My name is Marguerite Adelman and I'm the coordinator of the Vermont PFAS Military Poisons Coalition. Our coalition believes that the EPA's proposed drinking water standards, while a huge step forward, are not comprehensive enough, take too long to enact, and don't set PFOA and PFOS at the limits needed to protect people and animals from harm. EPA's chemical-by-chemical approach is just not good enough to protect public health and the environment. We must regulate PFAS as a class of chemicals, ban all but absolutely essential uses of these toxins and allow no new PFAS to enter the market. The EPA should do with the European Union's Chemical Agency has done, ECHA. ECHA proposes to ban PFAS production and the import of over 10,000 forms of PFAS chemicals in the European Union. 108 European countries have committed to phasing out PFAS chemicals from products and processes and have joined in calling for comprehensive laws to deal with PFAS. The proposed EU ban on PFAS is extensive as opposed to the EPA's approach of regulating a few PFAS at a time. The EPA's proposal to regulate PFAS doesn't even include all of the 26 most common forms of PFAS found in drinking water. There are no pending proposed standards for 20 of these, and 12 of these PFAS are not included in current monitoring. Three of these PFAS fall outside the working definition for PFAS that the EPA adopted without any outside review. Finally, the laws won't even take effect until 2026. The EPA and all U.S. government agencies need to start using the precautionary principle, especially in regard to PFAS. Before a product goes on the market, a company must prove it is safe for our health and the environment, and all ingredients must be listed and known to consumers. We have the right to know. If there is any doubt, we must err on the side of caution and logical scientific assumptions and not allow the product on the market. We must protect future generations. Thank you.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Michigan League of Conservation Voters (Doc. #3072-83, SBC-046392)

Thank you for this opportunity. My name's Jessica Schick. I'm a student from Grandville, Michigan and I also work as a regional organizer for the Michigan League of Conservation Voters. I applaud the EPA for proposing strong limits on six widely detected PFAS in our drinking water. I live a couple minutes away from Millennium Park, which is the largest urban park in West Michigan. In 2021, PFAS was discovered in a former landfill within the park. As someone who grew up visiting Millennium Park multiple times a week, I was devastated to learn that water flowed from that landfill into the parks, lakes, and wetlands. Six of the park's seven lakes were affected by PFAS contamination, but by current standards, they were deemed still safe for people to use. Previous speakers have noted the long list of health issues caused by PFAS and that no level of PFAS is truly safe. The park is a popular place for local families. We swim and fish in those lakes. And Millennium Park is one of over 12 identified PFAS sites along the Grand River, which flows into Lake Michigan. Both the river and Lake Michigan are the main sources of drinking water for people in West Michigan. We urge you to finalize these

standards as quickly as possible. While this is an important first step, in order to fully protect the health of people, communities, and the environment, we urge the EPA to move towards regulating PFAS as an entire class of chemicals instead of one by one. Addressing the entire class of PFAS will reduce overall PFAS exposure and improve drinking water safety in thousands of communities across the country. Thank you.

EPA Response: The commenter supports this PFOA, PFOS, PFHxS, PFNA, HFPO-DA, and PFBS rulemaking. In regard to regulating other PFAS, please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Author (Doc. #3072-85, SBC-046394)

My name is Callie Lyons and I'm the author of "Stain-Resistant, Non-Stick, Waterproof and Lethal," the first book about this PFAS plague on our population. I want to commend the many students who we're hearing from today. Your time is well spent and much appreciated. I encourage you to visit the place where I live and see what has happened here. You see, I live near Parkersburg, West Virginia, and if you've seen the movie Dark Waters, you know our story. As ground zero in the public's awareness of this problem, many people, including local residents, believe this problem has been tackled and is behind us. They do not realize the poisoning continues. While some of our communities have filtration systems, many do not. Parkersburg, for instance, does not. I count more of my friends and neighbors as sick from exposure related illness than those who are not. And the people here who get sick don't just get one related illness, they often suffer through two or three or more before it ends their lives. Please regulate these dangerous substances as a class and do it with all haste, but please do it in a way that will not leave us behind. A very real concern is that the unintended consequences of these measures could easily lead to a situation where filtration materials and processes become so widely in demand that solutions would be available only to the highest bidder or the most populous areas. That would leave us in the same desperate situation we find ourselves in today. This proposed action regarding water is a start, but it is only a start as we will continue to be exposed in so many other ways. Since 2003, I've heard one comment more than any other when it comes to our pollution situation. If it was really a problem, the EPA would do something about it. Please do something about it and now. Make it meaningful and fulfill your promise to protect our people. Thank you.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

WWALS Watershed Coalition Inc. (Doc. #3072-86, SBC-046395)

Thank you. Yes. I'm John Quarterman. I'm the Suwannee Riverkeeper with WWALS Watershed Coalition Inc. trying to keep waters clean in the 10,000 square miles Suwannee River Basin in Georgia and Florida. I would like to urge EPA to rapidly complete the process of setting Maximum Contaminant Levels for the most toxic PFAS as well as total PFAS in drinking water. As others have noted, EPA needs to use PFAS classes since the manufacturers can avoid specific

chemicals by tinkering with the formula to change it slightly. We have previously requested and continue to request requiring producers to label products with each PFAS or PFOAS. Now we ask to add the class of each. While it's necessary to deal with point sources such as wastewater treatment plants, the rule also needs to deal with non-point sources such as human waste used as fertilizer, whether processed or not, such waste washes off into waterways. In tests we conducted last year in Georgia and Florida, we found PFAS in our Withlacoochee River, both upstream and downstream of the most relevant point sources, so we suspect some is coming from non-point sources. Back in 2014, PFAS was found in much higher levels in fish in our Alapaha River. It accumulates in fish, which are often eaten by people. EPA needs to require and Congress needs to find a way to fund waterway quality testing and fish testing for PFAS. As observed in Maine, PFAS can pass through cows who eat fodder fertilized that way and then may come out in milk or possibly even in meat. The food supply also needs to be tested and regulated for PFAS. Most importantly, EPA needs to strongly regulate the producers of these substances to radically cut down on this problem. Yet there's so much of it out there that all of the above is also necessary and EPA should require the PFAS producers to pay the cost of labeling, testing, additional wastewater processing, regulation, and cleanup. If EPA cannot do that, then Congress needs to ask. Thank you.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Michigan League of Conservation Voters (Doc. #3072-88, SBC-046396)

Hi. Thank you very much for the opportunity to speak to this today. My name is Victoria Stewart and I work with the Michigan League of Conservation Voters. I also reside in the state of Wisconsin where many community members have personally experienced health problems or live in health effected communities. We urge you to finalize these standards as quickly as possible. And while we know that this is an important first step in order to fully protect the health of people, communities, and the environment, we urge the EPA to move toward regulating PFAS as an entire class of chemicals instead of one by one. PFAS have contaminated drinking water supplies for approximately 200 million people and the blood of nearly every individual in the United States, including newborn babies who are exposed in the womb. This proposal will save thousands of lives and prevent tens of thousands of serious PFAS related illnesses each year, but we cannot wait to do this one by one. We know that if we continue to wait year by year, we will just have more communities and more individuals impacted by the negative effects of PFAS. I work with groups like the Great Lakes PFAS Action Network who represent PFAS impacted communities across the Great Lakes region, and these impacted community members have been exposed to both individual PFAS and chemical mixtures of PFAS, which is why this is so important. These proposed regulations are long overdue when we fully support this first step of regulating six dangerous PFAS in drinking water, and as the EPA moves forward and considers additional standards and actions, we urge you to take a comprehensive approach to regulating the entire class of chemicals. Addressing the entire class of PFAS will reduce overall PFAS exposure

and improve drinking water safety in thousands of communities across the country. Thank you very much.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Catherine Daligga (Doc. #3072-89, SBC-046397)

My name is Catherine Daligga and I'm a 65-year-old mother, grandmother, cancer survivor, climate and environmental activist and up. Every day of delay in imposing and enforcing these strict standards is a day lost to preventing future harm. Like others speaking today, I'm horrified by the scope of the problem and I consider it urgent lifelong resident of Southeast Michigan. Thank you for hosting this public comment period on water protection standards. I appreciate being in our virtual room with so many concerned and engaged citizens, and I'm grateful that the EPA is proposing limits for these six PFAS-related compounds in accordance with the scientific evidence, recognizing that basically no amount of these chemicals is safe to have in our water. My current hometown of Ypsilanti, Michigan is in the Huron River Watershed, already known to be impacted by PFAS contamination and thus affecting the Ann Arbor water system that does draw from the Huron. Since Ypsi is on the Detroit water system instead, as far as I know, I'm not personally at immediate risk from increased PFAS exposure, but we do have at least six other identified PFAS sites in Washington County near me. And I'm deeply concerned regardless about the risk of PFAS contamination for everyone in my local community, county, region, state, and country. According to the Michigan PFAS Action Response Team, there's currently more than 200 confirmed PFAS contamination sites in the state of Michigan alone, with more than 11,000 suspected PFAS sites throughout the state. We know that this class of chemicals is already so ubiquitous that we face a massive challenge in cleaning it to address it as quickly and completely as possible. Inaction and delay are not justifiable. We have already lost too much. Too many people like Amara Strande, too many residents of communities like Boston, Michigan and Parkersburg, West Virginia. This step should be merely the first of many taken by the EPA to regulate PFAS compounds as a class rather than considering them one by one. The time to act is now, not only to implement these new regulations, but to devise more comprehensive measures for eliminating these dangerous toxins as well as for holding the original manufacturers rather than the general public responsible for the cleanup costs. Thank you again for your time.

EPA Response: The commenter supports this PFOA, PFOS, PFHxS, PFNA, HFPO-DA, and PFBS rulemaking. In regard to regulating other PFAS, please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Hanaloa Hillela (Doc. #3072-92, SBC-046400)

Aloha. My name is Hanaloa Hillela, and thank you for giving me this opportunity to speak. I am from Oahu, Hawaii, and I am new to dealing with this PFAS, and it is coming on the tail end. I've become deeply involved in a water struggle here in Hawaii. As many of you know, the Red Hill

crisis, the Navy's underground storage facility leaking into our aquifer. And we thought if that wasn't bad enough, about a year after a major spill, the 11/20/2021 spill, about a year and nine days later in 2022, there was a spill of 1,300 gallons of AFFF concentrate, which has lots of PFAS in it, and this is right coming out of the Red Hill facility as well. So, we're highly concerned about these continuing spills and tests revealing more and more PFAS in our environment. Lately in the news we're finding out Kunia village, we're finding high levels of PFAS in their drinking water wells, Wahiawa we're finding. And we're often finding the PFAS is directly associated with military facilities. In central Oahu, the Kunia village situation, it seems like that is coming from the Schofield wastewater treatment facility, which I believe was privatized back in early 2000s by the military. But that's processing a lot of the wastewater out of the military bases, which we know that not only for firefighting foam but for de-greasing and other maintenance and service needs PFAS is extensively used. So, I would like to support most of the testimony that's been given that we have to treat this as a class rather than individual chemicals, which the chemical industries will find loopholes through. And I think that we need to go zero tolerance. I applaud.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Kristina Winter (Doc. #1559, SBC-042544)

The proposed drinking water standards are a great first step to address these particular PFAS chemicals, however, I urge EPA to not stop here—it is critical that EPA next moves to regulate the full class of PFAS chemicals.

Thank you for your consideration.

Sincerely,

Miss Kristina Winter

161 Oakland Ave Miller Place, NY 11764-3406 kristinawinterdesigns@gmail.com

EPA Response: The commenter supports this PFOA, PFOS, PFHxS, PFNA, HFPO-DA, and PFBS rulemaking. In regard to regulating other PFAS, please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Minnesota Pollution Control Agency (MPCA) (Doc. #1569, SBC-042499)

MPCA strongly encourages EPA to continue developing MCLs for individual PFAS, groups of PFAS and their precursors, or other PFAS subgroups for drinking water regulations in the next round of regulatory determinations, including PFAS with completed IRIS assessments and considering development of a summed PFAS MCL or a similar means to address unregulated PFAS.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Minnesota Pollution Control Agency (MPCA) (Doc. #1569, SBC-042489)

The MPCA also urges EPA to take further steps to address PFAS in connection with this proposal. EPA should develop and adopt MCLs for additional PFAS with completed Integrated Risk Information System (IRIS) assessments (PFBA [Link: https://iris.epa.gov/ChemicalLanding/%26substance_nmbr=701] , PFHxA [Link: https://iris.epa.gov/ChemicalLanding/%26substance_nmbr=704] and soon, PFDA), either individually or as part of the HI-based PFAS MCL, in this rulemaking or as soon as possible. In addition, there is a need for a summed PFAS MCL or similar type of regulatory value to account for exposures to PFAS in drinking water that do not have MCLs (and are unlikely to any time soon, given the lack of toxicity data for the vast majority of PFAS).

We are aware that suggesting EPA develop an alternative and/or summed PFAS MCL is outside the bounds of "normal" with respect to the SDWA practice of developing individual MCLs. Nevertheless, the lack of toxicity data with which to develop traditional toxicity-based MCLs, and the serious human health impacts from PFAS that are being identified and verified (one resource is Kwiatkowski et al., 2020 and 2021), provide a strong driver for EPA to develop such an approach. Pelch et al. (2023) just published the results of a pilot study focused specifically on the Unregulated Contaminant Monitoring Program 5 or UCMR5, which will inform policy makers of the need to develop future PFAS MCLs. Pelch et al. suggest the design of the UCMR5, which is taking place now through 2025, will result in a number of gaps in detection of PFAS. A summed PFAS MCL is needed to better account for the variety of PFAS being detected in drinking water now, until a better approach can be formulated and promulgated.

Other entities have developed alternative and/or summed PFAS regulatory values. The European Union (EU) 2020 drinking water directive (DWD) includes drinking water standards for a defined sum of 20 PFAS at 100 ng/L or for a total PFAS at 500 ng/L. EU Member States have until 2023 to incorporate this into their national legislation. Bil et al. (2021) propose using a relative potency factor (RPF) that has PFOA as an index chemical. EPA itself is doing research to facilitate grouping PFAS chemicals regarding their toxicokinetic half-life, as a basis for prioritization (Dawson et al., 2023). While none of these approaches is likely fully developed or completely compatible with the dictates of the SDWA, they provide a basis for developing a summed PFAS MCL that has a scientific foundation and rationale to address the clearly demonstrated need.

Per EPA's Request for Comment (RFC), the MPCA has provided specific comments below, by section. Some, identified as such, respond specifically to the questions put forth by EPA in Section XIV of the RFC.

Section III- Regulatory Determinations for Additional PFAS

1) EPA asks: are there other peer-reviewed health or toxicity assessments for other PFAS the EPA should consider as part of this action?

MPCA response:

• The Integrated Risk Information System (IRIS) PFBA [Link: https://iris.epa.gov/ChemicalLanding/%26substance_nmbr=701] and PFHxA [Link: https://iris.epa.gov/ChemicalLanding/%26substance_nmbr=704] assessments are completed and should be considered for inclusion in this rulemaking, either for development of stand-alone MCLs/MCLGs or as part of the mixture of PFAS that are proposed to be regulated under the general Hazard Index (HI) approach, whichever would be most appropriate.

• Likewise, the IRIS PFDA [Link: https://iris.epa.gov/ChemicalLanding/%26substance_nmbr=702] draft assessment is out for public comment, EPA should consider whether this assessment will move towards finalization on a timeline where it could be incorporated into this rulemaking, either for development of a stand-alone MCL/MCLG or as part of the mixture of PFAS that are proposed to be regulated under the general HI approach.

2) EPA asks: will regulation of PFHxS, HFPO-DA, PFNA, PFBS and their mixtures, in addition to PFOA and PFOS, provide protection from PFAS that will not be regulated under this proposed rule?

MPCA response:

• MPCA does not believe regulation of PFHxS, HFPO-DA, PFNA, PFBS and their mixtures, in addition to PFOA and PFOS, provide protection from PFAS that will not be regulated under this proposed rule. That is why MPCA has urged EPA to adopt MCLs for additional PFAS with completed IRIS assessments (PFBA [Link: https://iris.epa.gov/ChemicalLanding/%26substance_nmbr=701] , PFHxA [Link: https://iris.epa.gov/ChemicalLanding/%26substance_nmbr=704] and soon, PFDA), either individually or as part of the HI-based PFAS MCL, in this rulemaking or as soon as possible. That is also why MPCA is urging EPA to consider development of a summed PFAS MCL or similar to account for exposures to PFAS in drinking water that do not have MCLs (and are unlikely to any time soon).

• If the HI-based PFAS MCL is exceeded, treating for PFHxS, HFPO-DA, PFNA, and PFBS will remove other PFAS that co-occur. However, the threshold for when treatment would be required is likely not low enough to protect public health from the occurrence of other PFAS. Inclusion of additional PFAS in the general HI approach could reasonably result in the HI being exceeded more often than if only four PFAS are included.

• Another possibility to improve the protectiveness of the HI-based PFAS MCL would be to add a “mixture factor” similar to a relative source contribution (RSC) adjustment with consideration of other unquantified PFAS in the drinking water. For example, a mixture factor of 80% would mean that there is 20% of the total quantified “toxicity” that is reserved for non-quantified PFAS.

• Note MPCA's previous comment about the need for a summed PFAS or similar type of MCL to protect for non-quantified or un-regulated PFAS.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document. Regarding the application of a "mixture factor," at this time, the EPA does not have the scientific basis for establishing or applying such a factor. Instead, the EPA is using the general Hazard Index method, which is supported by precedent in other regulatory contexts, agency chemical mixtures guidance, and the SAB review of the draft PFAS Mixtures Framework.

Minnesota Pollution Control Agency (MPCA) (Doc. #1569, SBC-042491)

There is a concurrent need for individual PFAS MCLs where completed IRIS assessments are available and/or where sufficient toxicological and toxico-kinetic data is available, per other comments in this letter.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Endocrine Society (Doc. #1579, SBC-042427)

We urge the EPA to build on the proposed regulation to advance more comprehensive solutions that regulate PFAS as a class of chemicals for the protection of public health and the environment. Thank you for considering our comments; if we can be of further assistance, please contact Joseph Laakso, PhD, Director of Science Policy at jlaakso@endocrine.org

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

American Public Works Association (APWA) (Doc. #1584, SBC-042392)

PFAS are a large, complex group composed of thousands of synthetic chemicals and testing for more and more of them would undoubtedly risk exacerbating other challenges. The lack of clarity on whether other PFAS might be slated for regulation as drinking water contaminants in the foreseeable future is also concerning especially as communities consider which treatment methods that may best capture a wider spectrum of PFAS chemicals.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Cape Fear Public Utility Authority (CFPUA) (Doc. #1588, SBC-042380)

As the most high-profile constituent of Chemours' PFAS contamination in the Cape Fear River, GenX remains a contaminant of concern for CFPUA and our customers. We commend EPA for including it in the proposed NPDWR, support the concept, and are grateful for the certainty it

brings to treatment standards. As CFPUA continues to evaluate EPA's proposal for regulating GenX, PFHxS, PFNA, and PFBS as components of a Hazard Index, we suggest that any future additions or modifications to the Hazard Index be introduced through formal rulemaking to ensure proper alignment with the public interest and the Administrative Procedures Act. As is the case with PFOA and PFOS, GenX and the other three hazard index compounds are being removed by CFPUA's new GAC filters to levels that, based on current raw water concentrations, will remain significantly below the proposed Hazard Index compliance threshold.

EPA Response: The commenter supports regulating GenX chemicals (referred to as HFPO-DA throughout this approach). In regard to regulating other PFAS, please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Public Health, Seattle & King County (PHSKC) (Doc. #1594, SBC-042356)

Below are recommendations that PHSKC feels would strengthen the proposed protective actions:

Include additional PFAS found in drinking water in the MCL/MCLG derivations for PFAS mixtures in drinking water and develop a system that rapidly incorporates regulatory limits for new PFAS found in drinking water. We have continued concerns about additional PFAS that are found in drinking water and hope that EPA will continue to rapidly include additional PFAS on this list. Additional PFAS beyond the ones identified above have been detected in drinking water [FN1: Pelch et al. 70 analyte PFAAS test method highlights need for expanded testing of PFAS in drinking water. Science of the Total Environment (2023) 876: 16298]. The PFAS selected for possible regulation are a small number of those that found in drinking water. EPA should also conduct research to determine which PFAS remain following drinking water treatment that exceed any of the proposed MCLs to inform how protective remediation will be for other PFAS not included in the proposed regulatory actions.

EPA Response: In regard to regulating additional PFAS, please see section 4.3.5 of the EPA response in this *Response to Comments* document. In regard to PFAS treatment, please see section 10 of the EPA response in this *Response to Comments* document. For a description of numerous current EPA activities related to PFAS, including PFAS treatment, please see the EPA PFAS Strategic Roadmap (https://www.epa.gov/pfas/pfas-strategic-roadmap-epas-commitments-action-2021-2024).

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043672)

[The treatment of these compounds in the proposed regulation is problematic for several reasons:]

2. Future Implications – PFOA and PFOS are the most common PFAS compounds found in the nation's drinking water and the family of PFAS compounds ranges in the thousands. The City

has a concern about the potential complexities with the Index when new PFAS compounds are added to future regulations.

EPA Response: Please see sections 4.3.2 and 5.2 of the EPA response in this *Response to Comments* document.

New York City Department of Environmental Protection (NYCDEP) (Doc. #1679, SBC-044209)

The HI excludes PFHpA (VII.e. p. 18678) based on a finding of no-toxicity (XIII.F.18719). PFHpA was included in the UCRM3 and has demonstrated occurrence data. The finding of no toxicity of PFHpA, which seems premature based on a "small number of studies investigating immunotoxicity," is used as rationale for exclusion from the HI. It would seem more appropriate to include this analyte in the HI with a high divisor level, rather than to exclude it from the HI altogether. The analyte is found using both approved methods, and data will be available at no additional cost (i.e., this suspected contaminant is excluded even though EPA has available data).

EPA Response: The EPA disagrees with this comment. The EPA did not state that the Hazard Index excludes PFHpA based on a finding of no toxicity. The commenter is citing excerpts from the *ATSDR Toxicological Profile for Perfluoroalkyls* that were cited by the EPA in the "Non quantifiable Benefits of Removal of PFAS Included in the Proposed Regulation and Co-Removed PFAS" section of the preamble to provide information about adverse health effects associated with exposure to unregulated co-occurring PFAS. Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Public Employees for Environmental Responsibility (PEER) (Doc. #1683, SBC-044969)

EPA needs to regulate more than six PFAS in drinking water. There are thousands of individual PFAS, depending on how they are defined [FN4: https://www.sciencedirect.com/science/article/pii/S2589004222002905]. When a particular PFAS comes under scrutiny, industry develops "regrettable substitutions" that are themselves toxic PFAS [FN5: https://www.env-health.org/wp-content/uploads/2023/04/Briefing-PFAS-biomonitoring-information-April2023.pdf]. When EPA finalizes this proposed rule, industry will likely turn to other PFAS with limited or nonexistent toxicity information, which will create additional human health and environmental concerns. Moreover, it is critical to note that this proposed rule does not take into account precursor compounds. PFAS compounds generally come in one of two forms: a precursor or a terminal form. EPA's proposed rule deal with six terminal compounds that do not degrade under normal environmental conditions. However, because unregulated precursor compounds can be transformed in the environment into the regulated terminal forms, regulating only the terminal compounds is not a solution. Indeed, Harvard University researchers recently found that roughly half of the PFAS found on a Cape Cod military base "consist of precursors that can transform into terminal compounds of known health concerns..." [FN6: https://pubs.acs.org/doi/full/10.1021/acs.est.3c00675].

Therefore, the only way for EPA to truly protect human health and the environment from PFAS is to: 1) define them broadly; 2) regulate them as a class; 3) ban all non-essential uses of PFAS; and 4) implement stringent disposal and cleanup standards. Regulating six PFAS in drinking water is a start, but it is the proverbial drop in the bucket.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Three Rivers Waterkeeper (3RWK) (Doc. #1689, SBC-044976)

The EPA's decision to base the MCLs for these four PFAS off of the Hazard Index (HI) approach expects and accounts for co-occurrence. By basing the MCL on the sum of each chemical's ratio of potential exposure to the level of exposure at which no health effects are expected, the EPA seems to have created a framework for the addition of further PFAS if and when new studies reveal those PFAS to be harmful. If in time it becomes necessary to regulate all PFAS as a class, we hope that this framework will help to determine the appropriate MCLs.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

City of Lancaster, Pennsylvania (Doc. #1695, SBC-044994)

3. USEPA Future Rule Making Shortcut: The USEPA has shown a new system/methodology of grouping future PFAS species directly into the hazard category without thorough testing of a chemical individually to determine its biological impact. Moreover, this ruling is being made without the UCMR5 study data which focuses on these compounds. It is a major issue when the known vetted rulemaking process is circumvented for ease in what appears to be a knee jerk reaction without proper scientific data to fully back up a decision. It shows a departure not only from the use of thorough scientific reasoning and methodology, but it can result in a significant chance for mislabeling and incorrectly assuming the risk/behaviors of the said chemical. The newer method of being able to link chemicals under the hazard grouping for PFAS without going through the appropriate rulemaking and analysis short circuits the ability to appropriately study and validate the results while potentially mischaracterizing a new chemical's potential risks and potential mitigation.

One critical example of this method having flaws is through the study of the periodic table of the elements. When you look at the group of elements 80-84 these all would be considered poisonous and deadly by the new grouping method being used by EPA. However, if that had happened then humanity would never have found that Bismuth (element 83), which is between two of the most poisonous elements known to man, is one of the best elements for helping human internal gut health when they are sick, and we would not have the universally known product of Pepto-Bismol.

EPA Response: Please see sections 4.3.5 and 4.3.2 of the EPA response in this *Response to Comments* document. Regarding the comment on bismuth, that topic is out of scope of this final NPDWR. Regarding UCMR 5 data, please see sections 3.1.2 and 6.8 of the EPA response in this *Response to Comments* document.

Susan Gorman-Chang (Doc. #1705, SBC-045082)

EPA-HQ-OW-2022-0114

Comments submitted by: Susan Gorman-Chang

I am appreciative of the EPA finally taking the threat of PFAS to human health seriously and these proposed regulations to regulate these harmful chemicals.

I have the following suggestions concerning these regulations:

1. Change the regulations to treat PFAS as a class of chemicals using regulation by class in the same manner as proposed by the Intergovernmental Organization for Economic Cooperation and Development and used by the members of the European Union. This would mean a comprehensive approach to the as many as 5,000 to 12,000 variations of PFAS chemicals and would provide more protection for the health of all human beings and wildlife.

2. I applaud your hazard index approach, as this can be a first step towards regulating PFAS as a class.

EPA Response: The commenter supports the use of the Hazard Index in this drinking water regulation. In regard to regulating other PFAS, please see section 4.3.5 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045125)

Comment: Please explain how states can account for PFAS other than the four PFAS included in the Hazard Index equation.

Explanation: While the Department appreciates EPA's cumulative approach to four PFAS, the Hazard Index approach is not adequate to protect health. The Hazard Index approach does not offer a path to add additional PFAS. For example, the EPA IRIS program published final toxicity values for PFHxA on April 10, 2023. The EPA IRIS program has several additional PFAS toxicity values in development. Yet the Hazard Index equation does not offer flexibility to include additional PFAS as toxicity values become available. In addition, the Hazard Index equation does not adequately address PFAS as a class. As EPA methods for PFAS analysis improve and additional PFAS are included, we gain more and more information on our exposures to PFAS. Yet the Hazard Index equation does not include additional PFAS either with or without final toxicity values. This sends the message that other PFAS are not of public health concern.

Given what we know of PFAS, including those under assessment by IRIS, this is not a health-protective assumption.

EPA Response: In regard to regulating other PFAS, please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Citizens Campaign for the Environment (CCE) (Doc. #1710, SBC-045138)

Regulate PFAS as a Class. The proposed EPA regulations are a great first step and should be implemented as soon as possible. However, there are thousands of PFAS chemicals with similar characteristics and health impacts as the PFAS chemicals covered by these regulations—this should only be the start for EPA and the Agency should ultimately move to regulate PFAS as a class.

EPA Response: The commenter supports this PFOA, PFOS, PFHxS, PFNA, HFPO-DA, and PFBS rulemaking. In regard to regulating other PFAS, please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Citizens Campaign for the Environment (CCE) (Doc. #1710, SBC-045135)

Recommendation to strengthen the Hazard Index: CCE recommends that EPA develop a process to add additional PFAS chemicals to the Hazard Index. We know that there are many thousands of PFAS chemicals, which have similar characteristics and cause similar adverse health impacts. As more information becomes available on additional PFAS chemicals, rather than starting a rulemaking process from scratch, which can take years to complete, EPA should develop a process to more efficiently add additional PFAS chemicals to this existing Hazard Index.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Private Citizen – General (Doc. #1722, SBC-043834)

3. Please regulate these chemicals as a class. We are tired of playing whack-a-mole with the manufacturers who slightly modify the chemical structure to stay ahead of health studies.

4. Regulating PFAS chemicals as a group would also stop the use of precursors that readily convert to legacy PFAS chemicals.

Thank you for your attention to this matter. Best,

Donna Reardon

Donna Reardon

Concord, New Hampshire 03301

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045176)

Inclusion of additional PFAS in the Hazard Index

EPA selected four PFAS for inclusion in an HI approach for MCLG development: hexafluoropropylene oxide (HFPO) dimer acid and its ammonium salt (also known as GenX chemicals), perfluorobutane sulfonic acid and its related compound potassium perfluorobutane sulfonate (PFBS), perfluorononanoic acid (PFNA), and perfluorohexanesulfonic acid (PFHxS). EPA identified these PFAS as having continued co- occurrence in drinking water and HBWCs that were available or could be calculated using recently published, peer-reviewed, publicly available assessments. MassDEP is supportive of the HI approach due to its ability to address co-exposures of PFAS in drinking water, but we recommend that EPA clarify its intent to incorporate additional PFAS into the HI. The EPA Integrated Risk Information System (IRIS) assessments for perfluorobutanoic acid (PFBA) and perfluorohexanoic acid (PFHxA) were finalized in December 2022 and April 2023, respectively, and could be used to derive HBWCs for inclusion in the HI approach. The IRIS Program also has assessments in development for perfluorodecanoic acid (PFDA), PFHxS, and PFNA that could be incorporated into the HI once finalized. Further, EPA should consider applying read across approaches to address additional PFAS with continued co-occurrence such as perfluoroheptanoic acid (PFHpA). EPA should clarify the inclusion criteria for PFAS compounds in the HI and the process for updating HBWCs as additional assessments and occurrence data become available to ensure that the MCLG and MCL are adequately protective of public health.

EPA Response: The commenter supports the Hazard Index in this regulation. In regard to regulating PFAS beyond those six regulated as part of this rulemaking, please see section 4.3.5 of the EPA response in this *Response to Comments* document.

North Carolina Conservation Network (Doc. #1728, SBC-043560)

In North Carolina, data from the Cape Fear River has indicated high levels of PFMOAA [FN1: See, for example, Cape Fear Public Utility Authority, website: Latest PFAS Test Results [Link: https://www.cfpua.org/779/Latest-PFAS-Test-Results], last visited May 30, 2023. The data indicates levels of PFMOAA and other PFAS in both raw and finished drinking water. See also, Frannie Nilsen, PFMOAA Summary [Link: https://www.deq.nc.gov/pfmoaa-summary-presentationpdf/download?attachment] (Presentation to the Secretaries' Science Advisory Board), February 8, 2023, slide 4 (noting that PFMOAA accounts for 67% of the total PFAS in the Cape Fear at the Huske Dam boat ramp, and 26% further downstream on the Cape Fear)]. We expect PFMOAA to have similar impacts on human health as other PFAS [FN2: Nilsen, slide 6 (summarizing toxicological indications for PFMOAA)]. As a short-chain PFAS, it breaks

through granular activated carbon treatment quickly. Because PFMOAA foils treatment so quickly, even where others of the four PFAS in EPA's proposed index are present, the index may not shield water system customers from exposure to PFMOAA. Where none of the six PFAS targeted by EPA's proposal are present, of course, the MCL will also not require drinking water treatment to remove PFMOAA or any other locally common PFAS.

We appreciate EPA's efforts to address PFAS nationally through the PFAS Strategic Roadmap [FN3: U.S. EPA, PFAS Strategic Roadmap [Link: https://www.epa.gov/system/files/documents/2021-10/pfas-roadmap_final-508.pdf], October 2021]. We also understand that, because PFMOAA is not common across the country, the agency has not prioritized it as a target for research to develop a health value. Yet, PFMOAA remains a leading source of exposure here. In February 2023, North Carolina's Secretaries' Science Advisory Board considered whether existing published literature was sufficient to establish a health value for PFMOAA. The advisory body found inadequate literature at the time, but noted that studies in publication may well provide a suitable basis to develop a reference dose and derive a health value for PFMOAA this year.

EPA's draft rule includes this formula for the index portion of the proposed MCL:

GenX + PFBS + PFNA + PFHxS = Hazard Index Value, with the Index required to be kept below 1.

10 2000 10 9

We recommend adjusting the index formula to read:

GenX + PFBS + PFNA + PFHxS + [additional PFAS] = Hazard Index Value

10 2000 10 9 [adopted health value] for that PFAS

That is, we recommend that EPA build into the final rule a path for states to add locally significant PFAS to the index formula as health values become available for them [FN4: We note that the Safe Drinking Water Act (SDWA) does not preclude states from adopting their own drinking water standards. But, in this case, that would require a state to duplicate four-fifths of the existing index. States are far more likely to fit themselves into an EPA rule that makes room for them to add locally common PFAS.]. To finalize the rule in this form, EPA likely needs to cite criteria for judging when a health value is sufficiently robust. It may also be wise for the final rule to require that a state wanting to add a PFAS to the index formula do so through an official state decision, separate from the scientific process of generating a health value.

In concrete terms, for PFMOAA in North Carolina, this pathway could look like this: health studies are published on PFMOAA. The state scientific advisory body reviews the information and recommends that the state adopt a health value. Toxicologists at the NC Department of Health and Human Services derive a health value for PFMOAA. Then, the Commission for Public Health (CPH) proposes, based on the availability of a health value, to add PFMOAA to the index formula as applied in North Carolina. After notice and public comment, CPH finalizes

that decision. The Department of Environmental Quality's (DEQ) Public Water Supply program then begins to phase in the five-PFAS index within Safe Drinking Water Act implementation.

We recognize that this would not be a fast process. On the other hand, it would allow states to address PFAS that present a serious threat to their residents but that are so generally uncommon that EPA is not itself likely to develop a health value for them. In North Carolina, PFMOAA is a known example of this problem; we think it likely that there are other similar threats across the nation.

Thank you for considering this recommendation, and for working to protect all of us from unsafe exposures to this class of toxic compounds.

Stephanie Schweickert

Senior Campaign Organizer

Grady McCallie

Policy Director

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Defend Our Health (Doc. #1741, SBC-045199)

We recommend setting regulatory thresholds for the precursor PFAS which are known to transform into the regulated group of 6 PFAS. Finally, we recommend working towards regulating PFAS in drinking water as a class by adopting a total organic fluorine standard to supplement the regulation of individual chemicals.

Respectfully submitted,

Christopher D. Chavis

Vice President of Programs and Policy Defend Our Health

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document. While some states have promulgated drinking water standards for various PFAS prior to promulgation of this NPDWR, this rule provides a nationwide, health-protective level for PFOA and PFOS (as well as four other PFAS) in drinking water and reflects regulatory development requirements under SDWA, including the EPA's analysis of the best available and most recent peer-reviewed science; available drinking water occurrence, treatment, and analytical feasibility information relevant to the PQL; and consideration of costs and benefits. Regarding state flexibility to add PFAS to the Hazard Index, after the NPDWR takes effect, SDWA requires primacy states to have a standard that is no less stringent than the NPDWR. States with primacy can promulgate their own standards which could include additional PFAS as

long as the state regulation is no less stringent than the NPDWR. For further information, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

Defend Our Health (Doc. #1741, SBC-045196)

The proposal fails to account for the presence of 'precursor PFAS' which are used in ongoing manufacturing, are present in consumer products and are frequent PFAS contaminants of drinking water. Precursors like PFOSA and EtFOSE/ MeFOSE have been demonstrated to degrade into PFOS [FN3: https://www.eurofins.se/media/1568225/top_precursor_short_facts_170613.pdf], and precursors like 8:2 FTOH and 8:diPAPS are known to degrade into PFOA [FN4: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC9335875/]. These chemical transformations can happen in biological systems, including inside of the bodies of mammals [FN5: vhttps://www.sciencedirect.com/science/article/pii/S0045653520302095/pdfft?md5=78e162fdde8642140283640ef2f1cf5c&pid=1-s2.0-S0045653520302095-main.pdf]. As reported recently by Grist.org [FN6: https://grist.org/health/the-epas-proposed-pfas-regulations-ignore-a-major-source-of-drinking-water-contamination/], a recent study of Aqueous Film Forming Foam impacted sites by Environmental Science and Technology [FN7: https://pubs.acs.org/doi/10.1021/acs.est.3c00675] indicates that still other precursors transform into the PFAS chemicals PFBS and PFHxS, which the Agency proposes to regulate under a Hazard Index. It would be an astonishing missed opportunity to ignore precursors to the PFAS the EPA is proposing to regulate when we know they are present in solution in drinking water across the country and we know they can bio-transform inside the body into the very chemicals we are trying to protect people from.

Beyond the specific concern over precursors, the proposal's narrow focus on six specific PFAS chemicals fails to protect the public from the vast array of PFAS currently in the environment including the many new PFAS chemicals currently being manufactured for which there exists little toxicological data. EPA's CompTox dashboard identifies more than 14,000 individual PFAS chemicals [FN8: https://echo.epa.gov/trends/pfas-tools]. As a class, these chemicals share the characteristics of environmental persistence and mobility. The PFAS which been the subject of vigorous medical research have been demonstrated to be associated with toxic health impacts, so the EPA should move beyond the chemical-by-chemical approach and regulate the presence of all PFAS in drinking water to prevent ongoing harm to communities. The agency should adopt a total organic fluorine drinking water standard to supplement the existing proposal. This would protect people from ongoing exposure to understudied members of this toxic class of chemicals.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Defend Our Health (Doc. #1741, SBC-045194)

The Agency should expand the list of regulated PFAS to include precursors which are known to degrade into the any of the six PFAS proposed for regulation under the National Primary Drinking Water Regulations. And finally, EPA should use this proposal to move towards a class-based regulation for PFAS in drinking water.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045201)

2. CT DPH recommends the regulation of additional PFAS through their addition to the Hazard Index (HI). PFAS other than those included in the Proposed PFAS NPDWR contain chemical structural similarities and potentially may adversely impact human health. As further studies are published, the addition of PFAS that are shown to pose a threat to human health might be regulated by their inclusion in the HI. Such a streamlined approach for the further regulation of harmful PFAS would be beneficial toward the protection of human health.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045243)

EPA is proposing to regulate six out of thousands of PFAS chemicals; the additional nonregulated PFAS contain chemical structural similarities and potentially may adversely impact human health. As additional occurrence data, such as UCMR 5, and additional human health data are peer-reviewed and published, EPA should consider a streamlined approach to be able to regulate the chemicals. Detections of PFOA, PFOS, PFNA, PFHxS, PFBS, PFHpA, PFHxA, and PFDA have all been reported in the finished water supply of Connecticut public water systems, but only five of these chemicals are included in the proposed Rule. If future studies indicate occurrence and human health impacts from additional PFAS, adding each PFAS individually to the NPDWR will be a time and resource intensive process. CT DPH supports regulating PFAS mixtures with a Hazard Index if implemented appropriately. By being able to add PFAS to the mixture list through regular revision, as opposed to an individual rule, it will help speed up the process and ensure the regulated PFAS list is representative of the rapidly changing science and most protective of human health.

EPA Response: Please see the section 4.3.5 of the EPA response in this *Response to Comments* document.

West Virginia Rivers Coalition et al. (Doc. #1746, SBC-045256)

West Virginia communities have been exposed to PFAS for decades and bear the cost of contamination with our health. The proposed PFAS drinking water regulations are monumental for our communities, and we commend EPA for taking this step. We support the comments of

Earthjustice and the Natural Resources Defense Council, as well as the National Wildlife Federation. In particular, we strongly support their calls for EPA to:

• Pursue a broader, class-based PFAS drinking water standard

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043862)

EPA should further commit to proposing a rule that sets a standard for them as a group using a novel approach currently under development by ORD.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Ohio Environmental Council (Doc. #1794, SBC-045324)

The PFAS addressed by EPA's proposal are among a class of thousands of forever chemicals. EPA's proposal to use a hazard index to address multiple co-occurring PFAS recognizes the risks associated with harmful chemical mixtures. Like many members of the PFAS class, PFBS, PFNA, GenX, and PFHxS have similar chemical structures and cause similar health effects. Many communities are exposed to, and harmed by, mixtures of those PFAS in their drinking water. EPA's approach provides a framework for addressing additional PFAS and mixtures of chemicals in the future, which would allow the Agency to move more rapidly to protect public health.

EPA Response: The commenter agrees with the EPA's approach.

Paula Okin (Doc. #1867, SBC-045861)

The proposed drinking water standards are a great first step to address these particular PFAS chemicals, however, I urge EPA to not stop here—it is critical that EPA next moves to regulate the full class of PFAS chemicals.

Thank you for your consideration.

Sincerely,

Ms. Paula Okin

10 Lake Dr New Hyde Park, NY 11040-1123

pokin@optonline.net

EPA Response: The commenter supports this regulation. In regard to potential future regulation of other PFAS, please see section 4.3.5 of the EPA response in this *Response to Comments* document.

North Carolina Conservation Network (Doc. #1869, SBC-045870)

Further, we ask that EPA moves rapidly to add even more PFAS chemicals to the hazard index, in order to protect North Carolina's public health.

Thank you.

Sincerely,

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1869]

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

North Carolina Conservation Network (Doc. #1869, SBC-045867)

Further, we ask that the EPA moves rapidly to add even more PFAS chemicals to the hazard index, in order to protect North Carolina's public health.

Thank you for your time and for the strong proposal to regulate PFAS in drinking water.

Sincerely,

Brittany Iery, Online Organizer

NC Conservation Network

234 Fayetteville Street, 5th Floor Raleigh, NC 27601

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #1913, SBC-046256)

A MCL for PFOA and PFOS is a good first step. However, short chain compounds such as PFBA will breakthrough conventional treatment technologies for PFAS such as GAC or IX well before PFOA or PFOS. If PFOA is present, PFBA is likely present as well. EPA needs to develop a MCL for PFBA too.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Michael Jones (Doc. #1962, SBC-046562)

The amount of any PFAS/PFOS compound that we should be exposed to is zero. We live near Taconic in Petersburgh, NY. This industry has released these toxins into our aquifer, our town water supply, our soil and most likely our food that we grow in this rural area during the last 40 years.

We smell the emissions almost daily. We have no idea of the compounds they are using and releasing into the air. Are they long or short chains? Are they both? Are these newer compounds safer, more dangerous or just as toxic than what has already been released into our community? The whole class of these chemicals should be regulated, all 14,000 of them. Why should the safety of these chemicals be tested on humans? Instead of spending money on treating our diseases, filtering our water and cleanup, stop these compounds from entering our bodies, our communities, our children, and our wildlife.

The proper MCL for this class of chemicals is as close to zero as possible. When a chemical from this group gets pulled out of use because people start getting sick, another is waiting to take its place. Industry is way ahead of our health, safety and regulations. We need strong policy from our government agencies charged with protecting our communities.

Thank you for your considersideration

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Titus Henry Presler (Doc. #2295, SBC-046214)

Thank you for your work! Please make sure the Environmental Protection Agency bans the entire class of PFAS chemicals from our drinking water.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Ellen Michele (Doc. #2488, SBC-046215)

I support a class-wide drinking water standard to include short and long-chain and polymerized forms rather than chemical by chemical regulation

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Kathryn Alessi (Doc. #2549, SBC-046591)

Thank you for the opportunity to comment on the proposed National Primary Drinking Water Regulation (NPDWR). I am a resident of New Jersey, and a fierce advocate for environmental justice. National standards to limit the concentration of PFAS in drinking water are long overdue. For decades, PFAS have been used in thousands of applications, and a peer-reviewed study

estimates that PFAS may be present in the drinking water of more than 200 million Americans. EPA's proposal for six PFAS would set the national standard for PFOA and PFOS at the lowest detection level approved by the agency, and would establish limits on GenX, PFBS, PFNA, and PFHxS using a hazard index, but this regulation does not cover the entire class of PFAS chemicals. EPA estimates that 94 million Americans currently receive drinking water contaminated by one or more PFAS chemicals at levels above the limits proposed by EPA. EPA's proposed National Primary Drinking Water Regulation (NPDWR) is needed, but it doesn't cover as much as it needs to for the health, safety, and well-being of everyone living in the United States. My further comments/suggestions for this proposed regulation are below.

1. EPA should expand the definition of PFAS to cover the entire class of PFAS chemicals as regulation of individual fluorinated compounds is insufficient to protect public health.

2. PFAS needs to be regulated at the source, in addition to remedial regulation of PFAS present in drinking water.

I urge EPA to promptly finalize this proposal and establish a National Primary Drinking Water Regulation (NPDWR) that will require monitoring for the entire class of PFAS in public water systems and provide mechanisms to address exceedances that threaten public health.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document. In regard to PFAS source control, please see section 10 of the EPA response in this *Response to Comments* document.

Coleen Wagner (Doc. #2551, SBC-046587)

Thank you for the opportunity to comment on the proposed National Primary Drinking Water Regulation (NPDWR).

National standards to limit the concentration of PFAS in drinking water are long overdue. For decades, PFAS have been used in thousands of applications, and a peer-reviewed study estimates that PFAS may be present in the drinking water of more than 200 million Americans. EPA's proposal for six PFAS would set the national standard for PFOA and PFOS at the lowest detection level approved by the agency, and would establish limits on GenX, PFBS, PFNA, and PFHxS using a hazard index, but this regulation does not cover the entire class of PFAS chemicals. EPA estimates that 94 million Americans currently receive drinking water contaminated by one or more PFAS chemicals at levels above the limits proposed by EPA.

EPA's proposed National Primary Drinking Water Regulation (NPDWR) is needed, but it doesn't cover as much as it needs to for the health, safety, and well-being of everyone living in the United States. My further comments/suggestions for this proposed regulation are below.

2. PFAS needs to be regulated at the source, in addition to remedial regulation of PFAS present in drinking water.do

I urge EPA to promptly finalize this proposal and establish a National Primary Drinking Water Regulation (NPDWR) that will require monitoring for the entire class of PFAS in public water systems and provide mechanisms to address exceedances that threaten public health.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document. In regard to PFAS source control, please see section 10 of the EPA response in this *Response to Comments* document.

Jim Sandoe (Doc. #2556, SBC-046251)

PFAS must be regulated as a class! This is too important to do one at a time. My drinking water is not safe, but my town won't do anything until you act. The Pentagon won't do anything until you act. The states won't do anything until you act. We are out of time.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Liz Furkay (Doc. #2644, SBC-046209)

We need to ban ALL of the PFAS chemicals, not just some of them. Any chemical that is toxic to life on earth should not be permitted!

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Karen Anderson (Doc. #2684, SBC-046421)

Dear Michael Regan,

It is imperative that the EPA take on full removal of PFAS as swiftly as possible. The contamination of our water is criminal and completely unacceptable.

Sincerely,

Karen Anderson

Berkeley, CA 94702

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Scott Howell (Doc. #2746, SBC-046532)

I strongly believe that the current proposal to develop MCL's for six specific PFAS chemicals is inadequate. EPA needs to consider other PFAS chemicals that could occur due to breakdown products of larger chain PFAS chemicals. A case in point is my current water provider which is impacted by PFAS contamination has installed cation exchange treatment and is currently meeting or exceeding the MCL's for all six proposed PFAS contaminants. However they are showing breakthrough on PFBA AT 40 PPT And PFPeA AT 24 PPT. These PFAS chemicals have also been shown to be hazardous to human health but would not be regulated in the proposed rules. These are only a few of the potential PFAS chemicals that would theoretically be missed by the current proposed rules. Please consider a more inclusive MCL for all PFAS chemicals and their derivatives.

Thank you for the opportunity to comment on the proposed drinking water regulation.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Quinn Montana (Doc. #2784, SBC-046486)

In addition to working to prevent the production of ANY further PFAS family chemicals (all 9000+), and working to remove those that are already in the environment, the agency should work to also prevent "precursor" chemicals from being released into the environment. It's well past time for the agency to regulate PFAS and their precursors as a class, rather than trying to evaluate their hazards individually.

https://grist.org/health/the-epas-proposed-pfas-regulations-ignore-a-major-source-of-drinking-water-contamination/

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Ed Davis (Doc. #2788, SBC-046447)

Please regulate the entire class of 9,000+ PFAS chemicals, and their precursor chemicals, down to the minimum concentration capable of causing biological harm. Please similarly regulate PFAS allowed in food, water bodies, ground water, sewage, rivers, soil, etc.

Also require labeling of all products that contain PFAS.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Marc LeMaire (Doc. #2830, SBC-046253)

I am writing to urge you all to strictly regulate all PFAS as they are a proven danger to human health, not to mention all other life here on earth . You must not cave in to industry pressure on these pollutants. They must be heavvily regulated, now, not later or never. 730

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-052952)

• DEP notes that since PFAS are emerging contaminants and research is ongoing, there is the potential for more PFAS to be regulated in the future. With the proposed introduction of the HI approach for regulating PFAS in drinking water, it is not clear what approach will be taken in the future for regulating additional PFAS. If more PFAS are added to the HI calculation in the future, that would further reduce the contribution of each PFAS to the HI (i.e., if eight PFAS are included in the HI calculation, each one can be present at only 12.5% of its HBWC before the MCLG/MCL is exceeded). This would continue to drive down not only analytical requirements and capabilities, but also requirements for treatment capability. As such, this proposed regulation sets the stage for an even more significant implementation challenge in the future.

EPA Response: In regard to regulating other PFAS, please see section 4.3.5 of the EPA response in this *Response to Comments* document. In regard to discussion related to the Hazard Index, please see section 4.3.2 of the EPA response in this *Response to Comments* document. For a description of numerous current EPA activities related to PFAS, please see the EPA PFAS Strategic Roadmap (https://www.epa.gov/pfas/pfas-strategic-roadmap-epas-commitments-action-2021-2024).

Association of California Water Agencies (ACWA) (Doc. #1675, SBC-052957)

Additionally, ACWA would like clarity from EPA on whether the agency plans to use the Hazard Index to regulate additional PFAS in the future. ACWA is concerned that the Hazard Index approach will be used as an avenue to circumvent the stringent requirements of SDWA to regulate PFAS moving forward. The traditional SDWA approach is comprehensive and ensures full consideration of all aspects and impacts of regulatory development.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

Natural Resources Defense Council (Doc. #3072-6, SBC-046343)

Good afternoon, my name is Katie Pelch, and I am a scientist at the Natural Resources Defense Council (NRDC). Today I'd like to start by just thanking Andrea and the community members for their very impactful stories and their testimonies that they are sharing with us today. I'd also like to thank the U.S. EPA for its groundbreaking MCL proposal for PFOA and PFOS, and the use of a hazard index for four additional PFAS. The proposal is a much needed and long-awaited

first step for regulating PFAS chemicals in drinking water as a class. Thousands of studies have investigated the health and toxicological effects of PFAS exposure, and a significant body of evidence suggests that there is no safe level of exposure to PFAS. Appropriately, EPA has proposed MCLGs of zero and MCLs of 4 parts per trillion for PFOA and PFOS, limits that are both scientifically supported and technologically available with currently available water treatment systems. PFAS is a class of thousands of chemicals, and our recent study published in Science of the Total Environment indicated that EPA's validated method for measuring PFAS in drinking water are missing a significant portion of PFAS that is present. Regulating each of these chemicals one at a time will take decades and leave many communities unprotected. This is why we support EPA's development of a hazard index as a way to efficiently take first steps towards a class-based approach and protect against the additive effects of PFAS that millions of Americans are exposed to. EPA's IRIS office has now finalized the toxicological reviews of PFBA and PFHxA and released a draft review of PFDA. All of these have been detected in drinking water. Therefore, EPA should include these additional PFAS in the hazard index as well, and we will be submitting additional comments that indicate that the hazard index for the four PFAS that are included in the hazard index should be lowered, the health-based values. Importantly, the benefit of removing PFAS from the drinking water of 70 to 94 million people is significantly underestimated in EPA's economic analysis. Whereas uncertainties for the cost analysis are estimated and modeled, uncertainties in the benefits analysis result in the benefit not being quantified, and by default, are assigned a value of zero. We will provide written comments, detailing additional benefits EPA should have considered. Thankfully, the treatment technologies that will be required to remove PFAS will also remove other known and unknown synthetic organic contaminants, and the true benefits achieved by this regulation will make a difference in the lives of millions of Americans.

EPA Response: Please see section 4.3.5 of the EPA response in this *Response to Comments* document.

5 Maximum Contaminant Levels

The EPA notes that a large majority of commenters who submitted feedback on the EPA's final Maximum Contaminant Levels (MCLs) did not distinguish between PFAS compounds in their comments. For example, many commenters cited their concerns for laboratory capability and capacity but often referred to "PFAS" generically and often did not distinguish between PFOA, PFOS, PFHxS, PFNA, HFPO-DA, and/or PFBS. The structure of this section follows the final MCLs promulgated in this National Primary Drinking Water Regulation (NPDWR): 1) PFOA and PFOS (section 5.1); 2) Hazard Index PFAS (section 5.2); 3) Individual PFAS MCLs (section 5.3). The EPA notes that where commenters are specific on the regulatory construct, their comments are categorized accordingly in that section (i.e., specific comments on the Hazard Index were categorized into 5.2). Otherwise, the non-specific comments that covers all the MCLs (including the individual and Hazard Index MCLs) and agency responses for those issues can be found in the sub-sections under 5.1.

5.1 PFOA and PFOS

5.1.1 General

Summary of Major Public Comments and EPA Responses

The EPA received many comments that strongly support the final MCLs of 4.0 ppt (ng/L) and the agency's determination that the standards are as close as feasible to the Maximum Contaminant Level Goals (MCLGs). Many of these commenters request the agency finalize the standards as expeditiously as possible. Based on the EPA's feasibility analysis and consistent with these comments, the agency is establishing drinking water standards for PFOA and PFOS (and four other PFAS) to provide health protection against these contaminants found in drinking water.

Some commenters expressed concern with implementing the MCL for PFOA and PFOS at 4.0 ng/l. Some of the commenters state that compliance would be difficult for rural or smaller to mid-sized water systems due to limited expertise or financial resources. Section 1412(b)(4)(E)(ii) of the Safe Drinking Water Act (SDWA) requires that the agency identify small system compliance technologies (SSCTs), which are affordable treatment technologies, or other means that can achieve compliance with the MCL. The EPA identified SSCTs using the affordability criteria methodology developed for drinking water rules (USEPA, 1998) and identified technologies that are affordable for each small system size category listed in Section 1412(b)(4)(E)(ii). These analyses support the EPA's findings that affordable technologies are available for small systems to comply with the MCL. Funds are also available through the passage of the Infrastructure Investment and Jobs Act (IIJA), also referred to as the Bipartisan Infrastructure Law (BIL), to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. The EPA further notes that in accordance with section 1412(b)(10) of SDWA, the agency is extending the

compliance date for the PFAS MCLs, regardless of system size, to 5 years from the date of promulgation of the standard. See section 12.1 of the EPA response in this *Response to Comments* document for further discussion. While implementation concerns as they relate to funding for small and rural water systems did not form the basis for the EPA's decision to extend the compliance date for the PFAS MCLs, the agency believes that this extension may, among other things, provide opportunities for systems who are close to exceeding the MCLs to investigate sources of contamination and allow systems additional time to compete for funding to implement the rule. Please see section 12.1 for additional discussion on exemptions and extensions.

Individual Public Comments

Midwest Environmental Advocates +more (Doc. #1846, SBC-045831)

A. EPA's proposed MCLs for PFOS and PFOA are set as close as feasible to the corresponding health-based MCLGs.

Commenters strongly support EPA's proposal to set the MCLs for PFOS and PFOA at 4 ppt, in accordance with the requirements of the SDWA, and the Agency's evaluation of feasibility. EPA properly set the standard at the lowest concentration at which PFOA and PFOS can be reliably quantified given (1) the substances' carcinogenic potential, (2) the available analytical methods for accurate detection and measurement of these substances, and (3) the best available treatment technologies capable of removing these PFAS, taking cost into consideration. Both the 5 ppt and 10 ppt MCL alternatives would be unlawful standards given the SDWA's mandate to set MCLs "as close as feasible" to the corresponding MCLGs.

As explained above, EPA had to set a health-based goal at a level at which no known or anticipated adverse effects on the health of persons occur, allowing an adequate margin of safety. Here, Because PFOA and PFOS are contaminants likely to be carcinogenic to humans, EPA set the MCLG for each contaminant at 0 ppt. [FN19: 88 Fed. Reg. 18,659-60, 63; see also 88 Fed. Reg. 18,652 ("For linear carcinogenic contaminants, where there is a proportional relationship between dose and carcinogenicity at low concentrations, EPA has a long-standing practice of establishing the MCLG at zero.").] Subsequently, following the standard-development process of the statute, the Agency evaluated the feasibility of the proposed NPDWR and its alternatives, rightfully concluding that a 4 ppt MCL constitutes a level "as close as feasible" to the corresponding MCLGs.

The SDWA defines feasibility as "feasible with the use of the best technology, treatment techniques and other means which the Administrator finds, after examination for efficacy under field conditions and not solely under laboratory conditions, are available (taking cost into consideration)." [FN20: 42 U.S.C. 300g-1(b)(4)(D).] Here, EPA first evaluated the analytical methods available to measure PFOS and PFOA in drinking water and determined that 4 ppt is the lowest concentration at which PFOA and PFOS can be reliably quantified, within specific limits of precision and accuracy under routine laboratory operating conditions. [FN21: 88 Fed. Reg.

18,666.] EPA reasoned that a 4 ppt MCL is feasible because: (1) "for almost all laboratories, the proposed [MCLs] for PFOA and PFOS … are at least 4 times greater than the lowest calibration standard;" [FN22: 88 Fed. Reg. 18,667.] (2) "there will be sufficient laboratory capacity with the MCLs set at 4.0 ppt;" [FN23: Id.] and (3) EPA has promulgated and successfully implemented NPDWRs with MCLs equal to the contaminant's quantitation level limit. [FN24: 88 Fed. Reg. 18,666.]

Further, in its review of available treatment technologies, EPA determined that multiple available technologies are capable of effectively removing the regulated PFAS from water supplies. As part of its review and assessment, the Agency considered cost to large and metropolitan water systems as intended by Congress. [FN25: 88 Fed. Reg. 18,668.] Legislative history shows that "the Administrator's determination of what [treatment] methods are generally available (taking cost into account) is to be based on what may reasonably be afforded by large metropolitan or regional public water systems." [FN 26: A Legislative History of the Safe Drinking Water Act, Committee Print, 97th Cong., 2d Sess. (1982) at 550. Commenters note that despite EPA's required focus on large and metropolitan water systems in its feasibility analysis, the Agency provided a robust "affordability" analysis related to small public water systems pursuant to other provisions of the SDWA—which also supports the proposed regulation.] Thus, because the installation of treatment technologies for the removal of these PFAS is feasible for large and metropolitan water systems, a 4 ppt MCL is justified as a protective and feasible standard.

EPA's proposed MCLs for PFOS and PFOA are consistent with the statutory requirements of the SDWA, and reasonable, in light of the Agency's feasibility analysis. . EPA would violate its statutory duty to set MCLs for these substances "as close as feasible" to the corresponding MCLGs if it were to choose to adopt either of the higher levels—5 ppt or 10 ppt—analyzed by EPA as "alternative MCLs." Moreover, doing so would unnecessarily leave many Americans exposed to dangerous levels of PFOA and PFOS, and the myriad adverse health effects that such exposures may entail. Accordingly, Commenters urge EPA to adopt the proposed MCL of 4 ppt as a protective and feasible standard.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. The commenter notes that they believe the MCLs for PFOA and PFOS at 4.0 ppt are feasible and that setting an MCL higher is contrary to SDWA's requirement to set the MCL "as close as feasible" to the MCLG. The agency agrees that the MCLs for PFOA and PFOS at 4.0 ppt are as close as feasible to the MCLG. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on cost considerations and regulatory alternatives, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

National Special Districts Coalition (NSDC) (Doc. #1571, SBC-042999)

The National Special Districts Coalition (NSDC) appreciates the opportunity to provide comment on EPA's proposed PFAS National Primary Drinking Water Standard. Attached is NSDC's formal comment citing key concerns regarding.

NSDC is comprised of the Arizona Fire Districts Association, Association of Washington Public Hospital Districts, California Special Districts Association, Florida Association of Special Districts, Special Districts Association of Colorado, Special Districts Association of Oregon, South Carolina Association of Special Purpose Districts, Utah Association of Special Districts, Washington Association of Sewer and Water Districts, Washington Fire Commissioners Association, Washington Public Utility Districts Association, and Wyoming Special Districts Association.

U.S. Environmental Protection Agency (USEPA)

Office of Ground Water and Drinking Water

Mail Code: 4606M

1200 Pennsylvania Avenue, NW

Washington, DC 20460

SUBMITTED ELECTRONICALLY via Federal Rulemaking Portal: www.regulations.gov

RE: DOCKET ID NO. EPA-HQ-OW-2022-0114

The National Special Districts Coalition (NSDC), representing special district local governments that provide essential services in thousands of communities across ten states, welcomes the opportunity to submit comments on the U.S. Environmental Protection Agency's (EPA) proposed National Primary Drinking Water Regulation (NPDWR) covering six common forms of per- and polyfluoroalkyl substances (PFAS), published in the Federal Register on March 28, 2023.

A special district is a political subdivision of a State, with specified boundaries, created pursuant to general law or act of the State, for the purpose of performing limited and specific governmental or proprietary functions. Special districts are established by a community to provide a critical public service, or set of services, that other units of local government typically do not otherwise provide. They provide a wide variety of services to urban, suburban, and rural communities – including more than 5,000 special districts that provide safe and reliable drinking water to millions of Americans across the country.

The proposed NPDWR includes enforceable maximum containment levels (MCL) and maximum containment level goals (MCLG) for the six types of PFAS known as perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), perfluorononanoic acid (PFNA), hexafluoropropylene oxide dimer acid (HFPO-DA), perfluorohexane sulfonic acid (PFHxS), and perfluorobutane sulfonic acid (PFBS).

NSDC is particularly concerned with proposed enforceable MCL at 4 parts per trillion for each PFOA and PFOS with MCLG at zero. The ability for many special districts operating small- to mid-size public water systems to monitor and comply with the NPDWR would be a costly, burdensome challenge to monitor for such small quantities of contaminant – primarily due to availability and affordability of necessary technology to comply with the proposed regulation.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's affordability analysis, please see section 9 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. Regarding rule implementation and enforcement issues, please see section 11 of the EPA response in this *Response to Comments* document. The agency notes that the NPDWR finalizes monitoring flexibilities such as the use of historical monitoring results to satisfy initial monitoring requirements – please see section 8 of the EPA response in this *Response to Comments* document for more information.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045454)

Specific Comments

Health Protective - If achievable, these maximum contaminant levels should be very protective of the public. Groundwater-supplied community water systems, typically serving small communities, are most impacted in incidence and in concentration for PFAS found previously.

Very small community water systems serving 500 or fewer people are 48% of all community water systems, 63% of all groundwater-supplied water systems, and 89% of all very small community water systems. Nearby private well owners may also be at risk. Small communities typically do not have the expertise and financial resources to manage their water systems sustainably for the delivery of safe drinking water. [FN4: U.S. Environmental Protection Agency (USEPA). 2021. 18th Annual EPA Drinking Water Workshop: Small System Challenges and Solutions. Dr. Christopher Frey, EPA Deputy Assistant Administrator for Science Policy, message delivered to Session 1, Plenary, August 30, 2021. https://www.youtube.com/watch?v=ycVa5uG7izg (Accessed April 19, 2023).] These small water systems need attention to treatment capabilities designed for their circumstances, including decentralized treatment that is both protective and affordable.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on SSCTs, please see section 10.5 of the EPA response in this *Response to Comments* document. SDWA does not regulate private wells and this final rule does not set any requirements or standards for private well owners, the EPA acknowledges that people who consume water from private wells may be concerned about contamination of their drinking water by PFAS or other contaminants. The EPA has resources to help people who rely on private wells for their drinking water at: https://www.epa.gov/privatewells.

U.S. Chamber of Commerce (Doc. #1537, SBC-042652)

In addition, the low proposed detection levels, for these PFAS, including PFOA and PFOS send a misleading message about the real degree of known risk to members of the public – especially as compared to the known risks of other hazards. Finally, setting the levels as low as EPA has proposed would inevitably lead to diversion of resources from other water quality priorities.

Thank you for your attention. I am happy to answer any questions you may have.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. Note that the EPA has set the MCLs for PFOA and PFOS at the practical quantitation limit and not the detection limit. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that at the practical quantitation levels (PQLs), or MCL levels, that PFOA and PFOS do not pose known risks. The best available peer-reviewed science indicates PFOA and PFOS pose significant risks above the MCLGs. See sections 4.1 and 4.2 of the EPA response in this *Response to Comments* document for further discussion. As discussed in the preamble for the final NPDWR, the EPA anticipates that this regulation will prevent tens of thousands of cases of serious disease and will save thousands of lives. With respect to risk communication and PFAS risk-communications with the public, please see section 1.2 of the EPA response in this *Response to Comments* document. The EPA recognizes that implementing a new NPDWR may cause systems to re-examine and, in some cases, prioritize expenditure of resources on implementing the new NPDWR. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water.

Kristina Winter (Doc. #1559, SBC-042543)

I urge the EPA to adopt the proposed enforceable limits for six PFAS chemicals in our drinking water. Specifically, I support proposed Maximum Contaminant Levels (MCLs) of 4 parts per trillion (ppt) for both PFOA and PFOS, as well as a Hazard Index (HI) of unitless 1 for PFNA, PFHxS, GenX, and PFBS.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index approach and regulation of additional PFAS, please see sections 5.2.1 and 5.3.1 of the EPA response in this *Response to Comments* document.

Citizens Campaign for the Environment (CCE) (Doc. #1710, SBC-045130)

CCE supports the proposed regulations, and offers the following specific recommendations:

• Adopt EPA's Proposed MCLs of 4ppt for PFOA and PFOS

PFOA and PFOS are a part of a group of man-made chemicals known as Per- or polyfluoroalkyl substances (PFAS). PFAS are often referred to as the "forever chemicals" due to their persistence in our environment and bodies—meaning that they don't break down and accumulate over time. PFAS has been detected in numerous water systems in New York, including high profile cases in Newburgh, Suffolk County, and Hoosick Falls. PFOA and PFOS in drinking water are a threat to public health and are associated with a host of significant adverse health impacts, including cancer, hormone disruption, liver and kidney damage, developmental and reproductive harm, changes in serum lipid levels, and immune system toxicity—some of which occur at extremely low levels of exposure.

Currently, New York's MCLs for PFOA and PFOS remains at 10 ppt, far higher than the EPA's proposed MCLs of 4 ppt for both PFOA and PFOS. We support strong, enforceable standards for PFOA and PFOS to what is likely the strongest, most health-protective standard that is technically feasible at this point in time—4ppt. Adopting the MCL's proposed by EPA would help protect the health of New Yorkers currently at risk. In fact, CCE analyzed drinking water quality reports for just Long Island in New York State and found that 1.48 million residents were served by water systems with levels of PFOA and/or PFOS lower than 10ppt (which is New York State's current MCL) and higher than EPA proposed MCLs of 4ppt. Therefore, the EPA standards would provide for additional public health protections for those 1.48 million people. That is a significant example of the importance of the 4ppt standard.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. The agency agrees with the commenter that the MCLs are "technically feasible at this point in time." For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on international and state drinking water standards, please see section 5.1.4 of the EPA response in this *Response to Comments* document.

Mary Anderson (Doc. #1863, SBC-045844)

I urge the EPA to adopt the proposed enforceable limits for six PFAS chemicals in our drinking water. Specifically, I support proposed Maximum Contaminant Levels (MCLs) of 4 parts per trillion (ppt) for both PFOA and PFOS, as well as a Hazard Index (HI) of unitless 1 for PFNA, PFHxS, GenX, and PFBS.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index approach and regulation of additional PFAS, please see sections 5.2.1 and 5.3.1 of the EPA response in this *Response to Comments* document.

Laura Spilotros (Doc. #1864, SBC-045848)

I urge the EPA to adopt the proposed enforceable limits for six PFAS chemicals in our drinking water. Specifically, I support proposed Maximum Contaminant Levels (MCLs) of 4 parts per trillion (ppt) for both PFOA and PFOS, as well as a Hazard Index (HI) of unitless 1 for PFNA, PFHxS, GenX, and PFBS.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index approach and regulation of additional PFAS, please see sections 5.2.1 and 5.3.1 of the EPA response in this *Response to Comments* document.

Jeanne Forster (Doc. #1865, SBC-045852)

I urge the EPA to adopt the proposed enforceable limits for six PFAS chemicals in our drinking water. Specifically, I support proposed Maximum Contaminant Levels (MCLs) of 4 parts per trillion (ppt) for both PFOA and PFOS, as well as a Hazard Index (HI) of unitless 1 for PFNA, PFHxS, GenX, and PFBS.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index approach and regulation of additional PFAS, please see sections 5.2.1 and 5.3.1 of the EPA response in this *Response to Comments* document.

K Murphy (Doc. #1866, SBC-045856)

I urge the EPA to adopt the proposed enforceable limits for six PFAS chemicals in our drinking water. Specifically, I support proposed Maximum Contaminant Levels (MCLs) of 4 parts per trillion (ppt) for both PFOA and PFOS, as well as a Hazard Index (HI) of unitless 1 for PFNA, PFHxS, GenX, and PFBS.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index approach and regulation of additional PFAS, please see section 5.2.1 and 5.3.1.

Paula Okin (Doc. #1867, SBC-045860)

I urge the EPA to adopt the proposed enforceable limits for six PFAS chemicals in our drinking water. Specifically, I support proposed Maximum Contaminant Levels (MCLs) of 4 parts per trillion (ppt) for both PFOA and PFOS, as well as a Hazard Index (HI) of unitless 1 for PFNA, PFHxS, GenX, and PFBS.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index approach and regulation of additional PFAS, please see section 5.2.1 and 5.3.1 of the EPA response in this *Response to Comments* document.

Katrina Rudmin (Doc. #1868, SBC-045864)

I urge the EPA to adopt the proposed enforceable limits for six PFAS chemicals in our drinking water. Specifically, I support proposed Maximum Contaminant Levels (MCLs) of 4 parts per trillion (ppt) for both PFOA and PFOS, as well as a Hazard Index (HI) of unitless 1 for PFNA, PFHxS, GenX, and PFBS.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index approach and regulation of additional PFAS, please see sections 5.2.1 and 5.3.1 of the EPA response in this *Response to Comments* document.

