ (Cordner et al. 2019). While states who develop their own standards can serve as important models, not all states have the ability to do so: for example, some lack the funding, technical expertise, and occurrence data to set protective state standards. Our article on this has been cited 229 times. As a result, these differences in state standards regarding PFAS can lend themselves to public health disparities across the country. In addition, it takes much energy from affected residents, scientists, and environmental organizations to seek regulations in each state. By contrast, a "sufficiently protective,

scientifically sound, and enforceable federal standard would provide more consistent protection" for all communities (Cordner et al. 2019). It has been over four years since we published this peer-reviewed article, underscoring how these federal drinking standards are long overdue.

EPA Response: Please see section 17.2 of the EPA response in this *Response to Comments* document. For more information on state drinking water standards, please see section V.I.V of the FRN for this action.

Mindi Messmer (Doc. #1788, SBC-044706)

Agencies empowered to protect public health must employ the Precautionary Principle – that "enables decision-makers to adopt precautionary measures when scientific evidence about an environmental or human health hazard is uncertain and the stakes are high." While the proposed maximum contaminant levels (MCLs) are a welcome step in the right direction, based on the above I submit the following:

1. Please do not capitulate to the delay tactics of the industry that wants you to extend the comment period.

EPA Response: In regard to requests to extend the comment period, please see section 17.1 of the EPA response in this *Response to Comments* document. The EPA has used the best available science to establish the MCLGs and MCLs in this PFAS NPDWR. The final rule is based on the EPA's SDWA authorities, not a general precautionary principle.

Mark Gearreald (Doc. #1792, SBC-044295)

Mr. Michael Regan,

Dear Administrator Regan,

In the closing years of my 19 years serving as the first in house Town Attorney for the Town of Hampton, NH, I became aware of the threat to the public posed by PFAS chemicals. These were detected in bedrock samples in the Coakley Landfill, an EPA superfund site, whose bedrock water flow to the south and east potentially imperils the wellhead protection area for Aquarion

Water Company, whose water serves the communities of Hampton, North Hampton, and two Rye Water Districts. Thankfully, your agency has become more insistent on the bedrock studies being extended in the face of the Coakley Landfill Group's downplaying of the PFAS results, which support the opinions on the direction of flow that I presented from an expert for the Towns of Hampton and North Hampton.

In 2021, I had our home well water tested from our home in Dover, NH and on a whim, included PFAS chemicals. To my shock, there were exceedences greater than 50 parts per trillion in two of the 4 PFAS chemicals for which NH has adopted maximum contaminant levels, and the presence of greater than 5 parts per trillion for two of the others. We have invested in a whole house GAC system recently, for which we have thankfully received a rebate from the State of NH DES PFAS rebate program, and our neighbors' are now having their wells tested, too.

I attended and spoke at the EPA sponsored regional forum at the Exeter, NH High School in 2021 and heard, as you probably have, the horror stories that exposure to PFAS can have on children and their families in the areas where St. Gobain has contaminated drinking water supplies in Vermont and New Hampshire, and where the Air Force's firefighting foam contaminated wells and properties in Newington, NH. The evidence is mounting that nothing good, and lots bad, results from PFAS exposure; now is the time for EPA to act, and not to balk, in the face of all this evidence, to protect human health and the environment from exposure to PFAS.

Please swiftly act to protect the public from exposure to dangerous PFAS chemicals in drinking water. While the March 2023 proposal is a step in the right direction we also need to do the following:

1. Please do not capitulate to the delay tactics by industry that wants you to extend the comment period.

EPA Response: Consistent with the concerns expressed by the commenter, the EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document. In regard to requests to extend the comment period, please see section 17.1 of the EPA response in this *Response to Comments* document.

While beyond the scope of this rulemaking activities, please see section 15.1 of the EPA response in this *Response to Comments* document for discussion of other activities in EPA's PFAS Strategic Roadmap.

Mr. Michael Regan,

Dear Administrator Regan,

I was a New Hampshire State Representative deeply involved in New Hampshire's early PFAS regulatory efforts. It is clear to me that any level of exposure to PFAS is extremely damaging.