North Carolina Conservation Network (Doc. #1869, SBC-045869)

We strongly support the proposed drinking water standards for PFOS and PFOA, as well as the use of the hazard index for additional PFAS chemicals and urge EPA to swiftly finalize the proposal.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index approach and regulation of additional PFAS, please see sections 5.2.1 and 5.3.1 of the EPA response in this *Response to Comments* document.

A. O. Smith Corporation (Doc. #1674, SBC-043693)

2. Maximum Contaminant Level

Similar to the Company's position cited above on the EPA's proposed MCLG and HI approaches, A. O. Smith is supportive of the EPA setting an MCL for PFOA and PFOS and agrees that these chemicals create adverse health impacts in human beings at high exposure levels. What the Company cannot determine at this time is if 4 ppt is the correct value for public water systems to treat to, assuming corrective action is triggered under the SDWA by a public water system's sample testing demonstrating the presence of the targeted PFAS chemicals at or below 4 ppt.

The Company believes that context is important. As the EPA knows, 1 ppt is roughly the equivalent of one grain of sand in an Olympic-size swimming pool [FN2: One Olympic-size swimming pool holds 2.5 million liters of water or approximately 660,000 gallons of water.] or one drop of water in twenty Olympic-size swimming pools. [FN3: See, https://www.michigan.gov/-/media/Project/Websites/PFAS-Response/Images/PPT-Swimming-Pool.pdf] Compared with studies that demonstrated an average exposure to PFAS in food packaging between one and twenty parts per billion (i.e., 1 – 20 million ppt), the amount of PFOA and PFOS to be removed from drinking water supplies at 4 ppt is daunting. [FN4: Beyond paper: PFAS linked to common plastic packaging used for food, cosmetics, and much more, Environmental Defense Fund, July 7, 2021 (https://blogs.edf.org/health/2021/07/07/beyond-paper-pfas/#:~:text=The%20total%20level%20of%20the,had%201%20ppb%20or%20less.)] Moreover, when analyzing the daily water use in the United States relative to the amount of drinking water consumed daily (on average) by a typical household, the numbers demonstrate the significant policy and regulatory challenge the EPA is proposing to be implemented by the nation's public water systems to centrally treat their drinking water supply to a 4 ppt value for PFOA and PFOS. Along those lines consider the following:

• In 2015, the United States used 322 billion gallons of water per day (Bgal/day). [FN5: See https://www.usgs.gov/faqs/how-much-water-used-people-

unitedstates#:~:text=Since%201950%2C%20the%20USGS%20has,day%20(Bgal%2Fday).] The three largest water-use categories were irrigation (118 Bgal/day), thermoelectric power (133 Bgal/day), and public supply (39 Bgal/day), cumulatively accounting for 90% of the national total. [FN6: Id.]

• Of the 39.0 Bgal/d of total withdrawals for public water supplies, 61% percent were from surface-water sources. Public-supply systems deliver water to domestic, industrial, commercial, and other users, and 60% of public-supply withdrawals provided 87% of the United States population (283 million) for domestic indoor and outdoor residential uses. Other residences are self-supplied from wells or other sources; these withdrawals were about 1 percent (3.26 Bgal/d) of total withdrawals and provided water to about 13 percent (42.5 million) of the United States population. Groundwater was used for 98% of the self-supplied domestic withdrawals. [FN7: See, United States Geological Survey, Summary of Estimated Water Use in the United States in 2015 Fact Sheet 2018-3035, June 2018.]

• More than 97% of the nation's 156,000 public water systems are small systems that serve 10,000 or fewer people, which includes municipalities, small towns, homeowner's associations, schools, and campgrounds. [FN8: See, https://www.epa.gov/dwcapacity/learn-about-capacity-development]

• The average daily use of water in the typical American household varies between 300 to 82 gallons for a variety of uses (e.g., bathing, toilets, clothes and dishwashing). [FN9: Id.; see also https://www.epa.gov/watersense/how-we-use-water;.] Of these amounts 50 – 70 % of water in the home is used for watering lawns and gardens [FN10: See, Common Daily Water Usage, APEC Water.] and according to one source, water for hygiene and hydration on average is approximately 3.5 gallons a day. [FN11: See, Philadelphia Water Department Home-water-use-infographic 5, April 2020.]

Therefore, taken in context, the overwhelming majority of water that will be centrally treated by public water systems under the PFAS NPDWS will be for uses other than human consumption.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. There are several considerations the commenter notes regarding water usage in the United States and its relationship with the final MCLs. While the commenter factually points out statistics on processed water, most processed water is not treated to potable drinking water standards and is not used for human consumption, so these points do form a basis for how the agency considers feasibility when setting drinking water standards consistent with SDWA. Further, SDWA requires the agency to treat potable water to standards that are fit for human consumption. For additional discussion on certification standards and drinking water treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

Bailey Smith (Doc. #1787, SBC-045814)

Lastly, with respect to EPA's request for comment on its "proposed determination to set MCLs at 4.0 ppt for PFOA and PFOS,"[FN48: Proposed Rule, supra note 3 at 18730.] this public comment agrees with the proposed MCLs the EPA has set (4.0 ppt).

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044904)

Section 3: Maximum Contaminant Level

Like the MCLGs, EPA is proposing individual Maximum Contaminant Levels (MCLs) for PFOA and PFOS, and an MCL for PFNA, PFHxS, GenX, and PFBS as a mixture. Under section 1412(b)(4)(B) of the SDWA, EPA must establish an enforceable MCL, "which is as close to the [MCLG] as is feasible." Section 1412(b)(4)(D) subsequently defines "feasible" to mean "feasible with the use of the best technology, treatment techniques and other means which the Administrator finds … are available (taking cost into consideration)."

Section 3.1: PFOA and PFOS

EPA has proposed individual MCLs of 4.0 parts per trillion (ppt) for each of PFOA and PFOS. EPA also explored the costs of potentially proposing 5.0 ppt and 10.0 ppt, individually. EPA determined the Best Available Technologies (BATs) have the capability to bring PFAS levels down below the proposed 4.0 ppt MCL, on this point Cleveland Water concurs. However, the costs, supply chain and labor challenges affecting the compliance timeline, and current and future simultaneous compliance challenges, invite questions as to whether this standard is actually feasible under SDWA, as defined in Section 1412(b)(4)(D).

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on extensions and exemptions, please see section 12.1 of the EPA response in this *Response to Comments* document.

New Hampshire Water Works Association, Inc. (NHWWA) (Doc. #1576, SBC-042451)

Preliminary data indicate PFAS concentrations in precipitation may exceed the proposed 4.0 ppt MCL, making background exceedances widespread and intractable to treat.

EPA Response: Studies have demonstrated that PFAS can be transported through precipitation and atmospheric deposition, however the EPA disagrees that due to precipitation potentially containing PFAS that the final MCLs for PFOA and PFOS are not feasible. First, the EPA's final NPDWR regulates public water systems (PWSs) and does not pose treatment requirements to precipitation. Second, the EPA's analysis of PFAS occurrence in drinking water is already reflective of any wet weather deposition to source waters (i.e., if precipitation contains PFAS and are deposited into source waters, any change to source water concentrations of PFAS as a result of this deposition is already reflected in the data that the EPA evaluated to support the current rulemaking). Third, PFAS in precipitation does not preclude the EPA from following the SDWA and developing a NPDWR to reduce human health exposure from this particular source. With respect to the EPA's regulation of additional PFAS through a Hazard Index MCL, please see the section 5.2.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. With respect to additional individual PFAS MCLs for PFHxS, HFPO-DA and PFNA, please see section 5.3 of the EPA response in this *Response to Comments* document. For EPA's related to other routes of PFAS human health exposure and sources of PFAS in the environment, please see sections 3.1.3 and 3.2.3 of the EPA response in this *Response to Comments* document.

Wagner Engineering (Doc. #3072-9, SBC-047362)

Lastly, what is the suggested message to the public when asked why the MCL is set at 4 parts per trillion but EPA's health advisory is 1,000 times less than that at 0.004 parts per trillion? Thank you for allowing me to provide my comments.

EPA Response: Health Advisories (HAs) are beyond the scope of this rulemaking. The EPA's HAs are non-enforceable and non-regulatory and provide technical information to state agencies and other public health officials on health effects, analytical methods, and treatment technologies associated with drinking water contamination. MCLs are regulatory and enforceable standards that are set consistent with SDWA requirements, including that the MCL level is as close as feasible to the MCLG. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045743)

In the interest of transparency, PWD is requesting that the occurrence data used to inform the development of a HI be made available to the public.

EPA Response: The occurrence data used to inform the NPDWR was made available at the time of proposal for public comment. Please see the *Occurrence Technical Support*

Document (USEPA, 2023a), section 6 of this *Response-to-Comments* document, and section VI of the final rule preamble for additional discussion on occurrence.

Massachusetts Coalition for Water Resources Stewardship (MCWRS) (Doc. #1691, SBC-044325)

5. It is unclear why EPA has not approached PFAS regulation from a relative risk perspective as is done with other drinking water contaminants and public health risks in general. For the regulation of the PFAS compounds under the proposed MCLs there appears to be a desire to have risk-free drinking water. That intent is limited due to current laboratory detection capabilities and treatment technologies. Based on the documents provided through this rule-making process one can surmise that should detection levels and treatment technology improve the MCLs would be adjusted downward. The "no-acceptable risk" perspective is not applied to other drinking water contaminants, many of which have MCLGs of zero, but have MCLs well above their respective detection levels. Acceptable risk levels are present in all aspects of society otherwise there would be speed limits of 5 MPH, no playing of sports and no gathering of crowds. That PFAS in drinking water must somehow be risk free does not speak of science or enlightened thinking but of fear mongering and environmental advocacy gone haywire.

EPA Response: The commenter does explain the meaning nor does the commenter provide sufficient detail in explaining the contention that the final NPDWR is not approached from a "relative risk perspective as is done with other drinking water contaminants." The commenter also indicated that EPA has taken a "no-acceptable risk" approach; the agency is clarifying for the commenter that the agency has never stated this in the proposed rule materials. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science and meet the statutory requirements under the SDWA: please see sections 5.1.2, 5.1.3, and 5.1.4 of the EPA response in this *Response to Comments* document for the agency's evaluation of feasibility with respect to analytic, cost and treatment considerations, respectively. For how the agency may consider future science in the MCLs, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045494)

IV. Conclusion

Advocacy is concerned that small water systems will not have adequate funds to ensure timely compliance with EPA's proposed requirements. Therefore, Advocacy recommends that the agency consider alternatives standards and provide regulatory flexibilities to reduce the compliance burden on small water systems.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. With respect to funding concerns, please see section 2.4 of the EPA response in this *Response to Comments* document. Specifically, the agency expects funds available under the BIL to significantly reduce some of these household costs (see for example,

the EPA's affordability analysis Tables 9-15 and 9-20 of the final Economic Analysis [EA]). Finally, EPA firmly believes that all members of a community should have access to have safe water. There are strategies that utilities may take to help rate payers such as variable rate structures, which allow free or low-cost essential-use amounts then scale for extra use, capping bills for low-income residents as a percent of income, discounts to low-income customers, aiding low-income consumers with plumbing leaks as well as repairs, consumer assistance programs, and infrastructure grants as well as subsidized loans from the State Revolving Funds (SRFs). The EPA further notes that the agency is finalizing flexibilities in the final NPDWR such as the use of previously acquired monitoring data to support the initial monitoring requirements of the rule (please see section 8 of the EPA response in this *Response to Comments* document for additional details).

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045476)

May 30, 2023

VIA ELECTRONIC SUBMISSION

The Honorable Michael S. Regan

Administrator

Environmental Protection Agency

Washington, DC 20460

Re: PFAS National Primary Drinking Water Regulation Rulemaking (Docket ID: EPAHQ-OW-2022-0114)

Dear Administrator Regan:

On March 29, 2023, the Environmental Protection Agency (EPA) published a proposed rule titled "PFAS National Primary Drinking Water Regulation Rulemaking."[FN1: 88 Fed. Reg. 18638 (March 29, 2023).] The Office of Advocacy (Advocacy) is concerned that small water systems will not have adequate funds to ensure timely compliance with EPA's proposed requirements. Therefore, Advocacy recommends that the agency consider alternative standards and provide regulatory flexibilities to reduce the compliance burden on small water systems.

EPA Response: Please see the EPA response to comment Doc. #1807, SBC-045494 in section 5.1.1 in this *Response to Comments* document.

Francesca S. (no surname provided) (Doc. #1472, SBC-042306)

Document ID: EPA-HQ-OW-2022-0114-0027

Federal Register Number: 2023-05471

PFAS and PFOS contaminants should have their MCLG be decreased to 4.0 ng/L or lower if possible. PFAS chemicals take multiple years to leave the human body, it is a slow process. However, if people are continuedly exposed and consuming high levels of these contaminants then it accumulates over time and it has an increased damaging effect on people's health. PFAS is known to cause a slew of different health conditions including cancer, liver disease, a decreased chance of women getting pregnant, and so on. A topic that should be of even more concern for the EPA and the FDA is that bottled water doesn't have a regulation on the levels of PFAS in their water. Comparing the two, the EPA according to this proposed rule is trying to get the MCLG of drinking water down to 4 parts per trillion, while there are brands out there such as the 365 Whole Foods bottled water brand that has nearly 140 parts per trillion of total PFAS in their water. Continuing with the example of the Whole Foods bottled water, that company makes billions of dollars per year, they have millions of customers so a large amount of Americans have consumed this beverage and yet there's still no regulations by the EPA or FDA on it. Bottled water PFAS levels should be a priority of the EPA's, however this proposed rule is focusing on drinking water in general, and lowering PFAS in any capacity is a good thing. It would be in the best interest of American's health for the EPA to have a goal of eventually creating a MCLG of 0 ppt of PFAS, but lowering it to 4 ppt currently is a good start. The Clean Water Act was a way to help protect people from the dangers of contaminants in drinking water since water is a necessity for human life, and people deserve the right to have a clean source of water so they can stay alive. Any organization that is permitting contaminants to continue to be in drinking water, when those said contaminants like PFAS cause diseases like cancer, should be striving continuously to work towards a future of no harmful contaminants being in the water.

EPA Response: The EPA is finalizing MCLGs for PFOA and PFOS at zero and enforceable MCLs at 4.0 ppt each based on the agency's feasibility analysis. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. The Food and Drug Administration (FDA) regulates the safety of bottled water and is therefore beyond the scope of this rulemaking.

Town of Petersburgh, NY (Doc. #1521, SBC-042609)

RE: PFOA regulation public comment: Docket No: EPA-HQ—OW-2022-0114

On March 14, 2023, the Environmental Protection Agency ("EPA") proposed the first ever national drinking standards with regards to PFAS in public drinking water. Specifically, the EPA has proposed to regulate PFOA at a level they can reliably measure at 4 parts per trillion ("ppt"). The EPA requested input on the proposal from all stakeholders. This letter shall constitute a response on the proposal from the Town of Petersburgh, New York.

PFOA was found in large concentrations (from 100ppt to over 1000ppt) across Petersburgh in 2016. Since, then, our small, rural town has gone through proverbial hell in dealing with this

contamination. We have the health scars and death certificates to prove it!! A granular activated carbon treatment system was installed to treat the water in our municipal water district, and individual POET systems were made available for residents to treat the water from their private wells. According to our New York State DEC representatives, these systems provide potable water that meets or exceeds New York State drinking standards. However, this is not enough. No solution or technology exists today that will permanently remove the PFOA contamination from our surface water resources or groundwater aquifer's.

We are told to live with these existing treatment systems as a permanent solution. We flatly reject this assumption that we should just learn to live with PFOA contamination in our local water resources. Furthermore, we believe your proposed 4 ppt mcl standard is effectively an admission to hundreds, if not thousands, of communities across the country to "just live with it." There is no science that we are aware of that says exposure at 3ppt or 4ppt of PFOA is somehow safer than exposure at 5ppt or higher. Contrary, any long-term exposure to PFOA is a national health concern. The drinking water standard should be set as close to 0 ppt as possible. Treatment solutions are an interim option to deliver potable drinking water. Future research efforts and budgets should be focused on developing technologies that can remove the contamination directly from the water resources. "Just live with it" should be a mantra that is stricken from the thought processes of our environmental regulators. Accepting failure in cleaning up the environment by proposing a 4ppt mcl is not sufficient. We ask that you reconsider this standard.

Sincerely,

Katie Murray

Town Supervisor

Heinz Noeding

Town Board Councilman

Nathan Michaels

Town Board Councilman

Thomas Berry

Town Board Councilman

EPA Response: The agency acknowledges the commenter's concerns on the public health risks posed by PFAS in drinking water. While beyond the scope of this rulemaking, the agency is taking steps to address PFAS through a holistic, all-of-agency approach as discussed in the EPA's PFAS Strategic Roadmap; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion.

City of Thornton, Colorado (Doc. #1748, SBC-044791)

Thornton does not support increasing the MCL to either 5 or 10 ppt even though it would reduce Thornton's capital and operational costs by 50% at an MCL of 5ppt and would eliminate Thornton's need for treatment at an MCL of 10ppt. Thornton believes that the EPA has demonstrated the health risks associated with these compounds and as such wants to protect the health of our consumers. There is a large amount, perhaps unduly earned, of fear in the general public about these compounds and their health risks due to messaging from the EPA, media, and environmental workgroups. Because of the EPA's revised HAL in 2022, Thornton's customers' perception is that there should be (essentially) zero PFAS in their water. It is difficult to explain to the public why the proposed regulated concentration is higher than those HALs; arguments of technological and economic feasibility are perceived as excuses when their health is at risk. It will be even more difficult to message an increase from the proposed MCL of 4 ppt to even higher levels of 5 or 10 ppt.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. Furthermore, the agency agrees that risk communication is important; please see section 1.2 of the EPA response in this *Response to Comments* document for additional discussion. The EPA notes that the Lifetime HAs are beyond the scope of this rulemaking. The MCLGs promulgated in this final NPDWR are based on the best available, peer-reviewed science and the agency's review of current scientific literature on human health effects; please see section 4 for additional discussion on health considerations for PFOA and PFOS when setting the MCLG. As required under the SDWA, EPA has set the MCLs for PFOA and PFOS at 4.0 ppt, which is as close to the MCLGs as feasible using the best available treatment technology and taking cost into consideration. See discussion in Section V of the preamble of the PFAS NPDWR for further discussion.

Anonymous (Doc. #1957, SBC-046600)

No science can prove or show that cancer or other illnesses is the result of water with PFAS at levels below 70 ppt. This is manipulated statistics not science. It is a means trying to justify an end. The cost to remove PFAS in well and surface water to below 15 ppt is unnecessary, unnecessarily expensive and will cost billions of dollars. Billions of dollars wasted just as all the money to remove lead service lines is a waste of money and energy and an inflation driver when zinc orthophosphate can contain the lead at a much more reasonable cost to below the 90th percentile.

Furthermore there is no proof that older people have more PFAS in their blood than younger people or whatever is driving the false narrative that the compounds build up in the blood over the years. That the amount in the blood is from drinking water as opposed to some other source is another fact of which there is no empirical evidence. This entire thing is politically driven as was the Covid protocols and the Covid shot. These are inert chemicals that don't break down easily in the environment and thus are not attacking the cells in the human body.

Hopefully the states will push back and sue the EPA over their false premises.

Testing for PFAS is expensive and should be once annually and not quarterly. 70 ppt for each chemical and 70 x the number of chemicals compounds should be the standard in drinking water if anything. Preferably these inert harmless chemicals will stay as just a health advisory where they belong and have been from past EPA's that weren't weaponized by the party currently in power. Your new data is just false twisting of data. There is no proof in the 5000 pages of manipulation that 50 ppt has any more effect on people than 4 ppt.

There is no reason for people to tell you about ourselves or our background and experience. People with common sense see what is going on with these new proposed standards and the further destruction of individual liberties and the cost to remove these chemicals in drinking water and the people oppose this new federal government over reach as injustice and not the role of the federal government under the constitution.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. The agency disagrees with the commenter on the human health hazards posed by the PFAS regulated through this NPDWR. As the record for this action demonstrates, and as is discussed in other parts of the rule, there are serious adverse health effects attributed to PFOA and PFOS exposure. See section 4 of the EPA response in this *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on the best available science, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Please see section 13 of the EPA response in this *Response to Comments* document for discussion about costs and benefits of the PFAS NPDWR. Please see section 13.3.4 of the EPA response in this *Response to Comments* document which discusses monitoring costs and steps EPA has taken to reduce monitoring burden. See also sections 8.3, 8.8, and 8.9 of the EPA response in this *Response to Comments* document about monitoring flexibilities designed to reduce burden. The demonstrated effectiveness of COVID-19 protocols or COVID-19 vaccines are beyond the scope of this PFAS NPDWR. Commenter provides no support or information how this rule does not meet SDWA requirements.

Kassidy Neuner (Doc. #2315, SBC-046321)

The EPA has installed a Maximum Level of Contaminant in Drinking Water (MLCG) for these PFOs or PFOAs so that they cause no harm to anyone, which is to the benefit of the consumer. The MLCG would only be a limit on water sent to the public water system. Recent findings have found that no dose of these PFOs is safe, therefore, it will need to be at a zero in all drinking water. These chemicals have been in use since the 1940s which means it has been contaminating water sources for many decades. Looser restrictions on products sold in stores for everyday use, such as insecticides, has been the root of most of our cancer-causing agents today. Silent Spring by Rachel Carson is a good source to know just how much damage insecticides with harmful

chemicals have caused to the environment in a short amount of time. It is plain to see the long-term effects decades later from lack of restriction from organizations like the EPA and FDA. However, resolving to limit the amount of PFOs and PFOAs to zero is a good initiative. Cancer is always on the rise in the United States, and to limit one's risk to cancer, by stripping every-day use items of cancer causing agents, is a good start. My only concern is how this will be dealt with. Atchison County, for example, still uses a single sewer system, meaning that both rain and fecal matter are mixed together and treated as one. This would mean that all water sources would need to be checked to make sure that the PFO and PFOA numbers are at zero. This would be time consuming and expensive for counties like Atchison County. Will this be up to the states to do, or will this be a federal job that uses tax dollars to fund? Will people be compensated for their general damages due to the chemicals in drinking water being at too high of a concentration, inevitability leading to cancer? These are important questions to consider. Overall, the phasing out of these chemicals in drinking water is a very good start to cleaning up the damage done by the government's once lax policies.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. As the record demonstrates and discussed in other parts of the rule (see section 4 of this *Response to Comments* document in particular), there are serious adverse health effects attributed to PFOA and PFOS exposure (as an example). The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Regarding funding concerns to support implementation of the NPDWR, please see the EPA's response in topic essay 2.4. Topics related to assigning liability for PFAS pollution or addressing sources of PFAS contamination are beyond the scope of this rulemaking (please see section 15.1 for additional discussion).

WaterPIO (Doc. #1624, SBC-043479)

The EPA's proposed MCLs and Hazard Index should not move forward without significant correction.

EPA Response: The EPA disagrees. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index approach and regulation of additional PFAS, please see sections 5.2.1 and 5.3.1 of the EPA response in this *Response to Comments* document.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044136)

Underground Injection Wells

It is unclear if NPDWR MCLs would impact pollution prevention activities for Class V injection wells. The proposed rulemaking could impact certain types of Class V injection wells in the Underground Injection Control (UIC) Program, specifically aquifer storage and recovery (ASR), aquifer recharge (AR), and other Class V designations. Currently TCEQ regulations state that:

"No permit or authorization by rule shall be allowed where an injection well causes or allows the movement of fluid that would result in the pollution of an underground source of drinking water (USDW)." [FN10: Title 40 Code of Federal Regulations (CFR) Part 144; Title 30 Texas Administrative Code § 331.5(a) (Prevention of Pollution).]

For ASR and AR, TCEQ must consider whether the injection of water will comply with the standards set forth under the Federal Safe Drinking Water Act. [FN11: Title 42 U.S. Code § 300f.] Other Class V wells that may potentially be affected as MCLs have always been used as a guideline for compliance. The PFAS proposed regulation states that "EPA is proposing a National Primary Drinking Water Regulation (NPDWR) to establish legally enforceable levels, called Maximum Contaminant Levels (MCLs), for six PFAS in drinking water." It is unclear whether these MCLs would be established only for drinking water regulations or if these MCLs also would be used to comply with prevention of pollution under 40 CFR Part 144.

EPA Response: This commenter asks if MCLs promulgated in this NPDWR will be used to comply with pollution prevention activities under 40 Code of Federal Regulations (CFR) Part 144. The SDWA requires the EPA to promulgate regulations for state Underground Injection Control (UIC) programs with minimum requirements for effective programs to prevent endangerment to underground sources of drinking water (USDWs). 42 U.S.C § 300h(a)(1)&(b)(1). Underground injection endangers USDWs if it may result in the presence in USDWs of any contaminant, and "if the presence of such contaminant may result in [a public water] system's not complying with any NPDWR or may otherwise adversely affect the health of persons." 42 U.S.C § 300h(d)(2); see also 40 CFR 144.12(a) (regulatory non-endangerment provision); 40 CFR 145.11(a)(6) (requiring state 1422 UIC programs to implement provisions as stringent as 40 CFR 144.12). The PFAS NPDWR regulates PWSs, and as required under SDWA, this NPDWR and analyses supporting the rulemaking only include costs that "are likely to occur solely as a result of compliance with the MCL." Thus, the EPA's cost analyses focused on the compliance costs of meeting the MCL to PWSs that are directly subject to this regulation. Potential use of MCLs in other regulatory and nonregulatory contexts are beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR.

GFL Environmental (Doc. #1648, SBC-043218)

May 30, 2023

Michael S. Regan Administrator

U.S. Environmental Protection Agency 1200 Pennsylvania Avenue NW

Mail Code: 4607M Washington, DC 20460

SUBMITTED ELECTRONICALLY TO REGULATIONS.GOV

RE: DOCKET ID NO. EPA-HQ-OW-2022-0114, COMMENTS ON THE DEVELOPMENT OF THE PROPOSED PER- AND POLYFLUOROALKYL SUBSTANCES (PFAS) NATIONAL PRIMARY DRINKING WATER REGULATION

Dear Administrator Regan,

GFL Environmental ("GFL") submits the following comments in response to the Proposed PFAS National Primary Drinking Water Regulation (NPDWR; EPA-HQ-OW-2022-0114). GFL is a diversified environmental services company in North America providing services in solid waste management and liquid waste management. Employing over 19,500 people company wide, GFL operates landfills [both municipal solid waste (MSW) and construction and demolition (C&D)] in 19 states in the US.

EPA is proposing a NPDWR to establish legally enforceable~~,~~ Maximum Contaminant Levels (MCLs)~~,~~ for six PFAS in drinking water: PFOA and PFOS as individual contaminants, and PFHxS, PFNA, PFBS, and HFPO-DA (commonly referred to as GenX Chemicals) as a PFAS mixture. The proposed MCL for both PFOA and PFOS is 4 nanograms per liter (ng/L) or parts per trillion (ppt). The MCL for the mixture of PFHxS, PFNA, PFBS, and GenX is proposed as a Hazard Index (HI) of 1.0. EPA is also proposing health-based, non-enforceable MCL Goals (MCLGs) of 0 ng/L for PFOA and PFOS.

GFL is pleased to be part of the long-term solution to PFAS management and recognizes the need to protect public health and the environment consistent with EPA's intentions. However, we are concerned about the unintended and disruptive consequences of this rule upon downstream or passive receivers of PFAS-containing waste. We are also concerned about the impacts that the new PFAS MCLs will have on other environmental programs and about the technical basis of the rule.

Trickle-Down Impact of MCLs

If promulgated, the application of these proposed MCLs may have impacts that extend well beyond safe drinking water. In other contexts, MCLs are used not just as standards at the point of water consumption but are also widely used to base groundwater and clean-up standards. While the PFAS MCLs are likely to present a challenge for water utilities, we believe that the application of these same standards to groundwater and remediation projects will present technical challenges that are not contemplated by EPA's proposal. These challenges include meeting the detection limit in the contaminated water or environmental media in question and then also treating the contaminated material to the MCLs. In addition, the new PFAS MCLs will likely be used as "Applicable or Relevant and Appropriate Requirements (ARARs) under

Section 121(d) of the Comprehensive Environmental Response and Compensation Liability Act (CERCLA) at clean-ups, which will itself present a host of additional technical issues, likely resulting in delays and added costs.

Given the current status of treatment options, unfortunately, groundwater restoration to the proposed MCLs is not practical or achievable. Risk-based clean-up standards are widely used in groundwater remediation projects and the absence of such standards for PFAS may drive clean-ups to meet the PFAS MCLs. There are no widely available in-situ groundwater remediation options and current options are anticipated to generate residuals that may also contain concentrated levels of PFAS and destruction technologies for residuals are not broadly available at commercial scale.

The ubiquitous and complex nature of PFAS is expected to complicate groundwater and surface water assessment activities from adjacent and pre-existing activities, due to the lack of targeted, accurate, and cost-effective 'fingerprinting' options to help characterize the source(s) of PFAS.

A similar concern arises with respect to the discharge of stormwater to a navigable water under a General National Pollutant Discharge Elimination System (NPDES) permit. While we understand that EPA will at some point be proposing pretreatment and effluent guidelines for PFAS under the Clean Water Act, we are concerned that the MCLs may become the default standard for discharges in the interim.

To help alleviate these unintended consequences, we recommend that EPA emphasize that the MCLs only apply to drinking water at the point of consumption and that EPA propose appropriate standards for other environmental media in subsequent rulemakings.

EPA Response: The EPA notes that consideration or reference to MCLs in non-drinking water programs (such as water quality criteria, National Pollutant Discharge Elimination System [NPDES], Effluent Limitation Guidelines, or Comprehensive Environmental Response and Compensation Liability Act [CERCLA] cleanups) is beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR. For further discussion about CERCLA clean-up costs and benefits, please also see the section 5.1.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1631, SBC-043434 in section 5.1.3 in this *Response to Comments* document.

<u>The Ground Water Protection Council (GWPC) (Doc. #1654, SBC-043198)</u>

Date: May 30, 2023

To: U.S. Environmental Protection Agency Docket ID No. EPA-HQ-OW-2022-0114

Re: Per- and Polyfluoroalkyl Substances (PFAS) Proposed PFAS National Primary Drinking Water Regulation for Six PFAS

The Ground Water Protection Council (GWPC) appreciates the opportunity to provide comments and feedback to the U.S. Environmental Protection Agency (EPA) on the proposed National Primary Drinking Water Regulation (NPDWR) for six PFAS.

The GWPC's membership consists of representatives of state groundwater and underground injection control (UIC) regulatory agencies that mutually work toward the protection of groundwater nationwide. Our focus is specifically on protecting groundwater supplies, conserving groundwater resources for all beneficial uses, and recognizing groundwater as a critical component of the ecosystem. The GWPC is unique among state associations in that its members are the state officials who set and enforce regulations on groundwater protection and UIC.

The GWPC comments on the proposed rulemaking express the concerns of its state agency members, including anticipated impacts to UIC programs and facilities as well as groundwater quality concerns. A primary tenet of the federal UIC rules is its non-degradation standard for underground sources of drinking water (USDWs). Per the federal UIC rules in 40 CFR § 144.1 (g):

All owners or operators of injection wells must be authorized either by permit or rule by the Director. In carrying out the mandate of the SDWA, this subpart provides that no injection shall be authorized by permit or rule if it results in the movement of fluid containing any contaminant into USDWs, if the presence of that contaminant may cause a violation of any primary drinking water regulation under 40 CFR part 141 or may adversely affect the health of persons (§ 144.12).

• If the proposed MCLs and HIs for the 6 PFAS are adopted, these rules will impact the regulation and operations of UIC Class V injection wells, many of which inject into or above USDWs. UIC Class V injection wells include stormwater drainage wells, groundwater remediation wells, aquifer storage and recovery (ASR) projects, managed aquifer recharge (MAR) facilities, and non- hazardous waste disposal wells, among other subtypes. While federal rules allow Class V injection wells to be authorized-by-rule, many states review applications and issue permits for these wells. State agency UIC programs will need definitive guidance from EPA on how to address the new water quality standards in the context of authorizing/permitting and regulating UIC facilities, particularly UIC Class V facilities. There are an estimated 580,000 UIC Class V injection wells distributed across the nation, according to EPA's 2021 nationwide UIC well inventory. The financial impact of recharacterizing injected fluids for PFAS and monitoring potential impacts to injection zone groundwater for even 20% of these wells is mind-boggling. Agencies administering the UIC Class V program would need funding for additional staff and activities to address any new programmatic requirements related to PFAS that may be detected in the injection streams or the receiving groundwater.

• The GWPC is concerned that the proposed PFAS rulemaking will affect permitted operating ASR and MAR projects. Already, states are assessing whether existing ASR and MAR projects have measurable PFAS in the injected water and in the injection zone aquifer. GWPC is aware that in North Carolina, one operating ASR project storing public drinking water has been

terminated and the operator had to extract all the injected water, treat the water, and discharge the treated water back into the original surface water source (Cape Fear River). The rulemaking also has the potential to make new ASR/MAR projects infeasible due to costs associated analytical testing and with pre-injection and/or post injection (recovery) water treatment and disposal costs for the treatment residuals.

• The GWPC is concerned with the potential loss of reused treated municipal wastewater as a viable water source for ASR and MAR projects because of the costs associated with treating for and removing PFAS, as well as the costs of disposing the treatment residuals.

• Until cost-effective destruction technologies are in place for PFAS removal, the volume of PFAS- laden liquid wastes that are likely to be disposed into deep UIC Class I injection wells will increase, which will affect current disposal capacity.

• In conjunction with the proposed drinking water regulation, the GWPC has concerns that EPA's proposed CERCLA hazardous substances rulemaking and the anticipated EPA Resource Conservation and Recovery Act (RCRA) rulemaking for these PFAS wastes may result in new regulatory steps, extra time, and additional costs to the permitting process for UIC Class I wells receiving water/wastewater treatment plant residuals and other PFAS-laden wastes. If, upon promulgation of the proposed PFAS rulemakings, these PFAS-laden wastes are considered hazardous under RCRA, it is presumed that EPA will include disposal of these wastes under the RCRA hazardous waste land disposal ban. Because EPA is the administrator of the RCRA hazardous waste land disposal restriction (LDR) program, its region office UIC staffs would be consumed with work to process new UIC Class I hazardous waste disposal well no-migration permits to allow Class I wells to dispose of PFAS laden wastes. The same EPA Regional UIC Programs that would evaluate LDR no-migration petitions are currently backlogged with the ramp up of UIC Class VI carbon sequestration projects, both as a permitting agency and in the process of evaluating UIC Class VI primacy applications from states.

Thank you for the opportunity to provide these comments. Our members will be tasked with meeting all regulatory requirements and standards related to this rulemaking if it is adopted. We ask that EPA address our concerns prior to finalizing the proposed regulations.

If you have any questions or would like to follow up on any of these items, please contact Dan Yates, GWPC Executive Director, at (405) 516-4972 or dyates@gwpc.org.

Sincerely

Dan Yates Executive Director

The Ground Water Protection Council

EPA Response: Please see the EPA response to comment Doc. #1632, SBC-044136 in section 5.1.1 in this *Response to Comments* document. The PFAS NPDWR regulates PWSs. Application of MCLs in other contexts are beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional

discussion on comments outside the scope of this NPDWR. With respect to potential cost concerns, the EPA notes that SDWA expressly states that EPA shall consider "quantifiable and nonquantifiable costs. . . excluding costs resulting from compliance with other proposed or promulgated regulations." Regarding disposal of PFAS laden waste as a result of drinking water treatment, the EPA notes that the likely disposal option for Reverse Osmosis/Nanofiltration Membrane (RO/NF) retentate is treatment and discharges through NPDES compliant facilities and, in limited circumstances, underground injection. Please see section 10.4 of the EPA response in this *Response to Comments* document for additional discussion on the management of treatment residuals.

National Association of Clean Water Agencies (NACWA) (Doc. #1659, SBC-043130)

May 30, 2023

The Honorable Michael Regan, Administrator

U.S. Environmental Protection Agency

Office of Groundwater and Drinking Water (Mail Code 2822IT) 1200 Pennsylvania Avenue NW

Washington, D.C. 20460

Submitted via Federal eRulemaking Portal: https://www.regulations.gov

Re: NACWA Comments on the U.S. Environmental Protection Agency's proposed PFAS National Primary Drinking Water Regulation Rulemaking (Docket ID No. EPA-HQ-OW-2022-0114).

Dear Administrator Regan:

The National Association of Clean Water Agencies (NACWA) appreciates the opportunity to comment on the U.S. Environmental Protection Agency's (EPA) proposed PFAS National Primary Drinking Water Regulation (NPDWR) rulemaking. NACWA has specific comments regarding EPA's plan to regulate perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS) as per the regulatory determination from March 2021, and EPA's more recent preliminary regulatory determination to target perfluorohexane sulfonic acid (PFHxS), hexafluoropropylene oxide dimer acid and its ammonium salt (HFPO-DA, or GenX chemicals), perfluorononanoic acid (PFNA), and perfluorobutane sulfonic acid (PFBS) and mixtures of these PFAS chemicals as drinking water contaminants under the Safe Drinking Water Act (SDWA).

NACWA represents the interests of more than 350 municipal clean water utilities, many of which are dual systems that provide safe drinking water supplies to their respective communities in addition to treating wastewater to high quality standards before beneficially reusing or discharging the water to surface waters. Many NACWA utilities also manage municipal stormwater. Our members are public health and environmental stewards that are anchor

institutions that provide a critical and essential function to their communities and strive each and every day to provide the highest level of service.

NACWA recognizes that the NPDWR is primarily an issue that impacts public water systems (PWSs) under the SDWA, and we know that our sister organizations in the water sector with substantial expertise in SDWA like the Association of Metropolitan Water Agencies (AMWA) and the American Water Works Association (AWWA) will provide EPA with valuable input during the rulemaking process.

However, the NPDWR also will impact wastewater and water recycling utilities primarily regulated under the Clean Water Act (CWA), particularly those that discharge to surface waters designated as drinking water supplies or to surface waters that overlie groundwater used or designated as drinking water supplies, as well as those that are engaged in innovative water recycling and reuse projects that sometimes require compliance with the SDWA's Maximum Contaminant Levels. EPA must also consider the potential interactions of the NPDWR with CWA regulations, including increasing imposition of PFAS monitoring requirements for clean water utilities at the same time that this NPDWR will impose new PFAS monitoring requirements on PWSs.

Further, EPA is developing ambient human health water quality standards that are based on the same reference doses developed during the NPDWR process. Clean water utilities will likely be required, in the not too distant future, to meet very stringent ambient human health water quality standards when there are no existing, affordable PFAS treatment techniques to manage or treat the significant volumes of wastewater and stormwater that clean water utilities manage on a daily basis.

EPA Response: The EPA notes that application of MCLs in non-drinking water programs (such as water quality criteria, NPDES) are beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR. The EPA clarifies that this rule is applicable to PWSs and does not pose direct standards nor monitoring requirements for wastewater treatment facilities. To the extent these entities are facilities for potable reuse that is distributed directly to consumers, these entities would be classified as a PWS and the EPA has considered the cost of compliance for these systems (please see section 13.3 of the EPA response in this *Response to Comments* document for additional discussion).

Massachusetts Coalition for Water Resources Stewardship (MCWRS) (Doc. #1691, SBC-044326)

6. The proposed MCLs raise the specter of serious unintended consequences that could pose public health risks for water consumers. Some of these are:

a. Diversion of local finances to PFAS treatment/remediation and reduced spending on critical water system needs such as pipe replacement, sources protection, staffing and water system

maintenance. The outcome could be drinking water that fails to comply with multiple other MCLs and risk of water borne disease or health impacts.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. Please see section 13.3 of the EPA response in this *Response to Comments* document which discusses cost, and section 13.10 which discusses affordability. Please see also section 2.4 of the EPA response in this *Response to Comments* document which discusses the role of additional federal funding to offset some direct costs associated with this regulation. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043579)

Our utility and our elected officials are committed to limiting exposure to PFAS and protecting the environment. At the same time, we want to ensure efforts do not impose unintended consequences by unnecessarily directing resources away from other water system priorities like noncompliance with existing pollutant MCLs, leak detection investment, replacement of lead service lines, cybersecurity, or conservation and resiliency efforts to address changes in climate such as increased droughts or flooding. The reallocation of resources by communities may also mean deferring on maintenance, which could risk failure of water infrastructure and be ultimately more costly in terms of quality of life in dollars, public health, and the environment.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. Please see section 13.3 of the EPA response in this *Response to Comments* document which discusses cost, and section 13.10 which discusses affordability. Please see also section 2.4 of the EPA response in this *Response to Comments* document which discusses the role of additional federal funding to offset some direct costs associated with this regulation. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water.

Kurt McCord (Doc. #2747, SBC-046590)

Tragic Recap: For decades, EPA has allowed wealthy businesses to poison our people and environment despite early warnings signs. All the while, advocates of these mega-polluters have been promoted as senior rank regulators and aided in this discrepantly disgusting affair. Even under the Biden administration, the leading defender of DuPont's PFOA production, Michael McCabe, gets appointed to the EPA agency review team. Our government continues to "let the fox in the hen house" at the expense of the people that it was created to protect.

So, I ask... what steps has EPA or in a broader context the US government taken to reduce the importation or disseminate of products containing PFAS? Are there programs in place to collect unused contaminated products for incineration? If not, why has an emphasis been placed on removal by utility owners without much effort to keep them out of the environment?

In general, I'm an advocate for clean water. However, an enormous burden has been placed on our public water providers (a recipient of the pollution) to the lowest MCLs ever proposed while profitable companies and poorly informed consumers continue to freely discharge these PFAS compounds into the environment. It's not a comprehensive approach. The recipients are penalized while the decrepit polluters get off easily. Ultimately, the American people (victims) have paid the price with pain, suffering, and the forfeiture of life. Furthermore, we will end-up paying to fix the problem with tax dollars and much higher water bills. Both then and now, the problem should've been stopped at its source by our appointed leaders. Unfortunately, it's another epic failure of the US government.

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index approach and regulation of additional PFAS, please see sections 5.2.1 and 5.3.1 of the EPA response in this *Response to Comments* document. Topics related to assigning liability for PFAS pollution or addressing sources of PFAS contamination are beyond the scope of this rulemaking (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion).

National Ground Water Association (NGWA) (Doc. #1804, SBC-045471)

[The steps identified in that letter include:]

• actively engaging water systems and state agencies as well as other key stakeholders in the practical implementation of PFAS risk management,

EPA Response: After finalization of the PFAS NPDWR, the EPA intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-045054)

I. EPA should consider source control as it implements its PFAS Strategic Roadmap to avoid cost-shifting PFAS remediation to water utilities and ratepayers.

Working its way through its PFAS Strategic Roadmap, EPA is using CERLCA to address sites that are contaminated with PFAS, and the SDWA to address water that is contaminated with PFAS. One option that it did not consider is a direct campaign to eliminate additional PFAS load in our water and soil: to ban the manufacture and use of PFAS, except for in extraordinary circumstances with stringent controls. While most manufacturers voluntarily phased out PFOA and PFOS in the early 2000's for most uses, there is nothing being done to stop the active loading of new PFAS into our environment— onto our soil and into our water—from PFAS laden products that continue to be rolled out to consumers. At this very minute, manufacturers that produce and use PFAS are profiting from the pollution that ratepayers will be paying to clean out of their water for years to come. Water utilities can dedicate billions of dollars to treat water for decades but will never be able to tackle the source. And the source, those companies profiting from a product that is a known health concern, can continue to lawfully pump those pollutants into our world.

An MCL set without proper recognition of implementation, social, and opportunity costs shifts the financial burden of minimizing risk of human exposure to PFAS from private businesses to the public. The proposed drinking water regulation (as currently written) would shift the financial and technical responsibility from the manufacturers that create and use PFAS in their processes to downstream utilities. This burden will be borne by ratepayers.

The MCL should be set with the understanding that PFAS exists in the background of the environment and everyday life. The cost-benefit to achieve these regulatory requirements in the water industry needs to be weighed against the cost-benefit of removing it from food packaging, personal care products, clothing, and other direct and indirect exposure routes. The only way to address and stop the growing concentration of PFAS contaminants in the hydrological cycle is to stop introducing additional PFAS loads. EPA should re-assess the navigation of its PFAS Roadmap.

EPA Response: For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on other actions the agency is taking related to the PFAS Strategic Roadmap (such as source reduction), please see section 15.1 of the EPA response in this *Response to Comments* document.

National Center for Health Research (Doc. #3072-101, SBC-046404)

Thank you very much and I appreciate so much, this chance for a second bite at the apple. Listening to this series of amazing passionate people with so much diversity of experience and so many different levels of personal story. I hope everybody who's still on will find a way to get the list of people who've testified here today and let's network on this. The EPA can only do so much. They're being hamstrung not only by a divided Congress, but of course, the Supreme Court is getting ready to crack down on administrative authority. So, I urge everyone on this call,

and it sounds like many already are, to work at your state and county levels. Here in Maryland, we've had individual bills that go after requiring no PFAS in food containers, and we're looking at AFFF and each state can start to push different municipalities and states and counties and towns are doing things all over the place. And it's going to take all these points of contact. So please everybody on this reach back out to each other. Let's get this network growing. There's a wonderful organization called Beyond Plastics, but I just want to remind people, Safe Healthy Playing Fields, we are a 501(c)(3) working to stop the PFAS of acres of plastic artificial turf that gets to 180 degrees that has massive injury rates that cost so much money that could be spent on grass and then cleaning up the PFAS that was there before. Thank you again so much for the second chance.

EPA Response: The EPA notes that the commenter did not provide specific comment on the PFAS NPDWR for the agency's consideration. Management of artificial turf is beyond the scope of this drinking water regulation.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043793)

Science Based regulations. Enforcement and compliance of proposed standards are not practicable. Early regulatory actions should be focused on advancing scientific understanding and exploring PFAS treatment and source control options. Given the high uncertainties for monitoring, treatment, and destruction of PFAS, it is premature to establish maximum contamination levels (MCL) or treatment requirements at this time. We recommend that drinking water regulations for PFAS include actions that support scientific understanding and exploring implementation solutions that would include actions such as:

• Assessment of total risk and exposure pathways for human health.

• Data collection and monitoring

EPA Response: The EPA has utilized best available, peer-reviewed science and information to inform finalization of this regulation. For the PFAS covered by this rule, the EPA concluded that the state of the science and information has sufficiently advanced to the point to satisfy the statutory requirements and fulfill SDWA's purpose to protect public health by addressing contaminants in the nation's PWSs. While beyond the scope of this action, the EPA notes that agency is also evaluating and developing technologies for reducing PFAS in the environment to inform decisions on drinking water and wastewater treatment, contaminated site cleanup and remediation, air emission controls, and end-of-life materials management. Additionally, the EPA is developing additional health effect information for additional PFAS which aids in contaminant prioritization. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

Blue Ridge Environmental Defense League (BREDL) (Doc. #1568, SBC-042997)

Case Study: Roanoke, Virginia

Authorities fail to notify public about contaminated drinking water

On January 22, 2020, the Western Virginia Water Authority (WVWA) received water testing results that indicated the Spring Hollow Reservoir was contaminated with hexafluoropropylene oxide dimer acid (HFPO-DA), commonly known as GenX. This PFAS (per- and polyfluoroalkyl substances) was found to be 62 parts per trillion (ppt) in the Spring Hollow Reservoir and 61 ppt in the finished drinking water. The Spring Hollow Reservoir provides drinking water for part of the Roanoke Valley and nearby communities. The reservoir is fed by the Roanoke River.

Surprised by the results, WVWA conducted another test in February 2020. Those results came back showing a GenX concentration of 65 ppt at the Spring Hollow Reservoir and 62 ppt in the finished water. This confirmed to WVWA that there was contamination in the Roanoke area drinking water, yet the public and press were not notified. Unbeknownst to WVWA customers, some were consuming GenX contaminated drinking water. Meanwhile, internal communications obtained by the Virginia Freedom of Information Act, indicate that WVWA personnel were discussing plans on locating the source of the contamination.

In March 2020, the Virginia General Assembly passed bills regarding PFAS – directing a Virginia Department of Health (VDH) working group to study the occurrence of PFAS in Virginia water systems. WVWA voluntarily participated in this study.

In May 2021, the VDH working group began testing for 10 PFAS contaminants including GenX. WVWA received a result of 51 ppt of GenX at Spring Hollow Reservoir – Finished Water. WVWA's Carvins Cove, another source of drinking water for the Roanoke Valley, had no detection of GenX. The Salem Water Department, about 11 miles downstream from Spring Hollow, had no detection levels of GenX at its water intake on the Roanoke River.

On June 18, 2021, WVWA added a PFAS information page on its website. The webpage lists information about PFAS and GenX testing results. However, the general public and press were not informed and remained unaware of the contamination issue. After all, how many people are going to look at a public water source's website?

Meanwhile, WVWA continued testing for GenX. WVWA received a result of 57 ppt of GenX at Spring Hollow Reservoir – Finished Water on September 15, 2021.

On September 30, 2021, VDH made the summary of the VDH PFAS working group study available to the general public on its website. Once again, this went unnoticed by the general public and media in the Roanoke Valley.

On December 1, 2021, the VDH working group presented its report to then Governor Ralph Northam, the chairmen/chairwomen of the Virginia General Assembly House Committees on Agriculture, Chesapeake and Natural Resources; and Health, Welfare and Institutions, and

Senate Committees on Agriculture, Conservation and Natural Resources; and Education and Health. The VDH working group included, but was not limited to, several state water systems, VA Dept. of Environmental Quality, as well as at least two state environmental groups. The statewide PFAS testing showed that the Spring Hollow contamination was the highest PFAS concentration in the state at 54 ppt.

The next highest result was 14 ppt of PFPeA PFAS by the Fairfax County Water Authority. Despite all of these people knowing about the report and knowing that the Roanoke area had the highest PFAS concentration in the state, in the Roanoke area, the public and local media were still in the dark that our local drinking water was contaminated by GenX. Meanwhile, monthly testing was still showing GenX contamination. In December 2021, WVWA received a result of 47 ppt of GenX at Spring Hollow Reservoir – Finished Water.

Internal communications showed that on February 25, 2022, WVWA staff discussed the upcoming annual Water Quality Report (CCR) for 2022. This reports for the 2021 calendar year and any recent testing. One staffer reported that "Last year we reported UCMR-4 and noted that it was collected in 2019. I think the rule is if we test our water and report the findings to VDH, we have to include it in the report. I have asked Scott Shirley if the PFAS/Gen-X testing has to be reported or not." In other words, WVWA was in no hurry to report the GenX contamination and would not have done so in the 2022 annual report if the VDH was not involved in that May 2021 testing.

On June 9, 2022, WVWA staff discussed options: "anticipates that we will have to initiate a process where we reduce flow from Spring Hollow and find paths for blending from other sources including purchasing water from Salem and other options." Staff said they were working on a website to assist with public interest on the issue.

WVWA staff were well aware of the upcoming June 15, 2022 EPA announcement on the health advisory of 10 ppt for GenX. May and June 2022 testing results of Spring Hollow finished water was showing GenX concentrations 4 times the health advisory. WVWA should have immediately sent out a public notice and press release notifying the public that Spring Hollow was above this new EPA Health Advisory. But, they didn't. WVWA did prepare a document listing GenX Response Activities. Of course, notifying the public was not on that list of responses. EPA guidance on the health advisory to water systems stated, "Drinking water systems and public health officials should also provide consumers with information about the levels of PFAS in their drinking water" [FN4: 4 https://www.epa.gov/system/files/documents/2022-06/drinking-water-ha-pfas-factsheet-watersystem.pdf] . At this point, the source of the GenX contamination was still unknown.

On June 21, 2022, WVWA internal communications stated that "Staff are shifting daily production from Spring Hollow to other water sources. While not a viable long term solution, staff believes a 35% to 40% reduction is possible."

On June 30, 2022, WVWA publishes their 2022 Annual Water Quality Report (Consumer Confidence Report). It is posted on their website. This report, for the first time, includes a

concentration range of GenX – listed as HFPO-DA in the Spring Hollow section. There was no additional information included in the CCR report.

July 2022 testing finally indicated that GenX was in the Roanoke River – which feeds the Spring Hollow Reservoir – and not just in the Reservoir. A sampling result of 139 ppt was measured along the river at the Spring Hollow Reservoir. However, just 11 miles downstream, a Salem Water Dept. test from 5 days earlier found no detection of GenX. This WVWA testing result was not received by the authority until August 24, 2022. During this time, WVWA had discussed reaching out to Salem. In addition, WVWA had been in communications with Virginia Dept. of Environmental Quality in attempts to determine the source of the contamination.

On August 25, 2022 the public notification process finally begins – but not initiated by WVWA or any other authority. A BREDL staff member was searching the WVWA website for the latest Water Quality Report and came across their PFAS information page which mentioned GenX being found in Spring Hollow. The BREDL staffer contacted a local reporter at the Roanoke Times to alert him to this contamination issue. When contacted by the reporter, WVWA asked him to hold the story until they could brief the local governing bodies. Fortunately, the newspaper went ahead and published the article on August 29, 2022. [FN5: "Tests detect 'forever chemical' in Spring Hollow reservoir", Laurence Hammack, Aug. 29, 2022, https://roanoke.com/news/local/tests-detect-forever-chemical-in-spring-hollow-reservoir/article_dd6515b2-27ed-11ed-8540-ffa05c3c2aaa.html] On August 29, 2022, with the publishing of the newspaper article, WVWA finally posted a letter to their customers on the WVWA website – the letter was also mailed to affected customers. [FN6: https:// www.westernvawater.org/home/showpublisheddocument/13082/637976336776500000]

After nearly 3 years since the WVWA first discovered GenX contamination in the Spring Hollow Reservoir public drinking source, the public finally learned about it. It also took nearly 2.5 months after the EPA health advisory for the public to be notified. This was only after an article in the local newspaper informed the public. [Please see Appendix 1.]

Public Notification expedited discovery of contaminant source

The source for the GenX contamination was finally found in November 2022 after public notification had intensified the search for the source. Public notification was essential in keeping the pressure on officials to locate and stop the contamination. In mid-November 2022, it was disclosed that ProChem, Inc. in Elliston, Virginia was the source of the GenX contamination at Spring Hollow. ProChem has been periodically releasing GenX that has found its way into the Roanoke River since 2014, according to the company. One recent sample at the nearby Montgomery County Water Treatment Plant showed that ProChem had discharged through its sewer system GenX at a concentration of 1.3 million ppt. ProChem claims it was unknowingly releasing the GenX. Upon finding out, ProChem has allegedly stopped doing business with the source company – Chemours of West Virginia.

The Roanoke Times published an Editorial on November 20, 2022 titled: If only forever chemical source had been shut down faster highlights the importance of public notification of

contaminants in drinking water. The Editorial stated, “While it’s a relief that the source of the problem has been identified, hopefully preventing the kind of public health problems these chemicals have caused in other communities, the length of time between discovery and revelation underscores that there is room for improvement.” ProChem told a Roanoke Times reporter that they were unaware of the forever chemical contaminants on the equipment they were cleaning and that as soon as they were notified, they terminated the contract with the Chemours Company out of West Virginia. The Editorial concluded that “Given how ProChem responded, one can’t help but imagine that they would have ended the relationship with Chemours sooner had they been notified sooner, and perhaps Spring Hollow wouldn’t have ranked first in the state for the presence of forever chemicals. While the consensus on the health hazards posed by GenX and other forever chemicals continues to evolve, had officials aware of the problem taken action before government warnings and public exposure forced them to do so, everyone involved, especially water authority customers, would have been better off.” [Please see Appendix 2.]

Attempts to obtain list of waterworks currently testing under UCMR #5

At the moment, if waterworks systems discover PFAS in our drinking water they are not required to notify the public. If this is part of the Unregulated Contaminants Monitoring Rule (UCMR) #5, which is currently requiring testing for 29 PFAS contaminants, then those results will have to be released to the public. However, those results will not be released until the following June 30 after the previous year’s testing – and only online. Thus, if any of these PFAS contaminants are discovered in January or February during initial testing, the public will not know about it until a year and a half later, and only if the public goes to their waterworks website to download the annual water quality report (Consumer Confidence Report).

We strongly believe the public needs to be notified ASAP after PFAS is discovered in our drinking water. Therefore, we have attempted to obtain a list of the waterworks systems currently doing their annual testing for the UCMR. Our aim is to obtain drinking water testing results from some of these facilities to see if any PFAS has been discovered in the community’s drinking water.

For three years, nationwide waterworks will be monitoring for a year for 29 PFAS. Each year a different set of waterworks will be doing the monitoring. On February 22, 2023 we asked EPA if they could provide a list of the waterworks that will be testing for UCMR in 2023, in 2024 and in 2025. In a February 27, 2023 response, EPA would not provide the list citing that the information is “only accessible to EPA, States, and the PWS via SDWARS.” [Please see Appendix 3.]

On May 15, 2023, I sent an email request to the Virginia Department of Health (VDH) requesting a list of Virginia waterworks who are currently testing for the 29 PFAS as part of the UCMR #5. On May 17, 2023 I received a response from the VDH stating that they are “reviewing my request”. VDH did send us the requested list on May 22, 2023.

Public notification of PFAS contaminants in our drinking water is lacking and information can be cumbersome to obtain.

EPA Response: The EPA is finalizing SDWA Right-to-Know requirements for the final NPDWR, including requirements for both Public Notification (PN) and Consumer Confidence Reports (CCRs). Please see section 9 of the EPA response in this *Response to Comments* document for additional discussion.

Massachusetts Water Resources Authority (Doc. #1645, SBC-043290)

MWRA strongly urges EPA to, at the minimum, wait until UCMR5 data collection and data review is complete to finalize any PFAS NPDWR. In the interim, MWRA urges EPA to focus on source control, keeping PFAS out of our nation's waterways, removing PFAS from consumer products (including food packaging, stain- and water-repellent fabrics, nonstick products, polishes, waxes, paints, cleaning products, etc.), and establishing a system where the polluters are paying for the costs of treatment and disposal, not water utility ratepayers.

Thank you for your due consideration of the preceding comments. Respectfully submitted,

David W. Coppes, P.E.

Chief Operating Officer

cc: Fred Laskey, Executive Director

Joseph Favaloro, Executive Director, MWRA Advisory Board

EPA Response: The EPA disagrees with commenter that the agency needs to wait for additional information on the national occurrence of these substances in order to finalize the NPDWR at this time. The EPA currently has sufficient data and information to promulgate standards for the PFAS regulated through this NPDWR: please see section 6 of the EPA response in this *Response to Comments* document for additional discussion on occurrence information and Unregulated Contaminant Monitoring Rule (UCMR) and section 6.8 of the EPA response in this *Response to Comments* document specifically for discussion of UCMR 5. Topics related to assigning liability for PFAS pollution or addressing sources of PFAS contamination are beyond the scope of this rulemaking (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion).

Massachusetts Coalition for Water Resources Stewardship (MCWRS) (Doc. #1691, SBC-044331)

[Alternative Approach-While MCWRS does not agree with the proposed MCLs, an alternative implementation plan is offered regardless of what the final MCLs may be. That plan would include:]

g. While UCMR 5 is being completed, work with other federal agencies to gather data on other PFAS exposure sources. This would allow critical information to be gathered in support of real public health protection.

EPA Response: The EPA disagrees with commenter that the agency needs to wait for additional information on the national occurrence of these substances in order to finalize the NPDWR at this time. The EPA currently has sufficient data and information to promulgate standards for the PFAS regulated through this NPDWR: please see section 6 of the EPA response in this *Response to Comments* document for additional discussion on occurrence information and UCMR and section 6.8 of the EPA response in this *Response to Comments* document specifically for discussion of UCMR 5. While EPA is developing new science, including by partnering with other entities such as federal agencies, the desire to develop new science is not a sufficient reason to suspend the use of best available, peer-reviewed science today to promulgate NPDWRs.

Oneida Nation (Doc. #1825, SBC-044274)

Further, we note that the list of benefits does not presently include the benefit of keeping these chemicals out of tribal subsistence resources – e.g., fish, wild game, plants and subsistence foods used by tribes. Tribal cultural and lifeway benefits derived from these resources surpass simple economic valuations and should be considered in rulemakings.

Conclusion

Thank you for the opportunity to submit comments. Please do not hesitate to reach out for additional information. You may contact me at thill7@oneidanation.org or 920.869.4420.

Sincerely,

Tehassi tasi Hill, Chairman Oneida Nation

EPA Response: Please see section 5.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on non-quantifiable benefits of this final NPDWR, please see sections 13.5 through 13.7 of the EPA response in this *Response to Comments* document. While protection of Tribal subsistence resources such as fish is important, it is beyond the scope of this drinking water rulemaking.

National Tribal Water Council-Tribal PFAS Working Group (NTWCTPWG) (Doc. #1598, SBC-042335)

On behalf of the National Tribal Water Council and the Tribal PFAS Working Group, I am submitting a comment letter in regards to this proposed rule for PFAS National Primary Drinking Water Regulation.

May 26, 2023

Jennifer McLain, Director

Office of Ground Water and Drinking Water

US Environmental Protection Agency

1201 Constitution Avenue NW

RE: Comments on the Proposed National Primary Drinking Water Regulation (NPDWR) for six PFAS: perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), perfluorononanoic acid (PFNA), hexafluoropropylene oxide dimer acid (HFPO-DA, commonly known as GenX Chemicals), perfluorohexane sulfonic acid (PFHxS), and perfluorobutane sulfonic acid (PFBS) EPA Docket ID: EPA-HQ-OW-2022-0114

Dear Director McLain,

Early in 2020, the National Tribal Water Council (NTWC) formed an ad hoc working group named the Tribal PFAS Working Group (NTWC-TPWG) to assist in outreach on Per-and polyfluoroalkyl substances (PFAS) to tribes and tribal members and to advocate for inclusion of tribes and tribal lifeways in policy decisions on PFAS risks and risk management. The NTWC-TPWG is supported by and working in collaboration with the National Tribal Toxics Council (NTTC), the Tribal Science Council (TSC), National Tribal Water Council (NTWC), Tribal Waste and Response Steering Committee (TWRSC) and Tribal Pesticide Program Council (TPPC). The US EPA supports these tribal partnership groups (TPGs).

On April 14, 2022, the National Tribal Water Council-Tribal PFAS Working Group (NTWCTPWG) provided comments as input to EPA's development of a National Primary Drinking Water Regulation (NPDWR) for PFAS.

Select comments provided to EPA in April of 2022 are reiterated in this letter, as necessary and appropriate. In developing this comment letter, the NTWC-TPWG considered both EPA's request for specific comments, as summarized in Section 14 (pages 18729-18732) in the Federal Register Notice (FRN), and commented on other topics as well.

Compounded Health Impacts on Human Health from Drinking Water and Subsistence Food Practices

The FRN (page 18654) appears to indicate that setting the Maximum Contaminant Level Goal (MCLG) for a given drinking water PFAS contaminant takes into consideration both drinking water and food sources thereof. However, we find nothing in the FRN that indicates a similar joint treatment of drinking water-borne and food-borne sources when setting the Maximum Contaminant Level (MCL) for the same given PFAS contaminant. This contrast is of interest to the NTWC-TPWG as subsistence food practices in tribal communities result in a pathway of

considerable PFAS chemical exposure and uptake via ingestion of PFAS-contaminated subsistence food supplies, both terrestrial and marine (Aker et al., 2023a and 2023b). Aker et al. (2023b) determined that overall exposure to perfluoroalkyl acids was twice as high in subsistence Inuit populations as compared to the general Canadian population and specifically perfluorononanoic acid (PFNA) was sevenfold higher. We encourage EPA to take a second look at this and either justify the contrasting approaches or bring them into alignment so that both consider food sources.

EPA Response: The EPA notes that the MCLs, as required under SDWA, considers feasibility which takes into account limits of analytical detection, treatment technology effectiveness, and cost. The MCLGs promulgated in this action are set at a level at which no known or anticipated effects on the health of persons occur, allowing for an adequate margin of safety. Because of SDWA requirements, the MCLs are set as close as feasible to the MCLG. MCLGs based on noncancer effects consider all potential non-drinking water sources of exposure (see section 4 of the EPA response in this *Response to Comments* document). The MCLs for PFNA, PFHxS, and HFPO-DA, as well as the Hazard Index MCL are all equal to the MCLGs. Therefore, these MCLs also consider non-drinking water sources of exposure. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion on the MCLGs for PFOA and PFOS, please see section 4 of the EPA response in this *Response to Comments* document. While protection of Tribal food resources is important, it is beyond the scope of this drinking water rulemaking.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042874)

The proposed drinking water standards are based on the default assumption that 20% of a person's exposure is allocated to drinking water, while 80% is comprised of all other potential exposure pathways. We question why drinking water seems to be the sole focus of regulation while potentially higher PFAS exposures exist in consumer products (including food packaging [FN4: Susmann, H.P., L.A. Schaider, K.M. Rodgers, R.A. Rudel. 2019. "Dietary Habits Related to Food Packaging and Population Exposure to PFASs," Environmental Health Perspectives. DOI: 10.1289/EHP409], stain- and water-repellent fabrics [FN5: https://toxicfreefuture.org/wp-content/uploads/2022/08/toxic-convenience.pdf], nonstick products, polishes, waxes, ski wax [FN6: https://www.epa.gov/system/files/documents/2022-01/pfasskiwax.pdf], paints, cleaning products), food [FN7: https://www.fda.gov/food/process-contaminants-food/testing-food-pfas-and-assessing-dietaryexposure#:~:text=PFAS%20can%20also%20enter%20the,PFAS%20entering%20the%20food%20supply], personal care products/makeup [FN8: https://www.fda.gov/cosmetics/cosmetic-ingredients/and-polyfluoroalkyl-substances-pfas-cosmetics], pesticides, and dust [FN9: Schildroth, S., K.M. Rodgers, M. Strynar, J. McCord, G. Poma, A. Covaci, R.E. Dodson. 2022.

Per-and polyfluoroalkyl substances (PFAS) and persistent chemical mixtures in dust from U.S. colleges. Environmental Research. 206. https://doi.org/10.1016/j.envres.2021.112530. Article], and these potential sources of exposure are not simultaneously being regulated. Time magazine has an excellent graphic [FN10: https://time.com/6281242/pfas-forever-chemicals-home-beauty-bodyproducts/?utm_source=twitter&utm_medium=social&utm_campaign=editorial&utm_term=health_environment&linkId=215849297] depicting all these points of exposure (GRAPHIC 1).

[Figure 1: See Docket ID EPA-HQ-OW-2022-0114-1601]

GRAPHIC 1: There aren't many places in your home that are PFAS-free. Lon Tweeten for TIME; Getty Images

We note that there was a study [FN11: https://agu.confex.com/agu/fm19/meetingapp.cgi/Paper/568254, https://dnr.wi.gov/topic/Contaminants/documents/wispac/WSLHPresentation20200116.pdf] of rainwater conducted by the National Atmospheric Deposition Program and the highest total concentration of PFAS was nearly 5.5 parts per trillion (ppt) in a single sample from Massachusetts. We have higher concentrations of PFAS falling from the atmosphere than EPA's proposed drinking water standards. If we are to have meaningful health risk reduction shouldn't the Biden Administration be truly taking a whole of government approach in addressing PFAS exposure by identifying and regulating all means of PFAS exposure simultaneously? Addressing only 20% or less of a person's potential exposure while the remaining 80% of exposure is allowed to continue unfettered seems irresponsible and an ineffective public health strategy.

EPA Response: The EPA notes that the MCLs, as required under SDWA, considers feasibility which takes into account limits of analytical detection, treatment technology effectiveness, and cost. The MCLGs promulgated in this action are set at a level at which no known or anticipated effects on the health of persons occur, allowing for an adequate margin of safety. Because of SDWA requirements, the MCLs are set as close as feasible to the MCLG. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion on the justification for the relative source contributions (RSCs) of 20 percent for the six PFAS considered in this rulemaking, please see sections 4.2.3 and 4.2.5 of the EPA response in this *Response to Comments* document. Please refer to section 15 of the EPA response in this *Response to Comments* document and the PFAS Strategic Roadmap (https://www.epa.gov/pfas/pfas-strategic-roadmap-epas-commitments-action-2021-2024) for discussion on other actions the EPA is taking to address PFAS pollution and exposure.

New England Water Works Association (Doc. #1836, SBC-045374)

May 30, 2023

Mr. Michael S. Regan, Administrator

U.S. Environmental Protection Agency

EPA Docket Center, OLEM Docket, Mail Code 28221T

1200 Pennsylvania Avenue, NW

Washington, DC 20460

RE: Docket ID No. EPA-HQ-OW-2022-0114 - National Primary Drinking Water Regulation Rulemaking for per- and polyfluoroalkyl substances (PFAS)

Dear Administrator Regan:

The New England Water Works Association (NEWWA) appreciates the opportunity to comment on the Environmental Protection Agency's proposed National Primary Drinking Water Regulation. NEWWA is a membership organization for those working or interested in the drinking water profession with more than 2,200 members who collectively serve more than 3 million water consumers across the six New England states. Headquartered in Holliston, Massachusetts, we bring together water utilities, consultants, manufacturers, vendors, regulators, academia, and other interested parties to network, educate, and advocate.

Let us state unequivocally for the record that public health protection is Public Water Systems' (PWS) primary mission and goal. PWS take this role very seriously and work hard to ensure that the water provided to residents across the region meets all Safe Drinking Water Act standards. As a testament to our success, we take great pride in the fact that according to the Environmental Protection Agency's (EPA) own statistics for Quarter 1 of 2023, 95% of community water systems in Region 1 met all applicable health-based standards and 93.8% of the population served by community water systems in Region 1 received drinking water which met all applicable health-based drinking water standards (Table 1).

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1836]

Table 1: EPA Safe Drinking Water Compliance Statistics – New England Public Water Systems
GPRA = Government Performance and Results Act

We are providing the following comments on EPA's proposed National Primary Drinking Water Regulation Rulemaking for per- and polyfluoroalkyl substances (PFAS). We note that EPA has engaged in rulemaking concurrently on several major rules that impact the water sector, with public comments all due within the past month, making it challenging to give each the thorough review it requires. This regulation is complicated, with new concepts not well understood by the drinking water profession. We are discouraged that EPA has denied requests to extend the public comment period to give more time for thoughtful review on a regulation which we well know

will have substantial impact on our industry. We fully support efforts to expand verified public health protections, but EPA needs to consider the challenges and costs associated with implementation of the proposed PFAS rule before finalizing these standards.

General Comments:

NEWWA and its members can offer technical expertise as it relates to the very real impact that new drinking water standards will have on PWS operations and related services, and the very significant cost burden it will have on our ratepayers – neither of whom have created this problem. However, our ability to offer comments and opinions on the scientific basis for setting the standards is limited. We are not toxicologists, nor epidemiologists, so we will leave it to other experts to comment on the appropriateness of the standards from a public health protection standpoint. We question why drinking water seems to be the sole focus of regulation at part-per trillion levels while potentially higher PFAS exposures may be happening due to PFAS concentrations in the part per billion and part per millions from a great variety of sources: consumer products (including food packaging [FN1: Susmann, H.P., L.A. Schaider, K.M. Rodgers, R.A. Rudel. 2019. "Dietary Habits Related to Food Packaging and Population Exposure to PFASs," Environmental Health Perspectives. DOI: 10.1289/EHP409], stain- and water-repellent fabrics [FN2: Microsoft Word - toxic-convenience.docx (toxicfreefuture.org)], nonstick products, polishes, waxes, paints, cleaning products), food, personal care products/makeup [FN3: Per and Polyfluoroalkyl Substances (PFAS) in Cosmetics | FDA], pesticides, and dust [FN4: Schildroth, S., K.M. Rodgers, M. Strynar, J. McCord, G. Poma, A. Covaci, R.E. Dodson. 2022. Per-and polyfluoroalkyl substances (PFAS) and persistent chemical mixtures in dust from U.S. colleges. Environmental Research. 206. https://doi.org/10.1016/j.envres.2021.112530. Article], and these potential sources of exposure are not simultaneously being regulated. We will note that there was a study of rainwater conducted by the National Atmospheric Deposition Program and the highest total concentration of PFAS was nearly 5.5 parts per trillion (ppt) in a single sample from Massachusetts [FN5: https://agu.confex.com/agu/fm19/meetingapp.cgi/Paper/568254]. With that said, we have higher concentrations of PFAS falling from the atmosphere than EPA's proposed drinking water standards. The proposed drinking water standards assume that 20% of a person's exposure is allocated to drinking water, while 80% is comprised of all other potential exposure pathways. In order to have meaningful health risk reduction the Biden Administration should be truly taking a whole-of-government approach to address PFAS exposure by regulating all means of PFAS exposure simultaneously. Addressing only 20% of a person's potential exposure while the remaining 80% of exposure is allowed to continue unfettered seems irresponsible.

EPA Response: The EPA notes that the MCLs, as required under SDWA, considers feasibility which takes into account limits of analytical detection, treatment technology effectiveness, and cost. The MCLGs promulgated in this action are set at a level at which no known or anticipated effects on the health of persons occur, allowing for an adequate margin of safety. Because of SDWA requirements, the MCLs are set as close as feasible to the MCLG. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory

considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. For discussion on how the EPA considers other sources of exposure when setting the MCLGs, please see sections 4.2.5 and 4.3.3 of the EPA response in this *Response to Comments* document. Please refer section 15 of the EPA response in this *Response to Comments* document and to the PFAS Strategic Roadmap (https://www.epa.gov/pfas/pfas-strategic-roadmap-epas-commitments-action-2021-2024) for discussion on other actions the EPA is taking to address PFAS pollution and exposure. For additional discussion on comment period extensions, please see section 17.1 of the EPA response in this *Response to Comments* document.

5.1.2 Laboratory Considerations (including Capability and Capacity) and Practical Quantitation Levels

Summary of Major Public Comments and EPA Responses

Some commenters stated that setting the MCL at the PQL is technically and economically feasible and supports the EPA's rationale that the MCLs at 4.0 for PFOA and PFOS are as close as feasible to the MCLG under SDWA. The EPA agrees with these commenters based on the agency's feasibility analysis. As discussed in section IV of the preamble for this regulation and section 4 of this *Response to Comments* document, first, the agency is establishing non-enforceable MCLGs at zero for contaminants where no known or anticipated adverse effects to the health of persons will occur, allowing for an adequate margin of safety. For the feasibility analysis, the EPA then examined the treatment capability of Best Available Technologies (BATs) and the accuracy of analytical techniques as reflected in the PQL in establishing the closest feasible level. In evaluating feasibility, the agency has determined that multiple treatment technologies (e.g., Granular Activated Carbon [GAC], anion exchange [AIX]) "examined for efficacy under field conditions and not solely under laboratory conditions" are found to be both effective and available to treat PFOA and PFOS to the standards and below. The EPA also determined that there are available analytical methods to measure PFOA and PFOS in drinking water and that the PQLs for both compounds reflect a level that can be achieved with sufficient precision and accuracy across laboratories nationwide using such methods. Since limits of analytical measurement for PFOA and PFOS require the MCL to be set at some level greater than the MCLG, the agency has determined that 4.0 ng/L (the PQL for each contaminant) represents the closest feasible level to the MCLG and the level at which laboratories using these methods can ensure, with sufficient accuracy and precision, that water systems nationwide can monitor and determine compliance so that they are ultimately delivering water that does not exceed the maximum permissible level of PFOA and PFOS to any user of their PWS. The EPA evaluates the availability and performance of BATs for treating water to minimize the presence of the contaminant consistent with the MCLG as well as the costs of applying those BATs to large and metropolitan water systems when treating to that level. In consideration of these factors, the EPA is therefore establishing the MCL of 4.0 ng/L for both PFOA and PFOS. The

EPA further notes that the agency has determined that the costs of SSCTs to reach 4.0 ng/L are affordable for households served by small drinking water systems.

Many commenters assert that implementation of the PFOA and PFOS standard would be challenging because the MCLs are set at the PQLs for each compound, and some commenters recommended alternative standards (e.g., 5.0 ng/L or 10.0 ng/L). These commenters contend that by setting the MCL at the PQL, utilities would not be able to reliably measure when the concentration of contaminants in their drinking water is approaching the MCL. Some of these commenters suggest that having a buffer between the PQL and the MCL may allow utilities to manage treatment technology performance more efficiently because utilities generally aim to achieve lower than the MCL to avoid a violation and that this buffer would provide some level of operational certainty for systems treating for PFAS. The EPA disagrees that the PFOA and PFOS standard is not implementable because the MCL is set at its respective PQL. The EPA has promulgated, and both the EPA and water systems have successfully implemented, several NPDWRs with MCLs equal to the contaminant PQLs. As examples, in 1987, the EPA finalized the Phase I Volatile Organic Compounds (VOC) rule (USEPA, 1987), where the agency set the MCL at the PQL for benzene, carbon tetrachloride, trichloroethylene, vinyl chloride, and 1,2-dichloroethane (52 FR 25690). Other examples where MCLs were set at the PQL include benzo(a)pyrene, di(2-ethylhexyl) phthalate, dioxin, dichloromethane, hexachlorobenzene, and PCBs (see USEPA, 1991a and USEPA, 1992). Some commenters at the time stated they believed implementation would be challenging because the MCLs were set at the PQL in these examples; however, the EPA notes that those rules have been implemented successfully despite commenters initial concerns.

In the proposal, the EPA discussed how utilities may be able to use sample results below the PQL to determine analyte presence or absence in managing their treatment operations; however, a few commenters contend that this is not practical to determine compliance with the MCL as these values are less precise and violations may result in expensive capital improvements. Commenters are conflating two different issues. While commenters are referring to quantitation of a sampling result for compliance with the rule, the EPA discussion on results below the PQL refers to determining simple presence or absence of a contaminant for other purposes. Sampling results below the PQL may not have the same precision as a sampling result at or above the PQL but they are useful for operational purposes such as understanding that PFOA and PFOS may be present, which can inform treatment decisions and monitoring frequency. For example, a utility may use sampling results below 4.0 ng/L as a warning that they are nearing the PFOA and PFOS MCLs of 4.0 ng/L prior to an exceedance. Then, the utility can make informed treatment decisions about managing their system (e.g., replacing GAC). Additionally, EPA evaluated data submitted as part of the UCMR 5 Laboratory Approval Program (LAP) and found that 47 of 53 laboratories (89 percent) that applied for UCMR 5 approval generated a minimum reporting level (MRL) confirmation at 2 ng/L (one-half the proposed MCL) or less for Method 533. This suggests that the majority of laboratories with the necessary instrumentation to support PFAS monitoring have the capability to provide useful screening measurement results below the PQL.

The agency does not agree with commenters that operational flexibility is relevant for purposes of setting an MCL. Such considerations may be relevant to other parts of the rule, such as determining monitoring and compliance with the rule. First, for purposes of determining compliance with the MCL, water systems must calculate the running annual average (RAA) of results, which could allow some results to exceed 4.0 ng/L for single measurements if the overall annual average is below the MCL. In other words, there is a buffer built into determining compliance with the MCL. Second, when calculating the RAA, zero will be used for results less than the PQL which provides an additional analytic buffer for utilities in their compliance calculations. This monitoring and compliance framework allows for temporal fluctuations in concentrations that may occur because of unexpected events such as premature PFOA and PFOS breakthrough or temporary elevated source water concentrations. Thus, periodic occurrences of PFOA or PFOS that are slightly above the PQLs do not necessarily result in a violation of the MCL if other quarterly samples are below the PQL. The agency notes that in general, PQLs are set well above the limit of detection; for PFAS specifically, all the PQLs are well above their limits of detection. The PQL is also different than detection limits because the PQL is set considering a level of precision, accuracy and quantitation. Systems may be able to use sample results below the PQL to understand whether PFOA and PFOS are present. While the EPA has determined that results below the PQL are insufficiently precise for determining compliance with the MCL, results below the PQL can be used to determine analyte presence or absence in managing a system's treatment operations and used for determining monitoring frequency.

Some commenters contend that the PQLs for PFOA and PFOS are not set at an appropriate level (e.g., the PQLs are either too high or too low for laboratories to meet). Specifically, these commenters question whether enough laboratories have the ability to analyze samples at 4.0 ng/L and, as a result, contend it is not a "reasonable quantitation level". The EPA disagrees with commenters who suggest the PQLs for PFOA and PFOS are not set at an appropriate level. As discussed above and in the March 2023 proposal, the EPA derives PQLs that reflect the level of contaminants that laboratories can reliably quantify within specific limits of precision and accuracy during routine laboratory operating conditions. The ability to reliably measure is an important consideration for feasibility to ensure that water systems nationwide can monitor and dependably comply with the MCLs and deliver drinking water that does not exceed the maximum permissible level.

In the rule proposal (USEPA, 2023b), the EPA explained that the MRLs under UCMR 5 reflect "a minimum quantitation level that, with 95 percent confidence, can be achieved by capable lab analysts at 75 percent or more of the laboratories using a specified analytical method" (USEPA, 2022a). The EPA uses this definition to provide a statistical framework for predicting the lowest level a laboratory can achieve using a specified method and is not directly correlated to the total number of laboratories available to meet these limits. In other words, the definition applied in setting MRLs established for UCMR 5 (which serve as the basis for the PQLs in this rulemaking) does not mean that there are only 75 percent of laboratories available to meet these reporting levels and, conversely, that 25 percent of laboratories cannot. In practice, the number of available laboratories to meet these quantitation limits is likely much greater (USEPA, 1999; USEPA,

2001). For example (and described further below), all UCMR 5 approved labs were able to meet or exceed the PFOA/PFOS minimum reporting limits at 4 ng/L. The EPA further explains below that there are 53 labs for PFAS methods and the UCMR 5 LAP found that 47 of 53 laboratories (89 percent) that applied for UCMR 5 approval generated a MRL confirmation at 2 ng/L (one-half the MCLs) or less for Method 533. Based on the EPA's experience in implementing previous UCMRs and NPDWRs, the agency believes that these conditions are reflective of commercial and non-EPA laboratory performance and capacity (USEPA, 1999; USEPA, 2001). Additionally, laboratories may be operated by water utilities themselves or by commercial environmental laboratories, many of whom specialize in drinking water analyses. These labs contribute to an even more robust national network of laboratories with experience in PFAS drinking water analysis as demonstrated in the various state-led PFAS monitoring campaigns precluding the proposal of the PFAS NPDWR (USEPA, 2024a). The EPA expects the environmental laboratory community will continue to develop their capabilities for the PFAS drinking water analysis at the PQL as demonstrated in previous drinking water regulations (USEPA, 1999; USEPA, 2001).

With respect to the calculation of the MRLs for UCMR 5 (e.g., 4 ng/L for PFOA and PFOS) that serve as the basis for the PQLs in this NPDWR, the EPA calculated the UCMR 5 MRLs using quantitation-limit data from multiple laboratories participating in a MRL setting study. The technical basis for the MRL calculation is further described in (USEPA, 2010). The calculations account for differences in the capability of laboratories across the country. Laboratories approved to analyze UCMR samples must demonstrate that they can consistently make accurate and precise measurements of PFOA and PFOS at or below the established MRLs. As part of the final UCMR 5, the EPA noted in 40 CFR 141.40(a)(3) Table 1, Footnote 4, "If EPA determines, after the first six months of monitoring that the specified MRLs result in excessive resampling, EPA will establish alternate MRLs and will notify affected PWSs and laboratories of the new MRLs." Since implementation of the UCMR 5 monitoring program, the agency found that laboratories were routinely able to meet the MRLs on a regular basis and the EPA did not reconsider these levels when monitoring began in 2023, providing confirmatory evidence that the MRLs are appropriate to use as the basis for the PQLs in this rulemaking (USEPA, 2021a). Therefore, the EPA disagrees with commenters who find it inappropriate to use the UCMR 5 MRLs as the basis for the PQLs. The agency finds that the UCMR 5 MRLs are appropriate for using as PQLs for this rulemaking: the EPA estimates that laboratories across the nation can precisely and accurately measure PFOA and PFOS reliably at this quantitation level. After reviewing data from laboratories that participated in the MRL setting study under UCMR 5 and in consideration of public comment, the EPA finds that the MRLs set in UCMR 5 of 4.0 ng/L for PFOA and PFOS, that are also the PQLs, are as close as feasible to the MCLG. A few commenters contend that establishing a quantitation level "that is too low may result in recurring QC failures," thereby requiring repeat sample analyses and straining laboratory capacity. The agency disagrees; neither methods 533 nor 537.1 ver. 2.0 which are approved to meet the monitoring requirements of the final NPDWR have inherent quality control (QC) issues when followed. With respect to the analytic requirements of the EPA methods and for additional

discussion on PQLs, please see sections 7.1 and 7.2 of the EPA response in this *Response to Comments* document.

The EPA agrees with commenters that it is inappropriate to make potentially costly compliance decisions based on measurements below the PQL because they do not have the same level of precision and accuracy as results at or above the PQL. As previously discussed, for compliance purposes, results less than the PQL will be recorded as zero. For additional details on monitoring and compliance requirements, please see section VIII of the final rule preamble.

Some commenters disagreed with the EPA's determination that the rule is feasible under SDWA asserting that there is insufficient laboratory capacity and other analytic challenges to measure samples at these thresholds. In the agency's approach toward evaluating feasibility, the EPA assesses, among other things, (1) the availability of analytical methods to reliably quantify levels of the contaminants in drinking water and (2) the lowest levels at which contaminants can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions using the approved methods (i.e., the PQLs). This framework inherently considers both the capacity and capability of labs available to meet the requirements of the NPDWR.

Based on the EPA's analysis of these factors, the EPA disagrees with commenter assertions that there is insufficient laboratory capacity at this time to support implementation of the NPDWR. Currently, there are 53 laboratories for PFAS methods (Method 533 or 537.1) in the EPA's UCMR 5 LAP, more than double the participation in UCMR 3 (21 laboratories), with several laboratory requests to participate after the lab approval closing date. At a minimum, these 53 labs alone have already demonstrated sufficient capacity for current UCMR 5 monitoring, which requires monitoring for all systems serving above 3,300 or more persons and 800 systems serving less than 3,300 persons over a three-year period. Sufficient laboratory capacity for UCMR 5 is demonstrated by reviewing reported results submitted during 2023, the first year of UCMR 5 sampling, where 17,800 PFAS samples were analyzed by approved laboratories with 80 percent of those analyses conducted by 20 percent of the approved laboratories (11 of 53) (USEPA, 2024b). These results provide confirmatory evidence that sufficient laboratory capacity exists to support the monitoring requirements of the NPDWR; the laboratory capacity established for UCMR 5 will become fully available once UCMR 5 monitoring concludes in December 2025 for PWS to comply with the PFAS NPDWR monitoring requirements after the PFAS rule promulgation. Participating labs are spread throughout the country and many commercial labs support out-of-state clients for compliance drinking water analysis, as labs may be certified or accredited by states they are not geographically located in. Additionally, the NELAC Institutes' National Environmental Laboratory Accreditation Management System (TNI LAMS) database currently has 57 laboratories accredited for either Methods 533, 537.1, or both (NELAC Institute, 2024). This number is likely an underestimate as it doesn't include states that are not part of the NELAC Institutes (TNI) (Mass.gov, 2024). However, these additional laboratories accredited for the PFAS methods approved for the monitoring requirements of this rule provides further confirmatory evidence supporting the EPA's determination that there is sufficient

laboratory capacity, demonstrating an additional network of laboratories experienced in PFAS drinking water analysis. Additionally, the 21 laboratories participating in UCMR 3 provided more than sufficient capacity for that monitoring effort, which required monitoring for all systems serving greater than 10,000 persons and 800 systems serving less than 10,000 (USEPA, 2016). This further demonstrates that laboratory capacity has grown since UCMR 3 and the EPA's conclusion that even more labs (beyond the 53 approved for UCMR 5) will become certified to support compliance monitoring for the PFAS NPDWR. Further, a recent review of state certification and third-party accreditation of laboratories for PFAS methods provides confirmatory evidence that an additional 25 laboratories outside the UCMR 5 LAP with a certification or accreditation for EPA Method 533 or 537.1. Additionally, as has happened with previous drinking water regulations, the EPA anticipates laboratory capacity to grow once the rule is finalized to include an even larger laboratory community, as the opportunity for increased revenue by laboratories would be realized by filling the analytical needs of the utilities (USEPA, 1987; USEPA, 1991a; USEPA, 1991b; USEPA, 1992; USEPA, 2001). Finally, the EPA is aware of PFAS monitoring efforts by States and local communities across the country to better understand PFAS occurrence in drinking water, including both statewide drinking water monitoring actions, and targeted sampling at locations that have potentially been impacted by releases or where PFAS-containing materials are known to have been used (USEPA, 2024a). These ongoing efforts have contributed to an even more robust national network of laboratories experienced in PFAS drinking water analysis.

With respect to the number of samples laboratories may receive for compliance monitoring, the agency is finalizing monitoring requirements (such as the use of a reduced monitoring schedule to once every three years for eligible systems and the ability for systems that are reliably and consistently below the MCLs of 4.0 ng/L to only monitor once per year) such that the EPA anticipates that a large number of utilities may be able to take advantage of reduced or annual monitoring, and will not require a more frequent monitoring schedule, thus easing the burden of laboratory capacity as well. In addition, the EPA received comment from the American Council of Independent Laboratories (ACIL) that states "ACIL assures the Agency that they, on behalf of the commercial environmental testing community, do not expect laboratory capacity to be an ongoing concern." (see Doc. #1692, SBC-044736 in section 5.1.2). Further, the Environmental Monitoring Coalition reflected confidence to meet the needs of drinking water utilities to monitor PFAS provided that appropriate resources are in place (see Doc. #1625, SBC-043105 in section 5.1.2). In consideration of the available labs supporting a national monitoring program like the UCMR 5; the availability of labs identified in TNI LAMS database certified for PFAS methods (533, 537.1 or both); previous and on-going state efforts in monitoring and sampling for PFAS; the ability for water systems to leverage monitoring flexibilities in the NPDWR, the EPA finds that there is sufficient laboratory capacity supporting the final NDPWR.

The EPA also disagrees with commenter assertions that there is insufficient laboratory capability at this time. As discussed above and in the proposed rule preamble, the EPA proposed a PQL of 4.0 ng/L for both PFOA and PFOS based on current analytical capability and from the MRLs generated for the UCMR 5 program. The MCLs for PFOA and PFOS were also set at 4.0 ng/L as

a result of the analytical capability assessment under the MRL setting study for UCMR 5, as well as consideration of other factors (e.g., treatment, costs) as required under SDWA. For UCMR 5, all UCMR-approved laboratories were able to meet or exceed the PFOS and PFOA UCMR MRLs, set at 4 ng/L, the final MCL for both. The UCMR 5 MRLs of 4 ng/L for PFOS and PFOA are based on a multi-laboratory MRL calculation using lowest concentration minimum reporting level (LCMRL) data. The LCMRL and MRL have a level of confidence associated with analytical results. More specifically, the LCMRL calculation is a statistical procedure for determining the lowest true concentration for which future analyte recovery is predicted with 99 percent confidence to fall between 50 and 150 percent recovery. In other words, this procedure allows for the determination of a method quantitation limit through simultaneous incorporation of precision and accuracy in analytical measurements.

The multi-laboratory MRL is a statistical calculation based on the incorporation of LCMRL data collected from multiple laboratories into a 95 percent one-sided confidence interval on the 75th percentile of the predicted distribution referred to as the 95-75 upper tolerance limit. This means that 75 percent or more of participating laboratories will be able to set a MRL with a 95 percent confidence interval. The quantitation level of 4 ng/L has been demonstrated to be achieved with precision and accuracy across laboratories nationwide, which is important to ensure that systems can dependably comply with the MCL and deliver drinking water that does not exceed the maximum permissible level. The agency anticipates that these quantitation capabilities and capacity for labs will continue to improve over time, as technology advances and as laboratories gain experience with the PFAS Methods. The EPA's expectation is supported by the record borne out by the significant improvements in analytical capabilities for measuring certain PFAS, including PFOA and PFOS, between UCMR 3 and UCMR 5. For example, the MRLs calculated for UCMR 3 (2012-2016) were 40 ng/L and 20 ng/L for PFOS and PFOA, respectively, the MRLs calculated for UCMR 5 (2022-2025) were 4 ng/L each for PFOA and PFOS. Such advances not only imply scientific advances in instrumentation technology but also the availability of more sensitive instrumentation for laboratories to support implementation of the rule.

Additionally, the EPA is promulgating individual MCLs for PFHxS, PFNA and HFPO-DA at the same level as their respective MCLGs (which are equivalent to the Health-Based Water Concentration [HBWCs]). The EPA is finalizing individual MCLs as follows: HFPO-DA MCL = 10 ng/L; PFHxS MCL = 10 ng/L; and PFNA MCL = 10 ng/L. Concurrent with this action, the EPA is making the required determinations to support both the individual MCLs for PFHxS, PFNA, and HFPO-DA as well the Hazard Index MCL for mixtures of PFHxS, PFNA, HFPO-DA and PFBS. The PQLs for HFPO-DA (5.0 ng/L), PFHxS (3.0 ng/L), PFNA (4.0 ng/L), and PFBS (3.0 ng/L), like PFOA and PFOS, are also based on current analytical capability and from the MRLs generated for the UCMR 5 program. Considering that the non-PFOA/PFOS PFAS MCLs are significantly higher than their PQLs (between 2 to 667 times higher), the EPA disagrees that there are reliability concerns with results for these four PFAS. For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see the EPA section 7.2 of the EPA response in this *Response to Comments* document.

Several commenters raised concern regarding on-going laboratory capacity for this final rule in context of required testing under other environmental programs (for example, NPDES permitting requirements, evaluation of impacts to wastewater systems, or laboratory analysis under cleanup programs). These commenters express concern that laboratories must conduct analyses in various matrices and this rule may complicate their ability to provide results for complying with the final NPDWR in time. The EPA disagrees with commenters that testing for PFAS in other matrices would interfere with laboratories' ability to test for PFAS in drinking water matrices. First, as discussed elsewhere in this *Response to Comments* document, there are already a number of laboratories testing for PFAS in drinking water using EPA methods 533 and 537.1. Significant laboratory capacity has already been developed to support the UCMR 5 program and numerous state PFAS drinking ater regulatory and monitoring programs. Specifically, in regard to UCMR 5, as of January 2024, in the first 9 months of the UCMR 5 sampling program, these laboratories have already tested over 16,000 samples for all 29 PFAS monitored under that program (resulting in approximately 500,000 individual analytes reported). With finalization of this final PFAS NPDWR, as is typical in with past regulatory programs, the EPA expects the laboratories certified to collect these samples to increase, not decrease (see preceding discussion on laboratory capacity and capability). Secondly, the EPA notes that for labs that analyze both drinking water, wastewater, and/or other matrices' data, laboratories typically have dedicated equipment to support analyzing drinking water contaminants to avoid cross contamination, particularly for methods that have strict quality assurance/quality control (QA/QC) requirements and low PQLs such as those required for the six PFAS regulated by this drinking water regulation. Additionally, the EPA notes that there are many utility associated labs that are established solely to monitor for drinking water or wastewater (e.g., see Adams et al., 2023) or dedicate separate instruments to analyze drinking water versus non-drinking water samples as they don't want cross contamination. Third, commenters concerns are not supported by any basis in fact or factual information to the record. Specifically, the data on the volume of additional samples to manage from other state and federal programs was not provided by commenters and the EPA is generally unaware of sources that project specific future laboratory needs across all potential matrices. Hence, the EPA cannot estimate the potential additional demand that other analyses may create, nor what potential impacts, if any, there could potentially be on drinking water laboratory capacity. Finally, even if data were to be available, SDWA section 1412.b(3)(C)(i)(III) requires that EPA include quantifiable and non-quantifiable costs that are likely to occur solely as a result of compliance with the MCL, including monitoring, treatment and other costs and excluding costs resulting from compliance with other proposed or promulgated regulations." Testing for other matrices such as wastewater testing or testing for contaminated sites is not part of routine compliance sampling under this regulation. In summary, despite the concerns raised by commenters that there may be additional demands on drinking water laboratory capacity as a direct result of non-drinking water analytical needs, the EPA does not anticipate non-drinking water related sampling will meaningfully impact national laboratory capacity for analyzing PFAS in drinking water samples.

A few commenters expressed concern on enforcement actions or PN of violations resulting from delays in receiving analytical results from certified laboratories (e.g., prolonged laboratory turn-around times). In particular, these commenters state that on-going laboratory capacity challenges are resulting in backlogs that cause delays in analysis and delivery of results, even when samples are collected in a timely manner. Some of these commenters suggest that water systems should not be penalized in this scenario. As a general matter, it is incumbent on the water system to meet the monitoring and reporting requirements of any NPDWR and to get the analysis completed in a timely manner consistent with these requirements. In this vein, the EPA recommends that the primacy agency working with the system to schedule sample collection well before the end of the monitoring period to allow ample time for results to be reported. Further, it is important to note that if a sample is collected on time but laboratory analysis was delayed, this would constitute as a reporting violation and not a monitoring violation. See 40 CFR § 141.31(a) which states that "the supplier of water shall report to the State the results of any test measurement or analysis required by this part within (1) The first ten days following the month in which the result is received, or (2) the first ten days following the end of the required monitoring period as stipulated by the State, whichever of these is shortest." Moreover, states that gain primary enforcement authority would respond to violations of NPDWRs, however the EPA retains independent enforcement authority and may take federal actions as appropriate in specific situations. *See* the EPA's SDWA Enforcement Response Policy for an explanation of how the EPA typically pursues enforcement cases involving a water system's violations of the SDWA.

The EPA is promulgating a two-year capital improvement extension pursuant to SDWA section 1412(b)(10) in response to comments on the compliance timeframe. Although the EPA disagrees with commenter's assertions about laboratory capacity at this time to support implementation of the NPDWR, to the extent there are some initial implementation issues just after promulgation, extending the compliance date may also provide ancillary benefits toward addressing any such laboratory capability and capacity issues by allowing laboratories additional time to respond to short-term, increased demands to fill analytical needs of utilities to comply with the final NPDWR. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Individual Public Comments

3M Company (Doc. #1774, SBC-045686)

VII. THE PROPOSED MCLs ARE NOT "FEASIBLE"

After determining to regulate a substance, EPA must set a "maximum contaminant level goal" (MCLG) for each identified substance at a level at which no known adverse health consequences will occur. [FN80: 42 U.S.C. [sec] 300g–1(b)(4)(A).] EPA must then set a "maximum contaminant level" (MCL) for each substance as close to the MCLG as is feasible. [FN81: Id.

[sec] 300g–1(b)(4)(B).] Under the statute, "feasible" means "feasible with the use of the best technology, treatment techniques and other means which the Administrator finds... are available (taking cost into consideration)." [FN82: Id. [sec] 300g–1(b)(4)(D)] Some basic factors such as insufficient lab capacity and inability to reliably measure samples at the ultra-low levels in the proposed NPDWR render the proposed MCLs infeasible, contrary to SDWA requirements.

EPA Response: The EPA disagrees with the commenter that the final MCLs are infeasible. The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please also see section 5.1.2 of the EPA response in this *Response to Comments* document.

A. O. Smith Corporation (Doc. #1674, SBC-043695)

3. Laboratory Capacity and Testing Cost Considerations

Having reviewed and being familiar with USEPA Test Methods 573.1 and 533, the Company agrees that each test protocol when accurately conducted can reliably quantify and detect PFOA and PFOS to 4 ppt. The test protocols, again when accurately conducted, should also address concerns surrounding "false positives" and non-detects which can be a persistent challenge for PFAS analysis, which in turn can affect the detection limit of the methods.

EPA Response: The commenter's agree that test protocols, when accurately conducted, can reliably quantify PFOA and PFOS to 4.0 ppt. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Robert Hollander (Doc. #1516, SBC-042709)

1. 88 FR 18667, 1st column

I agree it is appropriate to establish the MCL at the PQL for PFOA and PFOS. It would be not be acceptable for it to be lower for the reasons provided at 88 CFR 18667.

EPA Response: The commenter supports the feasibility of the final standards for PFOA and PFOS. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

American Council of Independent Laboratories (ACIL) (Doc. #1692, SBC-044736)

As measurement experts, our comments will pertain solely to method/measurement aspects of the regulation. Our comments/requests for clarification are detailed below.

1. Proposed MCLs

ACIL agrees with the EPA that the measurement of the listed PFAS at the sensitivity needed to support the proposed MCLs is achievable by the laboratory community.

EPA Response: The commenter supports the feasibility of the final standards. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Corix Infrastructure Inc. (Doc. #1834, SBC-045367)

[With regards to the specific items EPA has requested comment on, Corix provides below:]

• We support setting the MCL at the PQL for PFOA and PFOS.

EPA Response: The commenter supports the feasibility of the final standards for PFOA and PFOS. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043905)

In response to Section VI-Maximum Contaminant Level of the Proposed Rules, EPA requests comment on its proposed determination to set MCLs at 4.0 ppt for PFOA and PFOS and whether 4.0 ppt is the lowest PQL that can be achieved by laboratories nationwide.

• LCU would like to express concern over the proposed determination to set MCL's at 4.0 ppt. While the EPA states the evaluation "determined that 4.0 ppt is the lowest concentration that PFOA and PFOS can reliably be quantified within specific limits of precision and accuracy during routine laboratory operating conditions," LCU questions the feasibility of the proposed limit in practical application.

This uncertainty is further warranted due to the following:

1. In 2016 until recent, 70 ppt was the health level of concern.

2. According to the European Chemicals Agency, "The proposal to establish a new 'group limit' value for PFAS of 0.5 µg/L (500 ng/L), in addition to limits for 16 individual PFAS of 0.1µg/L (100 ng/L) in drinking water under the recast of the EU Drinking Water Directive is currently under consideration at EU level."

LCU questions the public water suppliers' ability to meet the proposed limit in an environment in which EPA confirms the ubiquitous prevalence of PFAS; If drinking water accounts for 20% of PFAS exposure, what other points of exposure can affect sample validity? There are countless possible sources of external contamination. Contamination during sampling can be as simple as a dust particle in the air at the time of sampling on a windy day, or a part per trillion that adhered to a sampler's nitrile glove.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document. HAs are beyond the scope of this rulemaking. The PFAS NPDWR is informed by regulatory development requirements under SDWA and includes the EPA's analysis of the best available and most recent peer-reviewed science. There also may be several reasons why the EPA's conclusions may differ from those of other health agencies (such as the European Chemicals Agency). As an example, the EPA uses established systematic review practices (USEPA, 2022b) to identify, evaluate, synthesize, integrate, and quantify evidence in a chemical database. These protocols have been repeatedly peer-reviewed and improved upon over time. Other health agencies do not follow these same practices and, as a result, may arrive at different conclusions. For further discussion on international and state drinking water standards and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. Regarding discussion on RSCs, please see section 4 of the EPA response in this *Response to Comments* document. Regarding analytical background contamination concerns, please see section 8.7 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043906)

In response to Section VI-Maximum Contaminant Level of the Proposed Rules, EPA requests comment on its proposed determination to set MCLs at 4.0 ppt for PFOA and PFOS and whether 4.0 ppt is the lowest PQL that can be achieved by laboratories nationwide.

• LCU would like to express concern over the proposed determination to set MCL's at 4.0 ppt. While the EPA states the evaluation "determined that 4.0 ppt is the lowest concentration that PFOA and PFOS can reliably be quantified within specific limits of precision and accuracy during routine laboratory operating conditions," LCU questions the feasibility of the proposed limit in practical application.

This uncertainty is further warranted due to the following:

1. In 2016 until recent, 70 ppt was the health level of concern.

2. According to the European Chemicals Agency, "The proposal to establish a new 'group limit' value for PFAS of 0.5 µg/L (500 ng/L), in addition to limits for 16 individual PFAS of 0.1µg/L (100 ng/L) in drinking water under the recast of the EU Drinking Water Directive is currently under consideration at EU level."

LCU questions the public water suppliers' ability to meet the proposed limit in an environment in which EPA confirms the ubiquitous prevalence of PFAS; If drinking water accounts for 20% of PFAS exposure, what other points of exposure can affect sample validity? There are countless possible sources of external contamination. Contamination during sampling can be as simple as a

dust particle in the air at the time of sampling on a windy day, or a part per trillion that adhered to a sampler's nitrile glove.

EPA Response: Please see the EPA response to comment Doc. #1753, SBC-043905 in section 5.1.2 in this *Response to Comments* document.

J.R. Simplot Company (Doc. #1661, SBC-044149)

II. Proposed MCL Values Have Considerable Analytical Uncertainty Associated with Measurements

Analytical Quantification/Precision

EPA has identified the following practical quantitation levels (PCL)

[Table 1: See Docket ID: EPA-HQ-OW-2022-0114-1661]

Table 1

PQLs for Regulated PFAS [FN2: Federal Register. 2023. Vol. 88 (60), p.18,680.]

There are two analytical methods approved by EPA for analyzing PFAS regulated under this proposed rule, USEPA Methods 537.1 and 533. In this evaluation, EPA determined that 4.0 parts per trillion (ppt) is the lowest concentration that PFOA and PFOS can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions.

These PQL values are problematic for several reasons. First, EPA is also proposing rule trigger levels for monitoring programs at 1/3 of the proposed MCLs. The use of the PQL as the MCL for PFAS substances tests the lower boundary of the accuracy of the test method when it is detected at very low concentrations, such as 4 parts per trillion or lower. So, the scientific certainty of a "trigger level" of measured 2.7 ppt is low. Furthermore, having the MCL set at the PQL significantly increases the possibility of false positives (i.e., exceeding the MCL when such an "exceedance" is due to the variation and limits of the analytical methodology. [FN3: EPA, in the Federal Register notice, describes the importance of Data Quality Objectives (DQO). EPA states that "DEQ should consider establishing reasonable quantification levels that laboratories can routinely meet. Establishing a quantitation level that is too low may result in recurring QC failures that will necessitate repeating sampling analyses, increase costs and potentially reducing laboratory capacity." However, by EPA "determining" that the PQL is 4 ng/L – that is exactly will happen. It is not certain that 4 ng/L is a "reasonable quantitation level" that laboratories can routinely meet. It is recommended that EPA further explain and seek comment on the appropriate PQLs for the contaminants listed in Table 1].

EPA Response: The EPA disagrees with the commenter that the PQLs are not set at a reasonable quantitation level. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see

section 5.1.2 of the EPA response in this *Response to Comments* document. Furthermore, EPA notes that a single exceedance of the PQL may not result in an exceedance of the PFOA or PFOS MCL because compliance is determined based on an RAA. For more discussion, please see section 8.2 of the EPA response in this *Response to Comments* document and section VIII of the final rule preamble. Regarding the rule trigger levels for reduced triennial monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document and section VIII of the final rule preamble. Lastly, for a discussion of potential "false positives," see section 8.7 of the EPA response in this *Response to Comments* document.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044955)

17. EPA requested comments on implementation challenges and requested feedback on considerations for setting MCLs at the PQLs. New York State has been implementing enforceable MCLs for PFOA and PFOS since August of 2020. In that time, approximately 250 public water systems have exceeded the MCL. During that same period, the cost of equipment, including treatment vessels and media have been subject to periodic disruptions in the supply chain, and have significantly increased in cost. Shortage of human capital, such as engineering services, has also emerged as a challenge to effective implementation. As the workforce emerges from a global pandemic both regulating and regulated communities are working to fill the voids left through attrition, while navigating a new workforce paradigm.

In addition, it is challenging to enforce regulations at the PQL when there is uncertainty in the analytical method. Enforcing MCLs is a legal proceeding where the respondent is entitled to due process. It is conceivable that public water suppliers will appeal MCL determinations on the grounds that results are within the standard error of the analytical method, further straining state enforcement resources as well as Federal resources in states that do not immediately obtain primacy.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. With respect to responses to address uncertainty in the analytical method, the agency recognizes that any analytical method being used at a certified laboratory will have a degree of uncertainty, however, this is true for the measurement of any compliance parameter, not unique to PFAS measurements and results that pass QC requirements in the methods are defensible to enforce the regulations. With respect to responses that utilities may appeal MCL violations on the ground that results are within the standard error provided in the analytical methods, the agency disagrees with this commenter's assertions that analytical methods include defined standard error criteria that laboratories would include with measurement results. Analytical methods, like those approved for PFAS, specify QC requirements that laboratories must meet to demonstrate the validity of the reported results and document the laboratory's performance is in control, but these are not synonymous with standard error. For additional discussion on supply chain and labor challenges

that may affect the compliance timeline, please see section 12.1 of the EPA response in this *Response to Comments* document on extensions and exemptions.

American Council of Independent Laboratories (ACIL) (Doc. #1692, SBC-044741)

The ACIL is concerned that the EPA setting required PQLs at the MCL while also stating in the document that laboratories can and will report at 4-8X lower than the minimum stated PQLs risks sending mixed messages and causing confusion. For example, consider the case where the concentration of PFOS in a sample was 2.1 ng/L. Laboratory A reporting at the maximum allowed PQL of 4.0 ng/L with an MDL of 2.5 ng/L would report an ND for PFOS, below the trigger value, whereas laboratory B at a reporting limit of 1 ng/L would report a value of 2.1 ng/L above the trigger value from the same sample. We believe this confusion could be resolved by setting the reporting limits as defined by a definitive LCMRL, at least for PFOS and PFOA, and with examination of the data, for the other 4 PFAS as well, at 1/3rd the MCL, the trigger value, rather than at the MCL. This ensures that the data for determining sampling frequency triggers is reported at a known precision and accuracy. As the EPA states, "this reporting limit was possible given that under the UCMR5 application program, 49 of the 54 laboratories seeking EPA approval included a lowest PFAS calibration standard level at 1 ppt or lower, with the median lowest calibration level among all laboratories at 0.5 ppt"

EPA Response: The agency disagrees with the commenter that defining laboratory quantitation or detection limits are needed to support compliance monitoring for the rule; for additional discussion, please see section 7.1 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For discussion of the trigger values, please see section 8.8 of the EPA response in this *Response to Comments* document.

American Council of Independent Laboratories (ACIL) (Doc. #1692, SBC-044739)

4. Clarity on Trigger Values and the MCL

The EPA has proposed an MCL of 4.0 ng/L for PFOS and PFOA, and 1.0 for the hazard index calculation that includes PFBS, PFHxS, PFNA and HFPO-DA. As the EPA mentions, laboratories can routinely support monitoring at these MCL values. The EPA sets minimum reporting requirements for laboratories in Table 19 (copied below)

[Table 19. See Docket ID EPA-HQ-OW-2022-0114-1692]

The EPA discusses at length the decision to set practical quantitation limits for PFOA and PFOS at the MCL rather than setting minimum reporting limits below the MCL in order to provide a buffer.

More cogently, the EPA proposes a trigger level that will result in increased monitoring if exceeded:

"While the values below the PQL will not be used to calculate compliance with the proposed MCLs under this proposed rule (see discussion above in Section VI of this preamble), values lower than the PQL are achievable by individual laboratories, and therefore lower levels can be used for purposes of screening and to determine compliance monitoring frequency. EPA is proposing the use of a rule trigger level for less frequent compliance monitoring under certain circumstances in which systems can demonstrate PFAS concentrations in finished drinking water are below: • one-third of the MCLs for PFOA and PFOS, i.e., 1.3 ppt; and • one-third of the HI MCL for the HI PFAS (PFHxS, HFPO–DA, PFNA, and PFBS), i.e., 0.33.

EPA Response: The agency disagrees that the trigger levels will result in increased monitoring if exceeded. On the contrary, results below the trigger levels can potentially decrease a system's monitoring frequency. For discussion of the rule trigger value, please see section 8.8 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For discussion on the Hazard Index PFAS, please see section 5.2.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045021)

MCLs for PFOA and PFOS

EPA has proposed to set the practical quantitation limits (PQLs) for PFOA and PFOS at 4.0 ppt. EPA requested comment on the proposed determination to set the MCLs for PFOA and PFOS at the proposed PQLs. NJDEP is requesting EPA to evaluate if the analytical methods identified in the proposal can achieve the PQLs and trigger levels for all listed PFAS. For PFOA and PFOS, NJDEP has found that most certified laboratories used by public water systems (PWS) in New Jersey have lowest calibration standards between 1.0 and 2.0 ppt, so there is potential for EPA to lower the PQLs for PFOA and PFOS; however, this would result in a lower trigger level, which laboratories may not be able to achieve.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-045053)

May 30, 2023

FILED VIA FEDERAL eRULEMAKING PORTAL

Assistant Administrator Radhika Fox

Office of Water

Office of Ground Water and Drinking Water

Environmental Protection Agency

1200 Pennsylvania Avenue, NW

Washington, DC 20460

RE: Proposed Rule, PFAS National Primary Drinking Water Regulation EPA-HQ-OW-2022-0114; 88 FR 18638 (March 29, 2023)

Dear Assistant Administrator Fox:

The City of Columbus, Department of Public Utilities ("CDPU") appreciates the opportunity to comment on EPA's proposed National Primary Drinking Water Regulation for PFOA, PFOS, and four other PFAS. CDPU operates drinking water and wastewater treatment plants serving over 220 square miles in the greater Columbus area. Our interest in PFAS stretches from the source water that feeds our drinking water plants to the effluent released from our wastewater plants, and everywhere in between. We are committed to improving water quality and protecting the environment, and we share EPA's concerns about the risks that PFAS chemicals pose to the public.

CDPU provides critical services to our community. The three drinking water plants operated by CDPU delivered over 50 billion gallons of clean, safe drinking water last year, averaging 145 million gallons daily, to over 1.3 million residents of the Greater Columbus area. The City of Columbus has many residents living in environmental justice communities including Linden, Franklinton, Hilltop, and Near South. CDPU uses a complex multi-barrier approach utilizing state of the art equipment and the latest treatment technologies to ensure all requirements of the Safe Drinking Water Act (SDWA) are continuously met. Ratepayers keep these plants running.

CDPU drinking water facilities do not use, produce, or profit from PFAS compounds. We passively receive source water into our facilities that may contain PFAS from industrial, commercial, and domestic sources. We treat and distribute water 24 hours a day, 7 days a week, 365 days each year. And we comply with our permits and protect public health and the environment by providing safe drinking water.

EPA requested comment on implementation challenges and considerations for setting the maximum contamination level (MCL) at the practical quantification level (PQL) for PFOA and PFOS, including on the costs and benefits related to this approach. EPA also asked for comment related to its evaluation of feasibility under the SDWA for the proposed PFOA and PFOS and hazard index MCLs. CDPU concurs with the comments made by the National Association of Clean Water Agencies (NACWA) and makes the additional comments below.

As a vested stakeholder with a duty to the public, CDPU supports EPA in its efforts to set its initial federal drinking water standard for PFAS at a protective, feasible (MCL). But CDPU urges EPA to consider the active loading of PFAS into water occurring through the manufacture and use of PFAS and PFAS containing products. CDPU also urges EPA to consider the accurate

costs and feasibility, consumer confidence, and regulatory alternatives before it mandates its first MCL at the PQL. Several states have established feasible state standards for PFOA and PFOS at twice the currently proposed federal standard. Those plans would result in the best use of limited resources because they address the greatest health risks by prioritizing systems with the highest concentrations of PFAS.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding actions the agency is taking to "active loading of PFAS into water occurring through the manufacture and use of PFAS and PFAS containing products," the EPA notes that these actions are outside the scope of the current rulemaking but directs the commenter's attention to the EPA PFAS Strategic Roadmap that outlines the whole-of-agency approach to "further the science and research, to restrict these dangerous chemicals from getting into the environment, and to immediately move to remediate the problem in communities across the country" (USEPA, 2022c). For more discussion on the PFAS Strategic Roadmap, please see section II.F of the Federal Register Notice (FRN), section 15 of this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. For additional discussion on cost considerations for the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-045060)

A. The MCL and the PQL are too close.

EPA requested comment on setting the MCL so close to the PQL and its effect on water utilities. In that discussion, EPA recognized that "[t]he agency must have a high degree of confidence in the quantified result as it may compel utilities to make potentially costly compliance decisions in order to comply with the MCL." It also recognized that water utilities operate conservatively to maintain water quality and "typically aim to achieve lower than the MCL to avoid a violation." In reality, this results in proactively adding treatment if there is any possibility of violating the MCL (as will play out at CDPU). But when the MCL is so low—measured in parts per trillion—and the difference between installing hundreds of millions of dollars of treatment, or not having to treat, is one drop in 20 Olympic size swimming pools, it is absolutely necessary to provide for quantitative reliability. The margins are too tight right now when the science is still emerging and the risks of overcommitting public money is high. The reality is that a water utility could graze the MCL level if the sampler applied deodorant that morning, wore a jacket while grabbing the sample, or used a typical sampling container [FN7: https://www.epa.gov/sites/default/files/2020-01/documents/pfas_methods-

sampling_tech_brief_7jan2020-update.pdf]. CDPU supports EPA in its decision that sample results below the PQL are to be recorded as zero. Setting the first ever PFAS MCL this low is not feasible (as discussed above) or reasonable when so much benefit can be realized with setting a higher MCL first to address the systems with significant PFAS contamination.

B. An overly-aggressive MCL for PFAS will shake consumer confidence.

Consumer confidence is key in any water regulation. Clean, safe drinking water is ultimately only as drinkable as the public understands it to be. In the case of PFAS, the science is clear on the risks of consuming high levels of the most damaging formulas of PFAS. Where science is still developing is in relation to the impacts and risks of health implications of low levels of less studied versions. Still further undeveloped is the science on how exposures vary between drinking water and the hundreds of other ways humans are exposed every day. What we know is that drinking water only accounts for 20% of human exposure to PFAS,[FN8: Relative Source Contribution (RSC) is an estimate that drinking water contributes 20% of total exposure to PFOA and PFOS. Other sources contributing 80% of exposure to PFOA and PFOS include but are not limited to air, foods, incidental soil/dust ingestion, and consumer products (U.S. EPA, 2016b) (U.S. EPA, 2016a).] but the risk that the public will be dissuaded from drinking safe tap water is increasingly high. This is especially true if the MCL is issued at the level proposed by EPA alongside the current compliance timeline. Widespread violations of the MCL may be triggered by EPA's proposed approach, and even if levels are close to the PQL and much lower than other sources of PFAS exposure, consumers will lose confidence in the safety of publicly supplied drinking water [FN9: Consumer confidence concerns affect low-income and underserved environmental justice area residents even more if they spend their limited resources on purchasing bottled water that is less-regulated.].

EPA Response: The EPA disagrees with the commenter that the PQLs are not set at a reasonable quantitation level and are "overly aggressive." For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For discussion on RSCs, please see section 4 of the EPA response in this *Response to Comments* document. For additional discussion on PFAS risk communication, please see section 1.2 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045098)

3) Implementation Challenges and Considerations for Setting MCL at PQL

While the proposed MCLs for PFOA and PFOS would increase public health protection, there is concern with setting a standard at a PQL which will be changing over time.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044778)

4. EPA Should Not Set the MCL for PFOA and PFOS at the PQL

EPA's proposed NPDW rule for PFOA and PFOS establish the MCL at the PQL for USEPA Methods 537.1 and 533. While WDEQ recognizes that the SDWA requires EPA to set the MCL "as close as feasible" to the MCLG, there is too much uncertainty in values this close to the PQL to use them as the basis for an MCL. In addition, setting the MCL for PFOA and PFOS at the PQL implies that the MCLs should be modified as analytical detection and quantitation improve. Instead, EPA should establish the MCL somewhere above the PQL where PWS can be confident that their data either does or does not exceed the MCL.

WDEQ recognizes the significant amount of work that went into EPA's development of the proposed rule, and we appreciate the opportunity to submit these comments. We would welcome the opportunity to meet with EPA to discuss these issues in greater detail, and we look forward to our continued partnership with EPA as we implement both voluntary and regulatory programs to reduce PFAS and protect human health and the environment.

Sincerely,

Todd Parfitt, Director

cc: Jennifer Zygmunt, WQD Administrator

Suzanne Engels, SHWD Administrator

Nolan Rap, Office of the Governor

EPA Response: The EPA disagrees with the commenter that the PQLs are not set at a reasonable quantitation level. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043779)

May 30, 2023

Michael Regan, Administrator U.S. Environmental Protection Agency 1200 Pennsylvania Avenue, N.W.

Mail Code: 1309

Washington, DC 20004

TRANSMITTED ELECTRONICALLY

RE: PFAS National Primary Drinking Water Regulation Rulemaking

(88 FR 18638, EPA-HQ-OW-2022-0114)

Dear Administrator Regan,

The City of Tulsa Water and Sewer Department (CoT WSD) would like to present the following comments to the Environmental Protection Agency (EPA) regarding the preliminary regulatory determination and proposed rule for per- and polyfluoroalkyl substances (PFAS) National Primary Drinking Water Regulation. Underlined items are EPA's requested items for comment in the proposed rule (Federal Register document citation 88 FR 18638, document number 202305471; or Docket Document ID# EPA-HQ-OW-2022-0114-0027), with City of Tulsa Water and Sewer Department's response following.

1. 88 FR 18667 (also 88 FR 18730). EPA requests comment on if setting PFOA and PFOS MCLs at PQLs (4.0 ng/L) is implementable and feasible.

CoT WSD responds that setting the MCLs for PFOA and PFOS at the 4.0 ng/L PQL may cause some treatment and compliance issues for water systems. It is helpful to water systems that the MCL determination is by a running annual average and not individual sampling results.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For discussion about the RAA, see section 8.2 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046075)

D. Monitoring and compliance

1. It is not technically feasible to manage operations to meet a PQL.

Under the Safe Drinking Water Act, attainment of a MCL must be technologically feasible for public water systems. SDWA Secs. 1401(1)(i), 1412(b)(4). It is not feasible for public water

systems to manage a system so that it will always achieve contaminant levels at the Practical Quantitation Limit (PQL), as EPA is proposing. EPA appears to be unjustifiably dismissive of these concerns.

In considering whether to set an MCL at 25% above the PQL, EPA states that in its outreach consultations, a commenter suggested a MCL of 5.0 ppt because "water systems operate with a margin of safety and plan for performance that maintains water quality below quantitation levels." In the commenter's opinion, "having an increased buffer between the PQL and the MCL may allow utilities to manage treatment technology performance more efficiently because utilities typically aim to achieve lower than the MCL to avoid a violation". 88 Fed. Reg. 18670. EPA dismissed this idea and instead states: "For results between the detection limit and the PQL, EPA has determined that utilities would be able to reliably conclude analyte presence, though this detection is less precise regarding specific concentration." It is arbitrary for EPA to rely on this imprecise presence/absence approach for managing compliance, when facilities are potentially subject to civil and criminal penalties if they are judged to be in noncompliance.

Due to variability in samples, sampling technique, laboratories, etc., managing a drinking water treatment process to the PQL does not make operational sense. Drinking water providers try to make sure they are not just reaching the levels of the MCLs, but are well below those levels, to provide some level of additional operational certainty. Setting MCLs at the PQL does not allow operators to do this.

EPA Response: The EPA disagrees with the commenter that the final MCLs are not set at a feasible level and that it is "not technically feasible to manage operations to meet a PQL." Additionally, values below the PQL are not used for "managing compliance." For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043851)

EPN agrees that EPA should set the MCL for PFOA and PFOS at the practical quantitation level of 4 ppt as implementable and feasible. EPA must be clear that this is not a health-based concentration. Four ppt is the lowest concentration that can be reliably quantified using EPA Methods 537.1 and 533 with specific limits of precision and accuracy during routine laboratory operating conditions. We recognize that 49 of the 54 laboratories seeking EPA certification to analyze UCMR5 samples can achieve a calibration standard of 1 ppt or lower, but we accept EPA's statement that there is not sufficient laboratory capacity nationwide if the quantitation level is set below 4 ppt. We support EPA's recommendation that water systems use measurements below 4 ppt as an early warning that treatment may need to be modified to ensure no exceedances of 4 ppt.

EPA Response: The commenter supports setting the MCLs for PFOA and PFOS at 4.0 ng/L. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045268)

I. Technical problems are not adequately considered and are unworkable.

1. Establishing the MCLs for PFOA and PFOS at the analytical method Practical Quantitation Limit (PQL) prior to completing UCMR 5 monitoring (2023-2025) is premature.

The basis for establishing the proposed Maximum Contaminant Levels (MCLs) for perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS) at 4 nanograms per liter (ppt) is not sufficiently supported by technical laboratory capacity and data quality. We support EPA's position to ensure data quality across multiple laboratories and an expectation to report levels achievable across multiple laboratories nationwide at a 95% confidence interval using specified methods. Per the proposed regulation, the PQLs were developed for laboratories reporting PFAS data for the Unregulated Contaminant Monitoring Rule 5 (UCMR 5). Monitoring under UCMR 5 started in January 2023 and will continue through 2025 for a total of two years. During this time, EPA will be able to collect and evaluate quarterly monitoring data. In addition to providing EPA with occurrence information for 29 PFAS compounds, the reliability of the established analytical methods and the feasibility of reportable data at the PQLs will be better understood. This information is necessary to support the proper development of MCLs, particularly at the ultra-low detection levels of the analytical methods.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with commenter assertions that the agency needs to wait for UCMR 5 results in order to finalize the NPDWR at this time. For additional discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document. For discussion about preliminary UCMR 5 results, please see section VI.G of the final rule preamble, section 6 of this *Response to Comments* document, and the *Occurrence Technical Support Document* (USEPA, 2024a).

Safe Drinking Water Branch, Hawaii Department of Hawaii (Doc. #1801, SBC-043754)

The MCL and PQL

The gap between the MCL and PQL is a potential loophole. Normally, the PQL is 5-30% of MCL, however, this time, the no-difference on the value between MCL and PQL leaves the lab

no room to have any error in the test. However, the instrumental, human, operational error is inevitable in the practice. EPA should either increase the MCL or decrease PQL.

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1801]

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The agency has determined that setting the MCLs at the PQLs for PFOA and PFOS is as close as feasible to the MCLG. Setting the MCL at the PQL has been demonstrated in other drinking water regulations: as examples, in 1987, the EPA finalized the Phase I VOC rule (USEPA, 1987), where the agency set the MCL at the PQL for benzene, carbon tetrachloride, trichloroethylene, vinyl chloride, and 1,2-dichloroethane.

Little Hocking Water Association (Doc. #1835, SBC-045509)

EPA also requests comment on its proposal to set MCLs at 4.0 ppt for PFOA and PFOS and whether 4.0 ppt is the lowest PQL (practical quantitation limit) that can be achieved by laboratories nationwide. EPA has specifically stated that many laboratories can reliably analyze PFAS to levels much less than the established PQL. Indeed, reporting limits for 18 PFAS under Method 537.1 are typically less than 2.0 ppt in datasets reported to LHWA. As a practical matter and given the concerns expressed by the agency in the proposed rule, LHWA does not object to a 4 ppt MCL. However, because many laboratories can reliably analyze PFAS to levels much less than the established PQL, because people have been unknowingly exposed to PFAS for decades, and because LHWA's customers have such high blood levels of PFOA, the MCLG must remain at zero and the MCL needs to be as low as possible.

EPA Response: The commenter does not object to the feasibility of the final standards for PFOA and PFOS. The agency notes that while some individual laboratories can potentially quantify to lower levels, the EPA's NPDWR is a standard that considers feasibility of laboratory capability nationwide. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on the agency's derivation of the MCLGs, please see section 4 of the EPA response in this *Response to Comments* document.

Citizens Energy Group (Doc. #1838, SBC-044855)

Section VI – Maximum Contaminant Level

EPA requests comment on its proposed determination to set MCLs at 4.0 ppt for PFOA and PFOS and whether 4.0 ppt is the lowest PQL that can be achieved by laboratories nationwide.

Citizens supports the proposed determination to establish the MCL at a value achievable by laboratories. While 4.0 ppt might not be the lowest PQL that can be achieved by some

laboratories, the EPA's proposal recognizes that the method detection limit and the PQL will vary from analyst to analyst in a single lab, and from lab to lab across the network of commercial laboratories. While laboratories are incentivized to improve their analytical capabilities with lower MDLs and PQLs, at present, setting the MCL at values less than 4.0 ppt could risk some water systems using "J-flagged" estimated data to make compliance decisions.

EPA Response: The commenter supports the feasibility of the final standards for PFOA and PFOS. Estimated (i.e., J-flagged) data are not used to support compliance decisions. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on monitoring and compliance requirements, please see section 8 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-047699)

The commenters agree with EPA's determination that utilities would still have an early warning that they may exceed the MCL prior to doing so when the MCLs for PFOA and PFOS are set at the PQL. Detections of PFOA and PFOS at concentrations below the PQL can provide utilities with the same type of information to make decisions related to monitoring frequency and treatment modifications, as measured concentrations between the PQL and 5.0 ppt would provide if the MCL were set at 5.0 ppt. However, the commenters encourage EPA not to consider imposing any uniform regulatory requirements for detections of PFOA or PFOS at concentrations below the PQL until and unless a uniform method detection limit below the PQL is required of analytical laboratories to become certified to perform these analyses. Otherwise, these requirements may lead to inequitable distribution of regulatory compliance requirements based on laboratory analytical capabilities.

EPA Response: For responses on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The agency is clarifying for the commenter that values below the PQL will not be used for compliance decisions in the NPDWR. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document.

Michigan Section American Water Works Association (MI-AWWA) (Doc. #1734, SBC-044476)

Feasibility

Another concern is the feasibility of reliable treatment methods at the proposed reporting levels. Sampling and analysis to such low levels also presents significant opportunities for cross contamination of samples and erroneous results. Setting the MCL at the MRL will present significant challenges because MRLs will continue to decrease overtime which will require treatment processes to achieve lower effluent concentrations to a point where PFAS removal is

cost prohibitive or not technically feasible. With that said, the cost of managing an ongoing problem versus routine monitoring will further impact the reliability of the treatment method employed.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that setting the MCL at the MRL will present significant challenges "because MRLs will continue to decrease overtime." The MCLs for PFOA and PFOS are set at the PQLs and the MCLs are not variable in implementing the NPDWR as finalized. If laboratory quantitation capabilities results in lower PQLs in the future, the agency could consider that information during the Six Year Review process under SDWA. For additional discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

North Penn Water Authority (NPWA) (Doc. #1470, SBC-043291)

March 24, 2023

Our Perspective on Proposed New PFAS Regulations

by Anthony J. Bellitto, Jr., P.E.

Executive Director

North Penn Water Authority, Lansdale, PA

With the newly proposed Maximum Contaminant Levels (MCL's) of 4 parts per trillion (ppt) for PFAS compounds, and a goal of "Non-detect," the federal Environmental Protection Agency (EPA) has taken an unprecedented regulatory action that will be extremely difficult and expensive for the water industry to meet. It will affect every water system around the country, since at these extremely low levels PFAS will be found everywhere, not just in areas that have had a known spill or contamination event.

Although the PFAS found at high levels in fire extinguishing foam around military bases is getting a lot of attention, PFAS is also found at much lower levels in many commonly used products that we use in our daily lives, including food wrappers, cookware, cosmetics, personal care products, and clothing, to name just a few. Its presence in drinking water is only one of several routes of exposure. Public water systems around the country should not be disproportionately targeted in the government's effort to reduce exposure to PFAS.

At these extremely low levels, it can be found in the environment all around us, even in the rainwater. In the approximately 150 years of water treatment history, there has never been a

regulatory standard set to such an infinitesimally small number, by any government anywhere in the world. Is it reasonable and justifiable to set a standard so low? That question needs to be answered before enormous amounts of money are expended to achieve this result.

To put this extremely low level in some comparative perspective, one part per trillion is the equivalent of one second in 32,000 years. The question remains – do levels that low have a measurable negative impact on human health? The scientific research on this matter has thus far not been conclusive, but there is good reason for skepticism. Is this recommendation from the EPA driven more by politics than by hard science?

Right now, several states have enacted water quality standards for PFAS that are quite different than what the EPA has proposed, yet both the federal government and the states have made the claim that their proposed standards were determined by rigorous scientific analysis. So which one is the correct science? They cannot all be right, as they each have arrived at different conclusions on what the acceptable number should be. It makes us wonder if maybe there is more politics at play here instead of science.

These extremely low levels, which have a questionable value, will unnecessarily frighten the average American citizen and cause an unjustified loss of confidence in the quality of the public water system. And the added costs could cause many publicly owned systems to be subjected to private takeovers, which inevitably leads to much higher rates charged to the customers.

There is also a lot of discussion that the goal for PFAS in water should be "Non-detect." But this is an unrealistic and unnecessary performance standard. No other water quality parameters are required to meet this standard. There are some measurable amounts of many parameters in all water, but those extremely low levels are well below the point where they would cause a negative health impact. Just because modern laboratory equipment can detect levels in the part per trillion range does not mean we can conclude that it causes harm to humans. "Non-detect" is a moving target, as new lab technology allows us to measure lower and lower amounts. Non-detect meant something quite different only 5 years ago, and it will likely mean something different 5 years in the future, as technology improves.

All of this is publicly reported by all water utilities across the country in their annual Water Quality Reports that are mandated for distribution to all its customers. For just one example, these reports show that the EPA's Maximum Contaminant Level (MCL) for lead is 15,000 parts per trillion (ppt), not "Non-detect." We hear people say "there is no safe level of lead" but really there is. The medical community has determined that any amount below 15,000 ppt in water is considered safe by scientific studies. This is quite appropriate, and the same kind of thinking should be applied in setting regulatory standards for PFAS.

EPA Response: The EPA disagrees with the commentor regarding the feasibility of the final standards. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for PFOA and PFOS) and section 5.2.1 (for the Hazard Index PFAS) of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter's assertions about the adverse health effects at low levels of PFOA and PFOS. The EPA's final rule

represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water (see section II.D and III of the final rule preamble and section 3 of the EPA response in this *Response to Comments* document for discussion on the science informing the EPA's regulatory determinations). The EPA disagrees with the commenter's assertions that the MCL was set a "non-detect." The MCLG is based on the statutory standard (see section 4 of the EPA response in this *Response to Comments* document) and the MCL is based on the agency's feasibility assessment as discussed in section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044365)

• EPA requests comment on its proposed determination to set MCLs at 4.0 ppt for PFOA and PFOS and whether 4.0 ppt is the lowest PQL that can be achieved by laboratories nationwide (pg. 18667 Federal Register Volume 88, Number 60).

o The commenters agree with EPA's determination that setting the MCLs at 4.0 ppt for PFOA and PFOS is technically and economically feasible and is therefore required pursuant to the SDWA requirement that EPA set the MCL as close as feasible to the MCLG. The commenters do not have expertise to provide feedback on whether 4.0 ppt is the lowest PQL that laboratories can achieve.

EPA Response: The commenter supports the feasibility of the final standards for PFOA and PFOS. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Consumer Reports (Doc. #1656, SBC-043191)

Section VI. Maximum Contaminant Level

Under section 1412(b)(4)(B) of SDWA, EPA must establish an enforceable MCL as close to the MCLG as feasible, taking costs into consideration. EPA has approved two analytical methods, USEPA Methods 537.1 and 533, for measuring PFAS regulated under this rule. For PFOA and PFOS, EPA has determined that 4.0 ppt is the "practical quantitation level" (or PQL), or the lowest concentration that, with 95 percent confidence, can be achieved by analysts at 75 percent or more of the laboratories using Method 533 and 537.1, according to the UCMR 5 rulemaking. Indeed, laboratory calibration data submitted as part of the UCMR 5 Laboratory Approval Program found that "49 of the 54 laboratories seeking EPA approval included a lowest PFAS calibration standard level to 1 ppt or lower, with the median lowest calibration level among all laboratories at 0.5 ppt."3 [FN3: See pg 18667 in https://www.govinfo.gov/content/pkg/FR-2023-03-29/pdf/2023-05471.pdf] Thus, it appears that for virtually all laboratories, the PQLs for

PFOA and PFOS of 4.0 ppt are at least 4 times greater than the lowest calibration standard meaning that it is technically feasible to set the MCL at the PQL.

Section 1412(b)(4)(d) of the SDWA defines feasibility in part as "feasible with the use of best available technologies." EPA has determined that multiple technologies (i.e., GAC, AIX, RO and NF) are both available and have demonstrated PFAS removal efficiencies that may exceed >99 percent and that achieve concentrations below 4.0 ppt for PFOA and PFOS. EPA proposes to determine that it is feasible to treat PFOA and PFOS to 4.0 ppt because multiple treatment technologies are effective and available at reasonable cost based on large and metropolitan water systems4 [FN4: USEPA. 2023b. Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water. EPA– 822–P–23–011.] and because there are methods available to reliably quantify PFOA and PFOS at 4.0 ppt.

Given this, we support EPA's proposal to set the MCL for PFOA and PFOS at the PQL of 4.0 ppt since it is feasible to test drinking water at that level and multiple treatment technologies exist to reduce PFOA and PFOS below 4.0 ppt at reasonable cost.

EPA Response: The commenter supports the final standards for PFOA and PFOS. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044412)

Page 18730. EPA requests comment on its proposed determination to set MCLs at 4.0 ppt for PFOA and PFOS and whether 4.0 ppt is the lowest PQL that can be achieved by laboratories nationwide.

• DOH cannot provide meaningful comment without reviewing the MDL/MRL studies used to determine the PQL.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. UCMR MRLs are determined using data from multiple laboratories that participate in the EPA's UCMR MRL-setting studies and is discussed in the proposed rule materials which the EPA solicited comment on. Nonetheless, this information has been published in the lab approval manual under UCMR 5, which is referenced in the PFAS NPDWR docket, included in the administrative record for this action, and cited here: https://www.epa.gov/dwucmr/fifth-unregulated-contaminant-monitoring-rule

Digamma Consulting (Doc. #3072-18, SBC-046348)

My name is Marco Troiani. I'm an organic chemist who's been doing water testing for a long time and my comments actually were very built on the comments of the last speaker of the

detection limits of 4 parts per trillion. There were two of them listed for PFOA and PFOS which are the two most well-known PFAS compounds, and we're seeing in the proposed regulations of 4 parts per trillion MCL which I guess is equivalent to sort of like the drinking water action level. And so, I know this isn't a place to make questions, but rather comments but I guess I'm commenting on that: what kind of levels are going to be seen for the other compounds, which is GenX and some of these other rare PFAS compounds that are not as well known that don't have specific numbers attached to them quite yet? And about that 4 parts per trillion number, I mean, it's a state-of-the-art number. The detection has not been able to do that up until very recently so this is pushing limits not just of water filtration and water management, but also analytical chemistry and testing. And from what I've spoken to people in the industry, they have developed quite a bit of techniques to improve the accuracy and repeatability of detections and concentrations down at these, up until previously, astronomically low levels. But I see that being a major challenge moving forward in implementing this act. Although, of course, it's going to be a necessary part of being able to get an accurate picture of how contaminated the American water table has become. And so obviously pushing the detections down as far as possible, it's critical, but I just want to make sure that there's a coordination between regulations and industry so that things that are being proposed are achievable and implementable in a sort of a reasonable time, and at a reasonable cost to the communities and the laboratories doing the testing. That's pretty much all I had. Thank you.

EPA Response: The commenter did not explain what it meant by "state-of-the-art number". Methods are available and there are at least dozens of labs nationwide that reach this PQL. For more information about analytical methods, please see section VII of the preamble and section 7 of the EPA response in this *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please also see section 5.1.2 of the EPA response in this *Response to Comments* document.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-047685)

PFOA and PFOS MCLs

CARE supports EPA's methodology and rationale in deriving the proposed MCLs for PFOA and PFOS. EPA's proposed MCLs for PFOA and PFOS as individual contaminants are 4 parts per trillion (ppt). [FN3: PFAS National Primary Drinking Water Regulation Rulemaking, 88 Fed. Reg. 18638, 18639 (proposed Mar. 29, 2023) (to be codified in 40 C.F.R. pts. 141 and 142), https://www.govinfo.gov/content/pkg/FR-2023-03-29/pdf/2023-05471.pdf.] Following systematic review of both human epidemiological studies and animal toxicity studies EPA determined that PFOA and PFOS are likely carcinogenic. [FN4: Id.] As such, there is no dose below which either chemical can be considered safe within the meaning of SDWA. Therefore,

EPA's main consideration in setting its MCL for PFOA and PFOS is feasibility, including currently available analytical and treatment methods. [FN5: Id.]

EPA determined that 4.0 ppt is the lowest concentration that PFOA and PFOS can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions. [FN6: Id. at 18666.] This is known as a practical quantitation level (PQL). This reporting level is the minimum quantitation level that, with 95 percent confidence, can be achieved by capable analysts at 75 percent or more of the laboratories using a specified analytical method. [FN7: Id.] Furthermore, the PQLs provide for consistency in data quality from a diverse group of laboratories across the country and provide routine performance goals that many laboratories must strive to achieve. [FN8: Id.]

EPA Response: The commenter supports the feasibility of the final standards for PFOA and PFOS. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045089)

Section VI – Maximum Contaminant Level

1) Determination to set MCL at 4.0 ppt and whether 4.0 ppt is the lowest PQL that can be achieved by laboratories nation-wide.

In Vermont's experience implementing our State MCL since 2019, the few laboratories that our systems have historically used can achieve a reporting level down to 2.0 ppt, we recognize, however, this reporting level is not currently consistently achieved by all laboratories across the country. Further, because this is a national standard, we have concerns about lab capacity moving forward, including the reliability and availability for laboratories to achieve even the proposed PQL of 4.0 ppt and meet the national demands for sample analysis. In other words, Vermont is concerned that we will have continued access to these established laboratories given the increased national demands. Vermont does not currently have in-state capacity for analysis as of the date of writing these comments.

As stated in the preamble, the PQL is set at the level that 75% of the laboratories can achieve 95% confidence. That is to say that 25% of those laboratories cannot achieve a level of 4 ppt. Given the strain on laboratories and the difficulty in implementing new analysis for PFAS in a new lab, 1 in 4 labs will not be able to achieve the PQL of 4 ppt.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges

to reliably measure samples for the final NPDWR, please also see section 5.1.2 of the EPA response in this *Response to Comments* document.