Please swiftly act to protect the public from exposure to dangerous PFAS chemicals in drinking water. While the March 2023 proposal is a step in the right direction we also need to do the following:

1. Please do not capitulate to the delay tactics by industry that wants you to extend the comment period.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document. Regarding requests to extend the comment period, please see section 17.1 of the EPA response in this *Response to Comments* document.

Ohio Environmental Council (Doc. #1794, SBC-045321)

EPA's proposal to set strong, scientifically supported drinking water standards for six PFAS is an important step toward fulfilling the Biden Administration's commitment to tackle these toxic forever chemicals. We commend EPA's recognition that both individual PFAS and chemical mixtures of PFAS can threaten human health. We urge you to finalize the standards as quickly as possible.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Peggy Kurtz (Doc. #1799, SBC-046047)

Please approve the draft PFAS regulations as quickly as possible – and move on to take further steps without delay.

Thank you,

Peggy Kurtz

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Safe Drinking Water Branch, Hawaii Department of Hawaii (Doc. #1801, SBC-043758)

Since the PFAS necessary will definitely compete with other EPA mandates, including compliance with the Lead and Copper Rule Revisions (LCRR) and recently announced cybersecurity measures, the state agent, we suggest EPA considering postpose the finalization of the PFSA rule to give us and water purveyors more time to prepare.

EPA Response: Please see section 17.2 of the EPA response in this *Response to Comments* document. For additional discussion about the compliance timeline, please see section 12.1 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Earthjustice et al. (Doc. #1808, SBC-046095)

With more than half of the nation drinking PFAS-contaminated water, [FN2: David Q. Andrews and Olga V. Naidenko, Population-Wide Exposure to Per- and Polyfluoroalkyl Substances from Drinking Water in the United States, Env't. Sci. & Tech. Letters 931 (2020), https://doi.org/10.1021/acs.estlett.0c00713.] the Proposed Rule is urgently needed and should be finalized expeditiously, with the revisions outlined below. But as EPA Administrator Michael Regan acknowledged, "[w]hile this proposal is a step forward, there's no doubt there's more work left to do." [FN3: Michael Regan, Admin., EPA, Remarks for the PFAS Drinking Water Standard Event, As Prepared for Delivery (Mar. 14, 2023), https://www.epa.gov/speeches/administrator-michael-regan-remarks-pfas-drinking-water-standard-event-prepared-delivery.]

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046098)

EPA has known of the harms associated with PFAS since at least 1998, and it has known of the presence of PFAS in drinking water since at least 2001. [FN18: Scott Faber, For 20-plus Years, EPA Has Failed to Regulate 'Forever Chemicals', Env't Working Grp. (Jan. 9, 2020), https://www.ewg.org/research/20-plus-years-epa-has-failed-regulate-forever-chemicals.] More than two decades later, however, EPA has yet to establish any federal limits on PFAS levels in drinking water. The Proposed Rule, which would regulate six widespread and highly toxic PFAS, is necessary and long overdue. EPA should act swiftly to issue final drinking water standards for PFAS, with the changes recommended below.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

Environmental Working Group et al. (Doc. #1810, SBC-044685)

Administrator Michael S. Regan

Mail Code 28221T

1200 Pennsylvania Avenue NW Washington, DC 20460

May 30, 2023

Dear Administrator Regan,

Re: Per- and Polyfluoroalkyl Substances (PFAS): Proposed National Primary Drinking Water Regulations (Docket ID: EPA-HQ-OW-2022-0114)

The undersigned organizations strongly support the regulation of per- and polyfluoroalkyl substances (PFAS) in drinking water under the authority of the federal Safe Drinking Water Act, as proposed by the Environmental Protection Agency (EPA) and published in the Federal Register on March 29, 2023. EPA's proposal to set strong, scientifically supported drinking water standards for six PFAS is an important step toward fulfilling the Biden Administration's commitment to tackle these toxic forever chemicals. We commend EPA's recognition that both individual PFAS and chemical mixtures of PFAS can threaten human health. We urge you to finalize the standards as quickly as possible.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

National Wildlife Federation Action Fund (Doc. #1811, SBC-045343)

We urge the Environmental Protection Agency to move swiftly to finalize health-protective standards to reduce PFAS in our drinking water. Thank you for your consideration and for your work to address our nation's PFAS crisis.