Water Environment Federation (WEF) (Doc. #1529, SBC-043306)

Testing: The demand for labs equipped to test PFAS will severely outweigh available lab capacity.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Robert Adamski (Doc. #1530, SBC-043335)

Further there is little laboratory capacity for testing. "But laboratory testing for PFAS isn't cheap. Or easy. Patrick Parsons, PhD, head of environmental health sciences at New York's Wadsworth Center [Link: https://wadsworth.org/]—the state public health laboratory—explained the hurdles. First is cost.

"The type of LC/MS/MS instrumentation for this analysis costs between $250-300K and a further $140K for the automated 96-well plate technologies for SPE for serum testing, and a further $40K for the automated SPE for water testing."

Older LC/MS/MS systems may be incapable of detecting PFAS at the low levels required, on the order of parts per trillion (ppt).

A second problem is contamination from PFAS already in the laboratory. Thus, sample introduction systems have to be stripped of Teflon® degassers, Teflon® SPE cartridges, PTFE vial caps and all other PFAS-containing components.

Of course, laboratories must also have staff experienced in mass spectrometry and assure additional, specialized training in trace analysis of the compounds."

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding responses regarding laboratory testing and potential contamination issues, please see section 8.7 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044086)

Analytical method requirements for temperature and timeframes to store and analyze PFAS samples may also require laboratories to significantly increase refrigeration storage. Primacy agencies have reported that some laboratories are currently unable to keep up with the volume of PFAS samples being run for UCMR 5 and other monitoring being conducted by primacy

agencies. The increased volume is creating delays in storing and processing samples while meeting the method requirements.

Additionally, some primacy agencies have found that systems are having problems meeting temperature and timeframe method requirements when shipping samples. Delays in shipping have caused water systems to take additional samples due to the inability to keep samples at temperature and ship them to the laboratory for processing in time to meet the method requirements.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding responses regarding laboratory testing and potential contamination issues, please see section 8.7 of the EPA response in this *Response to Comments* document. With respect to the analytic requirements of the EPA methods, please see section 7.1 of the EPA response in this *Response to Comments* document. The EPA notes that sample hold time and temperature requirement determinations (for both shipping and storage) were part of the PFAS method development; please see section 7.1 of the EPA response in this *Response to Comments* document for additional discussion on the validated analytical methods used to support the monitoring requirements of this final NPDWR.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043494)

All drinking water stakeholders agree that testing availability presents a significant hurdle, and EPA must develop a plan to make this rule workable. While there may be an opportunity for large facilities to create an in-house testing method, that is certainly outside the realm of possibility for small operations. Since the proposed MCLs for PFOA and PFOS are incredibly low, we also remain concerned about the risk of contamination during the testing process. Essentially any interference with a testing sample could lead to inaccurate results and costly compliance measures.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding responses regarding laboratory testing and potential contamination issues, please see section 8.7 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043717)

As a result of previous outsourcing of PFAS samples to local laboratories requiring significant time for analysis, Aurora Water has decided to invest in sampling equipment for in-house testing. This instrument is a significant up-front cost as well as long term investment for maintenance activities and the requirement of an additional analyst. An additional challenge with analyzing PFAS in-house is the ability to obtain the necessary reagents for the instrument since there will

be many labs looking to acquire the same thing. Aurora Water was concerned that the laboratories in the area would not be able to keep up with PFAS sampling demands and would cause the city to become out of compliance with this proposed rule.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 13.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

A. O. Smith Corporation (Doc. #1674, SBC-043698)

A. O. Smith recommends that the EPA engage stakeholders to ensure that additional laboratory capacity, including the recruitment and training of certified laboratory technicians, is increased in a timely manner.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding concerns on laboratory training, please see section 8.6 of the EPA response in this *Response to Comments* document.

Massachusetts Coalition for Water Resources Stewardship (MCWRS) (Doc. #1691, SBC-044329)

[The proposed MCLs raise the specter of serious unintended consequences that could pose public health risks for water consumers. Some of these are:]

e. Nationwide laboratory capacity to support PFAS testing under the MCL while also providing testing under UCMR must also be scrutinized. With MCLs at the detection level the implications of overstressed laboratories making errors as they try to keep up with the demand cannot be overstated. There is no room for lab error but laboratories are being set up to fail if they are overburdened.

EPA Response: The EPA considered lab capacity issues relating to UCMR and the final rule. Under the final rule, data from the UCMR 5 program and other applicable monitoring programs can be used to satisfy the initial monitoring requirements. Additionally, the laboratory capacity established for UCMR 5 will become fully available once UCMR 5 monitoring concludes in December 2025 for PWS to comply with the PFAS NPDWR monitoring requirements after the PFAS rule promulgation For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments*

document. For additional discussion on monitoring and compliance requirements for the final rule, please see section 8 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045955)

In the preamble, EPA refers to other regulations that have been set at the PQL, specifically the phase 1 Volatile Organic Carbon (VOC) rule. AMWA would like to point out that the levels proposed for PFAS are in the ppt range, while the VOC rule includes compounds like Benzene, which has an MCL in the parts per billion range. When dealing with levels of parts per trillion of ubiquitous chemicals like PFAS, there is significant sensitivity and variability in analytical capabilities. Additionally, at such small concentrations, any sample container, and the handling and transport of samples, create the opportunity for interference or contamination.

EPA Response: Regarding commenter concerns for unit concentrations and analytical sensitivity, measurement sensitivity is relative. In other words, the methods approved for compliance monitoring for this NPDWR were developed and demonstrated to meet performance and QC expectations. The method development performance and QC evaluations are conducted as an assessment of method ruggedness, which is demonstrated through testing in multiple types of drinking water matrices, including assessments off-site at other laboratories by other analysts. Therefore, the agency has empirically determined assurances that the methods can perform adequately at the final MCL levels, regardless of unit concentrations.

For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding analytical background contamination concerns, please see section 8.7 of the EPA response in this *Response to Comments* document.

Environmental Caucus of the Democratic Party of Hawai`i (Doc. #3072-103, SBC-046406)

Thank you. Yes, my name is Melodie Aduja. And thank you for the second opportunity to provide oral testimony. I'm from Hawaii, and I'm following up with the comments of Susan Gorman-Chang also from Hawaii. We really have a problem here in the 50th state because we are in the middle of the Pacific and we are like the forefront of all the Pacific Basin. And of course, we've got the threats of the other countries coming in. And I think the problem with what we have here is that we just don't have a certified lab. So, there was some discussion that Susan brought up that it takes about 8 to 10 weeks before we even get our test results back. And apparently the way our Department of Health is working, it's at a snail’s pace. I can give you an example. They take a sample in September and then it goes to the mainland or through the continent for testing and then it comes back to Hawaii giving us 30 days before it comes back.

And then there is a confirmation test that's done. So, September to October, November, confirmation test, December, then we have the confirm sample of PFAS being in the water and then the Department of Health will give the public notice that the water is therefore contaminated with PFAS. Without a certified lab on the islands, we cannot have real-time testing and I'm not sure how we can really address that. It costs about $50 to $100 million for a certified lab. And I know with the military, they're all going through PFAS testing, and we seem to be the last in line in order to get our confirmation that we are being poisoned in our water. So please, I'm not sure what can be done, but we do need to have a lab and we need to have the EPA's help on this. Thank you very much.

EPA Response: Compliance samples for numerous other regulated parameters are frequently shipped from Hazard Index to certified drinking water laboratories within the US mainland and these results are reported within adequate timeframes to satisfy reporting requirements. Furthermore, the EPA disagrees with the statement suggesting "real-time testing" methods are currently available for PFAS testing as there are no published reports of such methods that provide immediate results. However, certified laboratories typically provide clients the option to request "quick turn-around" sample processing and reporting, which expedite the delivery of sample analytical results back to the client, effectively addressing the commenter's concerns.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044907)

In the preamble, EPA refers to other regulations that have been set at the PQL, specifically the phase 1 Volatile Organic Carbon (VOC) rule. We would like to point out that the levels proposed for PFAS are in the ppt range, while the VOC rule includes compounds like Benzene, which has an MCL in the parts per billion range. When dealing with levels of parts per trillion of ubiquitous and widespread chemicals like PFAS, there is significant sensitivity and variability in in analytical capabilities. Additionally, at such small concentrations, any sample container, and the handling and transport of samples, creates the opportunity for contamination as well as other quality control problems.

EPA Response: Regarding commenter concerns for unit concentrations and analytical sensitivity, measurement sensitivity is relative. In other words, the methods approved for compliance monitoring for this NPDWR were developed and demonstrated to meet performance and QC expectations. The method development performance and QC evaluations are conducted as an assessment of method ruggedness, which is demonstrated through testing in multiple types of drinking water matrices, including assessments off-site at other laboratories by other analysts. Therefore, the agency has empirically determined assurances that the methods can perform adequately at the final MCL levels, regardless of unit concentrations.

For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response

in this *Response to Comments* document. Regarding analytical background contamination concerns, please see the section 8.7 of the EPA response in this *Response to Comments* document.

Water Quality Association (WQA) (Doc. #1694, SBC-044989)

Water Testing and Sampling

EPA should consider the risks of inaccurate water sample results when measuring at 4 ppt or below, considering the extensive use of PFAS in everyday products and those used under regular laboratory testing. EPA should refer to knowledgeable, experienced stakeholders on the best methods for water testing in the field and laboratory before and after treatment to help ensure results are accurate and are not compromised by cross-contamination.

Collecting samples for PFAS analysis requires advance planning. Specific shipping times, chilling temperatures, and other precautions must be taken when comparing testing with other contaminants to receive accurate results. It is important to note that normally sample collection, handling, storage, and testing are performed under very controlled laboratory conditions. Performing the same under field conditions as is proposed to be conducted to determine water system compliance will introduce significant challenges in producing reliable data.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

Orange Water and Sewer Authority (OWASA) (Doc. #1524, SBC-042618)

• Laboratory Availability

o Turn around time for sampling – can we get the results back in time to meet the required monitoring and reporting requirements given the current strain on laboratory services

o In addition to regulatory monitoring, utilities will also be tracking PFAS breakthrough in media filters and this will add additional samples and this could impact turnaround time for regulatory sampling as well as impact our ability to track breakthrough in a timely manner.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees that large amounts of additional samples in performance monitoring will be required, and the commenter provided no data to support their assertion that this would be necessary. The EPA anticipates that many water systems will conduct a pilot test before implementing a full-scale treatment installation and that the operational results from the pilot test will be a sufficient indicator of performance; therefore, water systems should not have to collect large amounts of performance samples indefinitely during the full-scale operation of treatment technologies.

Please see section 13.3.3 of the EPA response in this *Response to Comments* document for additional details on how these considerations were factored into the EPA's cost estimates.

Missouri Department of Natural Resources (Doc. #1563, SBC-042525)

EPA requests comment on the underlying assumptions that sufficient laboratory capacity will be available with the proposed MCLs; that demand will be sufficiently distributed during rule implementation to allow for laboratory capacity; and on the cost estimates related to these assumptions.

The Department disagrees with many of the underlying assumptions EPA used for determining sufficient laboratory capacity. First, the Department believes that water systems will be incentivized to use labs that have a PQL/MRL no less than the proposed 4.0 ppt MCL, to avoid the potential for a "J Qualified" result to be used in their compliance determinations. This will allow any "J Qualified" result to be reported as a no detect (<4.0 ppt) and a zero would be used in the compliance determination, resulting in a higher likelihood of compliance. Second, labs are not required to report "J Qualified" data. As such, water systems that use a lab with a 4.0 ppt PQL/MRL may not be notified of an unquantified instrument estimated detection below the PQL/MRL. Finally, in addition to utilities "shopping" for labs based on their PQL preference, a capacity issue will develop as other media (e.g., soil, air, and clean water) and other environmental programs (e.g, Clean Water Act, RCRA/CERCLA, Solid Waste, etc.) begin monitoring for PFAS. The Department is already seeing an increase in demand for laboratory services with the beginning of UCMR 5 sampling and, our contract lab having issues with meeting our demand for PFAS sampling as we try to sample systems in our state not sampled under UCMR 5.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that water systems will be "incentivized to use labs that have a PQL/MRL no less than the proposed 4.0 ppt MCL, to avoid the potential for a "J Qualified" result to be used in their compliance determinations." The EPA allows water systems to select any certified laboratories that they may choose and acknowledges that laboratories may have different analytical capabilities. EPA notes that any result below 4.0 ppt for PFOA or PFOS would be treated as zero in their RAA compliance calculations. See section 8.2 of the EPA response in this *Response to Comments* document for further discussion. Additionally, as discussed in greater detail in section 8.8 of the EPA response in this *Response to Comments* document on rule trigger levels and in section XIII of the final rule preamble, water systems must demonstrate they are below the final rule trigger levels to be eligible for reduced triennial monitoring (i.e., utilities who only go to labs who can go as low as the MCL will not be eligible for reduced monitoring). Additionally, regarding concerns for laboratory capacity as it relates to other environmental programs and regulations, the commenter provided no verifiable information to support this claim. For instance, the commenter references UCMR 5 as a source

of capacity concern but the agency notes that utilities may be able to use data from UCMR 5 sampling to satisfy initial monitoring requirements in the final NPDWR.

Missouri Department of Natural Resources (Doc. #1563, SBC-042533)

EPA requests comment on other monitoring related considerations including laboratory capacity and QA/ QC of drinking water sampling.

As discussed previously, the Department believes EPA has significantly underestimated the resource needs that will cause lab capacity issues for drinking water sampling when other media and environmental programs begin monitoring at nearly the same time.

EPA Response: Please see the EPA response to comment Doc. #1563, SBC-042525 in section 5.1.2 in this *Response to Comments* document.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042731)

Certified labs have been challenged with analyzing the number of samples that PWS sends them. PWS can wait upwards of three weeks for sample results and then the primacy agencies must perform quality assurance evaluations, which can take several more weeks. Samples are expensive ($250-$350 per sample), with field blanks being run in many cases, thereby doubling the costs. Follow-up confirmatory samples will be needed to validate initial results. MWUA recommends that monitoring should be phased in by system size to reduce the resource burden on the labs and primacy agencies who must review and verify the quality of the data.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring timing, please see section 8.1.1 of the EPA response in this *Response to Comments* document. The agency notes that the EPA accounted for confirmatory samples in the cost analysis supporting the final NPDWR and the Administrator determined at proposal that the benefits of the rule justify its costs. Specifically, for any samples that have a detection, the system will analyze the field reagent blank samples collected at the same time as the monitoring sample. Systems that have an MCL exceedance may collect one additional sample from the relevant entry point to confirm the results (i.e., a confirmation sample), at the discretion of the primacy agency.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042479)

o EPA recognizes most labs will not be able to reach the targets outlined in this proposal. The labs across the country are not ready for this regulation, and many will not be able to test with the accuracy necessary to provide dependable results for the proposed trigger level. The EPA's assumption that labs will reach analytical targets places PWSs in the precarious position of being able to prove compliance.

o EPA supports the proposed trigger level because 49 of the 54 labs who applied for the Laboratory Approval Program for UCMR5 were able to reach a lowest PFAS calibration standard level of 1 ppt or lower. While this may be sufficient for the 3,500 PWSs participating in UCMR5, it is not nearly enough for the nearly 150,000 PWSs in the country that will be required to verify compliance.

o Although the current list of accredited laboratories continues to grow there is concern that there are not enough labs accredited for PFAS to handle the influx of testing. Implementing new methods requires instrumentation, staff, training, and other resources that will take longer than the proposed timelines will allow for compliance.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding trigger levels, please see section 8.8. The EPA notes that this final rule will require monitoring from approximately 67,000 PWSs; not 150,000 PWSs as stated by the commenter. Additionally, the EPA estimates that approximately 10,300 systems will be collecting monitoring data under UCMR 5; not only 3,500 as claimed by the commenter. Finally, the EPA notes that many of the systems that are not required to monitor under the UCMR 5 program are small (<3,300 persons served) groundwater systems. These systems typically have fewer entry points to monitor than larger systems and they only have to monitor each entry point twice over the course of a year during their initial monitoring period, instead of four times per year for larger surface water systems. Hence, while there will be an increase in PFAS monitoring as a result of this rule, it will not be nearly as substantial as implied by the commenter. Please also see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document regarding the rule's initial monitoring requirements and use of previously collected data to satisfy monitoring requirements.

COMM Water Department (Doc. #1577, SBC-042438)

EPA needs to address laboratory capacity issues before finalizing the rule. Certified labs have been challenged with analyzing the number of samples that Massachusetts PWS send them. PWS can wait upwards of three weeks for sample results and then our primacy agency, MassDEP, must perform quality assurance evaluations, which can take several more weeks. EPA should do as Massachusetts did, and phase in monitoring by PWS size to reduce the resource burden on the labs and primacy agencies who must review and verify the quality of the data.

EPA Response: Please see the EPA response to comment Doc. #1567, SBC-042731 in section 5.1.2 in this *Response to Comments* document.

San Gabriel Valley Water Association (SGVWA) (Doc. #1580, SBC-042415)

May 25, 2023

Dr. Jennifer L. McLain

Director Office of Ground Water and Drinking Water

U.S. Environmental Protection Agency

1201 Constitution Ave NW Washington, DC 20004

Re: Docket ID No. EPA-HQ-OW-2022-0114

Dear Dr. McLain:

The San Gabriel Valley Water Association (SGVWA) represents municipal utilities, regulated utilities, special districts, and not-for-profit mutual water companies that supply water to nearly two million residents in the San Gabriel Valley of Los Angeles County, California. In response to the Environmental Protection Agency's request for public comment, the SGVWA is submitting this letter outlining the factors that must be addressed before the final adoption of the proposed per- and polyfluoroalkyl substances (PFAS) National Primary Drinking Water Regulations (NPDWR).

The SGVWA acknowledges that the proposed PFAS NPDWR does not mandate any actions until the four parts-per-trillion (4ppt) Maximum Contaminant Level (MCL) is approved or revised. However, the SGVWA is concerned about ensuring that the San Gabriel Valley water systems can comply with the final regulations. Several important factors negatively impact the economic feasibility of the proposed MCL for PFAS. Specifically, the proposed MCL presents significant challenges for water suppliers in the San Gabriel Valley in the following ways:

1. Transitions in the Laboratory Industry: The proposed standards for detecting and reporting PFOA and PFOS are very close to the limit. States will be responsible for certifying labs to ensure accurate compliance monitoring results. However, the initial monitoring requirements for over 70,000 systems conducting quarterly monitoring may exceed available lab capacity. In California, new accreditation requirements have caused a 25% decrease in public labs in the past two years, and commercial labs cannot meet the increased demand. As a result, the consolidation of California's laboratory industry has raised costs and limited access to water suppliers. Additionally, special procedures for collecting samples at such levels increase the risk of inaccurate results for certain volatile PFAS.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Association of State and Territorial Solid Waste Management Officials (ASTSWMO) (Doc. #1583, SBC-042401)

Analytical Laboratory Capacity: ASTSWMO anticipates an increase in sampling and analysis, warranting the need for sufficient analytical laboratory capacity to not only address the needs of the public water suppliers regulated under the SDWA, but also the needs of site discovery and cleanup programs managed under CERCLA, RCRA, and the States' cleanup programs, among

others. ASTSWMO recommends further communication between EPA and certified state and commercial laboratories to ensure that capacity issues do not impact PFAS analysis and site remediation.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Pennsylvania Chamber of Business and Industry (Doc. #1592, SBC-042794)

2. There Are Significant Laboratory Testing Constraints

There is a dearth of laboratory testing capacity to handle the volume of water and soil testing that will be needed for industries across the state and country to evaluate compliance with respect to PFAS.

EPA Response: Please see section 5.1.2 of the EPA response in this *Response to Comments* document for further discussion about laboratory capacity.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042973)

It is the experience of EGLE DWEHD that laboratory capacity has been sufficient for Michigan's needs. Based on projected sampling under the proposed NPDWR, this would remain true even in a case where our state must rely solely on State of Michigan Laboratory capacity. However, this resource may not be available for all states and should be considered during rule development.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042819)

Compliance & Implementation Challenges

There are several challenges that utilities like LCA will face in achieving compliance with this proposed rule, if approved as written.

1. Laboratory Capacity – Currently, there are only three commercial laboratories in Pennsylvania accredited to analyze drinking water via method EPA 533 or 537.1. While additional laboratories will certainly achieve accreditation in time, there will be a strain on the available laboratories to serve more than 9,000 public drinking water systems in Pennsylvania. Without ample laboratory capacity, water systems will have difficulty proactively preparing for and complying with the proposed regulation. In addition, not every laboratory that is accredited for methods EPA 533 or

537.1 will have the capability to reliably report PFAS results at levels less than the PQL. This will place additional strain on those selected labs that can report at lower levels, as many systems will be seeking the opportunity to achieve reduced monitoring.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding trigger levels for reduced monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042881)

Certified labs have been challenged with analyzing the number of samples that Massachusetts PWS send them. PWS can wait upwards of three weeks for sample results and then MassDEP must perform quality assurance evaluations, which can take several more weeks. Samples are expensive ($250-$350 per sample), with field blanks being run in most cases, thereby doubling the costs. Follow-up confirmatory samples will be needed to validate initial results. MWWA recommends that, as Massachusetts did, monitoring should be phased-in by system size to reduce the resource burden on the labs and primacy agencies who must review and verify the quality of the data. Nationwide laboratory capacity to perform the increased analysis also needs to be evaluated and additional laboratories will need to be approved and certified.

EPA Response: Please see the EPA response to comment Doc. #1567, SBC-042731 in section 5.1.2 in this *Response to Comments* document.

Town of Lincoln Water Department (Doc. #1613, SBC-043026)

EPA needs to address laboratory capacity issues before finalizing the rule. Certified labs have been challenged with analyzing the number of samples that Massachusetts PWS send them. PWS can wait upwards of three weeks for sample results and then our primacy agency, MassDEP, must perform quality assurance evaluations, which can take several more weeks. EPA should do as Massachusetts did, and phase in monitoring by PWS size to reduce the resource burden on the labs and primacy agencies who must review and verify the quality of the data.

EPA Response: Please see the EPA response to comment Doc. #1567, SBC-042731 in section 5.1.2 in this *Response to Comments* document.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043042)

Based on the relatively low number of UMCR5 approved laboratories, laboratory capacity will be an issue when monitoring requirements are rolled out. To date no survey has been completed to determine how many samples each of these labs could accept for this complex testing. In addition, UCMR5 labs may not have the ability (instrumentation and staffing) to test non-drinking water matrices for PFOS/PFAS.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Furthermore, as discussed in section 5.1.2 of the EPA response in this *Response to Comments* document, the EPA notes that "test[ing] non-drinking water matrices for PFOS/PFAS" are out of scope of this rulemaking.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044042)

23. EPA requests comment on other monitoring related considerations including laboratory capacity and QA/QC of drinking water sampling.

a. Turnaround times (TAT) for PFAS may be upwards of 2 months per sample, during normal times. With increased sampling nationwide, these times may be longer. These long TAT do not help utilities make treatment process modifications. Laboratories are also experiencing issues getting analytical reagents and instrument parts. We need more companies making standard reference materials. In addition to the trained employees needed to run these complex analyses. Contract labs are not consistently fulfilling their contractual obligations, and may not have reliable capacity or staff. EPA also needs to consider lab certification timeframes for new instruments or facilities.

b. EPA also should require any PFAS results due by 10th of month after results received (not after sampling). And realize that there may not be enough time to resample within the monitoring timeframe with these long of TAT.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Please see section 9.6 of the EPA response in this *Response to Comments* document for laboratory certification considerations.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044029)

11. EPA requests comment on the underlying assumptions that sufficient laboratory capacity will be available with the proposed MCLs; that demand will be sufficiently distributed during rule implementation to allow for laboratory capacity; and on the cost estimates related to these assumptions.

a. Lab capacity (along with reagent and labor availability) is a concern due to volume of samples nationwide. Not only for compliance and standard monitoring samples, but the multitude of additional sampling for plants undergoing pilot studies or new treatments will be doing as well. There will be significant difficulties with the enormous amounts of samples that will be required to be analyzed. We anticipate there will be continued and worsening lab backups. And if the utility wishes to perform the analyses in-house, there are huge costs for instruments, reagents,

and certification processes, as well as the uncertainty of availability of qualified lab analysts. A higher MCL could contribute to less systems being required to continuously or more frequently monitor.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043066)

Laboratory Capacity is Lagging Behind Demand

As noted above, more than 67,000 water systems will be driven to comply with the initial monitoring requirements to determine their PFAS levels. Given the timeline of the rule, water systems that may not leverage previously collected PFAS sampling data, will need to perform initial monitoring during the 12-months immediately following the rule's promulgation. The result of this surge in water monitoring sampling will require laboratories to process more than 220,000 water samples collected by these systems.

This is in addition to ongoing monitoring activities by the water sector that include compliance monitoring for systems subject to state drinking water standards, performance testing by systems with treatment facilities, and samples to support pilot testing by systems investigating and designing new treatment facilities. This is also in addition to sampling being performed outside of the water sector for environmental investigations and the implementation of recent actions for effluent discharges, which will rely on the same laboratories. By comparison, approximately 20,000 water samples will be processed annually as part of the UCMR 5 program.

Over the past few years, the demand for the analysis of samples has continued to grow and has outpaced the increase in laboratory capacity. Water systems are currently reporting sampling challenges including longer processing and turnaround times, higher analytical costs, and lower reporting reliability. The surge of sampling activity, especially with an emphasis on lower reporting levels, will further strain the existing laboratory capacity.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that water systems will be required to perform initial monitoring in the 12 months following rule promulgation as this is incorrect and water systems will instead have 3 years to complete the final rule's initial monitoring requirements (please see section 8.1.1 of the EPA response in this *Response to Comments* document.). See also section 12.1 of the EPA response in this *Response to Comments* document regarding the two-year capital extension granted by EPA in the final rulemaking. Additionally, the EPA disagrees with the commenters' sampling estimates which are based in the incorrect assumption that all water systems subject to the rule's monitoring requirements will be required to conduct new initial monitoring sampling

or that they will be required to collect quarterly samples. Moreover, many water systems will be eligible to utilize previously collected data to satisfy some or all of these requirements and small groundwater systems serving 10,000 or fewer, which accounts for approximately 80 percent of the systems subject to the final rule monitoring requirements, will only be required to collect two initial monitoring samples. Please see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document regarding the rule's initial monitoring requirements and use of previously collected data to satisfy these monitoring requirements.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044893)

DEP also notes that this estimated expenditure would be sufficient to add capacity for approximately 20 samples per week, at a maximum, using a manual extraction system. An automated extraction system could potentially increase this to up to approximately 40 samples per week but would add approximately $40,000 to the above cost estimates. Given the significant costs, it is not a given that more laboratories will seek to become accredited to add capacity for more samples.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For further discussion on the EPA's cost estimates as it relates to monitoring, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044064)

4. ASDWA recommends that EPA address anticipated laboratory capacity issues ahead of the final NPDWR. States continue to stress that the proposed rule will impact laboratory capacity. The number of laboratories that will be capable of sampling for PFAS in time to meet the new rule compliance demands is still uncertain. The number of samples that water systems will need to be analyzed will likely exceed laboratory capacity for all laboratories and each laboratory individually. ASDWA recommends that EPA further demonstrate the estimated sample demand and current national laboratory capacity to address this feasibility concern.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044087)

Laboratories have competing demands to analyze PFAS in other environmental media and, at the same time, meet other new and existing drinking water regulatory needs. PFAS detections in drinking water cause primacy agencies to launch investigations to find the source of the PFAS and other potential impacts, which typically include conducting sampling for surface water and

soils and nearby private wells. The LCRR and the future Lead and Copper Rule Improvements will likely create additional demands on laboratories, particularly if a significant number of systems will need to re-start initial monitoring based on revised compliance sampling locations. These revisions would significantly increase the number of lead and copper compliance samples.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. As discussed in the EPA response in section 5.1.2 of this *Response to Comments* document, there is sufficient laboratory capacity to the meet the compliance requirements of the PFAS NPDWR. Please also see section 12.1 of the EPA response in this *Response to Comments* document for a discussion on exemptions and extensions.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044084)

Laboratory Capacity

ASDWA recommends EPA stagger the initial monitoring requirements based on system size to help address anticipated laboratory capacity issues.

Despite EPA's assurance that laboratory capacity will not be a problem, laboratory capacity will clearly be impacted by several factors:

• Water systems will continue to test under the Fifth Unregulated Contaminant Monitoring Rule in 2024 and 2025;

• The time it takes to get a laboratory certified for PFAS methods;

• The number of laboratories that are currently capable of analyzing for PFAS and being able to manage the volume of samples;

• The method requirements for temperature and timeframes for laboratories to store and

• The competing demands for laboratories to analyze PFAS in other environmental media, while at the same time meeting other new and existing drinking water regulatory needs.

The additional time for more laboratories to get certified and prepare to analyze PFAS samples for the rule will impact laboratory capacity. Laboratories will need to purchase new equipment and instruments, set up, test, and validate the equipment, and hire new staff as part of this process. These needs will also impact the ability to get additional state laboratories certified and ready to analyze for PFAS because of inadequate funding. Laboratory capacity for analyzing PFAS in drinking water using EPA Methods 533 and 537.1 will also be impacted by laboratories concurrently getting ready to use EPA Method 1633 for analyzing PFAS in surface water, fish tissue, biosolids, and soils.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please

see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements and timing, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044132)

Sampling Costs and Laboratory Capacity

The lack of laboratory capacity and increased sampling costs may limit rule implementation. TCEQ recommends EPA address anticipated laboratory capacity shortfalls and the cost of sampling ahead of the rule becoming final. TCEQ expects, within the first 12-month monitoring period, about 22,000 samples will be collected in Texas with an estimated $3 million in collection costs. The associated sample analysis cost for Texas' initial monitoring cycle is estimated to be another $7 million. These costs create an additional funding obstacle for TCEQ and Texas' public water systems to collect and analyze associated samples across the state.

Currently, only two Texas laboratories are approved by EPA to perform UCMR5 analysis for PFAS in drinking water samples. These two laboratories will not have sufficient capacity to analyze Texas' 22,000 samples. To gain more capacity, laboratories will need to invest time to acquire new equipment or infrastructure, hire and train staff, become approved for PFAS methods, and address ongoing supply chain and shipping delays. Capacity will be further impacted by the continued demand to perform analysis under UCMR5, competing demands to analyze PFAS in other media, and the need to meet method requirements for time and temperature.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For further discussion on the EPA's cost estimates as it relates to monitoring, please see section 13.3.4.

Association of Environmental Authorities (AEA) (Doc. #1635, SBC-042964)

Laboratory services are certain to be in much higher demand as a result of adopting the NPWDR. Like NACWA, we are concerned that laboratories will struggle to meet that increase in demand for their services. This has implications for the ability of utilities to comply with regulatory deadlines and for the cost of the laboratory services themselves.

EPA Response: Regarding responses regarding laboratory testing and potential contamination issues, please see section 8.7 of the EPA response in this *Response to Comments* document. For further discussion on the EPA's cost estimates as it relates to monitoring, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043271)

• EPA requests comment on the underlying assumptions that sufficient laboratory capacity will be available with the proposed MCLs; that demand will be sufficiently distributed during rule implementation to allow for laboratory capacity; and on the cost estimates related to these assumptions.

Response: As previously stated, NRWA is not confident there will be sufficient laboratory capacity. Many states such as Kentucky do not have any certified laboratories. This will cause significant compliance challenges.

EPA Response: Regarding responses regarding laboratory testing and potential contamination issues, please see section 8.7 of the EPA response in this *Response to Comments* document. The EPA notes that states without in-state, certified laboratory services can seek those services in nearby states. Many PWSs use out-of-state laboratories to run their compliance monitoring so as long as the lab has a certification from that state. Many commercial laboratories have certifications from a number of states, either received directly or through reciprocity. Kentucky, for example, can start the process of certifying in-state labs after the NPDWR is promulgated and is adopted by the state.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043493)

Testing: The availability of testing is a significant concern for all drinking water utilities—both big and small. We are already experiencing a shortage of testing laboratories, and this will only be exacerbated once these national MCLs go into effect. Water utilities already required to comply with state issued drinking water standards are experiencing long delays in getting results back from laboratories. According to the AWWA, there are 66 laboratories that are available nationwide for PFAS testing. Currently, these labs test between 20,000-25,000 samples annually. The initial monitoring requirements of this rule will trigger testing requirements on up to 66,560 systems. It is estimated that over a three-year period, 280,000 (plus) samples will need to be tested to determine initial status, sampling for piloting and performance testing. There is simply no way that the current laboratory network is equipped to deal with this amount of testing.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043328)

Additionally, there are still concerns with laboratory capacity in some areas of the country, especially since these laboratories will also be needed to verify the results of engineering and pilot- testing, in addition to routine monitoring. This could cause delays in analysis and increase costs to obtain compliance data.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

GFL Environmental (Doc. #1648, SBC-043220)

Laboratories are already at or beyond capacity for PFAS analysis, with standard turn-around times typically measured in months. With the proposed quarterly system monitoring requirements and other regulatory drivers for PFAS sampling (e.g., products, environmental media), national capacity for PFAS testing already falls well short of demand and the gap is only expected to grow. EPA has itself noted in the NPDWR proposal that they anticipate potential laboratory capacity and supply chain issues. Before its implementation, EPA must ensure that adequate national laboratory capacity exists to meet the demands of the rule.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

J.R. Simplot Company (Doc. #1661, SBC-044150)

Laboratory Certification

EPA requires that:

"Analyses under this section for regulated PFAS must be conducted by laboratories that have received certification by the State."

There are only a limited number of laboratories that are currently certified for EPA methods 533 and 537.1, which will make it difficult for these laboratories to have adequate capacity to provide analytical services for the monitoring requirements of PFAS NPDWR.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Water Supply District of Acton (Doc. #1662, SBC-043661)

EPA must address laboratory capacity issues before finalizing the rule. Certified labs have been challenged with analyzing the number of samples that Massachusetts PWS send them. PWS can wait upwards of three weeks for sample results and then our primacy agency, MassDEP, must perform quality assurance evaluations, which can take several more weeks.

EPA Response: Please see the EPA response to comment Doc. #1567, SBC-042731 in section 5.1.2 in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044413)

Page 18730. Section VI – Maximum Contaminant Level

Page 18730. EPA requests comment on the underlying assumptions that sufficient laboratory capacity will be available with the proposed MCLs; that demand will be sufficiently distributed during rule implementation to allow for laboratory capacity; and on the cost estimates related to these assumptions.

• The 4.0 ng/L MCL/PQL should be high enough not to affect laboratory capacity. These proposed monitoring requirements and those already implemented by some states have helped create a new market for laboratories. In the proposed regulations, the overwhelming majority of UCMR 5 laboratory applicants had limits of quantitation (LOQ's) that were lower than 4.0 ng/L.

• The volume of samples required for quarterly monitoring may create laboratory capacity issues even as more laboratories are accredited for PFAS analysis. The preliminary testing in Washington has shown approximately 20 percent of sources have detections above 5 ppt. Using 1.3 ppt as the trigger will likely increase the number of water systems with detections required to monitor quarterly with no reduced monitoring options. Laboratories are already experiencing problems hiring and maintaining qualified staff.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding the rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044394)

Please consider short- and long-term solutions for insufficient laboratory capability and capacity. This rule could cause laboratories to be overburdened when the rule becomes effective and initial monitoring requirements trigger quarterly monitoring.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding initial and compliance monitoring requirements, please see section 8.1.1 and 8.1.2 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044424)

Given turnaround times for laboratories and lack of certified laboratories in Washington state, we are concerned that laboratory capacity may not match demand after implementation of this rule.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For concerns regarding in-state laboratory services, please see the EPA response to comment Doc. #1641, SBC-043271 in section 5.1.2 in this *Response to Comments* document.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043680)

Compliance & Implementation Challenges: There are several challenges that utilities like our operator, LCA will face in achieving compliance with this proposed rule, if approved as written.

1. Laboratory Capacity – Currently, there are only three commercial laboratories in Pennsylvania accredited to analyze drinking water via method EPA 533 or 537.1. While additional laboratories will certainly achieve accreditation in time, there will be a strain on the available laboratories to serve more than 9,000 public drinking water systems in Pennsylvania. Without ample laboratory capacity, water systems will have difficulty proactively preparing for and complying with the proposed regulation. In addition, not every laboratory that is accredited for methods EPA 533 or 537.1 will have the capability to reliably report PFAS results at levels less than the PQL. This will place additional strain on those selected labs that can report at lower levels, as many systems will be seeking the opportunity to achieve reduced monitoring.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels for reduced compliance monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document.

City of Hillsboro, Oregon (Doc. #1668, SBC-043118)

May 30, 2023

Michael S. Regan Administrator

U.S. Environmental Protection Agency 1200 Pennsylvania Ave, NW Washington, DC 20460

RE: National Primary Drinking Water Regulations: Per- and Polyfluoroalkyl Substances Proposed Rule (Docket ID: EPA-HQ-OW-2022-0114)

Dear Mr. Regan,

The City of Hillsboro Water Department (Hillsboro Water) shares the Environmental Protection Agency's (EPA's) commitment to using and advancing the best available science to tackle per- and polyfluoroalkyl substances (PFAS) pollution, protect public health, and harmonize policies that strengthen public health protections to deliver safe drinking water. Hillsboro Water manages four public water systems: Hillsboro, Butternut Creek, Cherry Grove, and the Joint Water

Commission (JWC). Four agencies share ownership in the JWC including the Cities of Hillsboro, Forest Grove, and Beaverton and the Tualatin Valley Water District (TVWD). The JWC is the primary drinking water supplier in Washington County, Oregon, and is responsible for treating, transmitting, and storing potable water for approximately 400,000 customers. It is within this context that reflects the Hillsboro Water's comments and concerns as they pertain to the proposed National Primary Drinking Water Regulation (NPDWR) for PFAS.

Hillsboro Water supports the overall goals of the proposed NPDWR for PFAS, however, in its current form there are concerns for water utilities that should be addressed:

1. Sampling and Reporting

Hillsboro Water has concerns about the number of accredited laboratories that can reliably test for PFAS under the approved methods (EPA Methods 533 and 537.1) given the 70,000 utilities that will be triggered into sampling through the proposed NPDWR. Moreover, staff availability of these laboratories as well as a laboratory's ability to report results within the compliance monitoring period are added concerns given these strains. In addition to the regulatory monitoring, many utilities will voluntarily monitor more frequently to track PFAS breakthrough in media filters. These investigative samples are necessary for properly managing a water system's treatment efficacy but will greatly increase the already heightened demand on laboratories.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding concerns for voluntary sampling to monitoring treatment performance (i.e., performance monitoring), the EPA anticipates that many water systems will conduct a pilot test before implementing a full-scale treatment installation and that the operational results from the pilot test will be a sufficient indicator of performance; therefore, water systems should not have to collect large amounts of performance samples indefinitely during the full-scale operation of treatment technologies. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for additional details on how these considerations were factored into the EPA's cost estimates.

<u>Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043716)</u>

Aurora Water is concerned with the availability of laboratory capacity for analyzing PFAS samples. There will be about 67,000 water systems that will need to complete the initial monitoring period. For a conservative estimate if all these systems are sampling on a quarterly monitoring schedule that would result in 280,000 samples being sent to labs for analysis of PFAS all within a 1–3-year time period. This does not consider pilot testing, continued monitoring or anything outside of baseline testing. In comparison, the UCMR 5 sampling requirement led to 40,000 samples across 3 years to be analyzed. During this time, Aurora Water experienced an average of a 2-month turnaround time for those sampling results. This is unacceptable for

gaining any useful information with respect to optimizing treatment or protection of public health.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding voluntary sampling to monitoring treatment performance (i.e., performance monitoring), the EPA anticipates that many water systems will conduct a pilot test before implementing a full-scale treatment installation and that the operational results from the pilot test will be a sufficient indicator of performance; therefore, water systems should not have to collect large amounts of performance samples indefinitely during the full-scale operation of treatment technologies. Please see sections 13.3.3 of the EPA response in this *Response to Comments* document for additional details on how these considerations were factored into the EPA's cost estimates. Further, the EPA disagrees with the commenters' sampling estimates which are based in the incorrect assumption that all water systems subject to the rule's monitoring requirements will be required to conduct new initial monitoring sampling or that they will be required to collect quarterly samples. Moreover, many water systems will be eligible to utilize previously collected data to satisfy some or all of these requirements and small groundwater systems serving 10,000 or fewer, which accounts for approximately 80 percent of the systems subject to the final rule monitoring requirements, will only be required to collect two initial monitoring samples. Please see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document regarding the rule's initial monitoring requirements and use of previously collected data to satisfy these monitoring requirements.

California Association of Mutual Water Companies (Doc. #1676, SBC-043777)

3. Implementation Challenges – Lab Capacity

CalMutuals is concerned about implementation challenges that will impact small systems particularly hard. The initial monitoring requirements for over 70,000 systems to conduct quarterly monitoring will likely exceed available lab capacity. In California, due to new accreditation requirements, the number of public labs has shrunk by 25% in the past two years, and commercial labs cannot meet the demands. As a matter of supply and demand, rising lab fees will place additional financial burdens that will be hard for small systems to absorb.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044312)

Furthermore, laboratories are already experiencing problems hiring and maintaining qualified staff.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

American Council of Independent Laboratories (ACIL) (Doc. #1692, SBC-044743)

6. Available Analytical Capacity

One issue that has been raised concerns the availability of the necessary analytical and field sampling capacity needed to implement the proposed rule. On behalf of the commercial environmental testing community, ACIL wants to assure the Agency that we do not expect laboratory capacity to be an ongoing concern.

EPA Response: The EPA acknowledges the comment regarding feasibility of the final standards as it relates to laboratory capacity.

California Farm Bureau Federation (Doc. #1704, SBC-045076)

Testing

Testing availability is a significant concern for all drinking water utilities regardless of size. National implementation of additional MCLs will further compound the shortage. Many water utilities are already having to comply with state issued drinking water standards and are experiencing long delays in getting results back from laboratories. According to the AWWA, there are 66 laboratories that are available nationwide for PFAS testing. Currently, these labs test between 20,000-25,000 samples annually. Should the proposed rule be finalized, initial monitoring requirements will trigger testing requirements on up to 66,560 systems. It is estimated that over a three-year period, upwards of 280,000 samples will need to be tested to determine initial status, sampling for piloting, and performance testing. We believe that testing availability presents a significant hurdle and EPA must develop a plan. Additionally, while there may be an opportunity for large facilities to create an in-house testing method, that will not be a universal option for smaller operations.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenters' sampling estimates which are based on the incorrect assumption that all water systems subject to the rule's monitoring requirements will be required to conduct new initial monitoring sampling or that they will be required to collect quarterly samples. Moreover, many water systems will be eligible to utilize previously collected data to satisfy some or all of these requirements and small groundwater systems serving 10,000 or fewer, which accounts for approximately 80 percent of the systems subject to the final rule monitoring requirements, will only be required to collect two initial monitoring samples. Please see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document regarding the rule's

initial monitoring requirements and use of previously collected data to satisfy these monitoring requirements.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045100)

5) Laboratory Capacity

In 2019 when Vermont was implementing its legislation and requiring systems to sample, other neighboring states were doing the same thing. We were required to reject multiple samples due to exceeded hold times at the laboratory. Unfortunately, many of the reports came to us with what appeared to be valid results, despite missing the respective hold time or both hold times for sample preservation or method run times, so it was up to program staff to wade through all reports (each 30-70 pages in length) prior to accepting the data. This was with just 3-4 local states vying for the same laboratories. While the number of available labs has grown, given national pressure, it is still unlikely that there are sufficient labs to perform the analysis. With additional resources to procure and retrofit analytic equipment and provide necessary training for analysts this could be more feasible. As discussed above, when considering the aspect of the need for well-trained, experienced analysts running the sample analysis, it will take time to grow that capacity to report out below 4 ppt. Also, regulating to the PQL is problematic for 25% of the labs in the country, as is discussed in the preamble where 75% of the labs can achieve 95% confidence; that means that 25% cannot.

Under 537.1 a field reagent blank is required for quality control. In Vermont we have required this blank. In our experience with busy labs and limited equipment, it can be difficult to meet hold times. Labs initially had intended to wait to analyze the field reagent blank until after the compliance sample was analyzed and then run the blank if there was a need from a quality control standpoint. The problem with this is that they were barely making hold times for the compliance sample, and once it went through validation/QC itself, it was too late to run the field reagent blank. To address this, the labs started analyzing the field reagent blanks at the same time as the compliance samples, doubling the cost to the water system. So, either the lab doubles the cost to the water system or they produce invalid samples, neither is system-friendly. As the need for samples goes up nationwide, it would be expected that the labs simply cannot accommodate the needs. The $1 million needed to get, retrofit, and implement equipment and then several month timeframe, at least, for procurement, installation, training and validating of equipment does not mean that a lab can simply add new staff and be able to accommodate more analysis. There need to be more laboratories and resources to provide this analysis nation-wide.

When applying for primacy, it states in 142.16 (i) that the initial monitoring plan must describe how systems will be scheduled during the initial monitoring period and demonstrate that the analytical workload on certified laboratories has been taken into account. In Vermont this would mean one staff tasked with the “Phase II/V” regulations would need to drop everything else to set schedules for nearly 600 systems, who already have at least 2 data points, if not 3 based on state-required sampling, and re-set monitoring schedules. This is a very large burden and would

require additional state resources. There are no labs within Vermont at this time who can perform PFAS analysis, so any assessment on lab capacity and lab feasibility is outside of our control and would be difficult to provide to EPA as part of the primacy application. If there were in-state capacity, it would be easier to forecast, but there would not be a mandate that systems would need to use the State lab, and for any one of several reasons, such as cost or logistics, systems may elect to not use the State laboratory.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding the circumstance described by the commenter regarding sample preservation times, the EPA notes that the six PFAS regulated by the NPDWR can be analyzed by either Method 533 or 537.1 and neither method has inherent QC issues when appropriately followed. For EPA Method 533, laboratories have 28 days to hold the sample prior to extraction, and then another 28 days to hold the extract before analysis. For EPA Method 537.1, laboratories have 14 days to hold the sample prior to extraction, and then another 28 days to hold the extract before analysis. This means laboratories have 56 and 42 days, respectively, to analyze samples that they receive. Based on the application of these methods for the UCMR 5 Program, it has been shown that the vast majority of laboratories approved for the UCMR 5 Program can meet these hold times. Any labs that were unable to consistently meet hold times were evaluated for inefficiencies in their sample processing and addressed on a case-by-case basis. The EPA also disagrees with the commenter claims' that "25% [of labs] cannot" meet the PQL; as discussed in the final rule preamble, the PQL reflects a minimum quantitation level that "with 95 percent confidence, can be achieved by capable analysts at 75 percent *or more* of the laboratories using a specified analytical method" (emphasis added). Greater than 75 percent of labs requesting participation in UCMR 5 were able to meet the PQLs/MRLs, and EPA anticipates the number of labs available for compliance monitoring to grow (see section 5.1.2 of the EPA response in this *Response to Comments* document). Regarding rule primacy requirements, please section 11.1 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA also notes that the use of pre-existing data, as the commentor discusses, can be used to meet the initial monitoring requirements and is discussed in section 8.3 of the EPA response in this *Response to Comments* document. See also section 13.3.1 of the EPA response in this *Response to Comments* document a discussion concerning primacy agency costs (including regulatory start-up).

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045107)

8) Monitoring related concerns including lab capacity and Qa/Qc of sample results

As has been discussed elsewhere in these comments, we have significant concerns about lab capacity. Vermont does not have a lab capable of providing PFAS analysis within the state, so samples must be sent out for analysis and thereby compete with neighboring states or nation-wide for laboratory capacity. When many New England states were implementing PFAS standards several years ago, there were several issues with laboratories not being able to meet hold times. Additionally, the equipment is so specialized and expensive that they often do not have redundancy or backup; if the sole piece of equipment goes down, it could seriously impact hold times and sample analysis. As we attempt to get analytic equipment and personnel in-state to perform the analysis, the time it takes to retrofit equipment, train staff, and receive necessary accreditation is not insignificant. We experienced situations where slight differences in the volume of water provided in the sample bottle dictated changes in the method reporting level, making it possible to drive up the reporting level by insufficiently filling the bottle.

EPA Response: Please see the EPA response to comment Doc. #1708, SBC-045100 in section 5.1.2 in this *Response to Comments* document.

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045938)

Based on the information provided, it is unclear that the number of EPA certified water quality laboratories is sufficient to test the samples as required by the rule.

In the proposed rule, EPA states that there are 54 labs across the United States that submitted applications for EPA approval to analyze PFOA and PFOS to quantification limits of 4.0 ppt pursuant to EPA Analytical Method 533 and 537.1. [FN20: Proposed Rule, 88 Fed. Reg. at 18667.] Additionally, the proposed rule requires that large groundwater systems serving more than 10,0000 people and all surface water systems are required to test quarterly. [FN21: Proposed Rule, 88 Fed. Reg. at 18681.]

Methods 533 and 537.1 require testing of a large number of samples. Besides the field reagent blank sample, both Method 533 and 537.1 require a minimum of one Field Duplicate sample and if this is not possible, one Laboratory Fortified Sample Matrix Duplicate per sample. Given that the extraction batch for both Method 533 and 537.1 is 20 samples, each instrument will be able to analyze samples from 6 water systems a day assuming that there are only 2 samples from each water system. With 148,000 water systems and 54 labs running, each lab is required to have a minimum of 7 instruments running 260 days-a-year to complete the required samples. Although the rule proposes to allow reduced sampling requirements once the initial monitoring results show compliance, it is not clear that there will be sufficient approved lab capacity to meet the heightened testing load and it is also unclear how many water systems will qualify for reduced sampling, given the growing pervasiveness of PFAS in water supplies. At a minimum, EPA

should wait to implement the proposed rule until all required systems provide data under UCMR 5. .

This estimate is conservative and relies on two major assumptions that are likely inaccurate. First, it assumes that the samples are perfectly staggered in a way that would allow the samples to be prepared and ready without any overlap. Second, this assumes that there are only two samples per water system that are measured per day. If either of these two assumptions are improper, then additional labs or instruments would be necessary to handle the additional samples.

For these reasons, it would be premature to finalize the NPDWR without additional analysis and confirmation that there are enough approved labs nationwide to test to the required levels. And once the NPDWR is finalized, it should allow a longer time period for water and wastewater agencies to bring the significant investments online that are required to achieve compliance.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA disagrees with the commenter on their estimate of the number of systems subject to the rule's monitoring requirements, which is incorrectly cited as 148,000 systems. Instead, there are approximately 67,000 water systems many of which will not be required to conduct new initial monitoring as discussed in sections 8.1.1. and 8.3 of the EPA response in this *Response to Comments* document. For additional discussion on UCMR 5, please see sections 3.1.2 (under Preliminary Regulatory Determinations) and 6.8 (under Occurrence) of the EPA response in this *Response to Comments* document.

HRSD (Doc. #1719, SBC-043544)

Laboratory capacity is already limited and HRSD is experiencing delays in data turnaround of approximately 8 weeks.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045149)

Laboratory capacity

MassDEP believes that tripling the number of PWSs needing laboratory services, as the PFAS NPDWR is expected to do, will likely affect laboratory capacity. MassDEP recommends staggering the initial monitoring requirements across the three years between the effective and compliance dates of the final rule, as was done in the Stage 2 Disinfectants/Disinfection

Byproduct Rule, to avoid overwhelming laboratories. States are obligated, pursuant to 40 CFR § 142.16(e)(2)(i), to include a plan in their primacy applications that addresses scheduling of initial monitoring and "demonstrate[s] that analytical workload on certified laboratories has been taken into account", to identify and/or develop contingencies should capacity issues arise. While it is possible that this NPDWR will encourage more laboratories to establish PFAS analytical capabilities, EPA should work with the states to plan sufficient laboratory capacity until any such increased capacity is established.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. In addition, in response to this comment, to clarify the requirements for obtaining primacy, EPA notes that in the final rule, language has been added to clarify that the requirements of 40 CFR § 142.16(r) apply in lieu of the requirements of 40 CFR § 142.16(e). Finally, as noted in section 11.1 summary, in the final rule, there is no longer a requirement in § 142.16(r) for a monitoring plan that describes when systems will be scheduled to conduct initial monitoring and demonstrating that the analytical workload on certified laboratories has been taken into account. Regarding staggering initial monitoring schedules, see section 8.1.1 of the EPA response in this *Response to Comments* document.

U.S Conference of Mayors, National League of Cities and National Association of Counties (Doc. #1733, SBC-043895)

b. Inadequate Laboratory Capacity

Laboratories across the nation will need to be drastically scaled up in order to manage the surging demand from public water systems as they implement and comply with the proposed regulation. Compliance monitoring is only a small fraction of the number of samples that will need to be collected and analyzed as public water systems that have test samples above the limit will also need to monitor for PFAS while installing and operating treatment techniques.

Therefore, laboratory capacity must be able to not only handle initial compliance monitoring, but also monitoring from public water systems as they continue to operate and treat PFAS.

With such an increase in demand, we have serious concerns regarding laboratory capacity across the nation and the ability for public water systems to receive and process sample results in a timely and cost-efficient manner. Currently, public water systems are reporting wait times of up to three months to receive PFAS sample results. With the Agency's current proposal giving public water systems only three years to comply, water systems will be forced to move as expeditiously as possible, resulting in increased monitoring and longer sample response times than what is already being reported. As laboratories across the nation become overwhelmed, EPA should consider the importance of having reliable, accessible and affordable laboratory capacity as it relates to local governments' capability to work towards compliance.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Michigan Section American Water Works Association (MI-AWWA) (Doc. #1734, SBC-044478)

Finally, there are not sufficient laboratories in Michigan that are designed for this type of testing.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045972)

In the months following the promulgation of the rule, utilities with PFAS near or above the finalized MCLs will start the sprint toward treatment. Pilot studies will need to be conducted to determine the best treatment approach, how the treatment will affect other regulated and non-regulated contaminants, and the total efficacy of the treatment. As the investment in this treatment will be extremely significant, utilities need to be sure they are making the right long-term decision. This will result in many more samples being taken to assess what route a utility should take and what effect this will have on other elements of the treatment process.

Due to the cost compared to the other options and the success of granular activated carbon (GAC) and Ion Exchange (IX) at removing PFAS from drinking water, these will likely be options that many utilities choose. For these treatment techniques, water flows through a media that removes the PFAS from the water, leaving it in the media. While the media remove certain PFAS, media will become spent, requiring replacement or reactivation.

In the proposed rule, EPA estimates PWSs serving over 3,300 people will, at most, sample quarterly for initial and long-term compliance. While that timeline may be what EPA requires to show compliance, it is not the reality for many water systems. Because a water system needs to know how often it needs to replace its media, water systems will have to perform sampling throughout the column or bed to ensure PFAS is still being removed from the water and the media is still performing adequately. This will significantly increase the number of samples water systems have to take and, therefore, get analyzed by a lab. For example, one specific member serving over 2 million people has been consulting on the potential treatment they will need to comply with the rule. This system would have to install concrete 24 gravity contactors – 12 lead and 12 lag – that include four sample ports at different depths to assess GAC performance. This water system's sampling protocol to assess the efficacy of the GAC and switch between lead/lag arrangement would result in (12x4) + 12 = 60 samples per month on average, or 720 samples a year. That is significantly more than the four per year per entry point

required under the rule, is not unique to this singular utility, and is less than other utilities are projecting.

Another PWS, serving almost one million people, indicates that it plans on carrying out biweekly sampling of raw and finished water at all treatment plants for operational control and treatment performance, totaling approximately 415 samples per year. Additional testing for other aspects of treatment, such as developing dosage curves with specific carbon under varying water-quality conditions, carbon-type testing for procurement, and more uses, could result in around 50 more samples a year. Adding these to general compliance sampling, this PWS will have to process about 500 samples a year using EPA methods 537.1 or 533, or in some cases both. A final AMWA member serving around 400,000 people estimates that between UCMR/NPDWR samples, source water investigation (2-3 years), rapid small-scale column tests and pilot (2-3 years), and full-scale treatment applications, it will have to analyze at least 168 samples per year through 2026 at least, with only 8 of those being compliance/UCMR 5 monitoring samples.

EPA states in the proposal that 54 laboratories submitted applications for EPA approval to analyze PFOA and PFOS under UCMR 5. While more labs can become certified in the future once the rule is promulgated, the initial demand for sample analysis will be overwhelming. Using EPA's estimated number of systems, a mean of about 4,300, without factoring in required compliance monitoring, leads to an additional 258,000 samples a month. Split between 54 approved labs, each of them would have to process approximately 4,700 samples a month. Add in UCMR 5 and required monitoring under this proposal for every PWS, and that number increases. This is a back-of-the-envelope calculation, but these are additional strains EPA may not have considered and will be the reality for many water systems trying to get data back in a timely manner. This estimate also does not account for other wastewater and/or biosolids samples that will likely be competing for lab analysis.

Several AMWA members are looking into the creation of an in-house or affiliate lab to avoid the issues they currently or may face with limited lab capacity for PFAS samples. In-house labs are extremely costly to startup and require extensive operational and maintenance costs. Utilities who have explored this option, typically mid- and large-sized utilities, have seen a minimum equipment cost of $0.5 million, $400,000 for analytical instruments, and $100,000 for the autosampler and extraction system. This does not include space procurement, labor, and maintenance costs, which would likely be greater than the equipment cost. Additionally, the certification process can be time-consuming and tedious. Even with high start-up costs, PWSs are still considering it due to the ongoing issues with other labs and concerns about being held non-compliant for actions outside their control.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. Regarding concerns for voluntary sampling to access monitoring treatment

performance (i.e., performance monitoring), the EPA anticipates that many water systems will conduct a pilot test before implementing a full-scale treatment installation and that the operational results from the pilot test will be a sufficient indicator of performance; therefore, water systems should not have to collect large amounts of performance samples indefinitely during the full-scale operation of treatment technologies. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for additional details on how these considerations were factored into the EPA's cost estimates. Further, the commenter states that, "In the proposed rule, EPA estimates PWSs serving over 3,300 people will, at most, sample quarterly for initial and long-term compliance." While the EPA agrees that some water systems will sample quarterly, the agency disagrees with the commenter's estimates and overall intent because both during initial monitoring and compliance monitoring, the majority of systems will not be required to conduct quarterly initial monitoring. The agency is allowing the use of previously collected data to satisfy the initial monitoring requirements and small groundwater systems, which account for approximately 80 percent of the systems subject to the final rule's monitoring requirements, will only be required to collect two samples (assuming they do not have available previously collected data which would further decrease this number of samples). For compliance monitoring, the EPA then anticipates based on national occurrence estimates that many water systems will be eligible for triennial monitoring.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045970)

Section 5.5: Lab capacity

EPA is requesting comment on the underlying assumptions: that sufficient laboratory capacity will be available with the MCLs set at 4.0 ppt; that demand will be sufficiently distributed during rule implementation to allow for laboratory capacity; and on the cost estimates related to these assumptions. AMWA has serious concerns over the ability of certified labs to not only reliably process the number of samples this rule will require, but also to evaluate the number of additional samples water systems will take for their own system evaluation purposes. While EPA has proposed some possible avenues to reduce the number of samples required under this proposed rule, the agency should also consider the number of samples beyond general compliance that will be generated due to the proposal.

AMWA members are currently underway with UCMR 5 sampling. UCMR 5 includes all six PFAS included under this proposed regulation. PWSs are already experiencing issues with getting data back in a timely manner, in addition to increased costs of sampling, sample transport, sample analysis, and even mishaps at labs where samples are thrown out before they can be retested. Many AMWA members rely on one commercial lab for PFAS analysis due to costs, availability, and access. Currently, AMWA members are waiting between one and three months for PFAS sample results. These issues are being seen during implementation of UCMR 5, even before other systems will have to start their initial monitoring.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

San Gabriel Basin Water Quality Authority (WQA) (Doc. #1743, SBC-043613)

3. EPA should evaluate whether there is an adequate number of certified laboratory service providers available to meet the potential increased demand for PFAS testing services. There have been many consolidations among the laboratories, and it appears that some are struggling to keep up with even the existing demand. EPA should also ensure that reliable and consistent results are being achieved at the proposed MCLs among the various laboratories.

WQA appreciates EPA's consideration of these comments. If you need additional information, I can be contacted at 626-338-5555.

Respectfully,

Randy Schoellerman Executive Director

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045218)

2. EPA requests comment on the underlying assumptions that sufficient laboratory capacity will be available with the proposed MCLs; that demand will be sufficiently distributed during rule implementation to allow for laboratory capacity; and on the cost estimates related to these assumptions.

CT DPH agrees that sufficient laboratory capacity will be available with the proposed MCLs, as all laboratories certified by the CT DPH ELCP are calibrating to concentrations less than 4.0 ppt. However, it is outside of the ELCPs scope to determine the capacity capabilities of individual laboratories. Additionally, ELCP cannot determine the capacity that will be needed to accommodate the testing for community and non-transient non-community public water systems in Connecticut. Currently, no instate laboratories are certified for EPA 533 but there are three in-state labs certified for EPA 537.1.

3. EPA requests comment on other monitoring related considerations including laboratory capacity and QA/ QC of drinking water sampling.

Laboratory capacity cannot be fully evaluated because of the change in monitoring requirements stemming from the trigger level.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Liberty (Doc. #1747, SBC-043623)

Upon review of the proposed rule, however, we have implementation considerations that should be addressed in order to ensure that industry can fully comply with the rule.

First, based on our experience, existing laboratory resources are not sufficiently available in the U.S. to meet the critical initial monitoring requirements outlined in the draft rule. For example, Liberty is currently engaged in UCMR5 monitoring for about one-third of our water systems. We must often ship samples to other states for processing, and have already experienced failed temperatures upon laboratory receipt despite following cooling protocols, as well as lost shipments. With well over 60,000 water systems that will need to collect initial monitoring samples within the first 12 - 18 months of promulgation, we believe access to laboratories that can provide timely, accurate, and cost-effective processing of these samples will be very challenging, if not impossible to find, for many utilities. EPA noted in the May 4, 2023, Public Hearing that it believes that there would be sufficient approved laboratory resources available to support initial monitoring by the time the regulation came to promulgation. Based on our experience, we respectfully disagree, and believe that the initial proposed monitoring timeline will lead to a tremendous burden on whatever qualified laboratories exist; an increase in processing and handling errors which could invalidate results; and higher prices for utilities, especially at those laboratories able to provide clients with reporting limits below the PQL.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that water systems will be required to perform initial monitoring in the 12-18 months following rule promulgation as this is incorrect and water systems will instead have 3 years to complete the final rule's initial monitoring requirements (please see section 8.1.1 of the EPA response in this *Response to Comments* document). Additionally, the EPA disagrees with the commenters' sampling estimates which are based in the incorrect assumption that all water systems subject to the rule's monitoring requirements will be required to conduct new initial monitoring sampling or that they will be required to collect quarterly samples. Moreover, many water systems will be eligible to utilize previously collected data to satisfy some or all of these requirements and small groundwater systems serving 10,000 or fewer, which accounts for approximately 80 percent of the systems subject to the final rule monitoring requirements, will only be required to collect two initial monitoring samples. Please see section 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document regarding the rule's initial monitoring requirements and use of previously collected data to satisfy these monitoring requirements.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043911)

In response to Section IX-Monitoring and Compliance Requirements, EPA requests comment on other monitoring related considerations including laboratory capacity and QA/QC of drinking water sampling.

• It is likely that sample costs and turnaround times will increase significantly. In New Mexico, there are a limited number of State approved laboratories, so many systems must ship samples to the laboratory, incurring additional cost for proper packaging and shipping.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For further discussion on the EPA's cost estimates as it relates to monitoring, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045627)

As PFAS occurrence data are required to be collected and used to drive decision-making, there will be higher demand for laboratories that are able to analyze samples with a greater degree of reliability at single digit, part per trillion levels to minimize the risks of inaccurately higher sample results from interferences and other technical challenges. Increased demand for better laboratories will contribute to higher lead times, per sample costs, and more frequent recognition of sample analysis errors. The consequences of these pressures on the analytical services market, will most negatively impact smaller systems with less financial capacity to access more experienced and better performing laboratories. To the degree small systems have limited access to high quality laboratory service, it creates inequitable access to reliable sample analysis.

EPA Response: The commenter did not provide data to support claims that smaller systems will have "inequitable access to reliable sample analysis." For funding concerns, the agency notes that funds are also available through the passage of the IIJA, also referred to as the BIL, to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045569)

Laboratory Capacity is Lagging Behind Demand

As noted above, more than 67,000 water systems will be driven to comply with the initial monitoring requirements to determine their PFAS levels. Given the timeline of the rule, as

described in the proposed rule preamble and reflected in the proposed rule text, water systems that may not leverage previously collected PFAS sampling data, will need to perform initial monitoring during the 12-months immediately following the rule's promulgation. The product of this surge in water monitoring sampling will require laboratories to process more than 220,000 water samples being collected by these systems.

This is in addition to ongoing monitoring activities by the water sector that include compliance monitoring for systems subject to state drinking water standards, performance testing by systems with treatment facilities, and samples to support pilot testing by systems investigating and designing new treatment facilities. Examples of sampling programs for testing new treatment facilities are laid out in detail in AWWA's "Drinking Water Treatment Selection Guide for PFAS" (AWWA, 2020a). This is also in addition to sampling being performed outside of the water sector for environmental investigations and the implementation of recent actions for effluent discharges, which will largely rely on the same laboratories (EPA, 2022d; EPA, 2022e). By comparison, approximately 20,000 water samples will be processed annually as part of the UCMR 5 program. Initial monitoring requirements will increase the demand for laboratory capacity by a factor of more than 11.

Over the past few years, the demand for the analysis of samples has continued to grow and has outpaced the increase in laboratory capacity. Water systems are currently reporting sampling challenges like longer processing and turnaround times, higher analytical costs, and less reliable reporting data quality. The surge of sampling activity, especially with an emphasis on lower reporting levels, will further strain the existing laboratory capacity. EPA will therefore create unavoidable compliance risks for public water systems unless it extends the implementation timeline to the maximum extent possible.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 on extensions and exemptions. The EPA disagrees with the commenter that water systems will be required to perform initial monitoring in the 12 months following rule promulgation as this is incorrect and water systems will instead have 3 years to complete the final rule's initial monitoring requirements (please see section 8.1.1 of the EPA response in this *Response to Comments* document.) Additionally, the EPA disagrees with the commenters' sampling estimates which are based in the incorrect assumption that all water systems subject to the rule's monitoring requirements will be required to conduct new initial monitoring sampling or that they will be required to collect quarterly samples. Moreover, many water systems will be eligible to utilize previously collected data to satisfy some or all of these requirements and small groundwater systems serving 10,000 or fewer, which accounts for approximately 80 percent of the systems subject to the final rule monitoring requirements, will only be required to collect two initial monitoring samples. Please see sections 8.1.1 and 8.3 of the EPA response in this

Response to Comments document regarding the rule's initial monitoring requirements and use of previously collected data to satisfy these monitoring requirements.

PFAS Regulatory Coalition (Doc. #1761, SBC-046077)

3. Concerns about laboratory capacity must be adequately considered and addressed.

The Coalition is concerned that there will not be adequate laboratory capacity to accommodate the enormous amount of testing across the country that would be required by the Proposal. Laboratories with PFAS analytical capabilities are already receiving increased demand for NPDES permit compliance testing, as well as for testing for remediation projects. Coalition members are already experiencing delays of six weeks to three months in turnaround times for PFAS analyses. The thousands of additional samples required under the Proposal would only exacerbate this problem. Even as more laboratories try to come on-line and offer PFAS analytical services, it takes time for them to do so and to provide consistent, reliable results. Laboratories are not immune to the challenges that other employers are facing in finding qualified and reliable personnel. EPA needs to fully consider these laboratory capacity concerns before proceeding further with this rulemaking. Without adequate laboratory capacity, attaining and maintaining an MCL is not technically feasible.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Note that EPA Method 533 and EPA Method 537.1 are solely drinking water methods. Any testing conducted for NPDES permit compliance testing would be using different methods than those listed here and may have different analysis time requirements.

U.S. Poultry & Egg Association et al. (Doc. #1765, SBC-044544)

1. EPA has not considered the technical expertise necessary, and costs associated with, collecting and interpreting laboratory analytical results for PFAS.

Compliance with the EPA's proposed MCLs for PFAS requires regulated entities to collect water samples for analysis by an accredited laboratory running Method 537.1: Determination of Selected Per- and Polyfluorinated Alkyl Substances in Drinking Water by Solid Phase Extraction (SPE) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) [FN1:https://cfpub.epa.gov/si/si_public_record_Report.cfm?dirEntryId=343042&Lab=NERL]. EPA has not considered the level of education and training that will be necessary to appropriately collect the water samples and then accurately interpret analytical results from commercial labs. For many of the water suppliers subject to this regulation, this will be the first time they will be engaging with the more sophisticated commercial analytical laboratories. There are currently a limited number of commercial laboratories that are certified by EPA to run this method (see comment below), which causes significant concerns for timelines, hold times, and quality assurance. Moreover, as more commercial laboratories attempt to get NELAP certified,

there will inevitably be a learning curve, with quality assurance and quality control issues. The correct performance of Method 537.1 is technically challenging – and although procedures such as sample hold time, reagents, extraction, and interpretation of chromatograms will be documented by the analytical labs in detailed data packages, it is left up to the water provider to review and interpret the lab's procedures. Therefore, water suppliers will need to have on-staff expertise in the interpretation of Method 537.1 analytical results and in the review and analysis of laboratory quality assurance and data packages.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding training for EPA PFAS drinking water methods analysis, please see section 8.6 of the EPA response in this *Response to Comments* document.

U.S. Poultry & Egg Association et al. (Doc. #1765, SBC-044546)

2. EPA has not appropriately considered the lack of available accredited commercial laboratories capable of running Method 537.1, especially in the southern United States.

There are currently a limited number of commercial laboratories that are certified by the EPA to run this method (see comment below), which causes significant concerns for timelines, hold times, and quality assurance. According to the National Environmental Laboratory Accreditation Management System [FN2: https://lams.nelac-institute.org/SearchResults], there are currently only 49 labs accredited to run Method 537.1. Of those, only seven (7) are located within the southern U.S. While this number is certain to increase with market demand, there will be a significant learning curve and challenges with quality assurance with new labs. As discussed above, the burden to ensure appropriate laboratory quality assurance and quality control and data interpretation is on the water provider. With decision thresholds at the quantitation limit, there is no room for even minor biased high or low results. EPA has not adequately considered the lack of available accredited commercial laboratories capable of running Method 537.1, especially for water providers in the southern U.S. region. This lack of resources will put a significant additional burden on stakeholders located in the southern U.S., which includes some of the most vulnerable communities, and the largest concentration of non-transient, non-community water suppliers.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA notes there are two drinking water analytical methods approved for the monitoring provisions of this final NDPWR: the EPA Methods 537.1 and 533.

New Mexico Environment Department (NMED) (Doc. #1766, SBC-044255)

Lab Capacity

NMED requests that EPA address lab capacity issues ahead of final regulations including availability of existing labs certified to analyze PFAS and the logistics of sampling and transport in primarily rural states. Additionally, costs for training and certifications of laboratory personnel and sampling personnel, physical facility expansion requirements, and equipment procurements need to be factored into EPA's cost analysis.

The ability of labs to report their results electronically needs to be considered as additional costs will be incurred and resources required.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. In response to primacy agency costs and costs related to monitoring, please see section 13.3 of the EPA response in this *Response to Comments* document. In response to the commenter's recommendation that EPA should include the costs of establishing new laboratories and associated laboratory training costs in the economic analysis for the final rule, please see the EPA response to comment Doc. #1628, SBC-044091 in section 13.3.4 in this *Response to Comments* document. The EPA disagrees that those costs should be estimated and included. The sampling costs EPA included in the cost analysis are derived from a set of current labs and reflect the market price at the time of the survey. New labs entering the market would likely be competing with currently operating labs that have the option to expand their services. Expanding labs will likely lower their unit sample costs given the potential for shared existing overhead like billing platforms/other systems in general, floor space, or trained personnel, therefore potential new labs could not charge significant per sample rates above the current labs in the market. The costs to larger water systems considering creating a new lab would be equal to or less than the market rate charged by commercial labs already in the market.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043947)

B. Laboratory Capacity

WUWC is also concerned that EPA has overestimated the availability of laboratories with capacity to evaluate water systems' compliance with the Proposed Rule. [FN22: 88 Fed. Reg. at 18667–68 (requesting public comment on the underlying assumptions that sufficient laboratory capacity will be available with the proposed MCLs; that demand will be sufficiently distributed during rule implementation to allow for laboratory capacity; and on the cost estimates related to these assumptions).] Based on its experience certifying laboratories as part of the Fifth Unregulated Contaminant Monitoring Regulation (UCMR5) process, EPA assumes that "the commercial market for PFAS analysis is likely to remain strong and, in fact, grow as more laboratories develop the technical capacity."[FN23: Id. at 18667] EPA also assumes that, by

allowing existing PFAS monitoring data to meet initial monitoring requirements, the Proposed Rule mitigates the potential for a "sudden spike in laboratory demands."[FN24: Id. At 18667–68.]

From WUWC members' perspective, which is informed by decades of experience with drinking water sampling and analysis, the effects of new drinking water regulations on laboratory capacity are difficult to project. EPA has approved only 53 laboratories in the country to analyze UCMR5 samples by EPA Method 533 and/or EPA Method 537.1. [FN25: U.S. EPA, Laboratories Approved by EPA to Support UCMR5 (Mar. 1, 2023), available at https://www.epa.gov/dwucmr/list-laboratories-approved-epa-fifth-unregulated-contaminant-monitoring-rule-ucmr-5] Of those laboratories, seven do not offer commercial services. [FN26: Id.] Further, our members have reported a decrease in the number of accredited state labs in California of approximately 25 percent since 2020. [FN27: The California State Water Resources Control Board confirmed a decrease in the number of accredited labs during a workshop on Environmental Laboratory Accreditation Program Fees held on March 10, 2023.] Our members also report that recent typical laboratory turnaround times for internal and UCMR5 sampling have ranged widely from two to eight weeks. That range is likely to grow, because the Proposed Rule would increase the number of water systems obligated to test for PFAS beyond those subject to the UCMR5. Additional proposed regulations of other emerging contaminants, such as perchlorate, may soon follow that would further stress available laboratories. [FN28: See, e.g., NRDC v. Regan, No. 20-1335, 2023 WL 3312344(D.C. Cir., May 9, 2023)(overturning EPA's withdrawal of its prior determination not to regulate perchlorate in drinking water).] EPA should not assume that all water agencies in possession of existing UCMR5 data will elect to forego further sampling for the purpose of demonstrating compliance.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding use of previously collected data to satisfy the final rule's initial monitoring requirements (see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document), the EPA acknowledges that primacy agencies may require or water systems may choose to collect additional data even if they have available previously collected data. However, with this provision, the EPA is seeking to reduce burden and reduce potential laboratory capacity issues by allowing this flexibility and does make some reasonable assumptions, based on the overwhelming support from commenters on its use and allowance of this data will reduce burden for thousands of water systems, that water systems will choose to use this data if available. While beyond the scope of this PFAS regulatory action, regarding concerns related to perchlorate monitoring competing for laboratory space with PFAS monitoring, the EPA notes that the agency intends to propose the Perchlorate NPDWR by November 2025, and finalize that regulation by May 2027. Monitoring completed for perchlorate would, therefore, start after the initial monitoring period for this PFAS regulation.

3M Company (Doc. #1774, SBC-045687)

a. There is Insufficient Analytical Laboratory Capacity to Process the Quantity of Samples Required Under the Proposed Rule

EPA overstates the number of approved laboratories for the analysis of PFAS in drinking water and overestimates laboratory capacity. As of March 2023, there are 53 laboratories approved to support UCMR5, only 46 of which accept commercial samples (USEPA 2023g). As of April 21, 2023, the National Environmental Laboratory Accreditation Program (NELAP) Accreditation Management System lists only 38 total active laboratories certified to perform either EPA Method 533, 537.1, or both, and that accept commercial samples for drinking water (NELAP 2023).

Moreover, analytical capacity varies by laboratory and, for that reason, the number of approved laboratories is a poor indicator of overall capacity. The larger laboratory networks are currently at or near capacity for PFAS analyses in non-drinking water matrices (e.g., non-potable waters, soils); as a result, customers are experiencing considerable delays in receiving analytical results. In the past year, 3M has experienced several commercial testing labs move from standard 10 business day turnaround times for analysis of PFAS in water to straining to achieve turnaround times of less than 30 business days, despite adding equipment and other resources. This has impacted the ability to meet required timelines for regulatory-related obligations, as well as the operation, installation, and optimization of water treatment processes. The current PFAS testing capacity constraint is occurring prior to finalization of the EPA 1633 method, a more resource intensive test method than is currently employed by commercial contract testing labs. Further capacity constraints are expected after finalization and implementation of the EPA 1633 method. In fact, Metropolitan Council Environmental Services, which administers industrial discharge permits in Minnesota, notified 3M that there are only a small number of laboratories in North American that can perform EPA draft method 1633, and that turnaround times for analytical results can be as long as 4 months. It is not realistic to expect that growth in laboratory services will keep pace with increased demand, given all that is required to construct, permit, and staff an analytical laboratory.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA Method 1633 is not a drinking water method and, as such, may have different time and resource requirements than EPA Method 533 or EPA Method 537.1, ver. 2.0. As described above in the agency's approach toward evaluating feasibility, the EPA assesses (1) the availability of analytical methods to reliably quantify levels of the contaminants in drinking water and (2) the lowest levels at which contaminants can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions using the approved methods (i.e., the PQLs). This framework inherently considers both the capacity and capability of labs available to meet the requirements of the NPDWR. The EPA disagrees with commenter

assertions that there is insufficient laboratory capacity at this time to support implementation of the NPDWR. Based on the EPA's experience in implementing previous UCMRs and NPDWRs, the agency believes that current conditions are reflective of commercial and non-EPA laboratory performance and capacity, and the agency expects the environmental laboratory community will continue to develop their capabilities for the PFAS drinking water analysis at the PQL as demonstrated in previous drinking water regulations (USEPA, 1999; USEPA, 2001).

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045273)

4. Laboratory capacity should be considered and able to fulfill demands.

Initial monitoring requirements will trigger at least 70,000 public drinking water systems to conduct quarterly monitoring. Therefore, over 280,000 samples plus additional samples for pilot testing, performance testing, and other research by systems required to install treatment will be required during the first three years. EPA already acknowledged potential laboratory capacity issues, so if EPA were to promulgate MCLs, the Agency should also conduct a study to ensure sufficient laboratory capacity is available to fulfill demands. There are currently 49 laboratories approved to analyze UCMR 5 samples (by EPA Method 533) [FN4: https://www.epa.gov/system/files/documents/2022-01/ucmr5-approved-lab-list.pdf (accessed May 28, 2023).] Of those laboratories, 14 are public water system laboratories or state health department laboratories, which may not offer commercial services. It is not likely that thirty-five laboratories can meet the initial projected capacity demands.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenters' sampling estimates which are based in the incorrect assumption that all water systems subject to the rule's monitoring requirements will be required to conduct new initial monitoring sampling or that they will be required to collect quarterly samples. Moreover, many water systems will be eligible to utilize previously collected data to satisfy some or all of these requirements and small groundwater systems serving 10,000 or fewer, which accounts for approximately 80 percent of the systems subject to the final rule monitoring requirements, will only be required to collect two initial monitoring samples. Please see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document regarding the rule's initial monitoring requirements and use of previously collected data to satisfy these monitoring requirements. As described above in the agency's approach toward evaluating feasibility, the EPA assesses (1) the availability of analytical methods to reliably quantify levels of the contaminants in drinking water and (2) the lowest levels at which contaminants can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions using the approved methods (i.e., the PQLs). This framework inherently considers both the capacity and capability of labs available to meet the requirements of the NPDWR.

Based on the EPA's analysis of these factors, the EPA disagrees with commenter assertions that there is insufficient laboratory capacity at this time to support implementation of the NPDWR.

City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043781)

3. 88 FR 18668 (also 88 FR 18730). EPA requests comment on the underlying assumptions that sufficient laboratory capacity will be available with the proposed MCLs; that demand will be sufficiently distributed during rule implementation to allow for laboratory capacity; and on the cost estimates related to these assumptions.

CoT WSD responds that while EPA's allowance of existing PFAS monitoring data (i.e. UCMR5 data) to meet initial monitoring requirements may help to lessen certified laboratory capacity overload for THIS rule, EPA does not take into account other PFAS monitoring that is occurring at the same time, e.g. monitoring for Clean Water Act (CWA). EPA is currently urging states, and local pretreatment programs, to use existing authorities to incorporate quarterly monitoring into NPDES permit requirements. Pretreatment Programs are monitoring certain Industrial Users that can be dischargers of PFAS to determine if their NPDES permits should be altered. POTWs are routinely sampling their influent, effluent, and biosolids. In addition to UCMR5 monitoring, PWSs are monitoring their raw water sources, treatment effluent and residuals for PFAS. All of the analytical work is performed by the laboratories that are certified for UCMR5 and that will be performing the work for this proposed NPDWR. It is our opinion that EPA severely underestimated the demand on laboratory capacity, and that this could have an effect on meeting compliance deadlines.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Safe Drinking Water Branch, Hawaii Department of Hawaii (Doc. #1801, SBC-043753)

Lab Capacity

How many labs can test PFSA? How many labs can EPA and each state certify by the end of 2023? After the PFSA rule is finalized, can water systems find a certified lab to send the PFSA samples? Can labs conduct the test within the holding time? If the answer to either question is No, we, as the state agent, will issue the violation letter to the innocent water systems which will cause the public panic.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and

exemptions. For responses on holding times, please see the EPA response to comment Doc. #1708, SBC-045100 in section 5.1.2 in this *Response to Comments* document.

Palm Beach County Water Utilities Department (Doc. #1802, SBC-045335)

Page 18667, VI.A. Third column first full paragraph," EPA received strong interest from a significant number of laboratories seeking UCMR 5 laboratory approval, demonstrating there is effective laboratory capacity to support the program. The commercial market for PFAS analysis is likely to remain strong and, in fact, grow as more laboratories develop the technical capability further enhancing lab capacity to analyze PFAS for drinking water rule compliance purposes.":

PBCWUD Comment: PBCWUD understands the EPAs conclusion that current strong interested by laboratory's in gaining approval will equate to an increase in lab capacity. However, current lab turn-around-time (TAT) for some UCMRS analysis ranges from 45 to 80 days indicating there is already a significant lack of lab capacity. Once this rule is implemented nationwide lab TAT will be even more strained. The EPA should consider the current backlog of lab resources when determining future lab capacity as effected by this proposed rule.

Page 18668, VI.A. First column first partial paragraph," sufficient laboratory capacity will be available with the MCLs set at 4.0 ppt; that demand will be sufficiently distributed during rule implementation to allow for laboratory capacity; and on the cost estimates related to these assumptions":

PBCWUD Comment: UCMRS is already putting a strain on lab capacity which will be increasingly affected by this proposed rule.

Page 18681, IX.A. Third column last paragraph, " feasibility of the proposed MCLs and more generally on laboratory capacity. As noted earlier, EPA anticipates laboratories will be able to adjust to demand (including possible price effects), which the Agency anticipates will be distributed across the implementation period":

PBCWUD Comment: Current lab TAT for some UCMRS analysis ranges from 45 to 80 days indicating there is already a significant lack of lab capacity. Once this rule is implemented nationwide lab TAT will be even more strained. The EPA should consider the current backlog of lab resources when determining future lab capacity as affected by this proposed rule.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Based on the EPA's experience in implementing previous UCMRs and NPDWRs, the agency expects the environmental laboratory community will continue to develop their capabilities for the PFAS drinking water analysis at the PQL as demonstrated in previous drinking water regulations (USEPA, 1999; USEPA, 2001).

Millie Garcia-Serrano (Doc. #1803, SBC-044289)

5. Analytical Laboratory Capacity: ASTSWMO anticipates an increase in sampling and analysis, warranting the need for sufficient analytical laboratory capacity to not only address the needs of the public water suppliers regulated under the SDWA, but also the needs of site discovery and cleanup programs managed under CERCLA, RCRA, and the States' cleanup programs, among others. ASTSWMO recommends further communication between EPA and certified state and commercial laboratories to ensure that capacity issues do not impact PFAS analysis and site remediation.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Laurens County Water and Sewer Commission (LCWSC) (Doc. #1805, SBC-043747)

Laboratory capacity is another compelling reason to delay this rulemaking. EPA tries to allay this concern by saying lab capacity will work itself out during rule implementation period. In a normal economic period, EPA may be correct that the lab services industry would build capacity after a couple of years to address the historic increase in testing services demand However, like most professions, the lab services sector is experiencing significant worker shortages that cannot be rectified in the near term. What EPA does not acknowledge is that the testing capacity simply is not there, particularly when considering the wastewater, biosolids, stormwater, and all other product and media PFAS-related testing that will be demanded in the years and decades to come.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045486)

In addition, during Advocacy's roundtable discussion on this proposed rule, a small entity representative stated that small systems will bear the brunt of limited laboratory capacity for foreseeable future due to high sample cost, long turnaround times, and diminishing access to quality laboratories.

EPA Response: The commenter does not provide supporting data regarding assertions that small systems will "bear the brunt of limited laboratory capacity for foreseeable future…" Funds are also available through the passage of the IIJA, also referred to as the BIL, to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging; please see section 2.4 of the EPA response in this *Response to Comments* document for more information on funding. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA

response in this *Response to Comments* document. Pertaining to the EPA's actions to fulfill requirements under the Regulatory Flexibility Act and consult with small entities, please see section XIII.C of the final rule preamble.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044683)

IX. Laboratory Capacity & Delay

Laboratory capacity is another compelling reason to delay this rulemaking. Although EPA discusses the growing analytical capabilities of laboratories, see 88 Fed. Reg. at 18667, the amount of PFAS lab work that will be needed once the rule is finalized cannot be overstated. This ignores the fact of existing delays today with PFAS lab analytical result turnaround times. Recently, the New Jersey Association of Environmental Authorities issued an RFP for PFAS lab services for its members and only one lab responded. Several others reported that they did not have the capacity.

EPA tries to allay this concern by saying lab capacity will work itself out during the rule implementation period. In a normal economic period, EPA may be correct that the lab services industry would build capacity after a couple of years to address the historic increase in testing services demand. However, like most professions, the lab services sector is experiencing historic worker shortages that can't be rectified in the near term. See 88 Fed. Reg. at 18667-68. ("The commercial market for PFAS analysis is likely to remain strong and, in fact, grow…"). What EPA does not acknowledge is that the testing capacity simply is not there, particularly when considering the wastewater, biosolids, stormwater, and all other product and media PFAS-related testing that will be demanded in the years and decades to come.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044661)

IX. Laboratory Capacity & Delay

Laboratory capacity is another compelling reason to delay this rulemaking. Although EPA discusses the growing analytical capabilities of laboratories, see 88 Fed. Reg. at 18667, the amount of PFAS lab work that will be needed once the rule is finalized cannot be overstated. This ignores the fact of existing delays today with PFAS lab analytical result turnaround times. Recently, the New Jersey Association of Environmental Authorities issued an RFP for PFAS lab services for its members and only one lab responded. Several others reported that they did not have the capacity.

EPA tries to allay this concern by saying lab capacity will work itself out during the rule implementation period. In a normal economic period, EPA may be correct that the lab services industry would build capacity after a couple of years to address the historic increase in testing

services demand. However, like most professions, the lab services sector is experiencing historic worker shortages that can't be rectified in the near term. See 88 Fed. Reg. at 18667-68. ("The commercial market for PFAS analysis is likely to remain strong and, in fact, grow…"). NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044639)

IX. Laboratory Capacity & Delay

Laboratory capacity is another compelling reason to delay this rulemaking. Although EPA discusses the growing analytical capabilities of laboratories, see 88 Fed. Reg. at 18667, the amount of PFAS lab work that will be needed once the rule is finalized cannot be overstated. This ignores the fact of existing delays today with PFAS lab analytical result turnaround times. Recently, the New Jersey Association of Environmental Authorities issued an RFP for PFAS lab services for its members and only one lab responded. Several others reported that they did not have the capacity.

EPA tries to allay this concern by saying lab capacity will work itself out during the rule implementation period. In a normal economic period, EPA may be correct that the lab services industry would build capacity after a couple of years to address the historic increase in testing services demand. However, like most professions, the lab services sector is experiencing historic worker shortages that can't be rectified in the near term. See 88 Fed. Reg. at 18667-68. ("The commercial market for PFAS analysis is likely to remain strong and, in fact, grow…"). What EPA does not acknowledge is that the testing capacity simply is not there, particularly when considering the wastewater, biosolids, stormwater, and all other product and media PFAS-related testing that will be demanded in the years and decades to come.

EPA Response: Please see the EPA response to comment Doc. #1816, SBC-044683 in section 5.1.2 in this *Response to Comments* document.

South Carolina Water Quality Association (Doc. #1819, SBC-044617)

IX. Laboratory Capacity & Delay

Laboratory capacity is another compelling reason to delay this rulemaking. Although EPA discusses the growing analytical capabilities of laboratories, see 88 Fed. Reg. at 18667, the amount of PFAS lab work that will be needed once the rule is finalized cannot be overstated. This ignores the fact of existing delays today with PFAS lab analytical result turnaround times. Recently, the New Jersey Association of Environmental Authorities issued an RFP for PFAS lab

services for its members and only one lab responded. Several others reported that they did not have the capacity.

EPA tries to allay this concern by saying lab capacity will work itself out during the rule implementation period. In a normal economic period, EPA may be correct that the lab services industry would build capacity after a couple of years to address the historic increase in testing services demand. However, like most professions, the lab services sector is experiencing historic worker shortages that can't be rectified in the near term. See 88 Fed. Reg. at 18667-68. What EPA does not acknowledge is that the testing capacity simply is not there, particularly when considering the wastewater, biosolids, stormwater, and all other product and media PFAS-related testing that will be demanded in the years and decades to come.

EPA Response: Please see the EPA response to comment Doc. #1816, SBC-044683 in section 5.1.2 in this *Response to Comments* document.

Mississippi Farm Bureau Federation (Doc. #1826, SBC-044269)

EPA should also consider the burden placed on the state regulato1y agencies, and the state chemical labs and ensure that they have the resources necessary to conduct a new testing program without significantly affecting other required testing programs.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Pennsylvania Municipal Authorities Association (Doc. #1832, SBC-045789)

[PMAA's specific comments on the Proposal are as follows:]

13. In Pennsylvania, a staggered monitoring program under the Commonwealth's PFAS Rule was developed to address concerns with laboratory availability and capacity. Similar laboratory issues could cause delays in the implementation of the Proposal's monitoring requirements, specifically as to the analysis of samples, and could significantly increase the costs to municipal entities to obtain compliance data required by the Proposal.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding the final rule's initial monitoring requirements and timing, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Corix Infrastructure Inc. (Doc. #1834, SBC-045368)

[With regards to the specific items EPA has requested comment on, Corix provides below:]

• With regards to the laboratory capacity being available, we note that the rule will overlap with the UCMR-5 requirements, putting more demand on labs to perform PFAS testing. Having challenges in finding laboratory ability recently, Corix assumes that EPA has worked with laboratories in developing plans to expand capacity for all water systems.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Citizens Energy Group (Doc. #1838, SBC-044858)

EPA requests comment on the underlying assumptions that sufficient laboratory capacity will be available with the proposed MCLs; that demand will be sufficiently distributed during rule implementation to allow for laboratory capacity; and on the cost estimates related to these assumptions.

Based on conversations with the commercial lab used by Citizens, we have been told that they are certifying additional lab facilities to the drinking water standards, which will improve the availability of labs certified to perform PFAS analysis in drinking water. However, as demand for PFAS analysis increases across the U.S., more and more water systems will rely on commercial labs creating an uncertainty with regards to total sample capacity. This increase in the demand for commercial lab analysis of PFAS compounds may lead to delays in receipt of analytical data, as most labs prioritize analysis in a "first in/first out" queue. Water systems should not be penalized if samples are collected in a timely manner and delivered to the certified lab, but backlogs in the lab result in delays in analysis and delivery of analytical results.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA notes that EPA Method 533 and EPA Method 537.1, ver. 2.0, require adherence to holding times for samples and extracts. Samples held beyond those prescriptive holding times would be considered invalid results.

San Gabriel Valley Water Association (Doc. #3072-87, SBC-047403)

Yes, my name is Karina Servantees, and I'm here on behalf of the San Gabriel Valley Water Association. We represent municipal and regulated utilities, special districts, and not-for-profit mutual water companies that supply water to nearly 2 million residents in the San Gabriel Valley of Los Angeles County, California. We share in many of the concerns highlighted today regarding the economic feasibility of the proposed MCL. Compliance with monitoring results is a concern due to transitions in the laboratory industry. California's new accreditation requirements have caused a significant decrease in the accessibility to public labs within the past two years, and commercial labs are unlikely to be able to meet the increased demand, leading to higher cost and limited access for water suppliers.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Marlene Ladderbush (Doc. #1612, SBC-042914)

EPA needs to address laboratory capacity issues before finalizing the rule. Certified labs have been challenged with analyzing the number of samples that Massachusetts PWS send them. PWS can wait upwards of three weeks for sample results and then our primacy agency, MassDEP, must perform quality assurance evaluations, which can take several more weeks. EPA should do as Massachusetts did, and phase in monitoring by PWS size to reduce the resource burden on the labs and primacy agencies who must review and verify the quality of the data.

EPA Response: Please see the EPA response to comment Doc. #1567, SBC-042731 in section 5.1.2 in this *Response to Comments* document.

Town of Tewksbury, Massachusetts (Doc. #1637, SBC-043244)

EPA needs to address laboratory capacity issues before finalizing the rule. Certified labs have been challenged with analyzing the number of samples that Massachusetts PWS send them. PWS can wait upwards of three weeks for sample results and then our primacy agency, MassDEP, must perform quality assurance evaluations, which can take several more weeks. EPA should do as Massachusetts did, and phase in monitoring by PWS size to reduce the resource burden on the labs and primacy agencies who must review and verify the quality of the data.

EPA Response: Please see the EPA response to comment Doc. #1567, SBC-042731 in section 5.1.2 in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043268)

The laboratory capacity needed to test samples represents another challenge. The list of laboratories approved by EPA [Link: https://www.epa.gov/dwucmr/list-laboratories-approved-epa-fifth-unregulated-contaminant-monitoring-rule-ucmr-5] for the Fifth Unregulated Contaminant Rule (UCMR5) is around 60 nationwide. Many states do not have a lab that is certified. It is assumed additional labs will seek certification and this number will increase but steps will need to be taken by EPA to incentivize these labs and create a streamlined approval process to meet demand.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043300)

Additionally, APHL has significant concerns that the national testing needs are underestimated and that there will be insufficient analytical capability and capacity without investment in laboratory infrastructure related to the addition of skilled analysts, acquisition of dedicated laboratory instrumentation (LC/MS, LC/MS/MS), training of laboratory scientists on the new technology and PFAS drinking water methodology and informatics solutions to support the proposed reporting requirements. We also anticipate additional and repeat testing will result from decreased method ruggedness at or near the proposed MCLs and PQLs and heightened public awareness of contamination. It will be a challenge for the commercial market to meet these demands.

APHL believes that establishing a small, coordinated laboratory network of state laboratories, Centers of Emerging Contaminants Testing, which work collaboratively with EPA programs and laboratories, would provide additional analytical expertise to transfer the technology to high-throughput laboratories quickly. This would be accomplished through investment in state laboratory infrastructure to acquire and maintain the necessary instrumentation, staffing, and supplies and by leveraging the existing expertise of the network to facilitate laboratory training

for PFAS and other emergent contaminants in water and other matrices. Modeled on existing, effective laboratory systems, The Centers of Emerging Contaminants Testing would provide dedicated resources available to refine, extend and validate analytical methods, expedite technology transfer through developing and delivering critical analytical training, and provide technical assistance to higher through-put laboratories. Without the burden of turning a profit, the network laboratories would have the dedicated resources to assist in increasing national capacity for quality PFAS measurements in support of the proposed regulations.

Thank you for the opportunity to comment. APHL welcomes any follow-up; please contact Julianne Nassif, Environmental Health Director, at Julianne.Nassif@aphl.org or 240.485.2737.

Sincerely,

Daphne Ware, Ph.D.

President, Board of Directors

Association of Public Health Laboratories Director, Missouri State Laboratory

Peter Kyriacopoulos

Chief, Public Policy Officer

Association of Public Health Laboratories

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding the commenter's suggestion for the establishment of a coordinated laboratory network, the agency intends to provide support to utilities, primacy agencies, and other interested parties after finalization of the PFAS NPDWR to ensure successful rule implementation and will consider the issues suggested by the commenter. The EPA further notes that many of the issues suggested by the commenter (such as refine, extend and validate analytical methods, provide technical assistance, or training of laboratory certification officers) are activities that the EPA is already engaged in and perform on a regular basis.

<u>New England Interstate Water Pollution Control Commission (NEIWPCC) (Doc. #1650, SBC-043145)</u>

Lab Capacity

Once finalized, water suppliers will have three years to implement the required monitoring and reporting, and extensions of up to an additional two years may be authorized by EPA on a case-by-case basis. In Section IX. Monitoring and Compliance of the proposed rule, EPA states that there are currently 54 laboratories certified to analyze PFOA and PFOS to the quantification limits of 4.0 ppt using EPA Method 533, and a "significant number of laboratories" expressing

"strong interest" in gaining such approval. Our member states are concerned that adequate laboratory capacity to implement the rule does not already exist, and it is not assured.

There are currently more than 148,000 public water systems in the United States, [FN3: EPA, 2022 (https://www.epa.gov/dwreginfo/information-about-public-water-systems)] over 16,000 of which are located in the Northeast. Currently, there are just five certified laboratories in the Northeast capable of analyzing PFAS. [FN4: EPA, Office of Water, 2023 (https://www.epa.gov/system/files/documents/2022-01/ucmr5-approved-lab-list.pdf)] In addition there are State-labs that analyze PFAS without UCMR5-certification. [FN5: https://health.ri.gov/programs/detail.php?pgm_id=1089] While these labs may assist with screening activities, analysis from a certified lab is required for public water systems.

Even after accounting for the use of existing PFAS monitoring data to meet the initial monitoring requirements of the rule, our member states anticipate a shortage of available laboratory capacity. This shortage could be further exacerbated by each states' analytical protocols. For example, some of our member states currently require duplicate sampling which increases the demand for services.

In Section IX. Monitoring and Compliance, EPA states, "[S]ystems with previously acquired data from outside UCMR 5, including State-led or other appropriate occurrence monitoring using EPA methods 533 or 537.1 will also not be required to conduct initial monitoring for regulated PFAS." This provision was included to reduce the burden on certified laboratories during the initial implementation period. However, the state-led monitoring programs vary significantly in design and implementation. We urge EPA to take into consideration whether the existing state strategies are sufficient to comply with the rule, as these state strategies could further contribute to laboratory demand if not.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA clarifies for the commenter that not all PWSs estimated by the commenter, i.e., "148,000 are subject to the final rule's monitoring requirements." Rather, EPA estimates that approximately 67,000 community water systems (CWSs) and non-transient non-community water systems (NTNCWSs) are subject to the monitoring requirements. The EPA acknowledges in the final rule that while it is allowing use of previously collected data to satisfy the final rule's initial monitoring requirements, not all systems will have some or all of this data available. However, the agency maintains that this allowance will significantly reduce monitoring burden for many water systems and allows any eligible data to be used and then supplemented with newer monitoring to meet the full requirement. Please see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document regarding the rule initial monitoring requirements and use of previously collected data.

NCASI (Doc. #1651, SBC-043226)

In addition to the inability to operationalize a risk management plan when action levels exist below the PQL, there may not be adequate laboratory capacity to accommodate the enormous amount of testing across the country that would be required under this proposed rulemaking. The PQLs described by EPA are achieved by cutting edge technology and may not be considered standard instrumentation across commercial laboratories. Additionally, laboratories with PFAS analytical capabilities are already receiving increased demand for NPDES permit compliance testing, as well as for testing for remediation projects. If MCL concentrations are promulgated that are reasonably above the PQL, it will broaden the accessibility of robust analytical evaluation for risk management, which would increase the feasibility of operationalizing risk management of drinking water under PFAS MCLs.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. As described above in the agency's approach toward evaluating feasibility, the EPA assesses (1) the availability of analytical methods to reliably quantify levels of the contaminants in drinking water and (2) the lowest levels at which contaminants can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions using the approved methods (i.e., the PQLs). This framework inherently considers both the capacity and capability of labs available to meet the requirements of the NPDWR.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043169)

Second, there is currently a well-known shortage of laboratory capacity for PFAS testing. VMDWA Members report 2-3 month delays in received test results pre-MCL. Upcoming UCMR5 and MCL testing mandates will exacerbate the current shortage. VMDWA expects test availability and turnaround times will get worse before they get better. Testing is the first step in the process and it appears destined for delays until a sufficient number of new labs to support the national program can be funded, permitted, constructed, staffed, and certified, assuming no backorders or supply chain issues exist for analytical instruments and consumables (e.g., reagents, etc.).

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please

see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043404)

Second, there is currently a well-known shortage of laboratory capacity for PFAS testing. MAMWA Members report 2-3 month delays in received test results pre-MCL. Upcoming UCMR5 and MCL testing mandates will exacerbate the current shortage. MAMWA expects test availability and turnaround times will get worse before they get better. Testing is the first step in the process, and it appears destined for delays until a sufficient number of new labs to support the national program can be funded, permitted, constructed, staffed, and certified, assuming no backorders or supply chain issues exist for analytical instruments and consumables (e.g., reagents, etc.).

EPA Response: Please see the EPA response to comment Doc. #1657, SBC-043169 in section 5.1.2 in this *Response to Comments* document.

National Association of Clean Water Agencies (NACWA) (Doc. #1659, SBC-043155)

EPA Failed to Consider Laboratory Capacity

With an increased regulatory focus on PFAS, interest has grown in understanding where these chemicals are in the environment and in what concentrations. However, laboratory capacity for EPA's approved PFAS analytical methods has not caught up with the sheer demand to investigate PFAS sources. With limited laboratories currently available to provide PFAS analysis, a significant backlog is already occurring often resulting in utilities waiting six or more weeks to receive results which can exceed permit reporting deadlines.

NACWA has serious concerns that when this rule goes into effect, there will be nearly 66,000 PWSs newly and simultaneously seeking limited laboratory analysis, further straining laboratories and creating longer wait periods for analysis and results. The demand could also significantly raise costs, which already range from around $300 to $600 per sample. On the CWA side, EPA also continues to urge states to incorporate quarterly monitoring into National Pollutant Discharge Elimination System (NPDES) permits and require utilities to routinely sample their influent, effluent, and biosolids. The federal and state regulatory push for the water sector to quantify PFAS concentrations absent the necessary laboratory capacity to do this type of sensitive chemical analysis will present a significant problem for PWSs and clean water utilities alike that need to meet legally enforceable compliance deadlines in a timely manner.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenters' assumption that all water systems subject to the rule's

monitoring requirements will be required to conduct new initial monitoring sampling. Moreover, many water systems will be eligible to utilize previously collected data to satisfy some or all of these requirements. Please see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document regarding the rule's initial monitoring requirements and use of previously collected data to satisfy these monitoring requirements.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045035)

Laboratory Capacity

The EPA seeks comment on laboratory capacity to meet the monitoring requirements of its proposal. NJDEP believes that laboratory capacity has been sufficient for the limited number of states that are requiring PFAS testing in drinking water so far. However, as states across the nation implement the proposed drinking water standards, this capacity will be strained. As of May 22, 2023, 26 laboratories are certified by NJDEP's Office of Quality Assurance to analyze for PFAS using EPA Method 537.1 and 13 laboratories are certified for EPA Method 533. A majority of these laboratories (22) are located outside of New Jersey. Once the proposed rules are implemented, New Jersey water systems will be competing with systems from across the nation for access to these laboratories.

It is reasonable to believe that laboratory capacity will increase after promulgation of these proposed NPDWRs. This was the case in New Jersey after the adoption of its PFAS MCLs. However, it is important for EPA to consider the time it will take for laboratories to purchase equipment, train staff, and obtain certification, as necessary, and to coordinate with public water systems to ensure samples are collected and reported in accordance with proposed requirements, thus, avoiding monitoring violations.

The EPA should consider that testing for matrices other than drinking water may also increase soon. This could be because of investigations into potential sources impacting public water systems, increased testing for contaminated site cleanups, or for evaluating impacts to wastewater systems, and may affect the laboratory capacity for all samples overall, as the same universe of laboratories conduct these analyses in all matrices. While demand will be distributed over three years, it may take that much time or more for certified laboratories that can handle both drinking water samples and other matrices to meet analytical demands in a timely manner.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044759)

9. EPA Should Reevaluate Monitoring and Laboratory Analysis Capacity Impacts

According to the EPA's website, as of May 2023, only 53 UCMR 5 certified laboratories are capable of reaching EPA standards for UCMR 5 approved Analytical Methods 533 and 537.1. With over 70,000 PWSs across the United States anticipated to begin requiring analysis for regulated PFAS under the proposed PFAS NPDW rule, the demand placed on these laboratories will be tremendous. The method requirements for storage, temperature, and timelines to analyze make feasibility questionable given the anticipated demand. If demand outstrips the supply, the cost of the testing will increase.

WDEQ recommends EPA reevaluate its feasibility assessment of laboratory capacity in meeting the anticipated increased sample load.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenters' assumption that all water systems subject to the rule's monitoring requirements will be required to conduct new initial monitoring sampling. Moreover, many water systems will be eligible to utilize previously collected data to satisfy some or all of these requirements. Please see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document regarding the rule's initial monitoring requirements and use of previously collected data to satisfy these monitoring requirements.

Louisville Water Company (Doc. #1720, SBC-043555)

[In that regard, we are providing the following comments on key issues that we think require consideration.]

5. EPA has requested comment on the underlying assumptions that sufficient laboratory capacity will be available to implement the proposed rule. Our experience leads to concerns over the ability of certified labs to reliably process in an affordable manner the number of samples this rule will require, in addition to the samples utilities will generate for research and operational control purposes. UCMR5 presents an opportunity to assess nationwide lab capacity. Louisville Water recommends the agency consider holding off on finalizing the rule to make this assessment from UCMR5 metadata and then take the appropriate course of action.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding UCMR 5, please see sections 3.1.2 and 6.8 of the EPA response in this *Response to Comments* document.

Wisconsin Department of Natural Resources (Doc. #1828, SBC-044803)

Laboratory Capacity

WDNR recommends that EPA address anticipated laboratory capacity issues ahead of finalizing this PFAS rule. While WDNR notes that private labs will have three years to prepare and install instruments for PFAS analyses, the number of interested labs and interest in PFAS analyses should be assessed prior to rule implementation. Laboratories may not be interested in the large investment that would be necessary to establish PFAS analysis capability. Also, the limited PFAS monitoring frequency after initial monitoring requirements makes such an investment financially risky for smaller labs.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043884)

An additional issue raised during the comment period for Pennsylvania's PFAS drinking water MCL rule was the availability and capacity of accredited laboratories that could perform the testing. While some commenters may raise the issue with the proposed federal regulation, the schedule suggested in the NPDWR renders these objections invalid: The largest need for tests will take place during the initial period (12 months) of the proposed NPDWR, when quarterly or twice annual tests will need to be conducted by all PWSs (depending on the size of the population served). Following this initial period, compliance monitoring frequency will be reduced to once or twice every three years for the approximately 40% systems with PFAS below the trigger levels [FN67: 88 Fed. Reg. 18671–80. Note that the number of exempt systems may be higher since some of the studies used to identify the prevalence of PFAS in drinking water concentrated on areas where PFAS contamination was suspected. An example is Pennsylvania's sampling of PFAS in drinking water. 53 Pa.B. 533; Full PA Sampling Data]. EPA intends to alleviate the test load during the initial testing period by accepting data that was previously acquired. Therefore, PWSs in states where testing has already been conducted as part of a PFAS drinking water regulation (e.g. MA, MI, NY, NJ, NH, ME, PA) would not need to perform any additional tests. Testing of potentially contaminated PWSs finished water is also required in some states where no MCLs for drinking water have been set as yet (e.g. CA [FN68: Cal. Water Res. Control Bd., Section on PFAS, Drinking Water Resources, https://www.waterboards.ca.gov/pfas/drinking_water.html (last updated Mar. 1, 2023).]). Thus, a large number of PWSs will be able to present their previously acquired test data, receive exemptions, and then adopt the less frequent testing schedule. Reducing the total amount of testing needed across the nation increases the testing capacity available to PWSs in states that have not yet conducted testing because a PWS may send its samples to any accredited laboratory in the nation.

EPA Response: For additional discussion regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For the EPA's response related to use of previously collected data to satisfy the rule's initial monitoring requirements, please see section 8.3 of the EPA response in this *Response to Comments* document. For EPA's response related to initial monitoring requirements and timing, please see section 8.1.1 of the EPA response in this *Response to Comments* document. EPA clarifies for the commenter that the initial monitoring is required to occur in the 3 years following rule promulgation, not 12 months following rule promulgation.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043088)

If this data is required to be collected and used to drive decision-making, it will also lead to a higher demand for laboratories that are able to analyze samples with a greater degree of accuracy to these lower levels to minimize the risks of inaccurately higher sample results from interferences and other technical challenges. Increased demand for these laboratories will contribute to higher lead times, costs, and higher frequency of sample analysis errors. This will negatively impact smaller systems with less financial capacity to access these laboratories, creating inequitable access to nationally reliable sample analysis.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044892)

o EPA has noted an assumption that the demand for increased monitoring will trigger an increase in overall lab capacity because more labs will seek certification/accreditation in more states. However, DEP notes the significant expense of adding capacity for PFAS analysis for a laboratory. DEP estimates a total initial cost of over $542,000 to add PFAS analytical capacity, broken down as follows:

[Table 2: See Docket ID: EPA-HQ-OW-2022-0114-1626]

EPA Response: The EPA acknowledges the cost for analytical capacity submitted by the commenter. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding the rule's cost estimates, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044085)

The number of laboratories that will be capable of analyzing for PFAS in time to meet the new rule compliance demands is still uncertain. The volume and number of samples that water systems will need to be analyzed based on expected occurrence and sampling frequency will likely exceed laboratory capacity for all laboratories and each laboratory individually. Laboratory capacity is a significant feasibility concern that should be further analyzed. Some primacy agencies have noted impacts on their laboratory capacity due to limited suppliers for PFAS standard reagents. Primacy agencies have also reported that laboratories have had to modify sample bottle lids to fit their auto extractors, where the standard bottles and lids are incompatible.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044944)

6. The Department notes that EPA has historically recognized that the precision and accuracy of analytical results are sacrificed as reporting limits are set closer to method detection limits (MDL). EPA has historically used the reduction in health risk as justification for the sacrifice in analytical precision and accuracy, though only three other organic contaminants that are regulated through NPDWR have MCLs at a similar multiple of the MDL proposed for PFOA and PFOS.

In addition, EPA has in the past highlighted vulnerability assessments and the availability of monitoring waivers to respond to concerns about laboratory proficiency and, therefore, laboratory capacity when MCLs are established at such low levels. We posit that in this case the concerns about laboratory capacity are consistent with similar concerns raised in the past, but that the relief afforded by waivers may not be available to offset the burden under the proposed rule.

EPA Response: The final MCLs for PFOA and PFOS are set at the PQLs; please see the section 5.1.2 of the EPA response in this *Response to Comments* document for additional discussion on PQLs and how they were set for the final NPDWR. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels for reduced triennial monitoring and monitoring waivers, please see sections 8.8 and 8.5, respectively, of the EPA response in this *Response to Comments* document.

New York City Department of Environmental Protection (NYCDEP) (Doc. #1679, SBC-044212)

In section IX.A., p. 18681, EPA requests comment on feasibility of the proposed MCLs and on laboratory capacity. EPA has recognized the challenging nature of this testing and expects the lab community to adapt. There are very few labs currently capable of producing data that meet the Data Quality Objectives required for this monitoring, and those are likely to be overwhelmed with new work. While those few labs that possess the resources to increase capacity will do so, the barriers to developing this complex testing will likely prevent more labs from entering the pool of labs. As a result of a lack of competition, this testing will continue to be expensive relative to other laboratory tests. The current price for each test by Methods 533 or 537.1 is between $550 and $600, which is almost double the amount shown in Table 34 (p. 18698).

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding the rule's monitoring cost estimates, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Metropolitan Water District of Southern California (Doc. #1777, SBC-045432)

While EPA intends to have a trigger level that is more protective in the long run, it may not be feasible without a reliable analytical method. In addition, lab capacity may also be an issue, particularly the availability of labs that can reliably measure at such low concentrations. This is especially a concern in California, where accredited state labs have decreased from 626 to 475, or nearly 25%. [FN12: California State Water Resources Control Board's 2023-24 Environmental Laboratory Accreditation Program fees workshop on March 10, 2023.] Also, EPA has approved only 53 laboratories to analyze UCMR 5 PFAS samples by EPA Method 533 and/or EPA Method 537.1. [FN13: https://www.epa.gov/system/files/documents/2022-01/ucmr5-approved-lab-list.pdf.] Of those laboratories, 7 do not offer commercial services. [FN14: Id.] It is unclear if EPA has considered this fact in its feasibility analysis.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding the rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-042534)

Additionally, the Department believes that it is a mistake to set a MCL at or near the PQL when a PQL has a ±50% Method QA/QC acceptance level. As additional research on toxicity and lab analytical ability improves, EPA will have the opportunity during six year reviews to possibly

lower MCL and/or PQL in the future. Until then, the Department believes that a PQL of 4 ppt with a MCL of at least 9 ppt is feasible and appropriate.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1677, SBC-044955 in section 5.1.2 in this *Response to Comments* document for commenter claims on the 30 percent - 50 percent acceptance criteria in the reported result.

Missouri Department of Natural Resources (Doc. #1563, SBC-042521)

Section VI—Maximum Contaminant Level

EPA requests comment on its proposed determination to set MCLs at 4.0 ppt for PFOA and PFOS and whether 4.0 ppt is the lowest PQL that can be achieved by laboratories nationwide. EPA requests comment on implementation challenges and considerations for setting the MCL at the PQLs for PFOA and PFOS, including on the costs and benefits related to this approach. EPA requests comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the HI PFAS (PFHxS, HFPO–DA, PFNA, and PFBS), specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS. EPA also requests comment other monitoring flexibilities identified by commenters.

As described in the UCMR 5 Laboratory Approval Manual (Version 2.0 December 2021), the decision to have a PFOA and PFOS calculated minimum reporting level (MRL), also known as the lowest PQL, at 0.0040 µg/L (4.0 ppt) was based on a minimum of 3 LCMRL values from the participating laboratories. It appears from Appendix B this may have been done using only eight laboratories nationwide. While some states have reported using a lab that has the ability to reach near 2.0 ppt minimum reporting levels, not all labs are able to reach this MRL/PQL. Given such a small sample set from the UCMR 5 Laboratory Approval Manual, and the timing of this action being before the completion of UCMR 5, it seems premature to assume laboratories nationwide can achieve a lower result than 4.0 ppt. To do so, and be incorrect in the assumption, is setting up states to have lab capacity issues upon implementation of the rule.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. All UCMR 5 approved laboratories measuring for PFAS

were required to confirm that they could meet the UCMR 5 MRL using the MRL Confirmation procedures listed in EPA Methods 537.1, ver. 2.0 and 533. In other words, for UCMR 5, all UCMR-approved laboratories were able to meet or exceed the PFOS and PFOA UCMR MRLs, set at 4 ng/L. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042732)

Source Water and Analytical Variability:

Through the years of sampling that has been conducted by PWS, it is not uncommon for different labs to report a difference of several parts per trillion +/- in PFAS when analyzing the exact same source water. We question whether we are pushing the sensitivity of the equipment to a point where it cannot be reliably quantified. A sample is considered valid at +/-30%, when discussing regulatory compliance levels in the low parts per trillion, this is concerning. As a point of illustration, the following are split sample results for a utility in Massachusetts. The sample date was 12/11/2020, lab A's result was 12.7 ppt, while lab B's result was 20.56 – both were valid results, yet the swing was 7.86 ppt. This analytical variability is well over what EPA proposes as the MCL so PWS could be subject to noncompliance and enforcement due to analytical variability alone.

Some PWS have seen +/- parts per trillion variability in PFOS and PFOA concentrations when collecting monthly samples; even a 1-2 ppt variation can represent over 40% variability when close to the MDL. It is difficult to tell if this variability is attributable to changes of PFOS and PFOA concentrations in the source water or if it is linked to the variability of the analytical method (+/- 30%). Having a proposed Rule Trigger Level of 1/3, the PFOS and PFOA MCL or HI may have PWS and primacy agencies fluctuating back and forth on whether the PWS is eligible for a monitoring waiver and may impact the running annual average calculation. This uncertainty creates unnecessary complexity, increased level of effort, and continued erosion of public confidence.

We are also aware of several instances where it was found that lab instrumentation was not properly cleaned between sample runs, resulting in erroneous detections. It is paramount that labs are not doing cross matrix analysis on machines that analyze drinking water samples.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1677, SBC-044955 in section 5.1.2 in this *Response to Comments* document for commenter claims on the 30 percent - 50 percent acceptance criteria in the reported result. The EPA further notes that neither methods 533 nor 537.1 v2 have inherent QC issues when explicitly followed. Regarding laboratory or background contamination considerations, please see section 8.7 of the EPA response in this *Response to Comments*

document. For discussion of rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

COMM Water Department (Doc. #1577, SBC-042434)

COMM Water Department •Our experience in Massachusetts has shown that there can be a wide range in results when different labs analyze the same source water. PWS professionals question whether we are pushing the sensitivity of the equipment to a point where it cannot be reliably quantified. A sample is considered valid at +/-30%, when discussing regulatory compliance, or Maximum Contaminant Levels (MCL), in the low parts per trillion, this is concerning.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1677, SBC-044955 in section 5.1.2 in this *Response to Comments* document for commenter claims on the 30 percent - 50 percent acceptance criteria in the reported result.

New York Section American Water Works Association (NYSAWWA) (Doc. #1591, SBC-042368)

We are concerned that there are an inadequate numbers of labs with the capability to reliably report below 4 ppt, and feel strongly that this should not be a driver for regulatory framework.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding the EPA's rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Minnesota Department of Health (MDH) (Doc. #1610, SBC-042851)

• Based on our experience with laboratories already confidently achieving RLs below 4 ppt and information from our Public Health Laboratory (PHL) and the Environmental Monitoring Coalition (EMC), it appears that 4 ppt is currently not "the lowest concentration of analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory conditions."

o MDH's PHL already has attained reporting limits (RLs), or limits of quantification (LOQ), for EPA Method 533 that are below 4 ppt – current RLs for all analytes are 1.6-1.8 ppt. MDH has also contracted with other laboratories for PFAS analysis, who are also currently attaining RLs between 1.8-2 ppt. Therefore, MDH is already receiving results without any "J-flagged" qualifiers for both PFOS and PFOA that are below 4 ppt.

o The Minnesota Environmental Laboratory Accreditation Program (MNELAP), a NELAC accreditation body, asked its accredited laboratories for RL data pertaining to EPA Methods 533 and 537.1. Of the 13 laboratories MNELAP queried, seven responded; six stating their RL was 2 ppt for the six applicable analytes while one has a RL of 1 ppt.

o MDH reviewed comments from the Environmental Monitoring Coalition (EMC), which stated that "most laboratories set the PQL as their MRL equal to the low calibration point which in Method 533 is 2 ng/L."

o In the future, more laboratories will be able to achieve lower RLs, but this proposed rule is not flexible with regard to future laboratory capabilities.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees that the final NPDWR "is not flexible with regard to future laboratory capabilities." Under SDWA, EPA is required to review NPDWRs at least once every six years and, if appropriate, revise them (i.e., the Six-Year Review Process). This evaluation considers any newly available data, information and technologies to determine if any regulatory revisions are needed to maintain or strengthen public health protection. This process allows the agency to consider future laboratory capability and other information in deciding whether existing NPDWRs should be identified as candidates for revision as required by SDWA.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043043)

Additionally, the MCL being at the current detection limit of lab instrumentation requires a level of accuracy and precision that is not consistently attainable.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044052)

b. It is possible that some laboratories do not even have the report-generating capabilities to provide data for both the RL (PQL) and the MDL.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. A certified laboratory must be able to report results at or below the MCL or Hazard Index MCL. If a laboratory is required to provide multiple results, then they will need to have those report-generating capabilities. EPA further notes that using data submitted as part of the UCMR 5 LAP

as a reference point, the EPA notes that 47 of 53 laboratories (89 percent) that applied for UCMR 5 approval generated a MRL confirmation at 2 ng/L (one-half the proposed MCL) or less for Method 533. This suggests the majority of laboratories with the necessary instrumentation to support PFAS monitoring have the capability to provide screening measurement results at the revised trigger level of one-half of the MCL. This corresponds with commenters that provided their experience that laboratories are capable of reliably quantifying values below the PQLs, particularly to 2.0 ng/L for PFOA and PFOS. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043105)

With the appropriate investment in laboratories (staffing, instrumentation, platform and method training), the laboratory community is confident they can meet the technical requirements for the testing to support drinking water utilities in their efforts to monitor PFAS.

EPA Response: The commenter supports the EPA's feasibility considerations in the final NPDWR as it relates to laboratory capability. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044894)

Even if labs make the above investment to seek to add capacity for PFAS analysis, there is no guarantee that the lab will be able to meet the extremely low reporting levels required by this proposed rule. If a lab is not able to meet the trigger level of one-third of the PQL for reporting, water systems will not be able to reduce their burden of monitoring frequency and will likely seek the services of a lab that can meet those lower reporting levels. This will likely further discourage labs from adding analysis capacity.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. The commenter did not present evidence to support the assertion water systems will seek the services of a lab that can meet lower reporting limits and that this will "further discourage labs from adding analysis capacity."

Water One - Water District No. 1 of Johnson County, Kansas (Doc. #1627, SBC-042326)

Laboratory

The proposed Maximum Containment Levels (MCLs) of 4 parts per trillion (ppt) for PFAS is not based on sound science and is below detection limits of the EPA approved analytical methods originating from data collected for the PFAS compounds during UCMR 3. The analytical method that can achieve detection of these compounds at the proposed levels only became approved in

2020 and is just now being used in UCMR 5. There are a limited number of commercial laboratories with the capability to perform the analysis resulting in minimum turnaround times of 1-2 months that will be exacerbated when quarterly testing becomes required. Running this test internally, at our NELAC certified laboratory, would be a large investment ($500,000 or more) without a direct Return on Investment and likely take a year or more to become certified. Again, it should be reiterated that the proposed methodologies and regulation are premature and the laboratory infrastructure is not yet established to support this proposed rule.

Analyzing any compound at the part per trillion level is complicated at best and assigning health risks at values that low is even more challenging. Moreover, the risk of contaminated samples and analytical errors are extremely high at those levels. From a water utility perspective, those numbers are essentially zero as far as the public is concerned and other contaminant MCLs become more difficult to explain to the public.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The commenter incorrectly cites that the proposed and final MCLs for PFOA and PFOS are below detection limits of the EPA approved analytical methods as they are instead equivalent to their PQLs which are distinctly different and significantly higher from the limits of detection. Regarding background contamination concerns, please see section 9.7 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044088)

Some primacy agencies have noted that the variation in sampling results at or near the PQL means that 25% or more of laboratories cannot meet below 4.0 ppt with a 95% confidence interval. This issue must be addressed before the final rule if EPA intends to maintain the proposed MCL of 4.0 ppt. Additionally, ASDWA's members have reported that some do not have state laboratories that can analyze PFAS samples, and even those with the capability do not necessarily analyze samples from water systems. Finally, since not all laboratories can provide results below 4.0 ppt, ASDWA's members anticipate a large influx of requests to those laboratories that can obtain results a lot lower than 4.0 ppt in order for systems to qualify for reduced monitoring. This will further strain laboratory capacity.

EPA Response: The EPA does not expect all laboratories to provide results below 4.0 ppt and disagrees that there is insufficient laboratory capacity at this time to support implementation of the NPDWR. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs

to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043302)

With the appropriate investment in laboratories (staffing, instrumentation, platform and method training), the laboratory community is confident they can meet the technical requirements for the testing to support drinking water utilities in their efforts to monitor PFAS.

EPA Response: The commenter supports the EPA's feasibility consideration in the final NPDWR as it relates to laboratory capability. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Association of California Water Agencies (ACWA) (Doc. #1675, SBC-044936)

EPA states that "while EPA anticipates potential laboratory capacity issues if the Agency were to propose MCLs below 4.0 ppt, EPA believes there will be sufficient laboratory capacity with the MCLs set at 4.0 ppt." [FN29: 88 Fed. Reg. at 18,667.] ACWA disagrees with this belief and is concerned that there is already insufficient laboratory capacity. For example, during the California State Water Resources Control Board's (SWRCB's) recent 2023-24 Environmental Laboratory Accreditation Program fees workshop on March 10, 2023, and in e-mails afterward, SWRCB staff confirmed there had been a decrease of accredited state labs in California from 626 to 475, or nearly 25%.

EPA acknowledges this reality when it stated that "rigorous laboratory certification and quality assurance/ quality control procedures could limit the number of laboratories that can achieve lower quantitation levels and many water systems would not be able to secure the services of laboratories that are capable of consistently providing precise and accurate quantitation of concentrations of PFOA and PFOS at levels lower than 4.0 ppt." [FN30: 88 Fed. Reg. at 18.667.]

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Rockbridge Area Conservation Council (RACC) (Doc. #1678, SBC-043741)

EPA's rational for selecting the 4 ppt MCL levels for these chemicals may be a practical acknowledgement of the current inadequate analytical reality, however, it does not justify them toxicologically, nor does it 1) establish a timeline for EPA-certified commercial labs to improve their detection and quantification capabilities toward those commonly available in university and industry research labs – or 2) establish a parallel automatic adoption of the lower limits of quantification as MCLs. Both are needed to create the incentives for improving the degree of

protection of public health through investment in better lab technology and eliminate the undue burden on the Agency to repeatedly promulgate new MCL's for the same PFAS as those improvements are realized.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. The agency disagrees that establishing a "parallel automatic adoption of the lower limits of quantification as MCLs" is needed to improve public health protection. Under SDWA, EPA is required to review NPDWRs at least once every six years and, if appropriate, revise them (i.e., the Six-Year Review Process). This evaluation considers any newly available data, information and technologies to determine if any regulatory revisions are needed to maintain or strengthen public health protection. This process allows the agency to consider future improved laboratory capability and other information in deciding whether existing NPDWRs should be identified as candidates for revision as required by SDWA.

Private Citizen – General (Doc. #1722, SBC-043833)

2. Please pass the MCLGs as MCLs for PFAS chemicals. Labs can detect them much lower than 4 parts per trillion. For decades we have been exposed to these chemicals without our knowledge and we do not want to assume any additional risk - as scientists have been saying, there is no safe level of PFAS exposure.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Please also see section 5.1.3 of the EPA response in this *Response to Comments* document on alternative MCLs which includes a discussion on a lower MCL alternative.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043589)

8. On page 18,667, the document addresses laboratories. We had issues with laboratories not having the capability to adequately and accurately test the Washington State SAL level, let alone the very low MCL levels being considered by the EPA. Our utility had to send samples out-of-state for testing because there was not a lab available in Washington State that could test our samples. Not every laboratory applied to participate in UCMR5.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043585)

4. Please consider short-term and long-term solutions for insufficient laboratory capability and capacity. This rule could cause laboratories to be overburdened when the rule becomes effective and when initial monitoring requirements trigger quarterly monitoring.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045216)

Lab Methods & Capacity

1. EPA requests comment on its proposed determination to set MCLs at 4.0 ppt for PFOA and PFOS and whether 4.0 ppt is the lowest Practical Quantification Level (PQL) that can be achieved by laboratories nationwide.

Of the ten laboratories that the CT DPH Environmental Laboratory Certification Program (ELCP) currently has certified for EPA method 533, seven have calibrations established at concentrations less than 1.0 ppt, and the other three have calibrations established at 2.0 ppt. However, the current levels are being demonstrated on brand new equipment. At this time, it is difficult to determine if instrument sensitivity will decrease over time and if labs will have difficulty meeting these low levels in the future. However, setting the Maximum Contaminant Level (MCL) at the PQL limits the ability for PWSs to accurately monitor the annual running average of PFAS if the concentrations fluctuate near the MCL.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document.

El Paso Water (Doc. #1757, SBC-044522)

Further, there are very few laboratories that currently have the capability to test at the new levels. In the state of Texas, we only have knowledge of one laboratory that can perform this testing. That could result in a monopoly situation, sky-high prices, and back-logs that create compliance challenges.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045688)

b. Testing Methods Do Not Provide the Analytical Capacity to Identify or Distinguish Between the Ultra-low Levels at Issue in the Proposed Rule

The proposed MCLs for PFOA and PFOS are set at the practical quantitation level (PQL) of 4.0 ng/L and EPA proposes setting a rule trigger level of one-third the MCL to determine compliance monitoring frequency (USEPA 2023f, p. 18681). The PQL is defined as "the lowest concentration that PFOA and PFOS can be reliably quantified" (USEPA 2023f, p. 18666). By definition, measurement results less than the PQL are not reliably quantified and therefore not suitable for quantitative comparison against a standard. EPA notes that most of the laboratories seeking UCMR 5 approval included a calibration standard below the 4.0 ng/L PQL, while also noting that, "measuring PFOA and PFOS results below the PQLs may not be achievable from all laboratories" (USEPA 2023f, p. 18867). EPA also assumes the laboratory market for PFAS analyses will expand (USEPA 2023f, p. 18867). It is not safe to assume that as the market grows, new laboratories will have the same proficiency as existing experienced laboratories that already may not be able to measure below the PQL.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. Results below the PQL are only used in the determination of monitoring frequency and not compliance calculations. Additionally, as it was incompletely cited by the commenter, the EPA further clarifies that the PQL is defined as "the lowest levels at which contaminants can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions using the approved methods." For the purposes of determining whether a system can reduce their monitoring frequency, the values do not need the same level of precision and accuracy. Please see sections 8.2 and 8.8 of the EPA response in this *Response to Comments* document regarding the compliance calculation and rule trigger levels, respectively. The commenter also did not provide data or rationale to support their claims that "it is not safe to assume that as the market grows, new laboratories will have the same proficiency as existing experienced laboratories that already may not be able to measure below the PQL." As reflected in the PQL, 75 percent or more of participating laboratories will be able to set a MRL with a 95 percent confidence interval. As discussed in 5.1.2 of the EPA response in this *Response to Comments* document, the EPA's historical experience with other NPDWRs provides a record demonstrating that laboratory capacity is expected to grow once the rule is finalized as the opportunity for increased revenue by laboratories would be realized by filling the analytical needs of the utilities.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043802)

Sampling and Laboratory Limitations. There are limited laboratories capable of testing water for PFAS at these reduced limits and arduous sampling protocols that require additional tools, instrumentation and very specific requirements of the person(s) doing the sampling (i.e. no laundered clothing can be worn, no showers for several days, no brushing of teeth, specific clothing). All these additional steps will require resources that clean water facilities are not currently funded for.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The validated methods (Method 533 and 537.1 v2) used to support the final rule do not have inherent QC issues if appropriately followed; these methods do not include the sampling protocols such as "no showers for several days" as suggested by the commenter. For concerns related to sampling and background contamination issues, please see section 9.7 of the EPA response in this *Response to Comments* document. Regarding the rule trigger levels for reduced triennial monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document.

Mindi Messmer (Doc. #1788, SBC-044707)

2. Please pass the MCLGs (from June 2022) as MCLs for PFAS chemicals. Labs can detect PFOA and PFOS in the range of 1 to 2 parts per trillion (ppt) now which is about half the proposed MCL. For decades we have been exposed to these chemicals without our knowledge and we do not want to assume any additional risk – as scientists have been saying, there is no safe level of PFAS exposure.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Please also see section 5.1.3 of the EPA response in this *Response to Comments* document on alternative MCLs which includes a discussion on a lower MCL alternative.

Fairfax Water (Doc. #1789, SBC-045309)

Inadequate Laboratory Capacity for PFAS Analysis

The EPA proposed MCLs for PFOA and PFOS are at the limits of detection. The ubiquity of PFAS in the environment and the extreme precautions that must be taken when collecting and analyzing PFAS samples to avoid cross-contamination, increase the risk of error in PFAS testing results. There is currently no EPA regulation for PFAS in drinking water and UCMR5 testing is just now beginning, yet utilities are experiencing longer and longer turnaround times for PFAS

analysis from certified laboratories. In our most recent rounds of sampling, Fairfax Water's turnaround times from contract laboratories have gone from weeks to months.

The capacity of certified labs to keep up with the increasing demands for PFAS testing for multiple regulatory tracks, e.g., UCMR5, drinking water, wastewater, and others is a significant concern.

No on-line instrumentation currently exists to monitor PFAS concentrations for process control in a water treatment plant. A utility using GAC for PFAS removal must instead rely on a series of routine samples analyzed in a laboratory to ensure that PFAS levels in the treated drinking water remain within compliance. Whether using pressure vessels or gravity contactors filled with GAC, in an operational setting water samples must be taken from various depths in the media on a regular basis and analyzed for PFAS. The results of these samples then provide an indication of where the PFAS breakthrough is within the GAC column, indicating remaining adsorptive capacity so that utilities know when they need to replace GAC media.

Consultants for Fairfax Water estimate that our Griffith plant would require the construction of twenty-four gravity GAC contactors to meet the proposed MCLs for PFOA and PFOS, operating in a lead-lag configuration. Once in service, on a monthly basis the lead contactors would each have to be sampled at four different levels within the filter column as well as at the individual contactor effluent. This equates to 60 PFAS samples per month (12x5) or 720 PFAS samples to be analyzed annually for process monitoring. That compares to 12 point of entry compliance samples specified in the proposed rule or a 60-fold increase in the number of samples that would have to be analyzed annually. The current laboratory turnaround times are unacceptable to support PFAS treatment operations. When the proposed rule is finalized the demand for laboratory analyses for PFAS will grow exponentially to support treatment operations. EPA should delay the compliance period for the rule to provide time for laboratories to develop the capacity necessary to support the significant increase in operational process control analyses for PFAS, otherwise operation of PFAS removal treatment trains will be adversely impacted.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that the MCLs are set at the limits of detection, but rather they are set at the PQLs which are distinctly different than the limit of detection and significantly higher. For concerns related to sampling and background contamination issues, please see section 9.7 of the EPA response in this *Response to Comments* document. Regarding concerns for voluntary sampling to monitor treatment performance (i.e., performance monitoring), the EPA anticipates that many water systems will conduct a pilot test before implementing a full-scale treatment installation and that the results from the pilot test will be a sufficient enough indicator of performance as well as break through

curves to inform operational monitoring; therefore, water systems should not have to collect large amounts of performance samples indefinitely during the full-scale operation of treatment technologies. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for additional details on how these considerations were factored into the EPA's cost estimates. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Mark Gearreald (Doc. #1792, SBC-044296)

2. Please pass the MCLGs as MCLs for PFAS chemicals. Labs can detect them much lower than 4 parts per trillion. For decades we have been exposed to these chemicals without our knowledge and we do not want to assume any additional risk - as scientists have been saying, there is no safe level of PFAS exposure.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Please also see section 5.1.3 of the EPA response in this *Response to Comments* document on alternative MCLs which includes a discussion on a lower MCL alternative.

James McConnell (Doc. #1793, SBC-044702)

2. Please pass the MCLGs as MCLs for PFAS chemicals. Labs can detect them much lower than 4 parts per trillion. For decades we have been exposed to these chemicals without our knowledge and we do not want to assume any additional risk - as scientists have been saying, there is no safe level of PFAS exposure.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Please also see section 5.1.3 of the EPA response in this *Response to Comments* document on alternative MCLs which includes a discussion on a lower MCL alternative.

New England Water Works Association (Doc. #1836, SBC-045384)

Source Water and Analytical Variability:

Through the years of sampling by PWS across New England, it is not uncommon for different labs to report a variance of several parts per trillion +/- in PFAS when analyzing the exact same source water. We question whether we are pushing the sensitivity of the equipment to a point where it cannot be reliably quantified. A sample is considered valid at +/-30%, and when

discussing regulatory compliance levels in the low parts per trillion, this is concerning. As a point of illustration, the following are split sample results for a utility in Massachusetts. The sample date was 12/11/2020, lab A's result was 12.7 ppt, while lab B's result was 20.56 – both were valid results, yet the swing was 7.86 ppt. This analytical variability is well over what EPA proposes as the MCL so PWS could be subject to noncompliance and enforcement due to analytical variability alone.

Some PWS have seen +/- parts per trillion variability in PFOS and PFOA concentrations when collecting monthly samples; even a 1-2 ppt variation can represent over 40% variability when close to the Method Detection Limit (MDL). It is difficult to tell if this variability is attributable to changes of PFOS and PFOA concentrations in the source water or if it is linked to the variability of the analytical method (+/- 30%). Having a proposed Rule Trigger Level of 1/3, the PFOS and PFOA MCL or Hazard Index may have PWS and primacy agencies fluctuating back and forth on whether the PWS is eligible for a monitoring waiver, and may impact the running annual average calculation. This uncertainty creates unnecessary complexity, increased level of effort, and continued erosion of public confidence.

We are also aware of several instances where it was found that lab instrumentation was not properly cleaned between sample runs, resulting in erroneous detections. It is paramount that labs are not doing cross matrix analysis on machines that analyze drinking water samples.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For concerns related to sampling and background contamination issues, please see section 9.7 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1677, SBC-044955 in section 5.1.2 in this *Response to Comments* document for commenter claims on the 30 percent - 50 percent acceptance criteria in the reported result.

Douglas Whitbeck (Doc. #1853, SBC-045503)

2. Please pass the MCLGs as MCLs for PFAS chemicals. Labs can detect them much lower than 4 parts per trillion. For decades we have been exposed to these chemicals without our knowledge and we do not want to assume any additional risk - as scientists have been saying, there is no safe level of PFAS exposure.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Idaho Environmental Coalition (Doc. #3030, SBC-047328)

Significant costs may be realized for laboratory analysis and treatment methods because sampling existing groundwater wells that contain equipment with PFAS components could indicate groundwater contamination when PFAS contamination is not present in the groundwater. Costs could also be significant if existing well equipment had to be removed and

replaced with equipment that is free of PFAS components, or if new wells were drilled to obtain background samples with PFAS-free well equipment. Existing laboratory contracts would need to be renegotiated to determine if the laboratory had the capability to report PFOA and PFOS at levels below the 4 ppt proposed MCL. Laboratories that state PFOA and PFOS detection levels of 1 to 2 ppt would most likely flag results below 10 ppt as J or UJ. Is it cost effective to implement treatment methods if a result of 8 ppt has a J flag? Can treatment methods be shown to meet the MCL if effluent data have J flags?

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Please see section 9.7 of the EPA response in this *Response to Comments* document regarding sample and background contamination issues. Additionally, under the EPA drinking water PFAS methods, laboratories are required to meet MRLs which are no less than any of the regulated PFAS PQLs. Therefore, any level above the PQLs is required to be quantified and would not be flagged as a non-quantifiable value. Furthermore, for the purpose of calculating MCL compliance, if a sample result is less than the PQL for a regulated PFAS, zero is used for that analyte solely to calculate the RAA. (see section 8.2 of the EPA response in this *Response to Comments* document), and water systems would not be required to take actions such as treatment for levels below the EPA's PQLs.

Citizens Energy Group (Doc. #1838, SBC-044865)

EPA requests comment on other monitoring related considerations including laboratory capacity and QA/QC of drinking water sampling.

Citizens is concerned with the long-term availability of certified drinking water laboratories to perform analysis for PFAS in a timely way given the limited number of laboratories certified and capable of performing the analysis under the Safe Drinking Water Act.

Constraints in the laboratory supply chain can lead to delays in receiving data. If a water system performs sampling as required (e.g., on a quarterly basis) but the analytical results are delayed beyond the end of the reporting period, water systems should not be subject to enforcement actions or public notifications for "failure to monitor".

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For a discussion of PN requirements, see section 9.2 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045953)

EPA creates some confusion when it states in the preamble, "Measuring PFOA and PFOS results below the practical quantification level (PQL) may not be achievable from all laboratories and may not have the same precision as higher-level measurements, nor does EPA believe it is appropriate to make potentially costly compliance decisions based on such lower-level measurements." However, EPA also states that it assumes water systems will treat to 80% of the proposed MCL to include "a margin of safety." Installing these treatment techniques will take several years, so a utility risks being in noncompliance at any moment if it is approaching detection at the proposed 4.0 ppt MCL, even though EPA has expressed that it is not "appropriate" to make costly decisions on these low-level measurements. Therefore, water systems with 3.2-4.0 ppt samples whose running annual average (RAA) is below 4.0 ppt will have to decide to install treatment in case there is seasonal variability or spikes that may put them out of compliance, potentially costing them, and therefore ratepayers, millions of dollars to get under this margin of safety that cannot be reliably measured.