Sincerely,

Jim Murphy

Senior Advisor

National Wildlife Federation Action Fund

May 1, 2023

Re: Proposed PFAS National Primary Drinking Water Regulation Rulemaking Docket ID: EPA-HQ-OW-2022-0114

Dear Administrator Regan,

Thank you for taking this historic step to keep our drinking water safe from PFAS contamination. For decades, PFAS chemicals have contaminated both public and private drinking water supplies across the country. PFAS contamination exposes communities to serious health risks, including cancers, impacts to the immune and reproductive systems, and other harms. The EPA's proposed drinking water standards would provide long overdue federal protections against six types of highly toxic PFAS. I strongly support this proposed rule and urge EPA to move swiftly to finalize health-protective standards to reduce PFAS in our drinking water.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.

National Wildlife Federation Action Fund (Doc. #1811, SBC-045346)

I urge you to quickly finalize and implement the proposed PFAS drinking water standards rule to begin federally regulating PFAS in drinking water.

Thank you,

Jennifer Rier

Clean Water Action (Doc. #1813, SBC-045496)

Re: EPA-HQ-OW-2022-0114-0027

Included in this submission are [89 public comments from three attachments] signed in support of Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation and the following statement:

"Thank you for proposing health-protective limits for PFAS chemicals in drinking water that reflect the latest scientific information on their health effects.

EPA should finalize these Safe Drinking Water Act regulations as quickly as possible, including the Hazard Index approach for four PFAS chemicals.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document. For discussion of the Hazard Index, please see sections 4.3.2 and 5.2 of the EPA response in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-047708)

Closing:

Thank you for the opportunity to provide these comments. As mentioned previously and throughout this letter, PWS understand the importance of ensuring that the drinking water that reaches their customers meets Safe Drinking Water Act requirements and supports continued public health protection. Water suppliers work hard each day to meet these goals and satisfy their customers' expectations. Addressing emerging contaminants is a huge challenge. Our members will be tasked with meeting regulatory requirements and standards. Therefore, EPA has an obligation to address our implementation concerns before finalizing the regulations. We look forward to working collaboratively with EPA and the state primacy agencies on reasonable and achievable standards.

Sincerely,

James DeCelles, PE President

CC: NEWWA Board of Directors

EPA Response: The EPA has considered all significant public comments submitted on this PFAS NPDWR rulemaking, including those from the commenter. Please see section 17.2 of

the EPA response in this *Response to Comments* document and section XI of the FRN for this action for concerns regarding implementation.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045840)

IV. Conclusion

We appreciate the opportunity to comment on EPA's proposed NPDWRs. The proposed standards, which are science-based, protective, feasible, and cost-justified, are necessary to deliver meaningful risk reduction benefits to millions of Americans exposed to harmful PFAS. Thus, Commenters urge the Agency to finalize the rule expeditiously in protection of impacted communities in Wisconsin and nationwide.

Respectfully Submitted,

Mr. Michael Regan,

Dear Administrator Regan,

Please swiftly act to protect the public from exposure to dangerous PFAS chemicals in drinking water. While the March 2023 proposal is a step in the right direction we also need to do the following:

1. Please do not capitulate to the delay tactics by industry that wants you to extend the comment period.

EPA Response: Please see the EPA response to comment Doc. #1853, SBC-045502 in section 17.2 in this *Response to Comments* document.

Sherry Masiulaniec (Doc. #3012, SBC-047512)

I urge you to quickly finalize the regulations of these six PFAS chemicals, implement a rule that is health protective, and then begin addressing all other types of PFAS...we have had some proems with our drinking water..they came to the conclusion it could affect babies & people with amunity problems & eldery also . I'm on kidney dialisis and 2 months before the city informed us with a short letter in our water bill of the problem. I had already started drinking bottled water because the tap water was making me feel I'll. It had a grayish tint & a foul taste! I feel there should be more strict rules to the testing of everyone's water. Then maybe it won't take 2 months to notify the public of a possible problem. I'm sure other people were getting sick & maybe just couldn't figure out it was their darn city water !!!

Thank you for listening & I hope something can be done to prevent this from happening again.

EPA Response: The EPA has taken final action on the PFAS NPDWR as expeditiously as possible and ahead of its statutory deadline. Please see section 17.2 of the EPA response in this *Response to Comments* document.