Several AMWA members have detected PFOA and PFOS in the 3.0-5.0 ppt range and will have to make decisions on how to address PFAS (see Attachments 2, 3, and 4). Source control is an effective way for some water systems detecting PFOS and PFAS at these levels; however, it takes significant time to both identify the source and address the issue, and for levels to decrease in response to the action. Not only will source control save money for ratepayers in these service areas, but it will ease supply chain and labor demands for water systems with higher levels of PFAS that are a greater risk to public health. Source control will also address the problem of PFAS accumulation in the environment. PFAS are known as "forever chemicals" and are very persistent, so preventing PFAS pollution is more responsible and protective of public health than treating after PFAS are released into source waters.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA disagrees that a system would risk being out of compliance "at any moment if it is approaching a detection at the proposed 4.0 ppt MCL." This is because, for purposes of determining compliance with the MCL, the use of the RAA of results could allow some results to exceed 4.0 ng/L for single measurements if the overall annual average is below the MCL. In other words, there is a buffer built into determining compliance with the MCL. Second, when calculating the RAA, zero will be used for results less than the PQL which provides an additional analytic buffer for utilities in their compliance calculations. This monitoring and compliance framework allows for temporal fluctuations in concentrations that may occur because of unexpected events such as premature PFOA and PFOS breakthrough or temporary elevated source water concentrations. Thus, periodic occurrences of PFAS that are slightly above the PQLs do not necessarily result in a violation of the MCL if other quarterly samples are below the PQL. The EPA also notes that, for the PFAS regulated by the NPDWR, all the PQLs are well above their limits of detection. The

PQL is also different than detection limits because the PQL is set considering a level of precision, accuracy and quantitation. Systems may be able to use sample results below the PQL to understand whether PFAS are present. While the EPA has determined that results below the PQL are insufficiently precise for determining compliance with the MCL, results below the PQL can be used to determine analyte presence or absence in managing a system's treatment operations. In the example provided by the commenter, zero will be used for sample results below 4.0 ppt for PFOA and PFOS for purposes of compliance determinations and RAA calculations. For additional discussion on laboratory considerations and practical quantitation limits, please see section 5.1.2 summary, section 8.7 summary, and section 7.2 summary in this *Response to Comments* document.

The agency also acknowledges responses that it may be prudent for systems that are close to the MCL to have time to identify and address sources of PFAS in their watersheds rather than investing resources on treatment initially. Related to this matter, the EPA notes that the agency is exercising its authority under Section 1412(b)(10) of SDWA to implement a nationwide capital improvement extension to comply with the MCL such that the compliance date for the PFAS MCLs will be 5 years from the date of promulgation. While allowing time for source water investigation was not the basis for the agency's decision to extend the compliance date for the PFAS MCLs, the EPA believes that extending the compliance date may provide opportunities for systems who are close to exceeding the MCLs to investigate sources of contamination. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12.1 summary in this *Response to Comments* document on extensions and exemptions. The EPA also notes that the IIJA, also known as the BIL, has provided significant funding ($10 billion in total) available to PWSs through the SRFs and grant programs to reduce people's exposure to PFAS and other emerging contaminants through their drinking water, to help address discharges through wastewater, and to support source water protection efforts.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044896)

DEP believes that performance monitoring for systems with PFAS removal treatment will be an implementation challenge with regard to the proposed MCLs. Demonstrating treatment efficacy over time is critical for systems with PFAS removal treatment. Monitoring results are a key data point for system operators in knowing when to switch between lead and lag units and when to change out media. However, the proposed MCLs complicate this effort, because it is not clear what is considered a detection or at what level breakthrough would occur. From a treatment design standpoint, operators need room between detection limits and MCLs in order to ensure continuous compliance and treatment efficacy. This is another implementation challenge caused by setting MCLs at levels such that any detection over the PQL will cause an exceedance.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of

sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045462)

The HI approach ends up eliminating a PFAS in the calculation of the HI if it is non-detect (assuming it is 0). How is analytical dilution accounted for? If the reporting limit (RL) for a sample is above the heath-based water concentration (HBWC) then it would be incorrect to assume that non-detects are not present above the HBWC. Replacing non-detects with 0 is a long-known concern in the public health/environmental field. There are methods to handle these censored data. It is against best practices defined by EPA itself in its Unified Guidance to replace non-detects with 0. [FN5: U.S. Environmental Protection Agency (USEPA). 2009. Statistical Analysis Of Groundwater Monitoring Data At RCRA Facilities; Unified Guidance. EPA 530/R-09-007. https://nepis.epa.gov/Exe/ZyPURL.cgi?Dockey=P10055GQ.txt (Accessed April 7, 2023)]

The HI approach is an annual averaging approach. For example, if quarterly samples are collected then the HI for each quarter is calculated and then the 4 HIs are then averaged and if that average is below the HI no exceedance is found, even if 1 of the quarterly HIs is above 1.0. For EPA regulatory programs such as RCRA, exceedances of the MCL are determined based on the upper confidence limit (UCL) of the mean not the mean itself. The UCL approach accounts for observed variability.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. With respect to responses on analytical dilution for purposes of compliance monitoring, the agency is clarifying that the HBWCs for PFHxS, PFNA, and HFPO-DA are 10 ppt each. For PFBS, the HBWC is at 2000 ppt. Since these HBWCs are well above the PQLs for each of these respective compounds (the PQLs are between 3 to 5 ppt), there is no concern for censoring data. For additional discussion on compliance and the use of values below the PQL for compliance calculations, please see section 8.2 of the EPA response in this *Response to Comments* document. Further, the EPA notes that applications of the MCL in other EPA regulatory programs (such as Resource Conservation and Recovery Act [RCRA]) is beyond the scope of this rulemaking. Nonetheless, the approved drinking water methods use the measured value and do not apply confidence intervals as variance with the reported result.

Superfund Settlements Project (SSP) and RCRA Corrective Action Project (RCAP) (Doc. #1631, SBC-043440)

As a final point, SSP and RCAP agree with the commenter from EPA's outreach consultations that advised "water systems operate with a margin of safety and plan for performance that

maintains water quality below quantitation levels" and, accordingly, "having an increased buffer between the PQL and the MCL may allow utilities to manage treatment technology performance more efficiently because utilities typically aim to achieve lower than the MCL to avoid a violation." [FN61: 88 Fed. Reg. 18670.] Remediation treatment system equipment is similarly difficult to reliably operate when the treatment goal is the PQL of the analytical method. At the very minimum, therefore, the PFOA and PFOS MCLs should be sufficiently higher than the PQL to allow for reliable operations.

EPA Response: For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043054)

Whole-of-government Approach

DEQ recommends that EPA strengthen the source protection program to prevent PFAS from entering drinking water sources.

EPA should work to quickly finalize Draft Method 1633 for labs to analyze samples for surface water, ground water, and other media.

DEQ recommends that EPA use a holistic lifecycle approach that includes close coordination with other Federal agencies to administer all possible Federal statutory regulatory authorities to address PFAS concerns.

Using a holistic approach to reduce or eliminate the use of PFAS, and to prevent these compounds from entering the environment and drinking water sources throughout any part or all of the chemical's lifecycle, from manufacturing through processing, distribution, and disposal, is much more effective and less expensive than having to remove PFAS compounds once contamination has occurred.

Consideration should be given to potential impacts from disposal and incineration under each regulatory authority to ensure that the responsibility and cost for removing PFAS are not passed on from one media to another.

Thank you for this opportunity to provide comment. We hope these comments will be helpful to EPA in making a final decision on the rule. If you have any questions or would like to discuss these comments in more detail, please contact me or Shellie Chard at Shellie.Chard@deq.ok.gov and (405) 702-8157.

Sincerely,

Scott A. Thompson

Executive Director

Oklahoma Department of Environmental Quality

Scott.Thompson@deq.ok.gov

cc: Jennifer McLain, OGWDW

EPA Response: The EPA's PFAS Strategic Roadmap lays out EPA's whole of agency approach to tackling PFAS. The PFAS Strategic Roadmap describes how EPA will get upstream of the problem and bring deeper focus to preventing PFAS from entering the environment in the first place—a foundational step to reducing the exposure and potential risks of future PFAS contamination. The EPA notes that the other actions to address sources of PFAS are highlighted in the agency's PFAS Strategic Roadmap and are beyond the scope of this rulemaking (please see section 15.1 of the EPA response in this *Response to Comments* document for additional information). For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA's Office of Water, in partnership with the Department of Defense's (DoD) Strategic Environmental Research and Development Program, has published Method 1633, "Analysis of Per- and Polyfluoroalkyl Substances (PFAS) in Aqueous, Solid, Biosolids, and Tissue Samples by LC-MS/MS," a method to test for 40 PFAS compounds in wastewater, surface water, groundwater, soil, biosolids, sediment, landfill leachate, and fish tissue. The EPA notes that Method 1633 is not a drinking water method and is not approved to meet the monitoring requirements of this final NPDWR. The EPA notes that the agency has provided *Interim Guidance on Destroying and Disposing of Certain PFAS and PFAS-Containing Materials* and that the agency is updating that guidance which outlines the current state of the science on techniques and treatments (including incineration) that may be used to destroy or dispose of PFAS and PFAS-containing material.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043112)

3. Additional PFAS Analytes

Since the development of the original "Priority Pollutant" list in 1976, each EPA Program Office has developed their own unique monitoring list which tends to complicate cross media monitoring. As former EPA Assistant Administrator Paul Anastas stated in 2021:

While environmental chemistry has shown that chemicals move readily between media, the foundational U.S. environmental regulations do not. Many argue that controls on air pollutants, for instance, often result in the discharge of the same chemicals into the land or water without reducing the total number of harmful substances released into the environment. For example, the Clean Air Act requires most utilities that burn high-sulfur coal to use scrubbers to remove sulfur dioxide from their flue gases, but this type of air pollution control produces three to six tons of scrubber sludge for every ton of sulfur dioxide removed from the air. The limitations presented by this legal framing of environmental protection is reinforced and fortified by the analogous

organizational structure of the EPA, with offices closely aligned with each media/statute. There's an old design saying, "form follows function". The U.S. EPA perhaps has that saying backward because at the agency, function often follows form. Water standards are reviewed and enforced not because they are the greatest threat to human health of the environment but rather because it is simply what the Office of Water is legally mandated to do. Since EPA personnel have labored in an organizational structure where too often "form enables dysfunction," it is necessary to pursue new organizational models. In times of crisis, such as the 2010 oil spill in the Gulf of Mexico and the nuclear meltdown at Fukushima in 2011, the EPA draws together all of the capabilities and perspectives across the agency into the Emergency Operation Center. Together, all of the disciplines, skill sets, and resources of the agency are focused on the crisis at hand. This model is critically necessary now, at a time when we have numerous environmental and public health crises, some immediate and acute while others are slow and chronic, emerging in real-time, such as climate change resulting in wildfires throughout the American West; hurricanes increasingly devastating the American South; environmental injustice and health disparities in communities that are disproportionality poor and of color; and biodiversity resulting in degraded ecosystem health. While these crises may be chronic conditions resulting in acute impacts, and unfold over years rather than days, they are also crises that require an integrated and cohesive response that incorporates all of the talents across the EPA. The EPA's model must not continue to be fragmented, isolated, and myopically aligned with half-century old laws. It must instead break down old organizational barriers to create new agile, rapid response teams that are capable of addressing problems in the necessary time frame. This would require a complete restructuring of the EPAs organizational hierarchy. Instead of offices that are a reflection of outdated statutes, there would be a matrix that reflects the capabilities and resources within the agency. As problems are identified and prioritized, individuals from each of the "resource centers" would be assigned to work on that problem as part of a multidisciplinary team. These may range from small strike forces of a few individuals with the proper background for a short amount of time in discrete emergencies, to larger, complex teams that will be used to focus on an ongoing issue for years. All of these efforts would benefit from a matrix organizational structure that brings together the full capabilities of the agency and allows it to more effectively leverage and interconnect with other efforts in localities, states, and other federal entities. Of course, this activity could be decoupled from organizational structure and implemented while the longer-term process of reorganizing the agency is pursued. (Moving from Protection to Prosperity: Evolving the U.S. Environmental Protection Agency for the next 50 years, Environmental Science & Technology pubs.acs.org/est Policy Analysis https://dx.doi.org/10.1021/acs.est.0c07287 Environ. Sci. Technol. 2021, 55, 2779−2789)

Given that the EPA is increasing its scrutiny to more PFAS compounds, for example, the CERCLA Advanced Notice of Proposed Rulemaking published on April 13, 2023 (https://www.govinfo.gov/content/pkg/FR-2023-04-13/pdf/2023-07535.pdf) specifically addresses PFBA as becoming a "hazardous constituent" under CERCLA. In addition, the toxicity profile of PFBA is mentioned several times in the proposed drinking water rule. Furthermore, the EPA Clean Water Act and Resource Conservation and Recovery Act programs are also

developing methods 1633 and 8327 with their own lists of PFAS analytes, and the ORCR is also considering adding PFAS analytes to the Appendix VIII hazardous constituents in 40 FCFR 261.The EMC, therefore, recommends the Drinking Water program collaborate with other EPA program offices to come up with one standardized list. EMC seeks clarification on reporting additional PFAS analytes. EMC would note that some states have their own PFAS reporting lists.

EPA Response: The EPA is taking an all-of-agency approach toward addressing PFAS as discussed in the agency's PFAS Strategic Roadmap (please see section 15.1 of the EPA response in this *Response to Comments* document for additional information). For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. At the time of rule proposal, EPA did not have sufficient information to inform a regulatory determination for PFBA. The EPA notes that application of MCLs in non-drinking water programs (such as water quality criteria, NPDES, or CERCLA cleanups) is beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043320)

3. Additional PFAS Analytes

Since the development of the original "Priority Pollutant" list in 1976, each EPA Program Office has developed their own unique monitoring list which tends to complicate cross media monitoring. As former EPA Assistant Administrator Paul Anastas stated in 2021:

While environmental chemistry has shown that chemicals move readily between media, the foundational U.S. environmental regulations do not. Many argue that controls on air pollutants, for instance, often result in the discharge of the same chemicals into the land or water without reducing the total number of harmful substances released into the environment. For example, the Clean Air Act requires most utilities that burn high-sulfur coal to use scrubbers to remove sulfur dioxide from their flue gases, but this type of air pollution control produces three to six tons of scrubber sludge for every ton of sulfur dioxide removed from the air. The limitations presented by this legal framing of environmental protection is reinforced and fortified by the analogous organizational structure of the EPA, with offices closely aligned with each media/statute. There's an old design saying, "form follows function". The U.S. EPA perhaps has that saying backward because at the agency, function often follows form. Water standards are reviewed and enforced not because they are the greatest threat to human health of the environment but rather because it is simply what the Office of Water is legally mandated to do. Since EPA personnel have labored in an organizational structure where too often "form enables dysfunction," it is necessary to pursue new organizational models. In times of crisis, such as the 2010 oil spill in the Gulf of Mexico and the nuclear meltdown at Fukushima in 2011, the EPA draws together all of the capabilities and perspectives across the agency into the Emergency Operation Center. Together,

all of the disciplines, skill sets, and resources of the agency are focused on the crisis at hand. This model is critically necessary now, at a time when we have numerous environmental and public health crises, some immediate and acute while others are slow and chronic, emerging in real-time, such as climate change resulting in wildfires throughout the American West; hurricanes increasingly devastating the American South; environmental injustice and health disparities in communities that are disproportionality poor and of color; and biodiversity resulting in degraded ecosystem health. While these crises may be chronic conditions resulting in acute impacts, and unfold over years rather than days, they are also crises that require an integrated and cohesive response that incorporates all of the talents across the EPA. The EPA's model must not continue to be fragmented, isolated, and myopically aligned with half-century old laws. It must instead break down old organizational barriers to create new agile, rapid response teams that are capable of addressing problems in the necessary time frame. This would require a complete restructuring of the EPAs organizational hierarchy. Instead of offices that are a reflection of outdated statutes, there would be a matrix that reflects the capabilities and resources within the agency. As problems are identified and prioritized, individuals from each of the "resource centers" would be assigned to work on that problem as part of a multidisciplinary team. These may range from small strike forces of a few individuals with the proper background for a short amount of time in discrete emergencies, to larger, complex teams that will be used to focus on an ongoing issue for years. All of these efforts would benefit from a matrix organizational structure that brings together the full capabilities of the agency and allows it to more effectively leverage and interconnect with other efforts in localities, states, and other federal entities. Of course, this activity could be decoupled from organizational structure and implemented while the longer-term process of reorganizing the agency is pursued. (Moving from Protection to Prosperity: Evolving the U.S. Environmental Protection Agency for the next 50 years, Environmental Science & Technology pubs.acs.org/est Policy Analysis https://dx.doi.org/10.1021/acs.est.0c07287 Environ. Sci. Technol. 2021, 55, 2779−2789)

Given that the EPA is increasing its scrutiny to more PFAS compounds, for example, the CERCLA Advanced Notice of Proposed Rulemaking published on April 13, 2023 (https://www.govinfo.gov/content/pkg/FR2023-04-13/pdf/2023-07535.pdf) specifically addresses PFBA as becoming a "hazardous constituent" under CERCLA. In addition, the toxicity profile of PFBA is mentioned several times in the proposed drinking water rule. Furthermore, the EPA Clean Water Act and Resource Conservation and Recovery Act programs are also developing methods 1633 and 8327 with their own lists of PFAS analytes, and the ORCR is also considering adding PFAS analytes to the Appendix VIII hazardous constituents in 40 FCFR 261.The EMC, therefore, recommends the Drinking Water program collaborate with other EPA program offices to come up with one standardized list. EMC seeks clarification on reporting additional PFAS analytes. EMC would note that some states have their own PFAS reporting lists.

EPA Response: The EPA notes that the statutory authorities and organizational structure of the agency are outside the scope of this regulatory action. The EPA's Drinking Water Program regularly coordinates with the agency's Laboratory Enterprise Council on overarching analytical method and laboratory issues. The EPA further notes that the under the agency's PFAS Strategic

Roadmap the Office of Research and Development is leading the development and validation of methods to detect and measure PFAS in the environment, including additional targeted methods for detecting and measuring specific PFAS, non-targeted methods for identifying unknown PFAS in the environment, and exploring "total PFAS" methods. The development of these analytical methods must inherently consider the media being analyzed and the data quality objectives for the method. This may result in differing analytes for different methods. EPA has defined the reporting requirements for PFAS analytes under 40 CFR 141.904. Any current state reporting lists are outside the scope of this action. Please also see the EPA response to comment Doc. #1625, SBC-043112 in section 5.1.2 in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044170)

2. NCDEQ recommends that EPA use all the Agency's regulatory and non-regulatory authorities to prevent PFAS from entering drinking water sources.

NCDEQ continues to support EPA's work to holistically address PFAS under the Agency's PFAS Strategic Roadmap. The Agency's approaches to "get upstream of the problem" and "hold polluters accountable" are paramount to the long-term protection of both surface and groundwater sources of drinking water.

The principle of 'control of pollutants at the point of generation' is established for other contaminants, both chemical and microbial. Therefore, leveraging a holistic approach to reduce or eliminate the use of PFAS and to prevent these compounds from entering the environment and drinking water sources throughout any part or all of the chemical's lifecycle - from manufacturing through processing, distribution, and disposal - is much more effective and less expensive than removing PFAS compounds once contamination has occurred. Protecting drinking water sources (and preventing contamination) is essential for sustaining safe drinking water supplies, protecting public health and the economy, and has many additional environmental benefits.

NCDEQ requests that EPA prioritize the Agency's work to establish PFAS effluent limitations guidelines for wastewater and stormwater discharges from ever expanding list of contributing sources and new emerging industries. NCDEQ stands ready to work with EPA, states, and the stakeholder community to characterize sectors, processes and activities that contribute to PFAS discharges and develop source reduction solutions that reduce such discharges.

Additionally, the Agency should work to finalize Dra Method 1633 promptly for laboratories to analyze samples for surface water, groundwater, and other media. NCDEQ is beginning to require monitoring for pollutants in surface water and groundwater and is developing water quality criteria. The availability of certified laboratories in the state will ensure the increased demand for testing PFAS is adequately met and consistent and reliable data are reported.

3. NCDEQ recommends that EPA use a holistic lifecycle assessment approach that includes close coordination with other Federal agencies to administer all possible Federal statutory regulatory authorities to address PFAS concerns.

The PFAS NPDWR is a necessary first step in addressing PFAS contamination. Numerous other regulatory decisions are made based on drinking water standards (e.g., ground water remediation determinations, National Pollution Discharge Elimination System (NPDES) permits, and surface water standards). This includes considering impacts from disposal and incineration under each regulatory authority to ensure that the responsibility and cost for removing PFAS are not passed on to other media.

EPA is already examining and taking actions on the agency's programs related to air, waste, and land management. We encourage EPA to continue using a holistic lifecycle approach to PFAS management such that the contamination is not transferred across different media without appropriate regulations in place. This also includes consistent messaging on PFAS to regulators, regulated entities, and the public.

Similarly, we encourage EPA to coordinate across other federal Agencies (i.e., the Department of Defense, the Food and Drug Administration, and Centers for Disease Control) to prevent and reduce PFAS contamination and exposure. A unified approach across all Federal agencies will ensure advancements in PFAS science and regulatory actions are made and consistent messaging and implementation of federal regulatory and non-regulatory programs are delivered to the public.

EPA Response: The EPA is taking an all-of-agency approach toward addressing PFAS as discussed in the agency's PFAS Strategic Roadmap (please see section 15.1 of the EPA response in this *Response to Comments* document for additional information). Please also see the EPA response to comment Doc. #1616, SBC-043054 in section 5.1.2 in this *Response to Comments* document for a discussion on the EPA's whole of agency approach to "get upstream of the problem" and "hold polluters accountable." EPA further notes that the agency is coordinating other Federal agencies. EPA is a member of the cross government Interagency Policy Committee (IPC) created by the Council of Environmental Quality to share information and collaborate on new policy strategies to support research, remediation, and removal of PFAS in communities across the nation. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Tyson Foods, Inc. (Doc. #1750, SBC-043902)

Current technology to measure and detect the PFAS compounds at the proposed levels is not readily widely available nor is it affordable in comparison to other common testing requirements for our industry when scaled to the extent required by the proposed rule. Further, we strongly encourage EPA to convene an interagency working group with the Food Safety and Inspection Service (FSIS) and the Food and Drug Administration (FDA) to ensure alignment on regulatory

expectations of the stakeholders that are regulated by FSIS and/or FDA and EPA. This is critical as FSIS and FDA have regulatory requirements for water used in the food manufacturing.

Finally, Tyson Foods supports the comments provided by the North American Meat Institute, National Chicken Council, and the U.S. Chamber of Commerce. We respectfully request these points be considered before any modifications to the Proposed Rule are finalized.

Thank you for your consideration.

Sincerely,

Betsy Booren, Ph.D.

Managing Director, Regulatory Policy & Business Intelligence

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For a discussion of the EPA's work with other Federal Agencies to address PFAS, see the EPA response to comment Doc. #1652, SBC-044170 in section 5.1.2 in this *Response to Comments* document. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation.

<u>Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045929)</u>

POWER!'s comments on this proposed rule focus on three main concerns: (1) the rule is premature because EPA has not established the requisite technological standards and regulations; (2) the rule fails to adequately consider the costs of implementation; and (3) neither EPA Methods 533 nor 537.1 can be used to accurately and precisely determine compliance with the proposed standards for treatment or triggers for compliance monitoring.

EPA Response: For responses regarding feasibility of the final MCLs, please see sections 5.1.2 (laboratory considerations); 5.1.3 (cost considerations and alternative MCLs); and 5.1.4 (treatment considerations) of the EPA response in this *Response to Comments* document. Please also see section 8 (analytical methods) of the EPA response in this *response to Comments* document.

<u>Michigan Farm Bureau (MFB) (Doc. #1562, SBC-043356)</u>

Impacts of Setting Proposed Regulatory Limits

As stated above, EPA's proposed MCL rule sets MCL limits for six PFAS "[c]onsidering feasibility, including currently available analytical methods to measure and treat these chemicals in drinking water" [FN9: Fed. Reg. 18638.] based on the MCLG of 0 given the potential for carcinogenic effects of PFOS and PFOA. Essentially, this means EPA is setting PFOS and PFOA regulatory limits at or near the current technological capability of detecting PFOS and PFOA

based on approved analytical methods in order to get as close as feasible to 0, and a health index considering potential additive impacts of PFNA, PFBS, PFHxS, and GenX. In addition to the previously discussed uncertainty of health impacts and therefore assessment of meaningful MCLGs for PFAS, this "as close as technically possible to zero" proposal creates a huge burden and lack of clarity for water suppliers who must comply with the new regulations.

EPA Response: The commenter is incorrect that the NPDWR sets a MCLG of zero for six PFAS. Due to the carcinogenic potential of PFOA and PFOS, the EPA is promulgating MCLGs of zero for these two PFAS. For responses regarding feasibility of the final MCLs, please see sections 5.1.2 (laboratory considerations); 5.1.3 (cost considerations and alternative MCLs); and 5.1.4 (treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on the hazard index, please see section 5.2.1 of this *Response to Comments* document.

5.1.3 Cost Considerations and Alternative MCLs

Summary of Major Public Comments and EPA Responses

Some commenters argue that the EPA did not sufficiently consider cost in the agency's feasibility analysis of the final MCLs and therefore disagreed with the EPA that the standards are feasible. In particular, these commenters suggest that the agency did not adequately consider costs associated with implementation (e.g., costs for labor, materials and construction of capital improvements) and compliance (e.g., costs to monitor) with the final MCLs. Based on these factors, many of these commenters suggest either raising the MCLs or re-proposing the standard in its entirety. The EPA did consider these costs and therefore disagrees with commenters' assertions that the agency did not consider these issues in establishing the proposed MCLs for PFOA and PFOS (USEPA, 2024d; USEPA, 2024e; USEPA, 2024f). The EPA considers whether these costs are reasonable based on large metropolitan or regional drinking water systems (H.R. Rep. No 93-1185 (1978), *reprinted in* 1974 U.S.C.C.A.N. 6454, 6470-71)[1]. The EPA considered costs of treatment technologies that have been demonstrated under field conditions to be effective at removing PFOA and PFOS and determined that the cost of complying with an MCL at the PQL of 4.0 are reasonable for large metropolitan water systems at a system and national level (USEPA, 2024c; USEPA, 2024d). To designate technologies as BATs, the EPA evaluated each technology against six BAT criteria, including whether there is a reasonable cost basis for large water systems. The EPA evaluated whether the technologies are currently being used by systems, whether there were treatment studies available with sufficient information on design

[1] To designate technologies as BATs, the EPA evaluated each technology against six BAT criteria, including whether there is a reasonable cost basis for large and medium water systems. The U.S. Census Bureau defines a metropolitan statistical area consisting of one or more counties that contain a city of 50,000 or more inhabitants or containing a Census Bureau-defined urbanized area and have a total population of at least 100,000. A "large system" system is one that generally serves a population of more than 10,000 people, so all metropolitan systems are included in the set of large systems.

assumptions to allow cost modeling, and whether additional research was needed (USEPA, 2024e). In considering the results of this information, the EPA determined that these costs are reasonable to large metropolitan water systems and supports the EPA's decision to finalize standards for PFOA and PFOS at 4.0 ppt. In response to responses on the EPA's cost analysis, the agency notes after considering public comment, the EPA has made a number of adjustments to the cost model and collectively these changes have increased the agency's estimated annualized costs. For additional discussion on the EPA's cost analysis, please see section 13.3 of the EPA response in this *Response to Comments* document.

The EPA notes that there is a strong record supporting the agency's feasibility analysis supporting the final standards. Specifically, within the record the EPA evaluated the accuracy of analytical techniques as reflected in the PQL, the availability and performance of BATs for treating water to minimize the presence of the contaminant consistent with the MCLG, as well as the costs of applying those BATs to large metropolitan water systems when treating to that level. In consideration of these factors, the EPA is therefore establishing the MCL of 4.0 ng/L for both PFOA and PFOS; individual MCLs for PFHxS, PFNA and HFPO-DA at 10 ppt; and a Hazard Index MCL of 1 for mixtures of PFHxS, PFNA, HFPO-DA and PFBS. Please see sections 5.1.2 and 5.1.4 of the EPA response in this *Response to Comments* document for additional discussion on how the agency evaluated feasibility with respect to analytic and treatment considerations, respectively, in the final standards.

Some commenters expressed concern that in their opinion the EPA is selecting the "least cost-beneficial" standard among the options considered. Additionally, some commenters suggest the EPA promulgate one of the regulatory alternatives presented at proposal (i.e., 5.0 ppt or 10.0 ppt). Some of these commenters contend that these levels are "more closely balanced" among the options that the EPA considered in terms of costs and benefits. Some of these commenters pointed out that quantified net benefits decreased with increasing MCL stringency. With respect to responses on the net benefits of the rule in comparison to the regulatory options, the EPA emphasizes that under SDWA, the EPA must consider whether the costs of the rule are justified by the benefits based on all statutorily-prescribed costs and benefits, not just the quantified costs and benefits (see SDWA 1412(b)(3)(c)(i)). In other words, SDWA does not mandate that the EPA establish MCLs at levels where the quantified benefits exceed the quantified costs. This was many commenters' justification for the recommendation to promulgate a standard of 10.0 ppt each for PFOA and PFOS in lieu of the proposed rule, and the EPA therefore disagrees that quantified costs and benefits can or should be the sole determinant of an MCL value. As detailed above, the EPA is required to set an MCL as close as feasible to the MCLG, taking costs into consideration.

Some commenters specifically pointed out the differences in the quantified net benefits of the proposed rule compared to Option 1a (PFOA and PFOS standard only at 4.0 ppt each), noting that the Hazard Index MCL "add(s) no significant net benefit." As EPA clearly discusses the proposed and final rule preambles, the Hazard Index is anticipated to result in significant non quantifiable benefits (for more information see section XII of the final rule preamble). The EPA

anticipates significant additional benefits that cannot be quantified that will result from avoided developmental, cardiovascular, liver, immune, endocrine, metabolic, reproductive, musculoskeletal, and carcinogenic effects as a result of reductions in the levels of the regulated PFAS and other co-removed contaminants. For example, elevated concentrations of both PFOA and PFOS negatively impact the immune and endocrine systems, impacts which the agency is unable to quantify at this time. As another example, EPA assessed the developmental benefits associated with PFNA exposure reductions semi-quantitively in sensitivity analysis, and the analysis demonstrates significant additional benefits associated with reductions in PFNA. There are other nonquantifiable benefits for other PFNA health endpoints, and numerous endpoints for PFHxS, HFPO-DA, PFBS, and other PFAS that are anticipated to be removed as a result of the final NPDWR. Additionally, there are benefits not quantified for removal of co-occurring contaminants for this regulation (e.g., certain pesticides, volatile organic compounds). Considering both quantifiable and nonquantifiable costs and benefits of the rule, the EPA is reaffirming the Administrator's determination at the time of proposal, that the quantifiable and nonquantifiable benefits of the final rule justify the quantifiable and nonquantifiable costs. See section 13.8 of the EPA response in this *Response to Comments* document on the Administrator's benefit cost determination and section XII of the final rule preamble.

Some commenters argue for a lower PFOA and PFOS MCL due to the underlying health effects of these contaminants. These commenters suggest the EPA establish MCLs lower than the agency's proposed standard of 4.0 ng/L due to the capability of some laboratories to quantitate lower concentrations. Some of these commenters also argue that since PFOA and PFOS are likely human carcinogens, the EPA should consider an MCL at zero. While the EPA agrees with the health concerns posed by PFAS that are the basis for the proposed health based MCLGs for these contaminants, the agency disagrees with commenters on these alternative MCL thresholds given the EPA's consideration of feasibility as required by SDWA. These commenters did not provide evidence demonstrating the feasibility of achieving lower MCL thresholds (including an MCL at zero) consistent with SDWA requirements in establishing an MCL. For example, commenters did not provide evidence to support a lower PQL that can be consistently achieved by laboratories across the country. They also did not provide arguments supporting why the EPA should accept less than 75 percent of participating laboratories will be able to set a MRL with a 95 percent confidence interval. Thus, the agency is finalizing the MCLs for PFOA and PFOS at 4.0 ng/L (at the PQL) as this is the closest level to the MCLG that is feasible due to the ability of labs using approved analytical methods to determine with sufficient precision and accuracy whether such a level is actually being achieved. The record supports the EPA's determination that the lowest feasible MCL for PFOA and PFOS at this time is 4.0 ng/L.

Some commenters argue for a higher MCL (such as the regulatory alternatives that the EPA proposed for PFOA and PFOS at 5.0 ppt or 10.0 ppt). Some of these commenters note that by adopting this approach, the agency can "phase-down" to a more stringent MCL as advancements in analytical technology progresses. As detailed above, the EPA is required to set an MCL as close as feasible to the MCLG, taking costs into consideration. Consistent with SDWA requirements in setting the MCL as close as feasible to the MCLG and after careful consideration

of public comment, the EPA is finalizing the MCL of 4.0 ng/L for both PFOA and PFOS; individual MCLs for PFHxS, PFNA and HFPO-DA at 10 ppt; and a Hazard Index MCL of 1 for mixtures of PFHxS, PFNA, HFPO-DA and PFBS. Please see section 5.1.2 and 5.1.4 of the EPA response in this *Response to Comments* document for additional discussion on how the agency evaluated feasibility with respect to analytic and treatment considerations, respectively, in the final standards.

Some commenters recommend the EPA regulate PFAS precursors or all PFAS as a class. As discussed above, the agency reiterates the SDWA requirements to establish an MCL. Specifically, the agency has not made a regulatory determination for specific PFAS precursors or the entirety of PFAS as a class and the commenters did not provide evidence to support a determination that PFAS precursors or the entire class of PFAS meet SDWA statutory criteria for regulation. For example, commenters did not provide evidence that the entire PFAS class may have an adverse effect on the health of persons; that the entire PFAS class is known to occur or there is substantial likelihood the contaminant will occur in PWSs with a frequency and at levels of public health concern; and in the sole judgment of the Administrator, regulation of the entire PFAS class presents a meaningful opportunity for health risk reductions for persons served by PWSs.

Regarding the EPA's decision to exclude PFOA and PFOS from the Hazard Index MCL, please see section 5.2.1 of the EPA response in this *Response to Comments* document.

Some commenters raised concerns that the EPA did not consider a sufficient range of regulatory alternatives. For example, a few commenters contend that the EPA violated 1412(b)(3)(C)(i) of SDWA because the agency did not identify and consider what they deem a reasonable number of regulatory alternatives for PFHxS, PFNA, HFPO-DA and its ammonium salts, and PFBS. Specifically, these commenters cite that the EPA only considered a single HBWC and did not consider any alternatives to the Hazard Index MCL of 1 itself. The EPA disagrees with these commenters. First, SDWA does not require the agency to consider any certain number of alternative MCLs or a range of alternatives. SDWA 1412(b)(3)(C)(i)(IV) only requires that in developing the Health Risk Reduction and Cost Analysis (HRRCA), the agency must consider the "incremental costs and benefits associated with each alternative maximum contaminant level considered." Second, the agency explicitly considered and took comment on more than one option for PFHxS, PFNA, HFPO-DA and its ammonium salts, and PFBS. First, the proposed rule included a Hazard Index MCLG and MCL for any mixture of one or more of PFHxS, HFPO-DA, PFNA, and PFBS. Second, the proposed rule EA explicitly considered multiple regulatory options that did not establish any MCLGs or MCLs for these four PFAS. And third and fourth, the agency explicitly sought comment on whether to regulate these four PFAS with individual MCLGs and MCLs instead of the Hazard Index (third) or regulate them with individual MCLs in addition to the Hazard Index (fourth). These are four specific regulatory scenarios for PFHxS, PFNA, HFPO-DA and its ammonium salts, and PFBS upon which the agency explicitly sought and received comment.

The final rule includes a Hazard Index MCLG and MCL for any mixture of two or more of PFHxS, HFPO-DA, PFNA, and PFBS. The final rule also includes individual MCLGs and MCLs for PFHxS, PFNA, and HFPO-DA. The EPA's cost analysis at proposal considered the costs associated with the individual MCLs for PFHxS, PFNA, and HFPO-DA because the proposed Hazard Index MCL would function as individual MCLs when these contaminants occur in isolation. While the rule structure has changed in the final NPDWR based on public comment received, the costing framework used at proposal is still fully applicable in the final rule: what was considered a Hazard Index MCL exceedance at proposal would be an individual MCL exceedance under the final rule should those contaminants occur in isolation. Further, the combination of a Hazard Index exceedance in the final rule (defined as two or more of PFHxS, PFNA, HFPO-DA, and PFBS) or an individual MCL exceedance for PFHxS, PFNA, or HFPO-DA is unchanged from a costing perspective to what the EPA proposed. Whether a system exceeds a Hazard Index MCL or individual MCL in the final rule, these costs are captured in the cost estimates the EPA considered and presented in Appendix N.3 of the EA (USEPA, 2024d).

To understand the totality of national-level cost impacts for the Hazard Index MCL, the EPA considered both the contribution of PFHxS (estimated as part of the national level cost analysis), as well as the costs for PFNA, HFPO-DA, and PFBS (estimated in the Appendix N sensitivity analysis). Together, these provide information on the costs for the Hazard Index MCL and the individual MCLs for PFHxS, PFNA, and HFPO-DA, as a whole.

To fully weigh the costs and benefits of the action, the agency considered the totality of the monetized values, the potential impacts of the nonquantifiable uncertainties, the nonquantifiable costs and benefits, and public comments received by the agency related to the quantified and qualitative assessment of the costs and benefits. For the final rule, the EPA is reaffirming the Administrator's determination made at proposal that the quantified and nonquantifiable benefits of the rule justify its quantified and nonquantifiable costs. Please see section 13 of the EPA response in this *Response to Comments* document for additional information on the agency's HRRCA.

In light of finalizing the individual MCLs for PFHxS, PFNA, and HFPO-DA, the EPA has separately presented national level marginal costs associated with the individual MCLs for PFHxS, PFNA and HFPO-DA in the absence of the Hazard Index MCL; see Chapter 5.1.3 and Appendix N.4 of the HRRCA for details. The EPA notes that these costs were considered in the proposed regulation under the proposed hazard index, where an exceedance of any one or more of these PFAS' HBWC would have resulted in an exceedance of the MCL. Therefore, the costs for the individual PFHxS, PFNA, and HFPO-DA MCLs have been considered both in the proposed and final rule. For more information on the agency's methodology, findings, and limitations of the EPA's updated analysis of costs associated with compliance with the Hazard Index, please see Appendix N.3 of the EA (USEPA, 2024c).

The agency also took comment on regulatory alternatives for solely PFOA and PFOS MCLs at 4.0, 5.0 and 10.0 ppt and further summarized quantified costs and benefits for these alternative options within the proposed rule preamble and economic analysis supporting the proposal. The

agency described the basis for these alternatives which included a 25 percent operational buffer above the PQL (for 5.0 ppt) and a level consistent with some state drinking water regulators (for 10.0 ppt), thereby providing a basis for comparison of the different regulatory approaches.

The EPA identified and analyzed a reasonable number of regulatory alternatives to determine the MCL requirement in the proposed rule as required by the Unfunded Mandates Reform Act (UMRA). UMRA's requirement to identify and consider a reasonable number of regulatory alternatives builds on the assessment of feasible alternatives required in E.O. 12866. OMB Circular A-4 describes that "the number and choice of alternatives selected for detailed analysis is a matter of judgment." Specifically, as described in the proposed rule, the EPA considered an alternative approach to the one proposed that only used the Hazard Index MCL. The proposal took comment on establishing individual MCLs instead of and in addition to using a mixture-based approach for PFHxS, PFNA, HFPO-DA, and/or PFBS in mixtures. In that notice, the EPA described how a traditional approach may be warranted should the EPA not finalize a regulatory determination for mixtures of these PFAS. Under this alternative, "the proposed MCLG and MCL for PFHxS would be 9.0 ng/L; for HFPO-DA the MCLG and MCL would be 10.0 ng/L; for PFNA the MCLG and MCL would be 10.0 ng/L; and for PFBS the MCLG and MCL would be 2000.0 ng/L." The agency requested comment on these alternatives for PFHxS, PFNA, HFPO-DA, and PFBS and whether these individual MCLs instead of or in addition to the Hazard Index approach would change public health protection, improve clarity of the rule, or change costs. Additionally, the EPA considered alternative mixture-based approaches such as a target-specific Hazard Index (TOSHI) or relative potency factor (RPF) approach. The agency requested comment on these approaches. Based on the EPA's technical expertise, the agency determined that the General Hazard Index is the most cost-effective and least burdensome alternative for purposes of UMRA because this approach for mixtures that achieves the objectives of the rule because of the level of protection afforded for the evaluation of chemicals with shared health endpoints. The EPA followed agency chemical mixture guidance (USEPA, 1986; USEPA, 1991b; USEPA, 2000a), which explain that when the Hazard Index value is greater than one (1) then risk is indicated (because exposure exceeds toxicity). The agency did not propose alternative Hazard Index values (i.e., higher Hazard Index values) because the EPA determined that a Hazard Index MCL of 1 is feasible: multiple treatment technologies are available to treat or below the MCL; the costs of applying these technologies to large and metropolitan water systems are reasonable; and there are analytical methods available to reliably quantify the four PFAS captured in the Hazard Index MCL (please see the EPA response in section 5.2.1 below for additional discussion on the EPA's feasibility analysis for the Hazard Index MCL). In addition, these alternative Hazard Index or mixture-based approaches would not provide sufficient protection against dose-additive health concerns from co-occurring PFAS. For example, a higher Hazard Index value (e.g., Hazard Index equal to 2) allows for exposure to be much greater than the toxicity and will not result in a sufficient health-protective standard that is as close as feasible to the MCLG, which is a level at which there are no known or anticipated adverse effects on human health and allows for an adequate margin of safety. The EPA notes that

commenters have not provided support justifying an alternative MCL standard for the Hazard Index.

Some commenters suggest that the EPA failed to consider the costs and impacts of the MCLs in non-drinking water contexts, such as its potential uses as CERCLA clean-up standards, its potential application as water quality objectives or groundwater recharge objectives, or its potential application in food and poultry industries. As required by SDWA, this rulemaking and analyses supporting the rulemaking only includes costs that "are likely to occur solely as a result of compliance with the [MCL]." Thus, the EPA's cost analyses focused on the compliance costs of meeting the MCL to PWSs that are directly subject to this regulation. The same provision expressly directs the EPA to exclude "costs resulting from compliance with other proposed or promulgated regulations." Thus, the EPA cannot consider the costs of use of the MCLs under other EPA statutes (such as CERCLA) as part of its EA (i.e., Economic Analysis or Health Risk Reduction or Cost Analysis) because SDWA specifically excludes such consideration (42 U.S.C. § 300g-1(b)(3)(C)(i)(III)). See also City of Waukesha v. EPA, 320 F.3d 228, 243-244 (D.C. Cir. 2003) (finding that SDWA excludes consideration of the costs of, for example, CERCLA compliance, as part of the required cost/benefit analysis). With respect to CERCLA clean-up costs, whether and how MCLs might be used in any particular clean-up is very site-specific and as a practical matter cannot be evaluated in this rulemaking. Nevertheless, it is inappropriate for the EPA to consider any potential CERCLA clean-up costs under a drinking water regulation as these are separate site-specific decisions on which applicable or relevant and appropriate requirement (ARAR) to use and represent different agency actions. In other words, the decision to clean up soil at sites is done under separate statutory authority and is not relevant when considering whether drinking water authorities should remove PFAS. Furthermore, an MCL is not a necessary prerequisite for clean-ups. Currently available Removal Management Levels (RMLs) and Regional Screening Levels (RSLs) inform site-specific decisions yield actionable levels close to the MCLs. To assess these impacts, the EPA would have to make assumptions about potential future, separate policy decisions regarding clean up. In short, these cost concerns are beyond the scope of this regulation.

Individual Public Comments

Little Hocking Water Association (Doc. #1835, SBC-045508)

Support of stand-alone MCLs for PFOA and PFOS.

LHWA supports the adoption of MCLs for PFOA and PFOS at 4 ppt or less and a MCLG of zero for PFOA and PFOS. "EPA requests comment on its proposed decision to establish stand-alone MCLs for PFOA and PFOS in lieu of including them in the HI Approach." LHWA provides the following data and comments in support of stand-alone MCLs for PFOS and PFOA:

1. Since 2002, when LHWA first started to become aware of the presence of elevated concentrations of PFOA in its water, only PFOA and PFOS (the chain length C-8) were discussed as a target for regulation. As a result, the focus of data-gathering efforts and research

was initially focused only on these two chemicals. More is known about these two PFAS than any of the other approximately 15,000 PFAS estimated to be documented today.

2. Data to date in LHWA's wellfield and raw water has similarly focused on PFOA. The concentrations of PFOA are significantly higher than other measured PFAS in the raw water. Attachment 1 shows the measured concentrations of PFOA in the raw water of LHWA from October 16, 2007 through April 10, 2023. This data shows concentrations of PFOA as high as 15,000 ppt in 2013 even after DuPont/Chemours reduced discharge of PFOA in 2009. Disturbingly, the concentrations of PFOA appear to remain relatively constant and do not show a significant downward trend with time.

3. Little Hocking also has information on the nearby Belpre, Ohio water system. The Belpre wellfield is located along the Ohio River and is approximately 3.8 miles upstream from LHWA and approximately 3.5 miles upstream of the Chemours Washington Works facility. Although concentrations of PFOA are less in the Belpre public water system raw water than in LHWA's raw water, the concentrations also show a disturbing upward trend of concentrations of PFOA (Attachment 2). This data demonstrates the persistence of PFOA in the environment and the importance of adopting a singular MCL for such a well-studied compound.

EPA Response: For additional discussion on alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. Regarding the EPA's decision to exclude PFOA and PFOS from the Hazard Index MCL, please see section 5.2.1 of the EPA response in this *Response to Comments* document. Regarding the commenter's submission on occurrence trends, the EPA primarily considers finished drinking water data in the agency's occurrence analysis as this is the most reflective of conditions to determine whether a contaminant is known to occur or there is a substantial likelihood that the contaminant will occur in PWSs with a frequency and at levels of public health concern. A comprehensive discussion of all the available state PFAS drinking water occurrence data is included in the *Occurrence Technical Support Document* (USEPA, 2024a). See also sections 3.1.2, 3.2.2, and 6 of the EPA response in this *Response to Comments* document for further discussion about available occurrence data and how it informed the EPA's decision making for this rule.

Arcadis (Doc. #3072-17, SBC-047367)

Good morning and good afternoon. Thanks to EPA and the team for welcoming public comments on such an important rulemaking. I strongly support this rulemaking. However, I do have two quick questions with regards to the proposed rule. In the year 2022, EPA announced interim health advisory limits of PFOA and PFOS. Based on the toxicology studies and those health advisory limits are significantly less than the proposed MCLs of 4 parts per trillion for PFOA and PFOS, respectively. I understand that the current available analytical methods cannot get that low enough to be notified health advisory levels and hence the reason for the MCLs. But it is conflicting to understand that the new rule is to safeguard the public, but there is still uncertainty whether the drinking water would contain below 4 parts per trillion for PFOA and

PFOS, for example, but yet be unsafe. That's a question mark. So, I would request EPA reconsider ways to address this gap.

EPA Response: For additional discussion on alternative regulatory standards, including discussion on lower MCLs for PFOA and PFOS, please see section 5.1.3 of the EPA response in this *Response to Comments* document. HAs are beyond the scope of this rulemaking. The EPA's HAs are non-enforceable and non-regulatory and provide technical information to state agencies and other public health officials on health effects, analytical methods, and treatment technologies associated with drinking water contamination. MCLs are regulatory and enforceable standards that are informed by regulatory development requirements under SDWA and includes the EPA's analysis of the best available and most recent peer-reviewed science. For additional information on how the agency considers feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043880)

2. The proposed PFOA and PFOS MCLs and the HI are protective of public health, and their implementation is feasible.

a. The proposed stand-alone PFOA and PFOS MCLs of 4.0 ppt are appropriate for the protection of public health.

The adverse health effects of PFOA and PFAS have been clearly established in numerous studies, ranging from from birth defects to cancer [FN31: See, e.g., Nat'l Cancer Inst., Section on What We Study, PFAS Exposure and Risk of Cancer, https://dceg.cancer.gov/research/what-we-study/pfas (last visited May 24, 2023) (listing multiple studies); Vladislav Obsekov, Linda G. Kahn, & Leonardo Trasande, Leveraging Systematic Reviews to Explore Disease Burden and Costs of Per- and Polyfluoroalkyl Substance Exposures in the United States, 15 EXPOSURE & HEALTH 373–94 (Jul. 26, 2022), available at https://doi.org/10.1007/s12403-022-00496-y; Si-Yu Gui, et al., Association Between Exposure to Per- and Polyfluoroalkyl Substances and Birth Outcomes: A Systematic Review and Meta-Analysis, 10 FRONTIERS IN PUB. HEALTH Article No. 855348 (Mar. 24, 2022), available at https://doi.org/10.3389/fpubh.2022.855348; Scott M. Bartell & Verónica M. Vieira, Critical Review on PFOA, Kidney Cancer, and Testicular Cancer, 71:6 J. of the AIR & WASTE MGMT ASSOC'N 663 (June 2021), available at https://doi.org/10.1080/10962247.2021.1909668; Xuejun Li, et al., Perfluoroalkyl Substances (PFASs) as Risk Factors for Breast Cancer: A Case–Control Study in Chinese Population, 21 ENVTL. HEALTH Article No. 83 (Sept. 9, 2022), available at https://doi.org/10.1186/s12940-022-00895-3. Additional studies are cited in the proposed NPDWR. 88 Fed. Reg. 18638.]. Yet, state Maximum Contaminant Level Goals ("MCLG") for PFOA and PFOS differ significantly in value: For example, the Commonwealth of Pennsylvania's analysis conducted by the Drexel PFAS Advisory Group recommended Chronic Non-Cancer MCLGs of 8 ppt for PFOA and 14 for PFOS [FN32: Drexel PFAS Advisory Group, Maximum Contaminant Level Goal Drinking Water Recommendations for Per- and Polyfluoroalkyl Substances (PFAS) in the Commonwealth

of Pennsylvania 74 (Jan. 2021), available at https://files.dep.state.pa.us/PublicParticipation/Public%20Participation%20Center/PubPartCenterPortalFiles/Environmental%20Quality%20board/2021/June%2015/03_PFAS%20Petition/01a_App%201%20Drexel%20PFAS%20Report%20January%202021.pdf.]. However, New Hampshire set the MCLG levels for both at 0.0 ppt [FN33: N.H. Code Admin. R. Env. 705.06(b), available at https://www.des.nh.gov/sites/g/files/ehbemt341/files/documents/env-dw-702-706-adptpstd.pdf]. These differences are in large part due to the main health condition considered and the reference dose ("RfD") values chosen, in addition to the methodology of calculation. For example, although both New Jersey and New Hampshire focused on the impact of PFOA on the liver when determining PFOA's MCLG, using the same Loveless 2006 [FN34: Scott E. Loveless, et al., Comparative Responses of Rats and Mice Exposed to Linear/Branched, Linear, or Branched Ammonium Perfluorooctanoate (APFO), 220 TOXICOLOGY 203 (Mar. 15, 2006), available at https://doi.org/10.1016/j.tox.2006.01.003.] study, they reached widely differing RfD values of 2 ng/kg/d and 6.1 ng/kg/d, respectively. Michigan and Pennsylvania chose skeletal effects based on Onishchenko 2011 [FN35: Natalia Onishchenko, et al., Prenatal Exposure to PFOS or PFOA Alters Motor Function in Mice in a Sex- Related Manner, 19(3) NEUROTOXICITY RES. 452–61 (May 29, 2010), available at https://doi.org/10.1007/s12640-010-9200-4.] and Koskela 2016, [FN36: A. Koskela, et al., Effects of Developmental Exposure to Perfluorooctanoic Acid (PFOA) on Long Bone Morphology and Bone Cell Differentiation, 301 TOXICOLOGY & APPLIED PHARMACOLOGY 14 (June 15, 2016), available at https://doi.org/10.1016/j.taap.2016.04.002.] calculating an RfD of 3.9 ng/kg/d.

For PFOS, most states focused on the immune system based on Dong 2011 [FN37: Guang-Hui Dong, et al., Sub-Chronic Effect of Perfluorooctanesulfonate (PFOS) on the Balance of Type 1 and Type 2 Cytokine in Adult C57bl6 Mice, 85 ARCHIVES OF TOXICOLOGY 1235 (Feb. 16, 2011), available at https://doi.org/10.1007/s00204-011-0661-x.] to calculate RfD in the range of 1.8–3 ng/kg/d. However, Massachusetts and Vermont used developmental issues, [FN38: Deanna J. Luebker, Marvin T. Case, Raymond G. York, John A. Moore, Kristen J. Hansen, & John L. Butenhoff, Two-Generation Reproduction and Cross-Foster Studies of Perfluorooctanesulfonate (PFOS) in Rats, 215 TOXICOLOGY 126 (Nov. 5, 2005), available at https://doi.org/10.1016/j.tox.2005.07.018; Deanna J. Luebker, Raymond G. York, Kristen J. Hansen, John A. Moore, & John L. Butenhoff, Neonatal Mortality from In Utero Exposure to Perfluorooctanesulfonate (PFOS) in Sprague-Dawley Rats: Dose-Response, and Biochemical and Pharmacokinetic Parameters, 215 TOXICOLOGY 149 (Nov. 5 2005), available at https://doi.org/10.1016/j.tox.2005.07.019.] reaching RfD values of 5 ng/kg/d and 20 ng/kg/d, respectively. To the best of our knowledge, despite being well documented, no state has used cancer risk as the main receptor to determine RfD and MCLG.

In contrast to the states, the Chemical Contaminant Rule requires that the MCLG for known cancer-causing contaminants be set to zero [FN39: EPA, Section on Drinking Water Requirements for States & Pub. Water Sys., Chemical Contaminant Rules, https://www.epa.gov/dwreginfo/chemical-contaminant-rules (last updated Nov. 15, 2022).] This rule regulates contaminants in three contaminant groups and applies to all public water systems.

Since both PFOA and PFOS have been designated as carcinogens, setting the federal MCLGs for PFOA and PFOS at 0.0 ppt is necessary and unavoidable.

Designating separate MCLGs for PFOA and PFOS (rather than including them in the HI) is important for several reasons:

First, these two compounds are the most prevalent PFAS species in water samples in the USA: As shown in the data compiled in the proposed NPDWR, PFOA and/or PFOS were detected in more than 30% of the drinking water samples reviewed, reaching astounding levels of more than 50% in South Carolina, Massachusetts, and New Hampshire [FN40: 88 Fed. Reg. 18673–74, Table 5.]. In Pennsylvania, extensive sampling data shows 25–27% of samples with PFOA or PFOS [FN41: 53 Pa.B. 335, Table 1.] Other PFAS compounds are less prevalent as a rule. The prevalence of PFOA and PFOS is also reflected in data from the Agency for Toxic Substances and Disease Registry ("ATSDR") of the Centers for Disease Control and Prevention ("CDC"). The concentrations of these two compounds in the United States population's blood are the highest when compared to other PFAS compounds [FN42: ATSDR, PFAS in the US Population, https://www.atsdr.cdc.gov/pfas/health-effects/us-population.html (last reviewed Dec. 22, 2022).]. EPA proposes to set the MCLs for PFOA and PFOS at 4.0 ppt. This is not the lowest practical quantitation limit ("PQL") that can be achieved by laboratories, as shown in the Table below for the EPA currently certified PFAS testing methods (533 and 537.1), and the in-development method 1633:

[Table: see docket ID EPA-HQ-OW-2022-0114-1731]

The feasibility of reliably detecting values lower than 4 ppt is demonstrated, for example, in the Pennsylvania drinking sampling data, where PFOA and PFOS were detected at levels as low as 1.7 ppt [FN49: 53 Pa.B. 335.] Also, as noted, current water treatment methods can remove these compounds to non-detectable levels, which means it would be possible to remove PFOA and PFOS down to the lowest detectable limits of at least 1.7 ppt.

Setting the MCLs for PFOA and PFOS below 4 ppt is therefore possible and would benefit public health. However, Commenters acknowledge that a lower value may be subject to fluctuations and difficult to implement, and therefore could place a heavy burden on public water systems. While the proposed MCLs are a reasonable compromise, Commenters urge the EPA to review these values periodically as the associated technology improves.

EPA Response: For additional discussion on alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. Regarding the EPA's decision to exclude PFOA and PFOS from the Hazard Index MCL, please see section 5.2.1 of the EPA response in this *Response to Comments* document. The agency disagrees that a lower MCL is feasible for PFOA and PFOS due to analytical capabilities nationwide at this time; for additional discussion on alternative regulatory standards, including discussion on lower MCLs for PFOA and PFOS, please also see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to*

Comments document. Regarding the agency's determination that PFOA and PFOS are Likely to be Carcinogenic to Humans, please see section 4.1.4 of the EPA response in this *Response to Comments* document.

Uttara Jhaveri (Doc. #1778, SBC-045440)

Recently, the U.S. Environmental Protection Agency (EPA) proposed the National Primary Drinking Water Regulations (NPDWR) for six PFAS, including perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), perfluorononanoic acid (PFNA), hexafluoropropylene oxide dimer acid (HFPO-DA, commonly known as GenX Chemicals), perfluorohexane sulfonic acid (PFHxS), and perfluorobutane sulfonic acid (PFBS). [FN4: Environmental Protection Agency, PFAS National Primary Drinking Water Regulation Rulemaking, (2023), .]

NATIONAL PRIMARY DRINKING WATER REGULATIONS: COMMENT

PROPOSED PFAS LEVELS IN DRINKING WATER

The EPA's proposal to regulate PFOA and PFOS at 4 parts per trillion (ppt) is a practical decision considering the analytical levels at which the existing technologies in the drinking water can accurately identify the chemicals. [FN5: Id.]However, considering that the current limit of PFAS in drinking water is 70 ppt, the regulations have considerably decreased the limits. [FN6: Id.]It is estimated that about 100 million Americans are drinking water that probably has PFAS levels exceeding the current limit of 70 ppt. [FN7: Karen Feldscher, Stricter federal guidelines on 'forever chemicals' in drinking water pose challenges, HARVARD T.H. CHAN SCHOOL OF PUBLIC HEALTH, .]Therefore, the EPA must consider that near 0 levels of PFAS may be unachievable with the state of the technology to detect PFAS in drinking water.

Further, individual states, such as Vermont, Massachusetts, New Hampshire, Michigan, California, and New Jersey, have lowered the limit of PFAS in drinking water below 70 ppt but remain higher than the limits EPA announced via its regulations. [FN8: Id.]The EPA guidelines could serve as a goal, with the reduced limits being a binding intermediate limit for PFAS for the short term, which is achievable with the current technology.

EPA Response: For additional discussion on alternative regulatory standards, including discussion on lower MCLs for PFOA and PFOS, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA is clarifying for the commenter that before this final PFAS NPDWR, there were no national "limits" for PFAS in drinking water. While some states have promulgated drinking water standards for various PFAS prior to promulgation of this NPDWR, this rule provides a nationwide, health protective level for PFOA and PFOS (as well as four other PFAS) in drinking water and reflects regulatory development requirements under SDWA, including the EPA's analysis of the best available and most recent peer-reviewed science; available drinking water occurrence, treatment, and analytical feasibility information relevant to the PQL; and consideration of costs and benefits. After the NPDWR takes effect, SDWA requires primacy states to have a standard that is no less stringent than the NPDWR.

Missouri Department of Natural Resources (Doc. #1563, SBC-042537)

Section XIII—HRRCA [Health Risk Reduction and Cost Analysis]

In the Economic Analysis, EPA presented estimated costs and benefits of regulatory alternatives for PFOA and PFOS if setting MCLs at 5.0 ppt and 10.0 ppt. EPA is requesting comment on its evaluation of these alternatives within the Economic Analysis.

The Department disagrees with EPA's conclusion that the regulatory alternative for setting the PFOA and PFOS MCL at 10.0 ppt does not meet a significant reduction in American's exposure to PFAS. The Department believes that EPA significantly underestimated the cost of reducing the MCL below 10.0 ppt.

EPA Response: The EPA did not conclude at proposal that "PFOA and PFOS MCL at 10.0 ppt does not meet a significant reduction in American's exposure to PFAS." Rather, the Administrator determined that for PFOA and PFOS, 4.0 ppt is as close as feasible to the MCLG and that the benefits of the rule justified the costs, for more information see section 5.1.3 of the EPA response in this *Response to Comments* document.

The EPA notes that the record supporting the agency's feasibility analysis supports final standards at 4.0 ppt. For additional discussion on the EPA's feasibility analysis with respect to analytic and laboratory considerations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. Regarding responses regarding the agency's evaluation of compliance costs for the final NPDWR, please see section 13.3 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043629)

2. The USEPA has assessed the impact of different options of the Maximum Contaminant Levels (MCLs) for the two major PFAS compounds (PFOA and PFOS) in drinking water including 4, 5 and 10 ppt; however, USEPA's own analysis demonstrates that the option selected for the proposed rule (the most stringent of the options), is the least cost-beneficial of the options considered.

EPA Response: For additional discussion on benefit-cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043639)

Furthermore, cost-benefit analyses of setting the MCLs at thresholds incrementally higher than 4 ng/L (e.g., 5 ng/L, 10 ng/L, etc.) revealed that more stringent MCLs resulted in lower net

benefits. The USEPA considered four scenarios – the results of each presented in the tables below:

1) PFOA and PFOS MCLs of 4.0 ppt and HI of 1.0 (the proposed option) (Table 1)

2) PFOA and PFOS MCLs of 4.0 ppt (Table 2)

3) PFOA and PFOS MCLs of 5.0 ppt (Table 3)

4) PFOA and PFOS MCLs of 10.0 ppt (Table 4)

The proposed MCLs of 4.0 ppt for PFOA and PFOS and an HI of 1.0 (the most stringent of the options and the one selected for the proposed rule) had the least net benefit (Table 1) compared to other options considered in the USEPA cost-benefit analysis shown below.

Table 1. Annualized Quantified National Costs and Benefits, Proposed Option (PFOA and PFOS MCLs of 4.0 ppt and HI of 1.0; Million $2021), adapted from USEPA.

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1602]

Table 2. Annualized Quantified National Costs and Benefits, (PFOA and PFOS MCLs of 4.0 ppt; Million $2021), adapted from USEPA.

[Table 2: See Docket ID EPA-HQ-OW-2022-0114-1602]

Table 3. Annualized Quantified National Costs and Benefits, (PFOA and PFOS MCLs of 5.0 ppt; Million $2021), adapted from USEPA.

[Table 3: See Docket ID EPA-HQ-OW-2022-0114-1602]

Table 4. Annualized Quantified National Costs and Benefits, (PFOA and PFOS MCLs of 10.0 ppt; Million $2021), adapted from USEPA.

[Table 4: See Docket ID EPA-HQ-OW-2022-0114-1602]

BWWB acknowledges that the regulation of PFAS is an important step towards protecting public health and minimizing risks. However, USEPA's own analysis demonstrates that the option selected for the proposed rule (the most stringent of the options), is the least cost-beneficial of the options considered. BWWB requests that USEPA consider proposing MCLs that are demonstrated to be both economically feasible and cost justifiable.

EPA Response: For additional discussion on benefit-cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043728)

If the MCL is increased to 10 ppt as Aurora has proposed, then the focus for treatment will shift to the removal of HI compounds instead of PFOA and PFOS. Aurora would be able to have fewer GAC material change outs which would mean lower annual costs and less waste produced.

Treating to 10ppt would result in annual costs of about $300,000 per year while treating to 4ppt would be about $670,000 per year. Not only would Aurora Water have fewer financial impacts by a higher MCL, but it is also estimated that in Colorado there would be 20 water systems that would exceed an MCL of 10 ppt versus an estimated 60 water systems that would exceed the proposed 4 ppt MCLs. The fewer systems that exceed the MCLs, the fewer that will have to change their treatment processes. This should also be considered in the cost estimates and feasibility studies through EPA.

EPA Response: To clarify, a NPDWR is a national rule that sets enforceable standards for PWSs across the country. As such, the agency analyzed the quantifiable and non-quantifiable costs and benefits of the rule at a national level. The commenter raises a scenario that if fewer systems exceed the MCLs, fewer systems will have "change their treatment processes" and that this factor should be considered in the cost estimates in the rule. The EPA has considered these cost considerations and alternative regulatory standards; please see section 5.1.3 of the EPA response in this *Response to Comments* document. As required by SDWA, the EPA has set the MCLs for PFOA and PFOS as close to their MCLGs as feasible, taking cost into consideration. For additional discussion on the EPA's feasibility analysis with respect to analytic and laboratory considerations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. Finally, the EPA Administrator has determined that the costs of the rule are justified by the benefits. See section 13.8 of the EPA response in this *Response to Comments* document for further discussion.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043720)

Raising the proposed MCL would dramatically reduce costs for the water system. For Aurora, a change from removing PFOA/PFOS to 10 ppt instead of 4 ppt would mean a 10% increase in yearly costs versus a 200% increase and will serve as a balance for protecting public health while EPA works with manufacturers to remove PFAS sources. Additionally, raising the MCL would reduce the number of public notifications required, which is also an expense and degrades public confidence in their water. Bottled water companies are not required to disclose PFAS compounds in their water; however, some are reporting <5ppt. If consumers are turning to bottled water instead of tap, they may, unknowingly, be getting more exposure to PFAS.

EPA Response: Please see the EPA response to comment Doc. #1669, SBC-043728 in section 5.1.3 in this *Response to Comments* document. For additional discussion on cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that bottled water is under the purview of the FDA and is out of scope for this NPDWR.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044925)

Section 8: HRRCA for the proposed NPDWR

Section 8.1: Evaluation of Benefit-Cost Analysis: Regulatory Alternatives

In the Economic Analysis, EPA presented estimated costs and benefits of regulatory alternatives for PFOA and PFOS if setting MCLs at 5.0 ppt and 10.0 ppt. Cleveland Water asks EPA to carefully consider whether the benefits of finalizing the rule at 10 ppt better justifies the costs while still presenting a meaningful reduction in public health risks. Considering that the costs will be disproportionately borne by smaller systems and disadvantaged communities, EPA should explore what, if any, health benefits accrue from setting an MCL from 10 ppt to 4 ppt and consider if the social benefits and reduced overall costs of 10 ppt would be more appropriate. The limitations and uncertainties EPA acknowledges in its model application in the Economic Analysis warrant further investigation into quantified costs and benefits this rule will impose.

EPA Response: Please see the EPA response to comment Doc. #1669, SBC-043728 in section 5.1.3 in this *Response to Comments* document. For additional discussion on cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA is clarifying for the commenter that the agency did examine the health benefits and costs at each of the selected and alternative regulatory standards, and examined the quantifiable and non-quantifiable benefits that "accrue from setting an MCL from 10ppt to 4 ppt." The analysis is presented in the EPA's HRRCA for the final PFAS NPDWR and further discussed in section 13 of the EPA response in this *Response to Comments* document.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044952)

14. NYS appreciates the fact that EPA has estimated the net cost/benefit of different regulatory thresholds, 4, 5 and 10 ppt. We note that the estimated net benefit of 4 ppt is only slightly greater than the net benefit at 10 ppt ($240M vs $200M at 3% discount rate) when focusing solely on the direct health benefits of PFOA/PFOS mitigation and not including co-benefits from the removal of disinfection byproducts. As noted, the overwhelming majority of water supplies expected to be impacted by this proposal in New York State will not benefit from co-removal of TOC. Thus, when considering the direct impact of PFOA/PFOS regulation, the Department is pleased to see that EPA's analysis supports a high degree of net benefit from the MCLs already in place in NYS since 2020, and that this is not substantially different than the estimated benefit at 4 ppt.

EPA Response: For additional discussion on cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For EPA's *Response to Comments* on the disinfection by-product co-removal benefits anticipated as a result of the rule, see section 13.7 of the EPA response in this *Response to Comments* document. The EPA notes that under the SDWA, EPA must consider "Quantifiable and nonquantifiable health risk reduction benefits for which there is

a factual basis in the rulemaking record to conclude that such benefits are likely to occur from reductions in co-occurring contaminants that may be attributed solely to compliance with the MCL, excluding benefits resulting from compliance with other proposed or promulgated regulations" (See SDWA 1412(b)(3)(C)(i)(III). At a national level, the EPA has determined that total organic carbon (a Disinfection Byproduct [DBP] precursor) is a co-occurring contaminant that will be co-removed for those systems that elect to use granular activated carbon to remove PFAS. Since EPA has quantified benefits associated with DBP reduction due to total organic carbon (TOC) co-removal, it would be inconsistent with the SDWA statutory standards for EPA to exclude considering these benefits from consideration.

American Chemistry Council (ACC) (Doc. #1711, SBC-047703)

ACC further urges EPA to reconsider the proposed standards for PFOA and PFOS in light of the inability to determine that the benefits of the current proposal justify its costs, per Section 1412(b)(4)(C) of the SDWA.

Sincerely,

Steve Risotto

Stephen P. Risotto Senior Director

Enclosure

EPA Response: The EPA disagrees with commenter's statements regarding EPA's "inability to determine that the benefits of the current proposal justify the costs." In its proposed rule preamble, the Administrator determined the costs of the rule are justified by the benefits (see section XII of the final rule preamble). Furthermore, the EPA Administrator is re-affirming the decision made at proposal that the benefits of the final NPDWR justify the costs (see section 13.8 of the EPA response in this *Response to Comments* document and section XII of the preamble for the final rule for more information.) For additional discussion on benefit-cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045992)

Section 8.7: Evaluation of benefit-cost analysis: regulatory alternatives

Given the underestimation of costs, partially due to the social cost of carbon and social costs generally, AMWA asks EPA to carefully consider whether the benefits of finalizing the rule at 10 ppt better justify the costs while still presenting a meaningful reduction in public health risks. In the Economic Analysis, EPA presented estimated costs and benefits of regulatory alternatives for PFOA and PFOS of setting MCLs at 5.0 ppt and 10.0 ppt.

Considering that the costs will be disproportionately borne by smaller systems and disadvantaged communities, EPA should explore what, if any, health benefits accrue going from an MCL of 10

ppt to an MCL of 4.0 ppt, and consider if the social benefits and reduced overall costs of 10 ppt would be more appropriate. The limitations and uncertainties EPA acknowledges in its model application in the Economic Analysis warrant further investigation into quantified costs and benefits this rule will impose.

EPA's analysis falls short of analyzing the full impact of the proposed rulemaking by only including engineering costs. Not including the social costs of carbon and other social costs hinders the Administrator from having all necessary information to set the PFOA and PFOS drinking water standard at a level that maximizes health risk reduction benefits at a cost that is justified, given those benefits.

Figure 8 in Attachment 1, and copied below, shows that the most benefits will occur for the population that has the highest exposure to PFOA and PFOS.

(PNG, 2023 Figure 8) Probability Distribution of HED by Disease Type for All Ages and Probability of Dose from Drinking Water for the Population

[Figure 8: see docket ID EPA-HQ-OW-2022-0114-1738]

The analysis by PNG replicated work by Chen et al and described in Attachment 1 aims to identify the most comprehensive evaluation of possible biologic changes in response to PFOS exposure. An adverse effect starts with biologic change; if there is little change in response to PFOS exposure at a certain dose, the likelihood of an adverse effect at that dose is greatly diminished. The Chen et al. and Chou et al. papers show the principal cellular and genomic changes in animal and human cells across a range of doses and cell types. For the most sensitive tissue and with the longest duration of PFOS exposure, the analysis identified 108 potential cellular and genomic changes and the dose that led to a 10 percent change in activity. A 10 percent change in activity does mean an adverse effect will happen – it is a benchmark commonly used by regulatory agency to mark when a chemical has a clear effect on the body. From these estimated benchmark doses, the analysis applied an additional safety factor of 30 to account for variation in responses in the human population. As a result, the analysis shows that below an internal dose of 20 ng/kg/day, there is little biological activity from PFOS exposure. Assuming a simple model of accumulation and excretion in the body, this dose translates to a 70 kg person drinking 2 liters a day of drinking water containing PFOS at 46 ppt.

Therefore, below a level equivalent to that concentration, very few if any adverse effects are expected. As a result, reducing existing state MCLs that range up to 15 or 20 ppt are expected to have minimal benefit, and EPA could set MCLs at 10 ppt without imposing any additional public health risks.

EPA Response: With respect to the commenter's recommendation to consider the social cost of carbon associated with this rulemaking, based on this and other comments, the EPA has included that analysis in the final rule; for additional details on this analysis, please see section XIII of the final rule preamble and section 13.11 of the EPA response in this *Response to Comments* document. With respect to considerations for other social costs, see section 13.9. For

additional discussion on benefit-cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The agency however disagrees that "reducing existing state MCLs that range up to 15 or 20 ppt are expected to have minimal benefit, and the EPA could set MCLs at 10 ppt without imposing any additional public health risks." The agency points to the fact that PFOA and PFOS are likely human carcinogens and that there is no level in drinking water below which no known or anticipated adverse effect on the health of persons would occur while allowing for an adequate margin of safety. Second, there are many states that currently do not have a state standard or health-based guideline value for any PFAS and as such, there is no requirement for systems to monitor and control for PFAS in their drinking water. In fact, based on individual state laws, some states are prohibited from adopting such as standard until the EPA promulgates one. As such, regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Lastly, the EPA conducted a systematic review of all the available peer-reviewed literature reporting health effects associated with PFOS exposure..

The commenter is describing an approach to toxicity value derivation that is not commonly used by regulatory agencies and that is inconsistent with the currently established human health risk assessment methodologies and guidance developed by the EPA (e.g., USEPA, 2022b; USEPA, 2005, USEPA, 2002; USEPA, 2012). The commenter states that the analysis shows "that below an internal dose of 20 ng/kg/day, there is little biological activity from PFOS exposure. Assuming a simple model of accumulation and excretion in the body, this translates to a 70 kg person drinking 2 liters a day of drinking water containing PFOS at 46 ppt." The EPA disagrees with this analysis and with this approach to deriving a drinking water concentration. The EPA has shown that PFOA or PFOS exposures at doses several orders of magnitude lower are associated with multiple adverse health outcomes in humans (see section 4.2.2 of the EPA response in this *Response to Comments* document for how the EPA derived reference doses (RfDs) for PFOA and PFOS and section 4.2.1 of the EPA response in this *Response to Comments* document for the evidence supporting the critical effects that are the basis for the candidate RfDs derived in the final toxicity assessments (USEPA, 2024g; USEPA, 2024h)). The EPA has demonstrated that there is biological activity below the dose of 20 ng/kg/day recommended by the commenter. For more details on the EPA's MCLGs please see section 4 of the EPA response in this *Response to Comments* document.

LSP Association (LSPA) (Doc. #1742, SBC-043594)

See attached file(s)

Overall, while the LSPA absolutely believes that safe drinking water supplies are imperative, we urge USEPA to adopt the standard of 10.0 ppt (Option 1c) to more closely balance the costs and benefits of implementing this proposed rule. Simultaneously, the LSPA believes that the protection of public health will be much more effectively achieved by restricting the use of PFAS in consumer products.

Thank you for the opportunity to provide these comments.

EPA Response: The EPA Administrator is re-affirming the decision made at proposal that the benefits of the final NPDWR justify the costs. For additional discussion on benefit-cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

LSP Association (LSPA) (Doc. #1742, SBC-043605)

Slide 29: EPA appreciates additional information and will use input received in public comments to inform the economic analysis for the final rule.

• In Section 2.1 of EPA-822-P-23-001, USEPA presents an evaluation of three alternatives for the enforceable MCL values for PFOA and PFOS:

o 4.0 ppt in Option 1a;

o 5.0 ppt in Option 1b, because it is 25 percent above the compliance quantitation limit of 4.0 ppt established for today's regulation; and at the level at which the benefits would justify the costs.

• In the tables provided in Section 7.0, only Option 1c results in a net benefit (for quantified factors) using both the 3% and 7% discount rates. As noted in other LSPA comments, a significant portion of the costs associated with the proposed MCLs (which will also dictate standards for private drinking water wells, groundwater, and leachable soil) is not quantified in the economic evaluation, which only includes public water supplies. These costs are not listed in Table 7-5 as non-quantified costs that were considered. As a result, LSPA urges USEPA to consider adopting the standard of 10.0 ppt (Option 1c) to more closely balance costs and benefits.

EPA Response: For additional discussion on cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The agency notes that while SDWA does not regulate private wells and this final rule does not set any requirements or standards for private well owners, the EPA understands that people who consume water from private wells may be concerned about contamination of their drinking water by PFAS or other contaminants. The EPA has resources to help people who rely on private wells for their drinking water at: https://www.epa.gov/privatewells. Standards for "groundwater" and "leachable soil," and any potential cost impacts, are not in scope of this NPDWR. SDWA Section 1412b(3)(C)(i)(III) requires that EPA include quantifiable and non-quantifiable costs that are likely to occur solely as a result of compliance with the rule including monitoring, treatment and other costs and excluding costs resulting from compliance with other proposed or promulgated regulations.

LSP Association (LSPA) (Doc. #1742, SBC-043610)

Overall, while the LSPA absolutely believes that safe drinking water supplies are imperative, we urge USEPA to adopt the standard of 10.0 ppt (Option 1c) to more closely balance the costs and benefits of implementing this proposed rule. Simultaneously, the LSPA believes that the protection of public health will be much more effectively achieved by restricting the use of PFAS in consumer products.

Thank you for the opportunity to provide these comments. Sincerely,

THE LSP ASSOCIATION, INC.

Charles P. Young, LSP, President

Wendy Rundle, Executive Director

cc:

Commissioner Bonnie Heiple, MassDEP

EPA Response: The EPA Administrator is re-affirming the decision made at proposal that the benefits of the final NPDWR justify the costs. For additional discussion on benefit-cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045564)

4. The results of the health risk reduction and cost analysis (HRRCA) are mixed and demonstrate the uncertainty of actual outcomes on communities. Under one analysis (3% discount rate), net benefits are expected for each rule option. Under the other analysis (7% discount rate), though, only one rule option (10 ppt PFOA and 10 ppt PFOS) has net benefits. EPA should recognize the significance of these conflicting results, in conjunction with the concerns regarding the cost analysis, prior to finalizing any rule.

EPA Response: The EPA Administrator is re-affirming the decision made at proposal that the benefits of the final NPDWR justify the costs. For additional discussion on benefit-cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. Additionally, the EPA disagrees with the commenter that results at proposal using the 3 and 7 percent discount rate were "conflicting." The results presented at 3 and 7 percent represent identical impacts, both costs and benefits of the regulation over the period of analysis. Positive net benefits at one discount rate and negative at the other discount rate simply demonstrates the impacts of adjusting the discount rate. See section 13.2 of the EPA response in this *Response to Comments* document for further discussion about discount rates. Further, as discussed in section 5.1.3 of the EPA response in this *Response to Comments* document, quantified positive net benefits at both 3 and 7 percent discount rates are not required to promulgate an MCL, nor are quantified costs and

benefits the only information considered in the Administrator's determination that the benefits of the rule justify its costs. As discussed in section 13.5 of the EPA response in this *Response to Comments* document, substantial nonquantifiable benefits of the rule are anticipated to be realized by rule implementation in addition to the quantified benefits discussed by the commenter. Additionally, see section 13.3 of the EPA response in this *Response to Comments* document on the cost analysis. Regulating PFAS and consumer products is outside the scope of this current rulemaking (please see section 15 of the EPA response in this *Response to Comments* document).

American Water Works Association (AWWA) (Doc. #1759, SBC-045633)

13. Alternative Regulatory Options for Drinking Water Standards

The proposal provides a detailed overview of the four regulatory alternatives that were considered by the Administrator to support this rulemaking. These options are laid out both in the preamble of the proposal and the economic analysis. The economic analysis frames both the costs and benefits of the proposed option and its alternatives. The proposed option is 4 ppt PFOA, 4 ppt PFOS, and a hazard index for PFHxS, PFNA, HFPO-DA, and PFBS of 1.0. Option 1a, 1b, and 1c propose MCLs for PFOA and PFOS each at 4 ppt, 5 ppt, and 10 ppt, respectively. Figures 13-1 and 13-2 depict the results of EPA's analysis based on both discount rates of 3% and 7%. Presentation of both discount rates to inform decision-making is consistent with Office of Management and Budget guidance for regulatory analyses.

A striking observation from both figures is the difference in annualized costs for the Proposed Option and Options 1a and 1b compared with Option 1c. Under both discount rates, the cost to implement the rule doubles from Option 1c to 1b. This is reflective of the significant number of systems that would be required to install PFAS treatment facilities to mitigate PFAS to comply with rule Option 1b compared to Option 1c. This difference is expected to impact systems that have PFAS levels ranging from 4 to 8 ppt, as EPA assumes that only systems within 80% of the MCL will make costly infrastructure investments.

These figures demonstrate that, regardless of the discount rate, there are minimal incremental benefits with the addition of the hazard index MCL for PFHxS, PFNA, PFBS, and HFPO-DA. This is substantiated by the available occurrence data, which demonstrates that very few systems would be required to install treatment for the PFHxS, PFNA, PFBS, and HFPO-DA MCL but not the PFOA and PFOS MCL.

[Figure 13-1: See Docket ID EPA-HQ-OW-2022-0114-1759]

Figure 13-1 : Annualized Costs and Benefits (7% Discount Rate)

[Figure 13-2: See Docket ID EPA-HQ-OW-2022-0114-1759]

Figure 13-2 : Annualized Costs and Benefits (7% Discount Rate)

To evaluate each regulatory option, AWWA considered the various concerns with the underlying analyses to support the rule that are discussed throughout this letter and the guiding principles for PFAS regulation that were noted earlier, and has determined that any rule will require a substantial level of work to improve the analyses that support the decision by the EPA. Furthermore, AWWA recommends that – if any rule is finalized based on the proposal – EPA finalize the MCLs for PFOA and PFOS at 10 ppt each. AWWA makes this recommendation for several reasons, laid out in more detail below.

EPA Response: The EPA agrees with the commenter that the agency presented discount rates in the proposed rule consistent with guidance in the A-4 circular. With respect to discount rates used in the proposed and final EA consistent with Circular A-4 Guidance, see section 14.1 of the EPA response in this *Response to Comments* document, Chapter 2 of the EA (USEPA, 2024d), and section 13.2 of the EPA response in this *Response to Comments* document. With respect to the incremental benefits of the Hazard Index MCLs, see Chapter 6 of the EA where EPA details the extensive nonquantifiable benefits of reduced exposure to PFAS beyond PFOA and PFOS, including the compounds in the Hazard Index. The EPA disagrees that the "rule will require a substantial level of work to improve the analyses that support the decision by the EPA." The agency has updated several analyses, including cost, benefit, and occurrence analyses, incorporating updated information suggested by commenters that all confirm the EPA's proposed rule finding. For more information about updates to the cost analyses, please see section 13.3 of the EPA response in this *Response to Comments* document; for updates to the benefits analyses, please see 13.4 of the EPA response in this *Response to Comments* document, and for updates to the occurrence analyses, please see section 6 of the EPA response in this *Response to Comments* document. All updated analyses are confirmatory of the EPA's conclusions in the proposed rule. For the final rule, the EPA Administrator is re-affirming the decision made at proposal that the benefits of the final NPDWR justify the costs. For additional discussion on benefit-cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045689)

VIII. EPA's BENEFITS ANALYSIS DOES NOT COMPLY WITH THE SDWA

The SDWA requires EPA to analyze the "[q]uantifiable and nonquantifiable health risk reduction benefits for which there is a factual basis in the rulemaking record to conclude that such benefits are likely to occur as the result of the treatment to comply" with each alternative level the Agency considers. [FN83: SDWA [sec]1412(b)(3)(C)(i)(I).] As discussed below, EPA's benefits analysis fails to comply with this requirement and is arbitrary, opaque, and counter to fundamentals of toxicology.

A. EPA's Selection of Alternative MCLs for PFOA and PFOS is Arbitrary

In promulgating NPDWRs since the 1996 SDWA Amendments, which first require consideration of alternatives, EPA has routinely considered at least four regulatory alternatives.

[FN84: See National Primary Drinking Water Regulations: Lead and Copper Rule Revisions, 84 Fed. Reg. 61684 (2019) (considering four alternative regulatory options); National Primary Drinking Water Regulations; Arsenic and Clarifications to Compliance and New Source Contaminants Monitoring 66 Fed. Reg. 6976 (2001) (considering four alternative MCL levels); and National Primary Drinking Water Regulations; Radon-222, 60 Fed. Reg. 59246 (1999) (considering seven alternative MCL levels).] As discussed below, in this rulemaking EPA considers only two theoretical alternatives to the proposed MCL of 4.0 ppt for PFOA and PFOS: 5.0 ppt and 10.0 ppt. EPA justifies its selection of regulatory alternatives not based on meaningful toxicological considerations, but instead on arbitrary comparisons to analytical levels and inapplicable state regulations. EPA states (USEPA 2023f) that it "considered an MCL of 5.0 ppt for PFOA and PFOS because it is 25 percent above the [practical quantitation limit] PQL of 4.0 ppt." EPA notes that this selection was based on input from a commenter in EPA's outreach consultations who "suggested the Agency consider a buffer of approximately 20 percent if the MCL is close to the quantitation level because water systems operate with a margin of safety and plan for performance that maintains water quality below quantitation levels." Thus, this value is intended to be a buffer between the PQL and MCL that could allow utilities to manage treatment approaches. EPA states that it disagrees that such a consideration is necessary but nonetheless applies the value yielded by the approach.

EPA (USEPA 2023f) also states that it "considered the MCL of 10.0 ppt to evaluate the national costs and benefits and whether the expected reduction in costs would change EPA's determination of the level at which the benefits would justify the costs (see Safe Drinking Water Act [SDWA] Section 1412(b)(6)(A))." The Agency maintains that this regulatory alternative level is consistent with State-enacted MCLs for certain PFAS, citing New York's PFOA and PFOS MCLs of 10 ppt. [FN85: EPA ignores that states have implemented a range of PFAS MCLs, some greater than 10 ppt., without further explanation for its use of 10ppt] There is no evidence that EPA considered different approaches nor the toxicological bases of various states' MCLs.

b. As a Matter of Toxicology, the "Alternatives" EPA Selected All Represent the Same Level of Exposure.

The alternatives EPA considered for PFOA and PFOS are meaningless, in violation of SDWA [sec]1412 (b)(3)(C)(i). EPA prepared a health risk reduction and cost analysis and quantified health outcomes in the benefits analysis for the proposed NPDWR, where it purported to distinguish between national benefits at drinking water concentrations of PFOS and PFOA at 4.0 ppt, 5.0 ppt, and 10.0 ppt (USEPA 2023i). It is not possible to determine how EPA conducted its benefits analysis because EPA did not make its model or important inputs into the model available in the public docket. What is clear is that EPA failed to acknowledge that chemical exposures from drinking water at 4.0 ppt, 5.0 ppt, and 10.0 ppt are toxicologically indistinguishable based on fundamental principles of toxicology and dose-response (Waddell 2008, 2010) and further detailed below. The numerically quantified health outcomes for those concentrations are not meaningful for public health.

Toxicology at its most fundamental level is based on the chemical reaction of a substance with a biological receptor. The activity of such chemical reactions is measured based on a logarithmic scale (Waddell 2008). Thus, dose-response relationships which describe the relationship of the amount of a substance to the effects from these biological reactions are assessed using a logarithmic scale. Consequently, when considering a logarithmic scale, only doses that differ by an order of magnitude (i.e., 10-fold) or more are biologically distinguishable. [FN86: The logarithmic nature of toxicology is also the reason why the dose selection for dose-response studies is generally advised to span two to four orders of magnitude (e.g., OECD, 2018 Test No. 408; USEPA, 2000 Health Effects Test Guidelines OPPTS 870.3050): it allows for an investigation of equidistant doses on the logarithmic scale in half-unit steps, e.g. log(1)=0, log(3.16)=0.5, log(10)=1, log(31.62)=1.5, log(100)=2, etc..] EPA even incorporates this concept into its own definition of a reference dose (USEPA 1993) "is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime." [emphasis added]. This definition highlights that it is not meaningful to distinguish between exposure doses occurring within an order of magnitude (i.e., 10-fold) of one another.

EPA's attempt to differentiate among health effects associated with the proposed MCL and the two regulatory alternatives—4.0 ppt, 5.0 ppt, and 10.0 ppt—is at best a theoretical exercise that lacks any toxicological relevance. This lack of relevance becomes obvious when human exposure doses are derived from the respective concentrations in drinking water and compared on a logarithmic scale.

However, the EPA (USEPA 2019) Exposure Factors Handbook provides information on drinking water intakes, and the following calculations can be conducted for any age group without yielding fundamentally different results. For this calculation (Table 7-1, Figure 7-2), the two-day average per capita estimates of combined direct and indirect water ingestion for all ages at the 95th percentile, which EPA listed as 37.1 ml/kg-d, was applied.

Table VII-1. Calculation of Hypothetical Exposure Doses (pg/kg-d) at Each Regulatory Alternative.

[Table VII-1: see docket ID EPA-HQ-OW-2022-0114-1774]

And displayed graphically:

[Figure VII-1: see docket ID EPA-HQ-OW-2022-0114-1774]

Figure. VII-1. Presentation of Exposure Doses Resulting from Proposed PFOA and PFOS Regulatory Alternatives.

The plots of daily exposures from drinking water that contains 4.0 ppt, 5.0 ppt, or 10.0 ppt of a substance (Figure 9-2) powerfully clarifies why dose should be considered on a logarithmic scale. In this figure, the y-axis is adjusted to a logarithmic scale to demonstrate that the three doses are actually all within one order of magnitude of each other (i.e., between 100 and 1000 pg/kg/d, a 10-fold range). In fact, the difference is within 2.5-fold. Accordingly, applying EPA's

definition of a reference dose, there would be no discernable differences between exposures occurring at 4.0 ppt, 5.0 ppt, or 10.0 ppt. Therefore, when presented on a toxicologically accurate scale, these three exposures cannot be expected to be biologically different from one another. Any hypothesized health benefits from choosing one of the proposed concentrations over the other are just that: hypothetical and speculative.

c. The Uncertainties in Parameters Used by EPA Thwart the Ability to Accurately Distinguish Between 4.0, 5.0, and 10.0 ppt.

Even though EPA listed numerous uncertainties in its benefits analysis, it failed to acknowledge that these uncertainties make it impossible to practically distinguish effects at concentrations of 4.0 ppt, 5.0 ppt, and 10.0 ppt. A slight change in assumptions within the spectrum of uncertainties might mathematically result in completely different concentrations in drinking water. In other words, the uncertainties in EPA's analysis are so great that they dwarf the difference between these toxicologically indistinct alternatives such that they are not true alternatives.

The calculations in Table 7-1 represent daily exposure doses. In contrast, EPA derived human equivalent internal doses using sophisticated models, which are based on numerous assumptions regarding intra- and interspecies variables in toxicokinetics (e.g., volume of distribution, half-life, tissue distribution), toxicodynamics (e.g., gender differences, age differences, susceptible life stages, differences in adverse outcome pathways), exposure (e.g., translation of concentration in rat chow into systemic exposure dose, relative source contribution assumptions, deterministic vs. probabilistic exposure modeling), and more. The six tables named "Limitations and Uncertainties" in the Economic Analysis draft (USEPA 2023i) further document the myriad assumptions that underpin EPA's analysis.

Every assumption used for these models and endpoints introduces uncertainty. Multiple uncertainties can have combinations of effects. Those effects can be additive, synergistic, potentiating, or antagonistic, which in turn introduces even higher levels of uncertainty regarding the accuracy of the predicted effects at the three alternative drinking water concentrations—without even considering the precision of said models. The compounding effects of multiple uncertainties far outweigh the de minimis differences of exposures on the logarithmic scale, which makes any attempt to distinguish between the health benefits of 4.0 ppt, 5.0 ppt, and 10.0 ppt not only futile but impossible.

D. EPA's Calculation of PFAS Serum Concentration Lacks Transparency

In the Economic Analysis, EPA (USEPA 2023i) states that it "developed single-compartment PK models for adult males and females to estimate blood serum PFOA and PFOS concentrations," noting that they are described in the MCLG documents. EPA then states that it compares the differences in serum concentrations at each regulatory alternative level to published coefficients of changes in serum concentrations that have been associated with health effects (e.g., reduced birth weight). Although EPA states the pharmacokinetics models are described in the PFOA and

PFOS MCLG documents (USEPA 2023a,b,c,d), neither these specific models nor the blood serum predictions are provided in the referenced material.

EPA's documents describe other pharmacokinetics models used for cross-species dosimetry or predicting points of departure to derive reference doses, but the "single-compartment pharmacokinetics models" used for predicting serum concentrations from drinking water – and subsequently for calculating benefits – are not described. EPA's entire benefits analysis hinges on these predicted serum data. It is the first parameter entered into the sequence of analyses that are used to estimate the health risk reduction benefits for the proposed MCL and the regulatory alternatives (e.g., Figure 6.1 of USEPA 2023i). EPA failed to clearly provide its predictions of the serum concentrations expected in populations consuming drinking water at the proposed MCL of 4.0 ppt and each regulatory alternative (5.0 ppt and 10.0 ppt) and identify if there are meaningful differences between the steady-state serum concentrations at each alternative. Importantly, there is no evidence that these pharmacokinetics models have been peer-reviewed. EPA's lack of transparency in model details, data outputs, assessment of uncertainty, and interpretation of results are underlying critical deficiencies. Such an analysis requires peer review before it is used to support regulatory decision-making. Moreover, EPA's lack of transparency is particularly important with respect to serum concentration calculations because the outputs of those calculations are used to determine difference in benefits at each regulatory alternative.

e. Demonstration of Overlap in Serum Concentrations at Each Regulatory Alternative

Though EPA does not make available either its model or its predictions of serum concentrations, EPA cites a first-order single-compartment model pharmacokinetics model (Bartell 2017; Lu and Bartell 2020) that it adapts to calculate PFNA serum concentrations from drinking water exposures (USEPA 2023k). To highlight the shortcomings in EPA's approach, this same model could be used to predict PFOA and PFOS steady state serum concentrations at the proposed MCL and each regulatory alternative. The following example analysis is intended to illustrate that the small, predicted differences in serum concentrations are not meaningful because they do not account for uncertainties and inherent variability in the model input parameters (e.g., half-life).

Table 7-2 demonstrates the model's outputs using NHANES geometric mean serum concentrations as the starting serum concentrations and assumes the model's defaults for other toxicokinetic and intake parameters. The half-life parameter was adjusted based on the range of half-lives reported by EPA to illustrate how altering only the half-life parameter impacts the modeled serum concentrations. EPA (USEPA 2023a,c) states that, in humans, the half-lives of PFOA can range from 1.7 years (Xu et al. 2020) to 4.4 years (Fu et al. 2016). For PFOS, halflives can range from 1.04 (Xu et al. 2020) to 60.9 years (Fu et al. 2016). For the calculation of points of departure, EPA (USEPA 2023a,c) selected a half-life of 2.7 years for PFOA (Li et al. 2017) and a half-life of 3.4 years for PFOS (Li et al. 2018), which is consistent with the model default (Lu and Bartell 2020).

As illustrated in Table 7-2, there is significant overlap in potential serum concentrations when inputting a range of half-lives for each regulatory alternative. For example, for PFOA, the predicted serum concentration at the 10.0 ppt and the shortest half-life (1.7 years) is 2.54 ng/ml which is less than the serum concentration of 2.64 ng/ml predicted at the longest half-life (4.71 years) and the lowest regulatory level (4.0 ppt). When EPA's selected half-lives are applied to the comparison of 4.0 ppt and 10.0 ppt, there is less than a 0.82 ng/mL difference in the predicted PFOA and PFOS serum concentrations (Table 9-2). These minimal differences in serum concentrations do not represent a meaningful difference in dose. Thus, there are likely not biologically relevant differences in effects between these regulatory alternatives.

Table VII-2. Predicted Steady State Serum Concentrations (ng/mL) at Each Regulatory Alternative Using Lu and Bartell 2020.

[Table VII-2: see docket ID EPA-HQ-OW-2022-0114-1774]

Notes:

Model Source: Lu S, Bartell SM. Serum PFAS Calculator for Adults, Version 1.2, 2020, www.ics.uci.edu/~sbartell/pfascalc.html.

Calculations assume a default starting serum concentration based on the NHANES geometric mean values for PFOA and PFOS (NHANES 2017-2018 Total Population https://www.cdc.gov/exposurereport/data_tables.html)

CI = confidence interval Half-life

Sources:

Model Default: PFOA is from Bartell et al. 2010 and PFOS is from Li et al. 2018 EPA: PFOA Li et al 2017 and PFOS Li et al 2018

The above analysis demonstrates that considerations of variability are critical in conducting an accurate scientific assessment of serum concentrations. EPA correctly notes that factors such as age and health status of individuals can impact toxicokinetic parameters such as half-lives (USEPA 2023a,c). However, it is not clear if or how such biological variability was accounted for in EPA's assessment of serum concentrations. EPA (USEPA 2023c) also states that "linear PFOS molecules exhibit longer half-lives than branched forms," but it is not clear if EPA considered those differences. Variability in other toxicokinetic parameters, such as volume of distribution or clearance rates, would add further uncertainty to the serum predictions. This inherent uncertainty in the alternatives analysis renders the overlap in serum concentrations at 4 ppt and the regulatory alternatives too great to be biologically distinct.

Additionally, EPA's apparent approach to predicting serum concentrations based on intake of drinking water contradicts its own statements in the MCLG documents (USEPA 2023a,c). In describing studies on half-lives for both PFOA and PFOS, EPA states, "there is insufficient data to correlate PFOS [and PFOA] intake measurements to serum/plasma and urine concentrations" [emphasis added]. Given this conclusion, it is unclear why EPA determined that predicting

serum concentrations as the basis of the benefits analysis was appropriate, in light of the significant population and biological variability in the underlying estimates of exposure and toxicokinetics. EPA's approach is not scientifically supportable.

These critical flaws in EPA's prediction of serum concentrations are then propagated through its benefits analysis, where EPA attempts to apply exposure-response relationships to assess associations with adverse disease outcomes and other estimates of impacted populations. There is simply no basis for distinguishing health outcomes across the regulatory alternative concentrations. Because there are no biologically meaningful differences between the serum concentrations at each regulatory alternative concentration (as explained above), the outputs of the benefits analysis also are neither meaningful nor valid. EPA has not chosen appropriate regulatory alternatives and there are likely no distinctly quantifiable health benefits at each of the alternatives.

EPA Response: The EPA strongly disagrees with the commenter that the benefits analysis does not comply with the SDWA and is "arbitrary, opaque, and counter to fundamentals of toxicology." The commenter raises several issues to which the agency is responding to below. First, the commenter contends that the EPA did not consider a sufficient range of regulatory alternatives and that only "two theoretical alternatives" were proposed. These claims are incorrect. As discussed in the topic essay to 5.1.3, the EPA first notes that SDWA does not require the agency to consider any certain number of alternative MCLs or a range of alternatives. Second, the agency identified, analyzed, and sought public comment on a reasonable number of regulatory alternatives which included establishing PFOA and PFOS MCLs (at 5.0 and 10.0 ppt) and individual MCLs for PFHxS, PFNA, HFPO-DA and PFBS instead of and in addition to using a mixture-based approach. Additionally, the EPA requested comment on the TOSHI or RPF approach as part of deriving the mixture MCLG that would then be used to set the MCL. Please see the topic essay 5.1.3 for further discussion on regulatory alternatives. In reference to the alternative of PFOA and PFOS MCL at 10.0 ppt, the commenter continues to say that there is "no evidence that EPA considered different approaches nor the toxicological bases of various states' MCLs." The EPA notes again that SDWA does not require the agency to consider different approaches or the toxicological bases of states' MCLs but only requires that in developing the HRRCA, the agency must consider the "incremental costs and benefits associated with each alternative maximum contaminant level considered." OMB Circular A-4 (OMB, 2003; OMB, 2023) further describes that "the number and choice of alternatives selected for detailed analysis is a matter of judgment." (please see topic essay 5.1.3 for further discussion). Based on the agency's technical expertise and judgment, the agency took comment on regulatory alternatives for PFOA and PFOS MCLs at 5.0 and 10.0 ppt and further summarized quantified costs and benefits for these alternative options within the proposed rule preamble and economic analysis supporting the proposal. The agency described the basis for these alternatives which included a 25 percent operational buffer above the PQL (for 5.0 ppt) and a level consistent with some state drinking water regulators (for 10.0 ppt), thereby providing a basis for comparison of the different regulatory approaches. For example, the state of New York has similar regulatory thresholds for PFOA and PFOS at the time of proposal (i.e., 10.0 ppt). While states may establish

drinking water standards for systems in their jurisdiction prior to regulation under SDWA, once an NPDWR is in place, SDWA requires that primacy agencies adopt standards that are no less stringent than the NPDWR.

The commenter contends that the alternatives the agency proposed all represent the same level of exposure and are not meaningfully different. First, the commenter is factually incorrect on assertions that the "EPA did not make its model or important inputs into the model available in the public docket." The model is cited in the EA and final tox assessment documents and the EPA provided the Pharmacokinetic (PK) model materials on the GitHub platform. The PK modeling approach used in the EA and the PFOA and PFOS toxicity assessments was peer reviewed by the EPA Science Advisory Board (SAB) (cite). The EPA does not provide blood serum predictions as this is not a requirement under SDWA. Regardless, these are estimated endogenously in the EPA's economic modeling and not programmed as an output. Second, the commenter states "definition [of an RfD] highlights that it is not meaningful to distinguish between exposure doses occurring within an order of magnitude (i.e., 10-fold) of one another." The commenter is incorrectly equating the definition of the RfD with the MCL. The MCLs for PFOA and PFOS are not based on a RfD. They are set as close as feasible to the MCLG, taking into account cost and feasibility (please see section 5.1.2, 5.1.3 and 5.1.4 of the EPA responses in this *Response to Comments* document for additional information). The purpose of the regulatory alternatives is not to distinguish between toxicological relevancy among the alternatives but to understand the incremental costs and benefits associated with each alternative MCL considered. See SDWA 1412(b)(3)(C)(i)(IV). Third, the commenter claims that 4.0 ppt, 5.0 ppt and 10.0 ppt are "toxicologically indistinguishable based on fundamental principles of toxicology and dose-response" and that the health outcomes quantified at these concentrations are not meaningful to public health. The commenter further provides a non-peer reviewed and hypothetical illustration of this point in sections (d) I (e) of their submission. The agency disagrees. As discussed in section IV of the final rule preamble and section 4 of the *Response to Comments* document, the EPA has determined that PFOA and PFOS are *Likely to be Carcinogenic to Humans* based on sufficient evidence of carcinogenicity in humans and animals (USEPA, 2024k). The EPA has also determined that a linear default extrapolation approach is appropriate as there is no evidence demonstrating a threshold level of exposure below which there is no appreciable cancer risk (USEPA, 2005). Therefore, *any* increase in exposure would result in a linear increase in cancer risk which would result in anticipated adverse health effects.

Further, as discussed in the topic essay to 5.1.3, SDWA 1412(b)(3)(C)(i)(IV) states that in developing the HRRCA, the agency must consider the "incremental costs and benefits associated with each alternative maximum contaminant level considered." Thus, the agency must conduct a cost-benefit analysis with each alternative MCL that is considered, if any. The agency has conducted a thorough cost-benefit analysis that are based on the best available, peer-reviewed science and meet the requirements of SDWA (please see the document titled "*Economic Analysis for the Final Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation"* supporting the final NPDWR and section 13 of the *Response to Comments* document for more information on the economic analysis). Additionally, the regulatory

alternatives of 5.0 ppt and 10.0 ppt are meaningful different from a treatment operations standpoint. The SDWA requires the agency to establish MCLs as close as *feasible* to the MCLG (emphasis added). Consistent with the statute, EPA considers cost as well as analytical limits of best available treatment technology, including availability of analytical methods, laboratory capability, capacity, and quantitation. An MCL at 5.0 ppt is different from an MCL at 4.0 ppt from a treatment operations, monitoring, compliance, analytic and implementation standpoint (please see discussion in 5.1.2 for discussion on laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, as well as practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations; additionally, see section 8 for monitoring and compliance requirements for the final NPDWR). These factors are also important for an MCL at 10.0 ppt. For example, media change-outs are less frequent when treating to a higher standard, thereby impacting cost and benefit (please see section 5.1.4 for additional considerations for treatment feasibility). With respect to concerns regarding the EPA's PK modeling approach, please see section 4.2.4 of the *Response to Comments* document. With respect to the how the EPA considered other agencies' (including states') assessments and why the agency's health conclusions may have differed, please see section 4.2.6. With respect to conclusions about the adversity of the non-cancer critical effects, please see section 4.2.2.

The EPA also disagrees with the commenter's assertion that the benefits analysis uncertainties "are so great that they dwarf the difference between these toxicologically indistinct alternatives such that they are not true alternatives." The EPA has quantitatively characterized the uncertainty concerning health effect serum slope factors used in benefits analysis and the uncertainty related to this (or any) data input does not discredit the estimated benefits under any of the regulatory alternatives. The EPA maintains that after taking all key modeling uncertainties into account, the regulatory alternatives described in the rule and assessed in the economic analysis are meaningfully distinct. Moreover, the EPA maintains that the regulatory alternatives are meaningfully different from both health effects and treatment perspectives. The EPA went to great lengths to characterize the uncertainty for all key benefits analysis inputs, which is described in section XII of the preamble and also USEPA (2024d). See section 13.9 in this *Response to Comments* document for the EPA's responses to comments received on quantified uncertainties in the economic analysis.

With respect to the commenter claiming that the EPA's approach to the benefits analysis being contradictory to a statement made in the MCLG documents, the EPA has edited the quoted sentence in section 3.3.1.4.5 to avoid any misinterpretation (USEPA, 2024i; USEPA, 2024j). When taken out of context, as the commenter has done here, the sentence appears contradictory to the approach used in the economic analysis. However, in context, the sentence was commenting on sources of variability in reported measurements of the PFOA/S half-life. While variability in the half-life measurements exists, it doesn't preclude the ability for the EPA to conclude that the half-lives of PFOA/S are within the range of reported values nor the use of a value within that range to estimate how changes in PFOA/S exposure will affect serum/plasma

concentrations. The EPA maintains that predicting serum concentrations as the basis of the benefits analysis is appropriate.

Finally, as discussed in this response, the EPA had strong reasons firmly grounded in analytical methods, engineering, and treatment feasibility, among other things, for considering the different regulatory options in this proposal (see 88 Federal Register [FR] 18638). In short, they are not "meaningless" as claimed by commenter. Furthermore, as commenter themselves acknowledges, one of these options for setting PFOA and PFOS MCLs at 5.0 ng/L was partially informed by early public input. The EPA considering public input in developing regulatory options is not arbitrary; in contrast, it is responsive to stakeholder input consistent with the goals of the various consultation processes. Additionally, while the commenter focuses on considerations related to toxicology and PKs, the commenter ignores issues related to that is described in the 5.1.3 response essay and in section V of the preamble of this rule that the EPA must consider when setting an MCL at a feasible level. While toxicological information is relevant to setting the MCLG, the language in the SDWA is clear: the EPA must set the MCL as close as feasible to the MCLG. And as discussed previously in this response and elsewhere in this *Response to Comments* document, based on best available, peer-reviewed science, the EPA determined that PFOA and PFOS are *Likely to be Carcinogenic to Humans*, and therefore set the MCLGs at zero.

3M Company (Doc. #1774, SBC-045673)

Not only is the failure to consider any alternatives to the HI-MCL itself a direct violation of the SDWA, it also led to EPA's failure to identify the level at which the costs of the HI-MCL justify the benefits. The HBWCs are purely health-based and should be calculated to have a margin of safety, similar to an MCLG. But EPA effectively set MCLs for these four substances at the HBWC without considering whether the same benefits could be achieved for lower costs because it did not consider any alternatives to the HBWCs as required by the SDWA. [FN44: See SDWA [sec]1412(b)(3)(C)(i).]

EPA Response: The SDWA does not require the EPA to consider or propose any certain or minimum number of alternative MCLs, MCLGs or a range of alternatives. Please see the section in section 5.1.3 of the EPA response in this *Response to Comments* document for further discussion. Furthermore, the EPA disagrees with the commenter that the agency "failed to consider any alternatives to the HI-MCL". The EPA notes that the agency proposed two options for the Hazard Index PFAS: option 1 which set the HBWCs set at 10.0 for PFNA, 9.0 ng/L for PFHxS, 10.0 for HFPO-DA (GenX chemicals), and 2000 ug/L for PFBS and a hazard index of 1.0; options 1a, 2, and 3 would not regulate these four PFAS for this action (therefore setting no MCLGs or HBWCs). As discussed in section 5.1.3 of the EPA response in this *Response to Comments* document and in the proposed rule preamble, the agency took comment on establishing individual MCLs instead of and in addition to using a mixture-based approach for PFHxS, PFNA, HFPO-DA, and/or PFBS in mixtures. Additionally, the EPA requested comment on alternative mixture-based approaches such as a TOSHI or relative RPF approach.

The EPA also notes that the HBWCs do include a margin of safety. The equation used to calculate an HBWC is the same as the equation used to calculate an MCLG and includes a toxicity reference value and a RSC as inputs. The RSC, along with uncertainty factors applied to the toxicity reference value, afford a margin of safety. For additional discussion regarding the MCLG derivation for a PFAS mixture and additional individual PFAS, please see section 4.3 of the EPA response in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1841, SBC-044823)

[As outlined in these comments, the Agency's proposal suffers from a number of significant shortcomings, including the following –]

• The Agency's choice of regulatory alternatives does not provide a reasonable basis for comparison of the possible regulatory approaches.

EPA Response: The EPA disagrees that the regulatory alternatives considered in the final NDPWR did not "provide a reasonable basis for comparison of the possible regulatory approaches." Please see the please see section 5.1.3 of the EPA response in this *Response to Comments* document for additional details and the EPA response to comment Doc. #1669, SBC-045689 and Doc. #1774, SBC-045673 in section 5.1.3 in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1841, SBC-044850)

EPA has not Provided Information on an Appropriate Range of Regulatory Alternatives

EPA's economic analysis provides three alternatives to the current proposal to establish MCLs of 4 ppt for PFOA and PFOS and an HI MCL of 1.0 for PFBS, HFPO-DA, PFHxS, and PFNA. The alternatives include MCLs of 4.0 ppt, 5.0 ppt, and 10.0 ppt for PFOA and PFOS, with no MCL for the other four substances. As summarized in Table 6, EPA estimates essentially no difference in the number of systems impacted and the compliance cost by eliminating the HI MCL, a marginal reduction in impacts by increasing the MCLs to 5.0 ppt, and a significant reduction by

increasing the MCL to 10.0 ppt. The Agency's estimates for the total benefits achieved with each of the Options show a similar pattern.

Table 6. Comparison of Current Proposal and Alternatives

[Table 6: See Docket ID EPA-HQ-OW-2022-0114-1841]

The Agency's estimates for the three options likely suffer from the same shortcomings as the Agency's proposal, but there is not an independent analysis for each of the Options to use for comparison. We note, however, that the US Chamber of Commerce [FN200: The Chamber's analysis was submitted to the Office of Information and Regulatory Affairs of the Office of Management and Budget as part of an Executive Order 12866 meeting on November 1, 2022.] estimates a total cost of $16 billion to comply with MCLs of 10 ppt for PFOA and PFOS – which reflects an annualized cost well above the EPA estimate. [FN201: The Chamber's analysis does not provide an annualized estimate of costs.]

EPA has not provided a rationale for why the levels of 5.0 ppt and 10.0 ppt were chosen for its alternatives analysis. As the Agency readily acknowledges, it does not have actual occurrence data to determine the number of water systems likely to exceed each of these levels. While EPA has developed a statistical model to predict the number of exceedances, it has no way to validate the model until more sensitive occurrence data become available from UCMR 5. Consequently, it is not clear how accurately the model can predict differences among the small range of values that the Agency has chosen. In fact, a comparison of the Agency's modeling results with those from AWWA and the US Chamber of Commerce raises significant question about the model's reliability. Given the significant uncertainty, presenting information on a broader range of alternative values would be more instructive.

OMB's Circular A-4 offers guidance on the construction of regulatory alternatives. The following passages are particularly relevant for the proposed rule –

You should nevertheless explore modifications of some or all of a regulation's attributes or provisions to identify appropriate alternatives. . . You should study alternative levels of stringency to understand more fully the relationship between stringency and the size and distribution of benefits and costs among different groups. [FN202: OMB Circular A-4.]

To better understand this relationship, the Agency should at the very least provide a comparison of its proposal to an alternative based on the minimum reporting levels for PFOA and PFOS of the UCMR 3 survey data. [FN203: These levels were 20 ppt for PFOA and 40 ppt for PFOS.] This would provide the Agency and the stakeholders with a more accurate baseline for comparison with the current proposal.

EPA Response: For additional discussion on benefit-cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The commenter is factually incorrect when stating the EPA "has not provided a rationale for why the levels of 5.0 ppt and 10.0 ppt were chosen for its alternative analysis." Please also see section 5.1.3 of the EPA response in this *Response to*

Comments document for additional details. Regarding responses on the agency's occurrence analysis and consideration for UCMR 5 results, please see section 6 of the EPA response in this *Response to Comments* document. The agency also disagrees with the alternatives suggested by the commenter (20 ppt for PFOA and 40 ppt for PFOS); analytical accuracy and precision has improved since UCMR 3 data collection so these levels are not reflective of the current and best available, peer-reviewed science and supporting information which is a key consideration under SDWA. Proposing an option that's appreciably above current analytic capabilities will be disingenuous as the EPA fulfills these statutory requirements in promulgating a NPDWR. The EPA disagrees with the commenter's representation of costs in the report cited by this commenter. For more information, see the EPA response to comment Doc. #1537, SBC-042649 in section 13.3.3 in this *Response to Comments* document. In response to the commenter's reference to American Water Works Association Black & Veatch (AWWA B&V) estimates of national costs, EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. See section 13.3.3 of the EPA response in this *Response to Comments* document for more details. Importantly, the EPA notes that this analysis is not "independent" as characterized by the commenter. Rather, it is produced under contract to an organization that represents many of the entities that will be directly regulated under this rule.

The Chemours Company FC, LLC (Doc. #1845, SBC-046056)

EPA's analysis of the cost-benefit impact of the four-compound HI proposal is also flawed because EPA did not evaluate the costs and benefits of other options for regulating these four compounds. This stands in sharp contrast to the MCL proposal for PFOA and PFOS, where EPA analyzed the impacts of potential MCL levels of, respectively, 4.0 ppt,

5.0 ppt, and 10.0 ppt. But EPA did not analyze the impacts of setting the HI at levels other than 1.0.

EPA did analyze the option of setting the MCL for PFOA and PFOS at 4.0 ppt but with no MCL for PFHxS, PFBS, PFNA, and/or HFPO-DA. That analysis looks substantially similar to the analysis with PFOA and PFOS at 4.0 ppt and the HI of 1.0 included. The respective analyses are summarized in Tables 7-1 and 7-2 of the EPA Economic Analysis:

[Table 7-1: See Docket ID EPA-HQ-OW-2022-0114-1845]

[Table 7-2: See Docket ID EPA-HQ-OW-2022-0114-1845]

What these two tables show is that at a 3% discount rate, including the HI of 1.0 in the MCL would add no significant net benefit ($461.21 million annual expected value with the HI included compared to $460.26 million without it). And at a 7% discount rate, the costs would exceed the benefits by even more with the HI included (-$296.50 million compared to -$281.95 million). Of course, as discussed above, and recognized in the footnotes to Table 7-1, EPA's

analysis suffers from the critical uncertainty caused by the lack of occurrence data for HFPO-DA, PFBS, and PFNA.

Finally, EPA did not do a quantitative analysis of the costs and benefits of setting individual compound MCLs for each of PFHxS, PFBS, PFNA, and HFPO-DA. EPA recognizes its failure to do this analysis, but offers no explanation other than the conclusory statement that the HI approach would bring in more systems. Before embarking on use of an unprecedented multi-compound HI approach to ratchet down levels already set with multiple orders of magnitude of conservatism, sound public policy and the requirements of the SDWA necessitate an actual analysis of what the marginal costs and benefits will be.

In summary, EPA first promulgated a 10 ppt health advisory level for HFPO-DA, which it categorized as non-regulatory, without doing any cost-benefit analysis, asserting that none was required. Now when such an analysis is clearly required, EPA is again trying to avoid whether its proposal is justifiable by pointing to a lack of necessary occurrence data. EPA should never attempt to promulgate an MCL until it has the data it needs pursuant to the SDWA, and then should robustly evaluate other options. For all of the reasons set forth above, Chemours expects that a fully-informed cost-benefit analysis would show that regulating HFPO-DA at the levels proposed by EPA is neither warranted by the scientific evidence nor justifiable in light of the costs.

EPA Response: The agency disagrees with the commenter that the EPA did not consider a sufficient range of regulatory alternatives. The agency also provided an explanation as to why the EPA did not separately present changes in quantified costs and benefits for alternatives to the Hazard Index MCL. Please see section 5.1.3 of the EPA response in this *Response to Comments* document for additional information. Regarding responses on the agency's occurrence analysis, please see section 6 of the EPA response in this *Response to Comments* document. For responses on occurrence data for HFPO-DA and the agency's final regulatory determination, please see section 3.1.2 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's assertion that the agency did not consider costs and benefits for the four Hazard Index PFAS. As required by SDWA, the agency considered both the quantifiable and nonquantifiable costs and benefits associated with compliance with the rule, including removal of the Hazard Index PFAS. For an overview of nonquantifiable costs and benefits considered by the EPA, including those associated with regulating the four Hazard Index PFAS, please see Tables 5-22, 6-48, and 7-6 of the EA (USEPA, 2024d). Please see section 13.3.2 of the EPA response in this *Response to Comments* document on the costs associated with the Hazard Index and Appendix N of the EA (USEPA, 2024c) for EPA's national level analysis of the costs associated with PFNA, HFPO-DA and PFBS. See Section 5.1.3 of the EA (USEPA, 2024d) for a summary of the EPA's annualized national cost estimates, which include costs associated with PFHxS. Please see Appendix K for the EPA's sensitivity analysis assessing the quantified benefits associated with PFNA effects on birth weight. Please see section 13.8 for discussion of the EPA's comparison of costs and benefits of the rule, including the Administrator's determination that the costs of the rule are justified by the benefits.

Additionally, the EPA disagrees with the commenter's statement that the "EPA first promulgated a 10 ppt health advisory level for HFPO-DA." The EPA published a health advisory under its authority provided in SDWA section 1412(F). The EPA maintains that its 2022 HA for HFPO-DA is not a legally enforceable federal standard and is not subject to the HRRCA requirements. For more information on the agency's health advisories, please see: https://www.epa.gov/sdwa/drinking-water-health-advisories-has. Therefore, the EPA disagrees with the commenter's assertion that the agency is "trying to avoid whether its proposal is justifiable," as the agency considered the quantifiable and non-quantifiable costs associated with the Hazard Index MCL, including HFPO-DA in EA for both the proposed and final rule, pursuant to SDWA.

El Paso Water (Doc. #1757, SBC-044525)

Keep MCL at current level

Like many utilities across the country, EPWater is concerned with any possible reductions in the MCL. Any such change would pose incredible financial cost to PWSs and be a strain on staffing for utilities such as ours.

A reduction in the MCL will be incredibly costly for any PWS and its ratepayers at a time when many systems are struggling to attract and retain qualified workers, and at a time when the cost of construction of new facilities remains stubbornly high. Adding to these costs would be the additional cost to dispose of PFAS tainted treatment media, which would be considered hazardous material.

Also, a reduction in the MCL will not be based on sound scientifically reliable data. The EPA's approach to gathering national PFAS contamination data to help develop proposed revisions was to take representative samples from a small number of systems nationwide. This is NOT representative of all of the approximately 140,000 systems throughout the nation. We urge the EPA to reconsider implementing costly lower MCL regulations.

EPA Response: For additional discussion on cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA disagrees that the final MCLs are not based on sound and scientifically reliable data (for additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document). The EPA also disagrees with the commenter that the agency did not consider a representative number of small systems nationwide. The agency relied on multiple data sources, including UCMR 3 (which includes a representative sample of small systems) and state finished water data, to evaluate the occurrence of PFOA, PFOS, PFHxS, PFNA, and HFPO-DA and probability of co-occurrence of these PFAS and PFBS. The EPA also incorporated both the UCMR 3 and some state data into a Bayesian hierarchical model which supported exposure estimates for select PFAS at lower levels than were measured under UCMR 3. The specific modeling framework used to inform this regulatory action is based on the peer-reviewed model

published in Cadwallader et al. (2022). Further, the commenter is incorrect in stating that "adding to these costs would be the additional cost to dispose of PFAS tainted treatment media, which would be considered hazardous material." First, disposal options for PFAS are currently available. These destruction and disposal options include landfills, thermal treatment, and underground injection. Systems are currently disposing of spent media, such as activated carbon, through thermal treatment, to include reactivation, and at landfills. Second, there are currently no federal regulations that designates PFAS (or treatment residuals that contain PFAS) as hazardous waste. Third, the EPA has estimated the treatment costs for systems both with the use of hazardous waste disposal and non-hazardous disposal options to assess the effects of potentially increased disposal costs. Specifically, the EPA assessed the potential impact on PWS treatment costs associated with hazardous residual management requirements in a sensitivity analysis.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045952)

Section 3: Maximum Contaminant Level

Like the MCLGs, EPA is proposing individual Maximum Contaminant Levels (MCLs) for PFOA and PFOS, and an MCL for PFNA, PFHxS, GenX, and PFBS as a mixture. Under section 1412(b)(4)(B) of SDWA, EPA must establish an enforceable MCL, "which is as close to the [MCLG] as is feasible." Section 1412(b)(4)(D) subsequently defines "feasible" to mean "feasible with the use of the best technology, treatment techniques and other means which the Administrator finds … are available (taking cost into consideration)."

Section 3.1: PFOA and PFOS

EPA has proposed individual MCLs of 4.0 parts per trillion (ppt) each for PFOA and PFOS. EPA also explored the costs of potentially proposing 5.0 ppt and 10.0 ppt, individually. EPA determined the Best Available Technologies (BATs) have the capability to bring PFAS levels down below the proposed 4.0 ppt MCL, which AMWA believes is true. However, the costs, supply chain, and labor challenges affecting the compliance timeline, and current and future simultaneous compliance challenges, invite questions as to whether this standard is actually feasible under SDWA, as defined in Section 1412(b)(4)(D).

EPA Response: For additional discussion on cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 10 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043937)

I. EPA Has Not Evaluated the Proposed MCLs for Economic Feasibility

WUWC is concerned with the methods and standards used to evaluate the economic feasibility of the proposed Maximum Contaminant Levels (MCLs). [FN3: 88 Fed. Reg. at 18668–69, 18730

(requesting public comment on EPA's evaluation of the economic feasibility of MCLs under the Proposed Rule).] The SDWA requires EPA to set primary drinking water standards as close to the MCL goals (MCLGs) as "feasible," taking account of both technical feasibility and economic feasibility. [FN4: SDWA § 1412(b)(4)(B); 42 U.S.C. § 300g-1(b)(4)(B); Congressional Research Service, Regulating Contaminants under the Safe Drinking Water Act (SDWA), 2, 13 (Jan. 5, 2022).] Separately, the SDWA requires that EPA prepare a Health Risk Reduction and Cost Analysis (HRRCA) that considers the costs of compliance with a proposed MCL. [FN5: SDWA § 1412(b)(3)(C); 42 U.S.C. § 300g-1(b)(3)(C).] Because the Proposed Rule is considered a significant regulatory action, EPA is required by Executive Order 12866 to prepare an Economic Analysis (EA) weighing the Proposed Rule's reasonably foreseeable costs and benefits.

In light with these latter two requirements, EPA completed an EA [FN6: U.S. EPA, Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (Mar. 2023), EPA-822-P-23-001 (the "EA").] and HRRCA that comparatively evaluate the costs and benefits of the proposed MCLs and other less stringent potential MCLs not chosen under the Proposed Rule. EPA relies on the EA and HRRCA throughout the Proposed Rule wherever it references cost considerations. In this respect, EPA treats the requirement for economic feasibility analysis as equivalent to cost-benefit analysis and essentially procedural.

Instead, the economic feasibility analysis needed is both procedural and substantive. Procedurally, EPA cannot lawfully ignore entire categories of costs that necessarily will result from promulgation of a new MCL. Michigan recently ran afoul of this principle when a state court overturned its proposed state MCL for PFOA and PFOS. See 3M Company v. Mich. Dep't. of Env't, Great Lakes, and Energy, No. 21-000078 (Mich. Ct. Claims) (Nov. 15, 2022). The court faulted Michigan for preparing a Regulatory Impact Statement [FN7: The Regulatory Impact Statement required under Michigan law is akin to the requirements for an EA and HRRCA under federal law.] that failed to evaluate cleanup costs arising from the proposed MCL because existing Michigan law would have required the MCL to be used as a groundwater cleanup standard for aquifers contaminated with PFOA or PFOS "as a matter of law."

Substantively, the SDWA requires EPA to find that each proposed MCL is "technically possible and affordable." City of Portland v. EPA, 507 F.3d 706, 712 (D.C. Cir. 2007). California violated this principle in 2017 when a state court overturned its then-proposed MCL for hexavalent chromium under the California SDWA. See Cal. Mfrs. and Tech. Ass'n v. State Water Res. Control Bd., No. 34-2014-80001850 (Super. Ct. Cal.) (May 5, 2017). While acknowledging that the state's "cost estimates themselves [were] quite thorough," under the SDWA, the court found "simply coming up with cost estimates for seven MCLs and then selecting one of those MCLs is not equivalent to considering the economic feasibility of complying with the MCL." In particular, the court focused on the agency's failure to make findings concerning the affordability of the Proposed Rule to water utility customers.

EPA Response: For additional discussion on cost considerations when setting the MCL, please see section 5.1.3 for the EPA response in this *Response to Comments* document. The EPA disagrees with commenter that the EPA "treats the requirement for economic feasibility analysis

as equivalent to cost-benefit analysis and essentially procedural" and that the agency ignored "entire categories of costs that necessarily will result from promulgation of a new MCL." First, the commenter does not refer to any specific categories in its comment. Second, the EPA considered costs of treatment technologies that have been demonstrated under field conditions to be effective at removing the PFAS at issue and determined as part of its feasibility analysis that the costs of complying with an MCL at 4.0 for PFOA/PFOS, 10 ng/L for PFHxS, PFNA, and HFPO-DA, and the Hazard Index MCL of 1 is reasonable based on consideration of costs borne by large metropolitan PWSs. Please see sections 5.1.2, 5.1.3 and 5.14 for the EPA responses in this *Response to Comments* document for additional discussion on the agency's feasibility analysis with respect to laboratory considerations, cost, and treatment, respectively. In addition, the EPA used the HRRCA as the basis for its determination made under 1412(b)(4)(C) in the proposal and affirmed its final rule. The commenter's discussions of state law cases regarding adoption of state MCLs pursuant to state law prior to a federal standard are outside the scope of this rule.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044684)

CONCLUSION

We believe that EPA must reevaluate its proposed MCLs. We think EPA must fully consider the extensive human health data available to it. EPA must also fully engage its state partners in assessing health benefits (lack of any health clusters) as well as implementation costs. After all, the states are the primary entities that track such information – especially on the cost side as the states administer the federal State Revolving Fund programs.

At a minimum, EPA should reevaluate its proposed criteria, consistent with our comments, and republish revised draft MCLs for further public comment. After all, this is the most significant federal Safe Drinking Water Act-based proposed rule in decades. In reconsidering its proposed rule, we urge EPA to consider our suggestion about phasing/tiering the MCLs. We believe that is a practical necessity that will allow significant benefits including the prioritization of PFAS barrier technology in environmental justice communities and communities with higher source water PFAS levels.

We are available to discuss our comments and to provide any additional information which EPA may require.

Sincerely,

F. Paul Calamita

General Counsel

C: WVMWQA Members

EPA Response: Please see section for 5.1.4 of the EPA response in this *Response to Comments* document. The EPA disagrees that the final MCLs are not based on sound and

scientifically reliable data (please see discussion in section 5.1.2 of the EPA response in this *Response to Comments* document on how the agency evaluated feasibility of the MCLs). For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 10 of the EPA response in this *Response to Comments* document on extensions and exemptions. For environmental justice considerations, please see section 14 of the EPA response in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044662)

Daniel Varon (Doc. #1518, SBC-042725)

The EPA should be concerned about the cost, especially given the economic situation the country currently finds itself in. The EPA's proposed cost summary has two estimates, one at 3% discount rate and another at 7% discount rate, of $772 million and $1.20 billion respectively. [FN19: Id.] Given the current increased interest rates, the implementation cost will likely be

closer to the latter than the former. This is also not considering a $30-$61 million potential yearly cost if PFAS are treated as hazardous waste. [FN20: Id.]

At the very least, I believe further investigations into PFAS should be conducted before rushing hastily into a costly project. Further research can indicate what level of PFAS we should actually be aiming for, or if there are certain geographic areas that should be focused in a resolution.

In conclusion, this would be no small project, and we must maximize the amount resources at hand. There are still a lot of unknowns surrounding PFAS, this is self-admitted by the CDC, EPA, and other governmental agencies. Given the unknowns, I do not think it is the best idea to rush into a costly implementation plan that sets extreme conditions, costly blanket rulings, and only impacts one source of PFAS contamination. Rather, I believe alternative, less costly and more targeted solutions should be explored further.

Thank you for taking the time to consider my comment.

Sincerely,

Daniel Varon

EPA Response: For additional discussion on benefit-cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-045063)

V. CONCLUSION

CDPU looks to EPA to help ensure that access to the most basic human necessity—safe, clean drinking water—continues to be affordable and equitable. As EPA continues its determination on a final National Drinking Water Regulation related to these six PFAS, CDPU asks that EPA recognize that public water utility resources are limited as we try to rise to the challenge of meeting each increasingly stringent drinking water standard simultaneously. Additionally, CPDU asks that EPA's feasibility analysis include accurate costs for treatment, a quantification for the burden of opportunity costs, and the financial, human health, and environmental costs of increased greenhouse gas emissions, which will result from an MCL of 4 ppt. Finally, CPDU asks that EPA re-examine alternatives—regulations, timelines, and limits—that would provide a reliable, comprehensive benefit to the public by removing the greatest PFAS hazards, judicially using public funds, and ensuring the eventual end of the PFAS cycle.

The City of Columbus, Department of Public Utilities appreciates your consideration of these comments. Should you have any questions, please contact Kristin Atha at klatha@columbus.gov or call (614) 645-7541. Thank you again for your attention to and consideration of these comments.

Sincerely,

Kristin L. Atha Director

Columbus Department of Public Utilities

klatha@columbus.gov

Janean Weber, Assistant Director, Regulatory Compliance

John Newsome, Columbus CDPU, DOW Administrator

Matthew Steele, Columbus CDPU, DOW Assistant Administrator

Robert Priestas, Columbus CDPU, DOSD Administrator

Stacia Eckenwiler, Columbus CDPU, DOSD Assistant Administrator

EPA Response: For additional discussion on cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion regarding alternative MCLs, please also see section 5.1.3. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 10 of the EPA response in this *Response to Comments* document on extensions and exemptions. For EPA's response on additional social costs of the rule, including greenhouse gas emissions, see section 13.11 in this *Response to Comments* document.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045279)

8. Economic feasibility and technical feasibility cannot be adequately considered due to information gaps about contaminant occurrence and constraints on capital and operational necessities.

Due to incomplete knowledge of the occurrence and co-occurrence of the PFAS discussed above, EPA cannot evaluate the economic feasibility of its proposed MCLs. Occurrence in small water systems or in disadvantaged communities is of particular concern, but without knowing where, and to what extent the contaminants occur, it is logically impossible to adequately address the economic feasibility of the regulation.

A similar problem comes from severely restricted options for disposal of treatment residuals (liquid brine or reverse osmosis reject water, or solid waste) containing PFAS. As noted above, PFOA and PFOS are already designated as hazardous under CERCLA, and few landfills will accept these materials; destruction of the substances by incineration or other methods is even more uncertain. Operating expenses like these are important factors to consider in the economic assessment of PFAS regulations and should be re-evaluated to gain a more complete understanding of the economic and technical feasibility.

Problems with sampling and laboratory capacity call into question the technical feasibility of the MCLs proposed in this rulemaking. Additionally, shortages of necessary treatment chemicals

such as granular activated carbon are very likely, resulting in price spikes that will exacerbate affordability issues for small systems. Infrastructure projects continue to be plagued by supply chain disruptions, and are further complicated by Buy America, Build America requirements when any federal funding is involved.

All the "unknowns" cited here support our concern that EPA has not and could not yet reasonably address the economic feasibility and the technical feasibility of this proposed regulation. More data and more thorough analysis are required, and the regulation should be pulled back or paused while these information gaps are filled.

EPA Response: For additional discussion on cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The agency disagrees with commenter assertions that economic and technical feasibility cannot be adequately considered because of stated occurrence information gaps. For PFOA and PFOS, the EPA issued final regulatory determinations for contaminants on the fourth Contaminant Candidate List (CCL 4) in March of 2021 (USEPA, 2021b) which included determinations to regulate PFOA and PFOS in drinking water. The EPA found that PFOA and PFOS may have an adverse effect on the health of persons; that these contaminants are known to occur, or that there is a substantial likelihood that they will occur, in PWSs with a frequency and at levels that present a public health concern; and that regulation of PFOA and PFOS presents a meaningful opportunity for health risk reduction for persons served by PWSs. The EPA also carefully considered drinking water monitoring data collected as part of the UCMR 3 and state-led monitoring efforts. The EPA finds that PFHxS, PFNA, and HFPO-DA each have a substantial likelihood to occur in finished drinking water and that these three PFAS and PFBS are also likely to co-occur in mixtures and result in increased total PFAS exposure above levels of public health concern. Therefore, the agency is determining that exposure to PFHxS, PFNA, or HFPO-DA individually, and any mixture of these three PFAS and PFBS, may have adverse effects on the health of persons; there is a substantial likelihood that PFHxS, PFNA, and HFPO-DA will occur and combinations of these three PFAS plus PFBS will co-occur in a mixture in PWSs with a frequency and at levels of public health concern; and in the sole judgment of the Administrator, individual regulation of PFHxS, PFNA, and HFPO-DA, and mixtures of the three PFAS plus PFBS, presents a meaningful opportunity for health risk reductions for persons served by PWSs. A comprehensive discussion of all the available state PFAS drinking water occurrence data is included in the *Occurrence Technical Support Document* (USEPA, 2024a). For additional discussion on the EPA'S final regulatory determinations, please see section 3 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 10 on extensions and exemptions. The commenter also incorrectly stated that PFAS are "designated as hazardous under CERCLA". There are currently no federal regulations that designates PFAS (or treatment residuals that contain PFAS) as hazardous waste. Further, disposal options and guidance on management of treatment residuals for PFAS containing waste currently exist; please see section 10.4 for the EPA's response in this *Response to Comments* document for additional discussion on the management of treatment residuals. Also see the EPA response to comment Doc. #1577,

SBC-042446 in section 5.1.4 in this *Response to Comments* document for a discussion of EPA's *Interim Destruction and Disposal Guidance.*

Greater North Dakota Chamber et al. (Doc. #1593, SBC-042800)

May 26, 2023

The Honorable Radhika Fox

Assistant Administrator

Office of Water

Environmental Protection Agency

Washington, DC 20020

RE: PFAS National Primary Drinking Water Regulation Rulemaking

EPA Docket ID: EPA-HQ-OW-2022-0114 FRL 8543-01-OW

Dear Assistant Administrator Fox:

We, the undersigned organizations representing a coalition of state chambers of commerce are pleased to provide comments for 1) EPA's proposed regulatory determination for PFHxS, HPFO-DA, GenX chemicals, and PFNA; and 2) EPA's proposed maximum contaminant levels (MCLs) and proposed maximum contaminant level goals (MCLGs) for PFOA and PFOS and also the four PFAS chemistries for which EPA is proposing a regulatory determination.

State Chambers of Commerce across our nation support a national drinking water standard for PFOA and PFOS based on the best science and risk. State environmental policymakers are pursuing aggressive requirements including drinking water standard, broad bans, and disclosure regimes. EPA action could be helpful in replacing this current patchwork.

However, there are substantial questions with EPA's current proposal. It is critical that EPA gets this right, as the costs that the proposed rule would impose are significant, and likely underestimated, leading to several challenges to the water utilities and other industries. For example, the proposed rule does not consider that maximum contaminant levels (MCLs) set in this regulation would have direct relationship to the costs of Superfund cleanups, given the pending CERCLA hazardous substance designation for PFOA and PFOS. SDWA sets the standard for using the "best available peer-review science." The proposed MCL must be changed to properly balance these costs and benefits, as the statute requires and EPA has done in setting prior MCLs.

Accordingly, we request that the agency withdraw the proposal and await the results of the UCMR 5 process:

EPA Response: Regarding cost concerns when setting the MCL, including impacts of the MCLs in non-drinking water contexts, please see section 5.1.3 of the EPA response in this *Response to Comments* document. Additionally, please also see section 6.8 of the EPA response in this *Response to Comments* document for additional discussion on UCMR 5. For the EPA's response on costs associated with the rule, please see section 13.3 in this *Response to Comments* document. Finally, the EPA disagrees with the commenter that the "MCL must be changed to properly balance these costs and benefits," as the EPA has reaffirmed the Administrator's determination at proposal that the benefits of the rule justify its costs. For more information see section 13.8 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043938)

The Proposed Rule commits both of these errors. The Proposed Rule nowhere accounts for the National Contingency Plan (NCP), adopted pursuant to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), which will require these new MCLs to be used as cleanup standards by operation of law. [FN8: 40 C.F.R. § 300.430(e)(2)(i)(B)-(C) (requiring attainment of MCLs where MCLGs have been set at zero and contaminated groundwater or surface water is designated as a current or potential source of drinking water).] WUWC has previously expressed its significant concerns to EPA and Congress that regulating PFAS could cause water utilities to incur cleanup liability at CERCLA sites, the costs of which would ultimately be borne by ratepayers. These additional costs to ratepayers of the Proposed Rule have not been considered.

EPA Response: Regarding cost concerns when setting the MCL, including impacts of the MCLs in non-drinking water contexts, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For further discussion about CERCLA clean-up costs and benefits, please also see section 5.1.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1631, SBC-043434 in section 5.1.3 in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-047698)

The Department also believes that setting the MCL at 10.0 ppt would be appropriate and justifiable under the SDWA statutory criteria. An MCL of at least 9 ppt is necessary in order to allow detectable and reportable results for reliable and consistent compliance determinations. It will also allow utilities the opportunity to operate with a margin of safety and plan for performance that maintains water quality below quantitation levels. Having an increased buffer between the PQL and the MCL will also allow utilities to manage treatment technology performance more efficiently because utilities typically aim to achieve lower than the MCL to avoid a violation. With the MCL set at the PQL, utilities would not have the early warning that they may exceed the MCL prior to doing so.

EPA Response: For additional discussion on alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044377)

• In the Economic Analysis, EPA presented estimated costs and benefits of regulatory alternatives for PFOA and PFOS if setting MCLs at 5.0 ppt and 10.0 ppt. EPA is requesting comment on its evaluation of these alternatives within the Economic Analysis (pg. 18670-18671 Federal Register Volume 88, Number 60).

o The commenters agree with the EPA determination that the reduced costs and reduced public health protection associated with a 5.0 ppt MCL for PFOA and PFOS are not justified by the purported increased buffer that may allow utilities to manage treatment technology performance more effectively.

EPA Response: For additional discussion on cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-047700)

o The commenters agree with EPA's determination that the cost-reduction benefits of setting an MCL of 10.0 ppt for PFOA and PFOS do not outweigh the reduced public health protection associated with setting the MCL at that level. The commenters agree with EPA's determination that setting an MCL of 10.0 ppt for PFOA and PFOS would not be appropriate or justifiable under the SDWA statutory criteria.

EPA Response: Please see the EPA response to comment Doc. #1640, SBC-044377 in section 5.1.3 in this *Response to Comments* document.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-045062)

IV. EPA should reconsider the proposed alternatives before setting its initial MCL at the PQL.

As it conducted its required analysis when crafting the proposed rule, EPA deliberated various options to reduce PFAS from drinking water. One option that was considered but not selected,

was to address the water systems with the most harmful, highest concentrations first with a MCL at 10 ppt. As discussed above, the feasibility analysis for that decision was flawed.

The crux of EPA's decision to set the MCL at 4 ppt instead of 10 ppt is that EPA found the former to be feasible. But that determination was erroneous because EPA did not accurately account for the cost of treatment and other social costs to environmental justice communities and from increased GHG emissions. Once EPA adjusts its calculation, if it determines that an MCL of 4 ppt is not feasible, then it will have an opportunity to revisit the regulatory alternative of 10 ppt and perform the analysis again with more realistic costs and benefits to determine if a higher MCL is appropriate and justifiable under the SDWA statutory criteria.

EPA has already acknowledged that a higher MCL would decrease the number of water utilities that will need to treat their water at this time. But it will would also result in targeted funding and treatment in the areas across the country that need it the most, which will protect our most vulnerable citizens from soaring utility bills that may threaten their food and housing stability. It will lessen the impact of such a large number of water utilities vying for limited treatment equipment, labor, and resources. It will give time for regulation or legislation to prevent further introduction of PFAS into our environment through consumer products. It will allow labs to develop the capability to test on a larger scale. It will allow public water utilities to have flexibility in their budgets to address the current, multiple regulatory challenges of PFAS, lead and copper, and aging infrastructure. And it will preserve consumer confidence in the safety of people's utmost necessity: drinking water.

EPA Response: The MCLs that the EPA proposed (and finalizing) is consistent with the statutory requirements under SDWA: please see the sections 5.1.2, 5.1.3, and 5.1.4 of the EPA response in this *Response to Comments* document for the agency's evaluation of feasibility with respect to analytic, cost and treatment considerations, respectively. The agency also disagrees that it did not account for the cost of treatment in the final rule: the EPA's strong record supports the agency's feasibility analysis supporting the final standards. Specifically, within the record and further discussed in sections 5.1.3 and 5.1.4 of the EPA response in this *Response to Comments* document, the EPA evaluated the accuracy of analytical techniques as reflected in the PQL, the availability and performance of BATs for treating water to minimize the presence of the contaminant consistent with the MCLG, as well as the costs of applying those BATs to large water systems when treating to that level. In consideration of these factors, the EPA is therefore establishing the MCL of 4.0 ng/L for both PFOA and PFOS; individual MCLs for PFHxS, PFNA and HFPO-DA at 10 ppt; and a Hazard Index MCL of 1 for mixtures of PFHxS, PFNA, HFPO-DA and PFBS. The reviewer is incorrect that the cost analysis fails to account for the environmental justice impacts of the final rule. In Section 8.4.2.2 of the EA (USEPA, 2024d), the agency reports the estimated incremental household costs across different system size categories and demographic groups. For further discussion on the agency's analysis of the social cost of carbon, please see section 13.11 of the EPA response in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045672)

d. EPA Failed to Consider Any Alternatives to the HI-MCL, in Violation of SDWA [sec]1412 (b)(3)(C)(i)

EPA must consider a range of alternative MCLs but did not do so here in violation of the SDWA and the Unfunded Mandates Reform Act (UMRA). SDWA [sec]1412(b)(3)(C)(i) requires EPA to consider alternative MCLs. In promulgating other NPDWRs after the 1996 SDWA Amendments, EPA has routinely considered at least four alternatives. [FN40: See National Primary Drinking Water Regulations: Lead and Copper Rule Revisions, 84 Fed. Reg. 61684 (2019) (considering four alternative regulatory options); National Primary Drinking Water Regulations; Arsenic and Clarifications to Compliance and New Source Contaminants Monitoring 66 Fed. Reg. 6976 (2001) (considering four alternative MCL levels); National Primary Drinking Water Regulations; Radon-222, 60 Fed. Reg. 59246 (1999) (considering seven alternative MCL levels).] Additionally, the Unfunded Mandates Reform Act of 1995 requires EPA to consider alternative MCLs. [FN41:EPA identified that this rule is subject to the UMRA, see 88 Fed.Reg. 18733 (Mar. 29, 2023) ("This action contains a Federal mandate under the Unfunded Mandates Reform Act").] The Unfunded Mandates Reform Act of 1995 (UMRA). [FN42: 2 USC [sec] 1535 (1995)] UMRA requires any agency promulgating a rule with "Federal mandates" that may result in expenditures to State, local, and tribal governments, in the aggregate, or to the private sector, of $100 million or more in any one year to "identify and consider a reasonable number of regulatory alternatives and from those alternatives select the least costly, most cost-effective or least burdensome alternative that achieves the objectives of the rule." [FN43:Id.]

Here, EPA did not consider a "reasonable number of regulatory alternatives." For PFHxS, HFPO-DA and its ammonium salts, PFNA, and PFBS, EPA considered a single HBWC, which effectively functions as substance-specific MCL. Nor did EPA consider any alternatives to the HI-MCL of 1.0 itself. Clearly, the analysis of only one regulatory option is not a consideration of "alternatives." The lack of alternatives considered for the PFAS covered in the Hazard Index violates both the SDWA and UMRA.

EPA Response: With respect to responses on the agency's evaluation of regulatory alternatives, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The agency disagrees with the commenter that the EPA did not consider a reasonable number of regulatory alternatives. Specifically, as discussed in section 5.1.3 of the EPA response in this *Response to Comments* document: The proposal took comment on establishing individual MCLs instead of and in addition to using a mixture-based approach for PFHxS, PFNA, HFPO-DA, and/or PFBS in mixtures. In that notice, the EPA described how a traditional approach may be warranted should the EPA not finalize a regulatory determination for mixtures of these PFAS. Under this alternative, "the proposed MCLG and MCL for PFHxS would be 9.0 ng/L; for HFPO-DA the MCLG and MCL would be 10.0 ng/L; for PFNA the MCLG and MCL would be 10.0 ng/L; and for PFBS the MCLG and MCL would be 2000.0 ng/L." The agency requested

comment on these alternatives for PFHxS, PFNA, HFPO-DA, and PFBS and whether these individual MCLs instead of or in addition to the Hazard Index approach would change public health protection, improve clarity of the rule, or change costs. Additionally, the EPA considered alternative mixture-based approaches such as a TOSHI or RPF approach. The agency requested comment on these approaches. Based on the EPA's technical expertise, the agency determined that the Hazard Index is the most cost-effective and least burdensome alternative for purposes of UMRA because this approach for mixtures achieves the objectives of the rule because of the level of protection afforded for the evaluation of chemicals with diverse (but in many cases shared) health endpoints. The EPA followed agency chemical mixture guidance (USEPA, 1986; USEPA, 2000a, RAGS), which explain that when the Hazard Index value is greater than one (1) then risk is indicated (because exposure exceeds toxicity). The agency did not propose alternative Hazard Index values (i.e., higher Hazard Index values) because the EPA determined that these approaches would provide sufficient protection against dose-additive health concerns from co-occurring PFAS. For example, a higher Hazard Index value (e.g., Hazard Index equal to 2) allows for exposure to be greater than the toxicity and will result in a standard that is not protective of public health.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045489)

a. EPA should consider finalizing one of the regulatory alternatives in the proposal and/or consider phasing in the proposed MCLs.

EPA should consider finalizing one of the alternative standards included in the proposed rule. Alternatively, EPA should consider a phase-in approach using the alternative standard values to require compliance with the proposed MCLs. In the proposal, the agency considered regulatory alternatives for PFOA and PFOS MCLs at 4.0, 5.0 ppt and 10.0 ppt without regulating the other four PFAS. As mentioned above, EPA did not present any MCL values to the SERs during the SBREFA panel, therefore, EPA has not considered small water systems' feedback on the proposed and regulatory alternative MCL values and its impacts and their ability to comply. Also, EPA only specifically identified regulating PFOA and PFAS and did not discuss the other four PFAS. The agency should conduct targeted outreach with small water systems on the feasibility of the proposed and alternative MCLs. Advocacy recommends that EPA give full consideration to any direct or written feedback in support of alternative standards presented by the agency or those recommended by small water systems, including a phased-in approach for compliance with the proposed standards.

EPA Response: For additional discussion on alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. With respect to responses on the *Regulatory Flexibility Act* and how the agency considered advice from the Small Business Advocacy Review (SBAR) Panel, please see section 14.3 of the EPA response in this *Response to Comments* document. Specifically in regard to commenters' assertion that the EPA failed to provide specific MCLGs, MCLs, or other highly specific or specialized scientific information developed for the rule proposal, the EPA is not required under the RFA to provide

specific numerical regulatory standards, such as MCLs or MCLGs, to small entities during the SBAR Panel process. As a part of the development of the NPDWR, the EPA sought the input of the Small Entity Representatives (SERs) via the SBAR panel process to inform the proposed rule and its proposed regulatory requirements, specifically seeking ways to minimize the regulatory burden on small entities. The proposed regulatory requirements had not been determined at that time because the EPA specifically wanted to seek the input from the SBAR panel and from other mandated consultations prior to proposing any economically significant regulation. The EPA therefore appropriately waited to determine many of the specific requirements such as the MCLs until after seeking the SERs' and SBAR panel's input on such specific numerical regulatory standard values.

Cordell Spires Jr. (Doc. #1541, SBC-042663)

V. Conclusion

EPA's proposed rule continues the tradition of regulating individual PFAS chemicals, which has proven to be ineffective. Industries will continue to find structurally similar PFAS that are not subject to regulations yet likely pose the same health risks unless the entire class of PFAS is regulated. As a result, EPA should consider using a class-based approach to regulating PFAS.

Sincerely,

Cordell Spires Jr.

EPA Response: For additional discussion on alternative regulatory standards (including regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Greater Cincinnati Water Works (GCWW) (Doc. #1550, SBC-042694)

As an alternative to the proposed regulatory construct, we propose that the Agency consider a regulation based on tiered action. In such a construct, the agency could set an MCL at 10 ppt for PFOA and PFOS at which water utilities would need to install treatment. However, if a utility has concentrations between the PQL and 10 ppt for these compounds, the utility would initiate a source water investigation to determine the source of the PFAS and then work with the state to eliminate the sources. This construct would take advantage of the beneficial impacts of the other environmental regulations and would work with them to reduce exposure.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The agency's final MCLs are based on the EPA's analysis of feasibility and does not preclude a system to take actions recommended by the commenter (such as source water investigation).

Ann Cougle (Doc. #1557, SBC-042557)

No level of chemical substances in drinking water is safe.

Four PFAS PFOA, PFOS, PFHxS, and PFNA were detected in 99% of serum samples from humans over 12 in the US, indicating nearly universal exposure. (Calafat et al., 2007)

A ZERO limit is absolutely necessary unless you want everyone in the world to have cancer.

Analytical testing and in turn, our ability to detect and identify these manmade chemicals in our water has made significant advances. The EPA proposed limits are more than twice as high as laboratories can detect them (1 to 2 ppt) and 1,000 times higher than the EPA 2022 HA of 0.004 ppt. After decades of unknowingly being exposed to these dangerous chemicals, we need the agency to protect us, not the industry's bottom lines!!!

Thanks,

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-042518)

Further, in the Department's opinion, EPA should consider raising the MCL to a meaningful concentration level outside of the "at or near MRL" of 0.004 µg/L. As stated previously, EPA Method 533 Section 9.2.3.2 Evaluate Analyte Recovery "Results for analytes fortified at concentrations near or at the MRL [minimum reporting level also known as PQL] (within a factor of two times the MRL concentration) must be within 50–150% of the true value. Results for analytes fortified at all other concentrations must be within 70–130% of the true value. If the LFB [Laboratory Fortified Blank] results do not meet these criteria, then all data for the problem analytes must be considered invalid for all samples in the Extraction Batch." This difference in acceptance level identifies one of the key issues associated with proposing to set a MCL at the same value as the practical quantitation limit (PQL) or MRL. As noted previously, this issue is not one that can be solved by simply lowering the PQL/MRL to 2 ppt. Based on UCMR 5 lab approvals, it is already known that more than 25 percent of laboratories nationwide will not be able to meet a PQL lower than 4 ppt with a 95% confidence interval (CI). In addition to causing more issues with laboratory capacity nationwide, the number of samples that would be rejected under the method, and therefore requiring resampling, would increase even with a ±50% Method QA/QC acceptance level. If, for example, the PQL/MRL for PFOA and PFOS are set at 0.004 µg/L as is required by UCMR 5, then the MCL should be set at least greater than 0.008 µg/L (two times the MRL = 2 x 0.004 µg/L). Raising the MCL to a level that is quantifiable and above a "factor of two times the MRL", would equate to a MCL for PFOA and PFOS of at least 0.009 µg/L. An MCL at this level would allow reliable and consistent (R&C) compliance determinations to be made between the PQL/MRL of 0.004 µg/L and the MCL at 0.009 µg/L. The Department believes that the issues identified above, and in our previous comment regarding

the drawbacks to the HI approach, it is prudent for EPA to set the MCL at a level outside of a ±50% acceptance level. This would alleviate the need to rely on "J qualified" or data below the MRL for MCL calculation determinations, and would more closely follow the SOC standard monitoring framework for compliance determinations while relying on quantifiable results.

EPA Response: With respect to implementation concerns around variability around sample results, the agency disagrees with the commenter that excessive resampling would be required with MCLs at the PQLs and notes the following: First, the agency notes that quantitative sampling results do not have an estimate of standard error and therefore are generally not reported. Second, EPA does not expect laboratories to conduct intensive statistical analyses of their analytical results so there is no calculated error associated with their reported measurements. In effect, quantitated measurement values stand as a single reported result. Lastly, any laboratory that provides drinking water analyses on PFAS in support of the NPDWR are held to the same standard for reporting results per the analytical method. The EPA further notes that compliance with the MCL is determined by RAAs where individual sample results will not cause a system to be out of compliance (unless that result is 4x above the MCL in which they are in violation immediately). The EPA also disagrees with the commenter claims' that "25% [of labs] cannot" meet the PQL; as discussed in the final rule preamble, the PQL reflects a minimum quantitation level that "with 95 percent confidence, can be achieved by capable analysts at 75 percent *or more* of the laboratories using a specified analytical method" (emphasis added). Greater than 75 percent of labs requesting participation in UCMR 5 were able to meet the PQLs/MRLs, and EPA anticipates the number of labs available for compliance monitoring to grow (please see section 5.1.2 for the EPA response in this *Response to Comments* document for additional discussion on laboratory capacity and practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations). For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. With respect to the analytic requirements of the EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document. Finally, the agency does not find MCLs at 0.009 µg/L for PFOA and PFOS to be feasible as close as feasible to the MCLG per SDWA requirements; the EPA estimates that laboratories across the nation can precisely and accurately measure PFOA and PFOS at quantitation levels of 4 ng/L and that levels below the PQL. Further, sampling results below the PQL may not have the same precision as a sampling result at or above the PQL but they are useful for operational purposes such as understanding that PFOA and PFOS may be present, which can inform treatment decisions and monitoring frequency.

<u>Missouri Department of Natural Resources (Doc. #1563, SBC-042508)</u>

The Department recommends that EPA strongly consider raising the proposed maximum contaminant level (MCL) for PFOA and PFOS to a level in the 9 to10 parts per trillion (ppt) range as further detailed in our comments below. An MCL at this level provides a significant

reduction in PFAS exposure, and is appropriate and justifiable under the SDWA statutory criteria. Increasing the MCL to 9 to 10 ppt will allow for reliable and consistent (R&C), quantifiable, and reportable detections of PFOA and PFOS at concentrations above the proposed practical quantitation limit (PQL) of 4 ppt.

EPA Response: Please see the EPA response to comment Doc. #1563, SBC-042518 in section 5.1.3 in this *Response to Comments* document. For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-042523)

If, for example, the PQL/MRL are set at 0.004 µg/L for PFOA and PFOS as is required by UCMR 5, then the MCL should be set at least greater than 0.008 µg/L (two times the MRL = 2 x 0.004 µg/L). Raising the MCL to a level that is quantifiable and above a "factor of two times the MRL", would equate to a MCL for PFOA and PFOS of at least 0.009 µg/L. An MCL at this level would allow reliable and consistent (R&C) compliance determinations to be made between the PQL/MRL of 0.004 µg/L and the MCL at 0.009 µg/L. In addition, treatment added to remove PFOA or PFOS below 0.009 µg/L would also have the benefit of lowering mixtures of the PFAS identified for the hazard index to levels below the lowest HBWC of 0.009 µg/L for PFHxS.

The Department believes that the issues identified above, and in our previous comment regarding the drawbacks to the HI approach, it is prudent for EPA to set the MCL at a level outside of a ±50% acceptance level. This would alleviate the need to rely on "J qualified" or data below the MRL for MCL calculation determinations and would more closely follow the SOC standard monitoring framework for compliance determinations while relying on quantifiable results. Therefore, the Department recommends the EPA raise the MCL to at least 0.009 µg/L.

EPA Response: Please see the EPA response to comment Doc. #1563, SBC-042518 in section 5.1.3 in this *Response to Comments* document. For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on monitoring and compliance requirements, please see section 8 of the EPA response in this *Response to Comments* document.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-042769)

MCL for PFOA and PFOS:

The proposed MCLs of 4 ppt for PFOA and PFOS are considerably lower than any other final or proposed MCLs established by states. According to a survey of state-enacted MCLs, final or

proposed MCLs for PFOA are set within a range of 8 — 14 ppt, and for PFOS within a range of 8 — 18 ppt. WSSC Water recommends that EPA conduct a review of the health risk reduction and cost analysis assessments conducted by the states to ensure that EPA's analysis is in line with the most accurate health effects and cost information.

In this rulemaking, EPA refers to certain contaminants under Phase I VOC rule as a basis for setting the MCL at the same level as practical quantitation level (PQL). While WSSC Water agrees that those rules have been implemented successfully, it should be noted that compliance management of PFAS at such low levels, near the analytical limit of precision and accuracy, will be much more challenging than VOCs, due to its environmental ubiquity and analytical sensitivity.

Regulatory alternatives:

EPA is soliciting comments on 5 ppt and 10 ppt as regulatory alternatives. WSSC recommends that EPA establishes the MCL at a level above the PQL of 4 ppt to provide adequate margin of confidence for water systems to better gauge relative risk levels with respect to MCL, and to identify and correct issues that could potentially impact compliance status. EPA may also consider a phased approach, in which MCLs are set at 10 ppt initially, then lowered to 5 or 4 ppt in the next six-year review cycle. Although 10 ppt is considerably higher than the MCLG, and it is technologically feasible to reduce PFOA and PFOS levels to 4 ppt, adopting this approach would provide more water systems with opportunities to prepare for mitigation measures and allow the EPA to gather more evidence to support lower MCLs in the future. As EPA correctly noted in reference to Phase I rule, advancements in analytical technology in the coming years will provide opportunities to lower the MCL closer to MCLG while maintaining an appropriate margin of confidence between the MCL and PQL.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that the Six-Year Review process allows the agency to consider future information as appropriate in deciding whether existing NPDWRs should be identified as candidates for revision as required by SDWA; please see section 5.1.6 of the EPA response in this *Response to Comments* document for additional discussion.

Public Health, Seattle & King County (PHSKC) (Doc. #1594, SBC-042358)

Develop and quickly enact a class approach to regulate PFAS that are detected in water to avoid generations of regrettable substitutions and cleanups. The number and type of PFAS in drinking water are expected to change with time as manufacturers phase in new analogs to move away from those compounds that become regulated. Many of the replacement compounds may not yet have a significant amount of data available. It cannot be assumed that a lack of data on the large majority of PFAS means that they are safe, instead EPA should treat all PFAS as hazardous unless specific compounds are shown to be safe through substantial data and review.

EPA Response: Regarding commenter concerns for environmental ubiquity and analytical sensitivity, to the extent that challenges regarding ubiquity exist, the methods approved for compliance monitoring for this NPDWR were developed and demonstrated to meet performance and QC expectations with any such challenges present. The method development performance and QC evaluations are conducted as an assessment of method ruggedness, which is demonstrated through testing in multiple types of drinking water matrices, including assessments off-site at other laboratories by other analysts. Therefore, the agency has empirically determined assurances that the methods can perform adequately at the final MCL levels. In short, the methods are able to meet acceptable performance and QC acceptance criteria typical for drinking water methods in spite of any potential ubiquitous presence and background levels of PFAS. Please see sections 5.1.2 of the EPA response in this *Response to Comments* document for additional discussion on PQLs and laboratory capability considerations as well as sections 7.1 and 7.2 for additional discussion on the analytical methods approved for compliance monitoring for this NPDWR. For additional discussion on alternative regulatory standards (including regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document. With respect to considerations for state-enacted MCLs or other state drinking water standards and guidelines, please see sections 5.1.5 of the EPA response in this *Response to Comments* document. The EPA notes that the Six-Year Review process allows the agency to consider future information as appropriate in deciding whether existing NPDWRs should be identified as candidates for revision as required by SDWA; please see section 5.1.6 of the EPA response in this *Response to Comments* document for additional discussion.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042816)

Based on AWWA's extensive research on this topic since the early 2000s, we support their recommendation that EPA set the standard for PFOA and PFOS at 10 ppt. This level is lower than the MCLs previously established by some states, including Pennsylvania, and is therefore highly protective of public health. Establishing MCLs of 10 ppt for PFOA and PFOS also addresses some of the concerns discussed above related to establishing the MCL at the PQL.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Safe Healthy Playing Fields, Inc. (Doc. #1621, SBC-042942)

On 15 June 2022, the US EPA issued non-binding drinking water health advisories for four of the above PFAS: PFOA, PFOS, PFBA and GenX. The advisories rendered no safe level of PFOA or PFOS. The standards for PFOA and PFOS issued on 13 March 2023 at 4ppt does not render "no safe level" for these legacy PFAS. The addition of PFNA and PFHxS to the proposed Health Index adds chemicals also found in synthetic turf.

EPA Response: Please see the EPA response to comment Doc. #1621, SBC-042944 in section 5.1.3 in this *Response to Comments* document. The EPA notes that the Lifetime HAs are beyond the scope of this rulemaking. The MCLGs promulgated in this final NPDWR are based on the best available, peer-reviewed science and the agency's review of current scientific literature on human health effects; please see section 4 of the EPA response in this *Response to Comments* document for additional discussion on health considerations for PFOA and PFOS when setting the MCLG.

Safe Healthy Playing Fields, Inc. (Doc. #1621, SBC-042944)

4ppt each for PFOA and PFOS are not protective and not reflective of the current state of technology. Currently available technology in commercial labs is capable of detecting PFAS at 2ppt and can reasonably be expected to improve further. Just as there is zero safe level of PFAS, there is zero social or environmental justice in essentially stating you will require less exposure and by doing so hope to cause less harm. Leading scientists and researchers [Link: https://www.youtube.com/watch?v=keBi8G2mDr8] agree 4ppt, as well as the proposed Health Index for a mixture of GenX, PFNA, PFBA and PFHxS are not protective of human or environmental health. To our knowledge, no one has ever given informed consent to be exposed to any chemicals in the PFAS family. Continuing to allow additional exposure to humans and the environment should not be tolerated.

The limits set for PFOA and PFOS should not be based on financial considerations when the societal cost globally is $17.5 trillion annually [Link: https://www.theguardian.com/environment/2023/may/12/pfas-forever-chemicals-societal-cost-new-report] for clean ups and health care of impacted individuals. The 8% of PFAS theoretically required for "essential" purposes must be exclusive of non-essential products, such as synthetic turf.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044024)

7. EPA requests comment on its proposed determination to set MCLs at 4.0 ppt for PFOA and PFOS and whether 4.0 ppt is the lowest PQL that can be achieved by laboratories nationwide.

a. CWUC recommends that EPA consider an MCL of 8.0 ppt, based on analytical certainty. The trigger level should be set to the EPA established PQL of 4.0 ppt, and the MCL double that at 8.0 ppt. A PQL is set at a level that can accurately and consistently be measured, and any values obtained less than the PQL are suspect. Compliance cannot be based on suspect data. Setting the trigger level at the PQL is a more appropriate approach and gives systems the ability to address issues on more certain data, as well as provides the EPA opportunity to reevaluate levels at a later time as treatment and analytical technologies advance.

b. In calculating the MCLs, anything less than the Reporting Limit (or PQL) should be counted as zero.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The agency is clarifying for the commenter that for compliance calculation purposes, zero will be used for results below the PQL (see section 8.0 of the EPA response in this *Response to Comments* document for additional discussion on monitoring and compliance requirements).

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044053)

c. An improved and simpler solution is to raise the Trigger Level to the PQL of 4.0 ppt, and set the MCL at 8.0 ppt.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion on trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

American Association for Justice (AAJ) (Doc. #1636, SBC-042969)

II. While AAJ supports EPA's proposal we are concerned that the proposed standard is inadequate in protecting human health. The EPA should set MCLs to zero which is the only safe exposure level and allow the MCL to be more impactful as detection methods improve.

Recognizing that PFOA and PFOS are carcinogenic and pose other health risks to humans, AAJ also broadly supports the imposition of MCLs. However, we are concerned that EPA's proposed MCLs do not go far enough to safeguard public health. Under Section 1412(b)(4)(B) of SDWA, EPA must generally establish an enforceable MCL as close to the MCLG as is feasible. Despite this, EPA has proposed MCLs for PFOA and PFOS of 4 parts per trillion (ppt). Given that EPA has correctly recognized there is no safe amount of PFAS exposure, these MCLs do not go far enough to protect human health.

EPA's public notice of the rule makes clear that it set the proposed MCLs at 4.0 ppt based on the minimum reporting level (MRL) for PFOS which is set in EPA testing Method 533 and 537.1. "The MRL is the lowest analyte concentration which demonstrates known quantitative quality."1 [FN1: David Munch and Phyllis Branson, Statistical Protocol for the Determination of the Single-Laboratory Lowest Concentration Minimum Reporting Level (LCMRL) and Validation of Laboratory Performance at or Below the Minimum Reporting Level (MRL), EPA, 1 (May 5, 2023), https://nepis.epa.gov/Exe/ZyPDF.cgi/P1005EAE.PDF?Dockey=P1005EAE.PDF] It is closely related to the Lowest Concentration MRL (LCMRL) which "is the lowest true concentration for which the future recovery is predicted to fall, with high confidence (99%), between 50 and 150% recovery."2 [FN2:Id] EPA Method 533 calculated an LCMLR for PFOA

of 3.4 ng/L and for PFOS of 4.4 ng/L. The fifth Unregulated Contaminant Monitoring Rule (UCMR 5) therefore set MCLs of 0.004 μg/L (equal to 4 ng/L) for both PFOS and PFOA. EPA has now taken these minimum reporting levels and adopted them as MCLs.

Essentially, EPA is setting the MCL at the level which it believes PFAS can be reliably tested for using present day technology. As EPA said in its public notice, "this reporting level is the minimum quantitation level that, with 95 percent confidence, can be achieved by capable analysts at 75 percent or more of the laboratories."3 [FN3: PFAS National Primary Drinking Water Regulation Rulemaking, 88 Fed. Reg. 18, 666 (Mar. 29, 2023).] There are significant issues with this approach. EPA admits many laboratories can reliably detect PFAS at lower concentrations. As EPA Method 544 states, "[t]he values that a laboratory can obtain are dependent on the design and capability of the instrumentation used."4 [FN4: Laura Rosenblum and Steven C. Wendelken, Method 533: Determination of per- and polyfluoroalkyl substances in drinking water by isotope dilution anion exchange solid phase extraction and liquid chromatography/tandem mass spectrometry, EPA, 533-2 (May 5, 2023),https://www.epa.gov/sites/default/files/2019-12/documents/method-533-815b19020.pdf] So in practice, many detections will occur at levels which are dangerously unsafe, but which will not result in violations of the MCL. These events are contrary to the purpose EPA set out in the SWDA.

This problem will only grow worse over time. Broadly speaking, setting MCLs at the level of current laboratory competence is an overly conservative and ineffective approach. This approach means that as technology improves, EPA would have to take affirmative action to lower the MCL until eventually meeting the actual levels at which human health is endangered. A far more meaningful and forward-thinking approach is to set the MCL at the lowest safe human exposure, and then allow the current level of technological innovation to dictate whether a detection above that limit has occurred. In this way the effective MCL will shift downward as technology improves without the need for further EPA action.

Given that we know there is no safe human exposure level for PFAS, EPA should set MCLs to zero. Concerns over enforcement of the MCL are better addressed by imposing a confidence requirement in the result. For example, EPA could set the MCL at any level of PFAS above zero, where the confidence of the detection is 95% or higher. While in practice this may not result in meaningful difference in enforcement of the MCL today, it will result in the MCL having more meaningful impact as methods of detection and laboratory standards improve.

To the extent EPA wants to look for a middle ground, it should look to its own interim lifetime health advisories for PFOA and PFOS. EPA issued lifetime health advisories for PFOA and PFOS of 0.004 ppt and 0.02 ppt respectively. While these lifetime health advisories exceed the correctly determined MCLG of zero PFAS, they are far safer than EPA's proposed MCLs. At the proposed MCLs 4 ppt, PFAS could be present at levels 200 to 1000 times greater than EPA's lifetime health advisories, yet not violate the maximum contaminant level. This means humans will still experience significant risk of dangerous exposure to these chemicals despite the MCLs. This should not be allowed.

EPA has explained that "[h]ealth advisories provide technical information that federal, state, and local officials can use to inform the development of monitoring plans, investments in treatment solutions, and future policies to protect the public from PFAS exposure."5 [FN5: EPA, EPA Announces New Drinking Water Health Advisories for PFAS Chemicals, $1 Billion in Bipartisan Infrastructure Law Funding to Strengthen Health Protections, (2022), https://www.epa.gov/newsreleases/epaannounces-new-drinking-water-health-advisories-pfas-chemicals-1-billion-bipartisan.] EPA should follow its own lead on this point and inform its MCLs by its own health advisory levels.

Based on this reasoning, we strongly support the creation of MCLGs and MCLs for PFAS but urge EPA to set both the MCLG and MCLs at zero, or at most equal to the health advisory levels of 0.004 ppt for PFOA and 0.02 ppt for PFOS, rather than the much higher MCLs in EPA's proposal. An MCL of 4 ppt does adequately protect the public from the dangers of these chemicals.

AAJ strongly supports EPA's conclusion that there are no safe PFOA and PFAS exposure levels, we believe that the suggestions we have made can improve this proposed rule. The EPA should set MCL's at zero. This means that as methods of detection improve, the EPA will not have to undertake lengthy and expensive rulemakings to amend its standards. An MCL level above zero will expose humans to a significant and unnecessary level. If you have any questions, please contact Victor Diaz at Victor.Diaz@justice.org.

Respectfully submitted,

Tad Thomas

President

American Association for Justice

EPA Response: For additional discussion alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that MCLs of 0 ppt for PFOA and PFOS are not feasible within the meaning of SDWA for the reasons discussed in sections 5.1.2 and 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that the Six-Year Review Process under SDWA allows the agency to consider information as appropriate in deciding whether existing NPDWRs should be identified as candidates for revision. As such, the agency will periodically review promulgated standards in the future as required by SDWA. Please see section 5.1.6 of the EPA response in this *Response to Comments* document for additional discussion on how the EPA may consider pending and future science. The EPA notes that the Lifetime HAs are beyond the scope of this rulemaking. The MCLGs promulgated in this final NPDWR are based on the best available science and the agency's review of current scientific literature on human health effects; please see section 4 for additional discussion on health considerations for PFOA and PFOS when setting the MCLG.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043451)

While the identified effective treatment technologies required by the proposed NPDWR may provide an ancillary benefit of removing other PFAS not covered in the NPDWR [FN56: Economic Analysis, EPA at 1-4.], that benefit still requires test results of the six PFAS to be above the MCL to be implemented. By not moving to control PFAS as a group the thousands of compounds not included in the NPDWR could be passing into our drinking water at levels far exceeding those proposed by the EPA for the six PFAS. CARE believes that EPA should consider taking an approach similar to the European Union.

EPA Should Adopt An Approach Like the The European Approach

Regulating PFAS as a class would not be a novel approach to protecting drinking water. As of January 12, 2021 the European Union recast its Drinking Water Directive, setting a limit of 500ppts for all PFAS and committing to phase out all PFAS, save for where "they are proven to be irreplaceable and essential to society." [FN57: Per- and polyfluoroalkyl substances (PFAS), European Chemicals Agency, https://echa.europa.eu/hot-topics/perfluoroalkyl-chemicals-pfas (last visited May 21, 2023).]

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs or regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA has established this NPDWR under the authority of the SDWA, which has different requirements and considerations than those considered by the European Union when it established its Drinking Water Directive.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043677)

Based on AWWA's extensive research on this topic since the early 2000s, the City supports consideration of their recommendation that EPA set the standard for PFOA and PFOS at 10 ppt. This level is lower than the MCLs previously established by some states, including Pennsylvania, and is therefore highly protective of public health. Establishing MCLs of 10 ppt for PFOA and PFOS also addresses some of the concerns discussed above related to establishing the MCL at the PQL.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043732)

Communications

As proposed, water systems are required to publish a Tier 2 public notice if the NPDWR MCLs are exceeded. If the MCL is 4 ppt, this would result in more frequent - and expensive – Tier 2

public notifications, which would erode trust in water utilities nationally. Like all utilities, Aurora Water's operation system best practices ensures public notifications do not need to be sent. However, treating Aurora's water to a level under the proposed public notice level of 4 ppt may be the difference between increasing costs by nearly six-to-seven times, rather than setting the MCL to 10 ppt, which would still roughly double our treatment costs but would be more manageable. The higher the treatment costs, the more we would be forced to increase rates.

Additionally, with increased notifications, customers may be more likely to buy bottled water believing it has less risk, which, depending upon how the water is treated, may have higher levels of PFAS and has additional environmental impacts from plastic waste. Customers may also turn to expensive and often unnecessary in-home water treatment systems, which, if not properly maintained, may pose additional health risks and create issues with land disposal. These options would further increase costs to customers and provide a false sense of security. Aurora Water recommends the EPA consider setting the MCL at 10 ppt, which would lower GAC costs, the frequency of public notifications and help maintain community trust in their water utility.

EPA Response: For additional discussion on alternative regulatory standards (including cost considerations and higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that the safety of bottled water is regulated by the FDA and is beyond the scope of this rulemaking. For additional discussion on PN requirements for the final NPDWR, please see section 9.2 of the EPA response in this *Response to Comments* document.

Rockbridge Area Conservation Council (RACC) (Doc. #1678, SBC-043739)

2) EPA Statement:

"Considering feasibility, including currently available analytical methods to measure and treat these chemicals in drinking water, EPA is proposing individual MCLs of 4.0 nanograms per liter (ng/L) or parts per trillion (ppt) for PFOA and PFOS" … "the maximum level of a contaminant in drinking water at which no known or anticipated adverse effect on the health of persons would occur is ZERO. Understanding that these chemicals have "NO SAFE LEVEL" and that the MCL of 4 ppt was selected based on what can be accurately identified analytically"

The interim life-time health advisory drinking water levels recently established by EPA, based on the existing toxicological data, for PFOA was to 0.004 ppt and 0.02 ppt for PFOS. These values are significantly below the MCL of 4 ppt causing a 1,000-fold decrease in safety for PFOA, a 200-fold decrease in safety for PFOS, and an unknown decrease in safety for the combination of PFAS compounds.

It is extremely unfortunate that current regulatory guidelines and the analytic technologies on which they are based for analysis of specific contaminants are between 50 - 70 years old. This has caused a large gap between identifying what can be identified conventionally, and determining whether the quantified dose is toxic or safe. Regardless, using this type of logic to

determine what is legally enforceable compared to what is "safe" is not a sound toxicological principle. Additionally, this logic goes against a variety of medical, philosophical, and legal practices that employ the "Precautionary Principle".

"The precautionary principle is a broad epistemological, philosophical and legal approach to innovations with potential for causing harm when extensive scientific knowledge on the matter is lacking. It emphasizes caution, pausing and review before leaping into new innovations that may prove disastrous."

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. Lifetime HAs are beyond the scope of this rulemaking. The MCLGs promulgated in this final NPDWR are based on the best available, peer-reviewed science and the agency's review of current scientific literature on human health effects; please see section 4 for additional discussion on health considerations for PFOA and PFOS when setting the MCLG. See section 1412(b) of SDWA for factors EPA considers when setting MCLs.

Public Employees for Environmental Responsibility (PEER) (Doc. #1683, SBC-044970)

The proposed MCLs are too high. EPA claims that it chose 4.0 ug/L as an MCL for PFOS and PFOA because, "4.0 ppt is the lowest concentration that PFOA and PFOS can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions." This is not true. Private laboratories like Eurofins can reliably measure down to 2.0 ppt in water. As defined by the SDWA, an MCLG is the "maximum level of a contaminant in drinking water at which no known or anticipated adverse effect on the health of persons would occur, allowing an adequate margin of safety." [FN7: 40 CFR § 141.2] The SDWA generally requires EPA to set an MCL "as close as feasible to" the MCLG. [FN8: 88 Fed. Reg. 18639] In this case, EPA is proposing a MCLG of zero for PFOA and PFOS, yet proposes an MCL of 4.0 ppt. An MCL of 2.0 ppt would be closer to the MCLG, EPA should consider reducing the proposed MCLs.

The Hazard Index (HI) will be difficult for public water suppliers to use. While PEER was pleased to see EPA propose to also regulate PFHxS, HFPO-DA, PFBS, and PFNA, use of the HI is unnecessarily confusing to the regulated communities. While we agree that it is important to account for the increased risk from mixtures of PFAS that may be found in contaminated drinking water, we fear that the HI will be difficult to implement. Because the HI is unitless, it is difficult to form messaging around these chemicals. There is currently an abundance of confusion over MCLs, clean-up standards, the PFAS definition, and a patchwork of regulations across the states; utilizing a HI instead of low MCLs will simply add to this confusion. As such, PEER urges EPA to consider low MCLs for PFHxS, HFPO-DA, PFBS, and PFNA, instead of using a HI.

Conclusion. PEER agrees with EPA that these PFAS chemicals are dangerous and must be regulated in drinking water; however, we do not believe that these proposed rules have gone far

enough. We urge you to consider defining PFAS consistent with the Organisation for Economic Co-operation and Development (OECD) definition, and regulating them as a class in drinking water.

Thank you for the opportunity to comment.

Sincerely,

Kyla Bennett, Director

Science Policy

Public Employees for Environmental Responsibility (PEER)

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA promulgates standards that is achievable on a national scale (as reflected in the PQL). While some individual laboratories can achieve lower levels, this has not been demonstrated to be achievable at a national scale which the agency looks to when promulgation an NPDWR. The EPA finds that the Hazard Index approach is the most health-protective approach for PFAS that have dose additive health concerns and are known to co-occur as mixtures in the environment. The agency further notes that the hazard index calculation is also not mathematically different (i.e., summing up numbers and dividing) than a RAA calculation which is used frequently for compliance calculations for NPDWRs. Regardless, to assist in the calculation of these values, the agency is developing a calculator tool to easily determine your hazard index result. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. After a review of public comment and considering this and other comments, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS to aid in messaging, risk communication, and other factors. Please see section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns.

<u>The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-045059)</u>

III. EPA should consider reliability and consumer confidence before setting its initial MCL at the PQL.

Issuing the initial MCL at the PQL has high consequences because once EPA sets the MCL, water utilities will have to start expending the billions of dollars to comply to meet it. Here, where there is scientific uncertainty and the proposed MCL is pushing the available treatment and sampling techniques to their physical extremes, EPA should set a MCL that meets the requirements of the SDWA that also can be supported as rational to the public. As more data

becomes available from UCMR 5 and other studies, there will be opportunities to issue a more stringent MCL.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that the MCLs are not "initial" as the commenter describes; they are final standards that reflects the agency's analysis of feasibility consistent with SDWA requirements. For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Joe DiNardo (Doc. #1725, SBC-045760)

2) EPA Statement:

"Considering feasibility, including currently available analytical methods to measure and treat these chemicals in drinking water, EPA is proposing individual MCLs of 4.0 nanograms per liter (ng/L) or parts per trillion (ppt) for PFOA and PFOS" … "the maximum level of a contaminant in drinking water at which no known or anticipated adverse effect on the health of persons would occur is ZERO. Understanding that these chemicals have "NO SAFE LEVEL" and that the MCL of 4 ppt was selected based on what can be accurately identified analytically"

The interim life-time health advisory drinking water levels recently established by EPA, based on the existing toxicological data, for PFOA was to 0.004 ppt and 0.02 ppt for PFOS. These values are significantly below the MCL of 4 ppt causing a 1,000 fold decrease in safety for PFOA and a 200 fold decrease in safety for PFOS. Understanding EPA's rational for selecting the 4 ppt MCL levels for these chemicals may make sense analytically, however, it does not justify them toxicologically. It is extremely unfortunate that current regulatory guidelines, with respect to analytical identification of specific contaminants, are between 50 - 70 years old. This has caused a large gap between identifying what can be found in a substances and if that dose is toxic or safe. Regardless, using this type of logic to determine what is legally enforceable compared to was is "safe" is nonsensical in toxicology. Additionally, this logic goes against a variety of medical, philosophical and legal practices that employee the "Precautionary Principle".

"The precautionary prin16.0ciple is a broad epistemological, philosophical and legal approach to innovations with potential for causing harm when extensive scientific knowledge on the matter is lacking. It emphasizes caution, pausing and review before leaping into new innovations that may prove disastrous."

EPA Response: Please see the EPA response to comment Doc. #1678, SBC-043739 in section 5.1.3 in this *Response to Comments* document.

U.S Conference of Mayors, National League of Cities and National Association of Counties (Doc. #1733, SBC-043893)

Should EPA move forward, the Agency should establish a higher MCL, such as 10 ppt under Option 1 c in the proposed regulation. This will capture the systems where PFAS is more prevalent, without overburdening many more communities.

2. Practicality of Implementation

As mentioned above, local governments play a critical role in the effective implementation of federal regulations. Recognizing this, as the Agency moves forward with this regulation, we have serious concerns with several practical aspects that will impact local governments' capacity to effectively and economically achieve compliance, as outlined below. Many of these practical concerns can be minimized by establishing a higher MCL for PFOS and PFOA, which would prioritize systems with higher concentrations of the chemicals, and by granting a longer compliance timeframe.

a. MCLs for PFOS and PFOA set at detection levels

The Agency has proposed drinking water standards for PFOS and PFOA at 4 ppt, which is the lowest detection level at which the contaminant can be reliably measured. When comparing these MCL levels with other datasets in the international community, such as those from the World Health Organization, Australia, Japan and Canada, EPA's proposed standards are significantly lower. Additionally, several states have recently set their own drinking water standards for PFOS and PFOA. As proposed, EPA's standards are lower than any current international or state standard.

When taking into account that states as well as the international community have access to the same available science EPA used to develop its proposed regulation, there are questions about this wide discrepancy that requires further examination. Additionally, EPA's standards are set so strictly that thousands of systems will be in violation from the outset, necessitating immediate decision making and costly actions.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding responses on the compliance timeframe, the agency is authorizing a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. With respect to existing state and international drinking water standards, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

Washington County Department of Public Health and Environment (Doc. #1739, SBC-043569)

[To address the issues described here, EPA should make one of the following changes to the proposed NPDWR for PFAS:]

• Raise the MCLs for both PFOS and PFOA to be above the PQLs so that results below the MCLs can be considered when calculating a QRAA for compliance.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Defend Our Health (Doc. #1741, SBC-045195)

The EPA's draft lifetime health advisories for PFOA (0.004 ppt) and PFOS (0.02 ppt) were developed in recognition of the impacts of those chemicals to the developing immune systems of young children. While the proposed Hazard Index approach to regulating GenX and PFBS is faithful to the draft Health Advisory Levels (HALs) published in 2022, the proposed MCLs for PFOA and PFOS are two to three orders of magnitude higher than the HALs for those chemicals. The stated justification for this discrepancy is that the HALs for PFOA and PFOS are well below the point of laboratory detection. But the commercial laboratories serving Maine drinking water testing routinely report results with a reporting limit of only 2 parts per trillion [FN1: https://alphalab.com/index.php/pfas-analysis].

The additional regulatory focus by EPA is already spurring innovation in PFAS detection. A mere three months after the EPA's published its proposed Lifetime Health Advisory Levels for PFOA and PFOS in 2022, Eurofins Lab announced that it had successfully improved existing laboratory analytical technology, and was able to detect PFOA and PFOS in the parts-per-quadrillion range of the proposed HALs. The EPA should support this innovative push by commercial laboratories by adopting an evolving, technology-based standard.

The failure to protect people whose water is contaminated between the current, commercially available level of detection of 2 ppt and the proposed 4 ppt PFOA and PFOS MCLs will have a real impact. In Maine, all non-transient community water systems have been required to test for PFAS and filter if the water exceeds the current drinking water standard. Almost 9% of community water systems (64 systems total) who have submitted their results to Maine Centers for Disease Control to date would fall into this unprotected gap [FN2: https://www.maine.gov/dhhs/mecdc/environmental-health/dwp/cet/documents/PFASallResults.pdf]. The people whose drinking water is supplied to them by at least 14 Maine municipal water districts would be left unprotected. The likely low-income residents of at least 13 Maine mobile home parks would be left unprotected. Especially

troubling given the documented impacts of low level PFOA and PFOS exposure to young children on which the HALS are based, there are at least 22 schools and day care facilities in Maine whose students would be unprotected to the effects of ongoing, documented exposure. It is unlikely that Maine is unique in the scope of its drinking water contamination. Millions of Americans would be left at risk of the toxic health impacts of ongoing PFOA and PFOS exposure by setting the MCLS at twice the commercially available point of detection.

In recognition of the current and rapidly improving analytical capacity to test for low level PFOA and PFOAS contamination and in recognition for the real medical harm experienced by communities exposed EPA should adopt an evolving, technology-based standard for PFOA and PFOS in drinking with an initial working regulation 2 parts per trillion for those two chemicals.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA promulgates standards that is achievable on a national scale (as reflected in the PQL). While some individual laboratories can achieve lower levels, this has not been demonstrated to be achievable at a national scale which the agency looks to when promulgation an NPDWR. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on considerations for international and state drinking water standards and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

Defend Our Health (Doc. #1741, SBC-045193)

There is room for improvement in the EPA's proposal. We strongly urge the EPA to use a technology-based standard for PFOA and PFOS that correctly identifies the current, commercially available point of detection of 2 parts per trillion rather than 4 parts per trillion.

EPA Response: Please see the EPA response to comment Doc. #1741, SBC-045195 in section 5.1.3 in this *Response to Comments* document.

Defend Our Health (Doc. #1741, SBC-045198)

Defend Our Health supports the existing proposal to list regulate 6 PFAS of identified toxicity, which will likely protect millions of Americans from ongoing exposure to these chemicals. We recommend improving the existing proposal by adopting a technology-based standard for the detection and remediation PFOA and PFOS starting by regulating them to the current, commercially available point of detection of 2 ppt and evolving alongside improving commercially available analytical capability to further protect people from 'low level' contamination which exceeds HALs for those two chemicals.

EPA Response: Please see the EPA response to comment Doc. #1741, SBC-045195 in section 5.1.3 in this *Response to Comments* document.

National Center for Health Research (NCHR) (Doc. #1749, SBC-044496)

1. The PFAS limit should be changed to 2 parts per trillion (ppt).

We disagree with the EPA that 4 ppt is the lowest level that can be reliably tested and removed. Eurofins routinely and reliably measures 2 ppt in water and it is likely that 2 ppt will be widely usable to measure and remove PFOA and PFOS well before this rule is finalized. Since EPA acknowledges that no level of PFOA and PFOS is safe, the limit should be 2 ppt.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045636)

As with the EPA selected rule option, setting the nation's first drinking water MCLs for PFOA and PFOS at levels as low as 4 or 5 ppt will create a significant combination of implementation challenges. The effect of such a rule option selection will be to delay all water systems in installing treatment facilities and increase the burden on households to pay for doing so, rendering such levels infeasible. Instead, EPA should place an emphasis on higher-priority water systems by targeting those systems higher levels of PFAS first. Focusing on systems with higher levels of PFAS will ensure that communities with the greatest risk of exposure to PFOA and PFOS are able to control exposure via drinking water more cost-effectively and promptly. Setting the nation's first drinking water standard for PFOA and PFOS at 10 ppt does not preclude EPA from further reducing these standards as technology advances and available occurrence and toxicological data improve.

Ultimately, each of the proposed options is likely to represent a net cost to society (and drinking water consumers), requiring investments that will outweigh the benefits. These impacts will be most dramatically felt by smaller systems serving less than 10,000 people and the affordability analysis suggests that the costs to implement these treatment facilities will range from hundreds to thousands of dollars annually for individual households, significantly exceeding affordable margins for household expenditures for drinking water (i.e. drive the cost of water services beyond EPA's measure of affordable drinking water).

Consequently, EPA should significantly improve upon the analyses to strengthen any rule and to accurately capture the impacts on water systems and public health. The Administrator should reevaluate this rule with the improved analyses to determine if the benefits justify the costs and that the rule is feasible for small systems to implement. If any rule is finalized without the additional analysis and public review AWWA recommends that EPA utilize Option 1c and set MCLs of 10 ppt PFOA and 10 ppt PFOS. Option 1c affords the greatest opportunity for health

benefit for impacted communities while reducing affordability concerns associated with the rule. If EPA determines that regulation of additional PFAS is merited, the agency should propose a rule following a final determination to regulate, consistent with the authority provided by SDWA.

EPA Response: For additional discussion on cost considerations and alternative MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion on the agency's cost analysis, the EPA has provided a robust discussion of the basis for the EPA's cost estimates in section XII of the final rule preamble and section 13.3 of the EPA response in this *Response to Comments* document. The agency notes that funds available under the BIL will significantly reduce some of these household costs for small systems (see for example, the EPA's affordability analysis Tables 9-15 and 9-20 of the final EA). With respect to the phased-in MCL approach, the EPA believes the monitoring and compliance requirements finalized in the PFAS NPDWR addresses high-risk systems (i.e., systems with elevated concentrations will require more frequent monitoring whereas systems without contamination or low levels of contamination will monitor less frequently). Based on these monitoring results, water systems may then be required to change their monitoring frequency if the results suggest increasing or decreasing concentrations (for additional discussion on monitoring and compliance requirements for the rule, please see section 8 of the EPA response in this *Response to Comments* document). In scenarios where elevated levels of PFAS are found in presumably "lower-risk" systems, a phased-in approach is not public health protective for systems that may experience spikes in PFAS concentrations. These fluctuations have been demonstrated in the agency's evaluation of PFAS occurrence in drinking water. Please see sections 12 and 13 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045557)

Summary of Key Recommendations

AWWA reviewed all aspects of the proposal and the supporting documentation, including the agency's occurrence analysis, cost analysis, benefits analysis, and household affordability analysis. The proposal includes several major actions for PFAS in drinking water, including:

1. Proposal for drinking water standards for both PFOA and PFOS;

2. Preliminary determinations for perfluorohexanesulfonic acid (PFHxS), perfluorononanoic acid (PFNA), hexafluoropropylene oxide dimer acid (HFPO-DA), perfluorobutanesulfonic acid (PFBS), and the mixture of these four PFAS, and

3. Proposal for drinking water standard for PFHxS, PFNA, HFPO-DA, and PFBS as a mixture using a hazard index.

Based on the supporting documentation, and in consultation with drinking water technical experts, AWWA recommends that the agency consider withdrawing and re-proposing the drinking water standards for PFOA and PFOS given that the underlying analyses lack

transparency, are not consistent with use of best available science, and are not clear. However, if EPA issues a final rule setting standards PFOA and PFOS, the agency should set drinking water standards of 10 ppt PFOA and 10 ppt PFOS on the basis that these would be most defensible with the agency's current analysis.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The agency disagrees that the standards for PFOA and PFOS, as well as the Hazard Index MCL, are not based on the best available, peer-reviewed science and lacks transparency. The agency has made documentation supporting the NPDWR available for public comment and has described these analyses in detail in the proposed and final rule preamble. Specifically, please see the agency's proposed and final *Economic Analysis for the final PFAS NPDWR* and associated appendices (USEPA, 2023c; USEPA, 2023d; USEPA, 2024c; USEPA, 2024d).

American Water Works Association (AWWA) (Doc. #1759, SBC-045549)

In addition to providing feedback for improving the analyses to support the proposal, AWWA makes several key recommendations, which are further detailed in the comment letter.

These recommendations include:

1. The agency should consider withdrawing and re-proposing drinking water standards for PFOA and PFOS given the recurring issues with the underlying analyses. If the agency should finalize drinking water standards for PFOA and PFOS based on the current proposal, drinking water standards of 10 ppt, each, are most appropriate.

EPA Response: Please see the EPA response to comment Doc. #1759, SBC-045557 in section 5.1.3 in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045657)

Finally, EPA also violated the SDWA when it did not consider any alternatives for the HI-MCL itself, or for the HBWCs that underpin it. Consideration of a reasonable range of alternatives is required by both the SDWA, and the Unfunded Mandates Reform Act. [FN4: SDWA [sec] 1412(b)(3)(C)(i); 2 U.S.C. [sec] 1535.] It also meant that EPA did not adequately consider the point at which benefits expected to result from the proposed HI-MCL outweigh its costs, as required by the SDWA.

EPA Response: For additional discussion on alternative MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The agency disagrees with the commenter that the EPA did not consider any alternatives for the Hazard Index MCL (see 5.1.3 of the EPA response in this *Response to Comments* document for additional discussion). The agency further notes that SDWA 1412(b)(3)(C)(i)(IV) only requires that in developing the HRRCA, the agency must consider the "incremental costs and benefits associated with each

alternative maximum contaminant level considered" if there are any. That provision does not require the agency to consider the HBWCs that are an input to the Hazard Index. Additionally, the commenter is incorrect in stating that the agency is required under SDWA to select an MCL where benefits "outweigh its costs"; the EPA emphasizes that under SDWA, the EPA must consider whether the costs of the rule are justified by the benefits (see SDWA 1412(b)(3)(c)(i)).

Fairfax Water (Doc. #1789, SBC-045301)

Instead of the proposed MCLs of 4 ppt, EPA should set the initial MCL at 10 ppt for PFOA and 10 ppt for PFOS to mitigate some of the pressures related to competition for limited resources and reduce the risk of further cost acceleration due to resource constraints.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046134)

14. The EA includes several alternative regulatory options, but all options are less stringent than the proposed option. Why were no more stringent regulatory options considered?

OMB's Circular A4 (2003) and EPA's (2014) economic guidelines suggest analyzing an array of alternative regulatory options, with at least one more stringent and one less stringent than the proposed option. The proposed PFAS NPDWR EA only includes less stringent alternative regulatory options. To strengthen the EA, EPA should evaluate a more stringent regulatory option or explicitly describe the rationale for not including a more stringent option. For example, Circular A4 (OMB 2003) states that more stringent regulatory alternatives are not required in cases where the proposed option is near or at the limits of what is technically feasible.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA did not propose more stringent MCLs for PFOA and PFOS given the EPA's consideration of feasibility as required by SDWA. For example, the agency does not have sufficient evidence to support a lower PQL that can be consistently achieved by laboratories across the country. After review of public comment, the agency is finalizing the MCLs for PFOA and PFOS at 4.0 ng/L (at the PQL) as this is the closest level to the MCLG that is feasible due to the ability of labs using approved analytical methods to determine with sufficient precision and accuracy whether such a level is actually being achieved. The record supports the EPA's determination that the lowest feasible MCL for PFOA and PFOS at this time is 4.0 ng/L.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044682)

VIII. EPA is out of step with other health organizations around the world who have evaluated PFAS health issues.

As we noted at the outset, our members seek to serve the public in an affordable and cost-effective manner. We don't try to avoid necessary and appropriate requirements. To the contrary, we embrace them and prioritize them within our other infrastructure and operational requirements. However, EPA's proposed PFAS MCLs are so low that they give us pause – especially as we consider the fact that PFAS levels in our environment (and bodies) have been dropping dramatically and will plummet further given the intense focus on ending the use of these chemicals.

With this perspective, we are troubled that EPA's criteria are so much lower than other prominent health agencies. For example, the World Health Organization set a provisional guidance value in September 2022 of 100 ppt for PFOA/PFOS and 500 ppt for all other PFAS. WHO had the benefit of EPA's science when it adopted criteria five orders of magnitude higher for PFOA and four orders of magnitude for PFOS. This is an incredible difference between the world's two preeminent world health organizations.

WHO has not been alone in its repudiation of EPA's interim health advisory levels and now proposed MCLs. For example:

• The United Kingdom and European Union set their PFAS regulatory framework as follows:

<10ppt = no issue;

< 100ppt = research; and

>100ppt = action required.

• Australia set a standard of PFOS + PFHxS at < 70ppt and PFOA a < 560ppt (2022).

• Japan's standard for PFOS+PFOA is < 50 ppt.

• Canada's Guidelines for Canadian Drinking Water Quality, released in September 2022, show 600 ppt for PFOS and 200 ppt for PFOA. The application guidelines indicate the sum of PFOS and PFOA should not exceed 200 ppt. This remains much higher than the EPA proposal.

These are dramatic and, potentially, unprecedented differences between the PFAS standards of prominent health organizations and EPA's, which warrant significant caution on EPA's part. These differences also support our suggested phased implementation approach.

EPA Response: For additional discussion on considerations for international and state drinking water standards and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. With respect to a phased implementation approach, the EPA believes the monitoring and compliance requirements finalized in the PFAS NPDWR addresses high-risk systems (i.e., systems with elevated concentrations will require more frequent monitoring whereas systems without contamination or low levels of contamination will monitor less

frequently). Based on these monitoring results, water systems may then be required to change their monitoring frequency if the results suggest increasing or decreasing concentrations (for additional discussion on monitoring and compliance requirements for the rule, please see section 8 of the EPA response in this *Response to Comments* document). In scenarios where elevated levels of PFAS are found in presumably "lower-risk" systems, a phased-in approach is not public health protective for systems that may experience spikes in PFAS concentrations. These fluctuations have been demonstrated in the agency's evaluation of PFAS occurrence in drinking water. Please see section 12.1 and 13 of the EPA responses in this *Response to Comments* document.

Anonymous (Doc. #1950, SBC-046316)

PFAS and PFOS contaminants should have their MCLG be decreased to 4.0 ng/L or lower. As a resident in the Manorville area, approximately 1 mile from the Grumman site, now owned by the Navy, 64 residents in the surrounding area are dealing with contaminated well water. From Pfoa/Pfos to chemicals the average layman can not even pronounce. The Navy is not taking any responsibility, for the area outside the fence line where residents live. UNACCEPTABLE.. There are 22 out of 64 homes where residents have had, or have cancer, not to mention what can appear in the future for our children and animals. Lowering the acceptable number will hold businesses that have a responsibility to clean up the area before turning property over to someone else. It is the right of every American to have clean water. But there are sections in America that are the forgotten developments which is making people sick and or killing them. PLEASE lower the acceptable allowance numbers. If not for this generation, for our Childrens future

EPA Response: The EPA notes that MCLGs are public health goals and are not enforceable standards. For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Anne Schwartzman (Doc. #2203, SBC-046520)

Re: Docket ID No. EPA-HQ-OW-2022-0114

Water is needed for our lives. Clean water is necessary for humans and animals to live a healthy life. EPA's health advisories say no level of PFAS exposure is safe and so the enforcement levels should be the lowest they can be. People living on earth should not have to assume any additional level of risk to appease industry and trade organizations. The Chamber of Commerce does not speak for the health of all; please disregard their issues with it not being up to the polluters to curtail the PFAS created and used in products. Now is even late for us to be doing something; act now to do the decent thing in the USA.

Thank you,

Anne Schwartzman

Therefore, EPA should set regulations at the limit that the labs can detect rather than the proposed 4 ppt for PFOA and PFOS each.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2331, SBC-047291)

If it can not be proven definitively, and it can't that the health cost savings from 4 PPT removal is greater than the cost to remove to below 20 PPT then 20 PPT would be the MCL.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The Administrator has determined that the costs of this regulation are justified by the benefits: see section 13.8 of the EPA response in this *Response to Comments* document.

Mary Raven (Doc. #2435, SBC-047316)

Please set PFOA and PFAS levels as low as can possibly be detected -- lower than the current 4ppt.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Petersburgh C8 (PFAS) Committee (Doc. #2714, SBC-047423)

In addition, the whole class of these chemicals should be regulated as close to zero as possible, all 14,000 of them. Why should the safety of these chemicals be tested on humans? Instead of spending money on treating our diseases, filtering our water, and on cleanup, stop these compounds from entering our bodies, our communities, our children, and our wildlife. The research shows that this class of chemicals are dangerous and forever.

The proper MCL for this class of chemicals is as close to zero as possible. When a chemical from this group gets pulled out of use because people start getting sick, another is waiting to take its place. Industry is way ahead of our health, safety and regulations. We need strong policy from our government agencies charged with protecting our communities instead of letting industry profit from weaker regulations

Thank you for your consideration.

The Petersburgh C8 (PFAS) Committee

Petersburgh, New York

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs or regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

West Virginia Rivers Coalition (Doc. #3072-3, SBC-047358)

In this light, we urge EPA to expedite the publication of human health criteria for PFAS. State agencies are waiting on EPA's guidance to implement policy levers to reduce PFAS pollution at the source. In accordance with recently passed legislation, the West Virginia Department of Environmental Protection will establish statewide limits on PFAS discharges upon EPA's issuance of those recommended criteria. Lastly, as demonstrated by the Maximum Contaminant Level Goal of zero, there is no safe level of PFOA or PFOS. As technologies continue to advance and PFAS detected at even lower levels, we urge EPA to lower the MCLs to levels protective of public health. Thank you.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that "publication of human health criteria for PFAS" is beyond the scope of this rulemaking. For additional discussion on how the agency considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

National Center for Health Research (Doc. #3072-73, SBC-047400)

I'm Dr. Diana Zuckerman, president of the National Center for Health Research. Our non-profit think tank focuses on the safety of medical and consumer products. We provide research-based information to Congress, federal agencies, and the public, and we do not accept funding from companies that make the products we evaluate. My comment today relies on my research experience at Yale and Harvard and in my current position, as well as my policy expertise from working in the house, the Senate, federal agencies, and the White House. We agree that this proposed rule will greatly improve public health, reducing cancer, heart disease, stroke, low birth weight, and other harms to adults and children. It will save lives. But we have recommendations to improve it. Number one, we disagree that 4 parts per trillion is the lowest level that can be reliably tested and removed. Eurofins routinely and reliably measures 2 ppt in water and it's likely that 2 ppt will be widely used, usable to measure and remove PFOA and PFOS well before this rule is finalized. Since EPA acknowledges that no level of PFOA or PFOS is safe, the limit should be 2 ppt.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

New Mexico Rural Water Association (Doc. #3072-98, SBC-047413)

Lastly, having an MCL is a concern because of the hammer that comes with violations. We suggest a treatment technique without penalties for systems that had no role in creating the contaminant, which we're trying to solve. Thank you for the opportunity to comment.

EPA Response: For additional discussion on alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The agency notes that under SDWA, the EPA may establish a treatment technique in lieu of an MCL if it is not technologically feasible to ascertain the level of a contaminant in drinking water. The availability of analytical methods to monitor the targeted PFAS compounds in this NPDWR precludes the EPA from considering such a regulatory framework at this time. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

Daniel Varon (Doc. #1518, SBC-042724)

Further, the 4.0 ng/L seems too high of an allowable MCL. If the study conducted by the EPA used 30, 20, and 90 ng/L as threshold markers, why should the MCL not fall closer in line with this? I once again will mention that the studies linking PFAS to negative health consequences show correlation only at extremely high levels. If it becomes more costly to bring the MCL lower, it should be considered if there is a higher threshold that can yield comparable results. I note and am aware however, that if PFAS thresholds have little cost differences between a 30 ng/L threshold and a 4.0 ng/L threshold, then this point is not as significant.

EPA Response: For additional discussion on alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA did not use a "study" nor propose alternative standards at "30, 20, and 90 ng/L as threshold markers."

Brian Hackman (Doc. #1539, SBC-042910)

Raising the MCL's and HI to more significant values, on the order of the initial 70 ppt Health Advisory concentrations, would allow the Agency to show health improvements are being achieved at a reasonable cost through this regulatory opportunity to chase after a real and mitigatable risk with effective solutions.

This statement is in objection to the current PFAS proposed MCLs being discussed as part of the USEPA Docket EPA-HQ-OW-2022-0114, in light of a standard that would prove to be more effective and demonstratable at higher concentrations.

Respectfully Submitted,

Brian L Hackman

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Cordell Spires Jr. (Doc. #1541, SBC-042661)

IV. Why EPA Should Use a Class-Based Approach to Regulate PFAS

More than 12,000 PFAS chemicals have been identified, yet this regulation would only regulate 6 of them [FN-9: Id.] Therefore, this regulation does not go far enough in preventing the potential health effects associated with PFAS. Although PFAS exposure occurs in complex mixtures, at present, fewer than 50 PFAS are commonly measured. [FN-10: Carol F. Kwiatkowski et al., Scientific Basis for Managing PFAS as a Chemical Class, 7 ENV'T SCI. TECH. LETTERS 532, 533 (2020).] New testing methods have shown that humans are exposed to more PFAS than previously estimated. [FN-11: Id.] The most studied PFAS chemicals are PFOA and PFOS, which have been phased out by manufacturers. [FN-12: Id. at 534] Nonetheless, most industries have turned to structurally similar replacements and evidence suggests that these replacements are not safer alternatives. [FN-13: Id.]

Managing the risk of PFAS has focused primarily on regulating one chemical at a time or a small group of PFAS, and this approach has not been effective at controlling widespread exposure. [FN-14: Id.] The problem with this approach is that assessing each PFAS chemical individually or in small subgroups ignores the majority of PFAS and underestimates the overall risk, especially since most of the chemicals are not commonly measured and their risks are unknown. [FN-15: Id at 536.]

EPA Response: For additional discussion on alternative regulatory standards (including regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Cordell Spires Jr. (Doc. #1541, SBC-042659)

May 5, 2023

The Honorable Michael Regan

Environmental Protection Agency

Office of the Administrator, 1101A 1200 Pennsylvania Avenue, N.W. Washington, DC 20460

Re: Public Comment on the Proposed PFAS National Primary Drinking Water Regulation

(Docket ID: EPA-HQ-OW-2022-0114)

Dear Mr. Regan:

On March 14, 2023, EPA announced the proposed National Primary Drinking Water Regulation (NPDWR) for six PFAS including perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), perfluorononanoic acid (PFNA), hexafluoropropylene oxide dimer acid (HFPO-DA, commonly known as GenX Chemicals), perfluorohexane sulfonic acid (PFHxS), and perfluorobutane sulfonic acid (PFBS). I, a law student at Southern Methodist University Dedman School of Law, respectfully submit the following comment on the proposed regulation. I have an interest in this regulation because it will impact the future of our nation's water quality and I believe clean water should be the standard rather than the exception moving forward.

This regulation is a good start to regulating PFAS in drinking water, but it does not go far enough. Instead, EPA should regulate PFAS as a class of chemicals rather than regulating PFAS on a chemical-by-chemical basis.

EPA Response: For additional discussion on alternative regulatory standards (including regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Prince William County Service Authority (Doc. #1609, SBC-042845)

5. EPA should issue initial MCLs for PFOA and PFOS of at least 2-3 times higher than the proposed limits of 4 ppt.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Prince William County Service Authority (Doc. #1609, SBC-042831)

MCLs and Hazard Index

The proposed MCLs for the two PFAS chemicals are set at 4 parts per trillion (ppt), which is the lowest level that current technology can reliably detect and are lower than those enacted by every state that has regulated PFAS in drinking water thus far. The costs associated with the proposed regulation are likely to be substantial and the scientific basis for MCLs at levels this low has been called into question, thus raising the issue of whether the benefits outweigh the costs. The World Health Organization (WHO), based on its review of the relevant science, recently recommended a limit of 100 ppt for PFOA and PFOS in drinking water, a limit that is 25 times higher than that which EPA now proposes.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

Minnesota Department of Health (MDH) (Doc. #1610, SBC-042854)

Raise the MCLs for both PFOS and PFOA to be above the PQLs so that results below the MCLs can be considered when calculating a QRAA for compliance.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Safe Healthy Playing Fields, Inc. (Doc. #1621, SBC-042946)

With babies being born pre-polluted with PFAS, [Link: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7530144/] support of manufacturers 3M, Chemours, Solvay, Daikin, Dow, Dupont, Honeywell, BASF, Merck, Orteck, Innovative Chemical Technologies, and Bayer's use of Confidential Business Information so that they can collectively make $4 billion annual return on their investments is unconscionable.

Just four years ago, there were an estimated 4,000 - 5,000 PFAS chemicals in existence. Today, the EPA toxicity database, DSSTox, lists 14,735 unique PFAS chemical compounds; PubChem reports approximately 6 million. There is no conceivable way to evaluate each chemical individually or even as mixtures as currently proposed. The EPA must act to regulate PFAS as a class. By not doing so, the US EPA is de-incentivising development of alternatives that are safe, not carcinogenic and are non-toxic.

The job of the US EPA is to protect human and environmental health, not the chemical industry. We ask that you not delay further in enacting human and environmental health protective MCLs and regulation of PFAS as a class.

Respectfully submitted,

Diana Conway, President

Dianne Woelke MSN, Board Member Safe Healthy Playing Fields, Inc.

EPA Response: For additional discussion on alternative regulatory standards (including regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Maine Organic Farmers and Gardeners Association (MOFGA) (Doc. #1660, SBC-043383)

With as many as 14,000 chemicals in the PFAS family, setting standards one at a time will never succeed in protecting health and the environment. The high persistence, accumulation potential, and hazards of PFAS studied to date warrant treating all PFAS as a single class. [FN5: https://pubs.acs.org/doi/pdf/10.1021/acs.estlett.0c00255?src=getftr.] That should be EPA's next step.

EPA Response: For additional discussion on alternative regulatory standards (including regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046114)

Finally, EPA should evaluate a regulatory option that is more stringent than the proposed MCLs. Contrary to OMB Circular A4 and EPA's economic analysis guidelines, all the alternatives analyzed in the Draft EA are less stringent than the proposed option. EPA should evaluate a more stringent regulatory option in the final EA or, at a minimum, explain why such an analysis is not appropriate. [FN143: Id. at 10.]

EPA Response: Please see the EPA response to comment Doc. #1808, SBC-046134 in section 5.1.3 in this *Response to Comments* document.

CleanEarth4Kids.org (Doc. #3072-45, SBC-046368)

Good afternoon. My name is John Bottorff with the CleanEarth4Kids.org. We thank the EPA for this proposal, but it is not nearly enough. We ask the EPA to set MCLs for PFAS in drinking water at zero. It's essential to stop PFAS in drinking water. PFAS have been detected in drinking water and water sources throughout the United States. Exposure to PFAS through drinking water causes significant health risks to humans, like hormone disruptions, diabetes, pregnancy complications, and increased risk of thyroid disease along with kidney, liver, and testicular cancer. According to the EPA, the lower the levels, the lower the risk. While PFAS may be present in drinking water levels that cannot be currently measured, new testing procedures and filtering technologies are being developed and we must set the limit now to ensure public safety. The state of New York has set MCLs at 2.7 ppt for PFAS in drinking water, significantly lower than what the EPA is proposing. The EPA must lead the way as the top protection agency in the nation and take aggressive action by setting the limit at zero. PFAS must be regulated as a class using the broadest definition to cover the entire family of these toxic chemicals. Managing PFAS as a class is the only way to protect human and ecological health. There is no safe level of PFAS, the EPA must turn off the tap at the source. There is no limited or managed use of PFAS, the EPA must ban the use and manufacturer of all PFAS as a class and they must do it now and immediately stop the approval of any new PFAS. The U.S. regulatory process has completely failed to protect us from PFAS, and now must play catch up. Taxpayers are paying the health and

financial burden of PFAS toxicity despite their dangers being known for over 50 years. It is fundamentally wrong that people and communities have been burdened by the health impacts and now the cleanup cost of PFAS by corporations that have made billions and billions from these poisons. The EPA must hold companies like 3M and Dow accountable for the cost of testing, cleanup, and upgrading water treatment facilities. They knew PFAS were toxic in the 70s. Not only continued the use but hid their own research and have fought all regulations. Please take strong and immediate action to protect our health. Set limits at zero ppt in drinking water and ban all uses and manufacturing of PFAS as a class. No more extensions or delays. No more protecting profits instead of people. Please stop these poisons now. Thank you from CleanEarth4Kids.org.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs or regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Ira Share (Doc. #1900, SBC-046293)

Please set the PFOA family of chemicals as close to zero as possible. We live less than a mile from a SuperFund site that has ruined our community with these chemicals. Our town water supply is contaminated. Our private wells are contaminated. Our air is contaminated. We have had enough of these toxins. It has been 7 years since discovery and there has been no cleanup. BUT, our DEC and DOH knew about this problem long before 2016, neglecting to inform our town. So, please set these levels as slow as possible so other communities can avoid this tragedy.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Kathleen Share (Doc. #1901, SBC-046482)

Please determine that the MCL be 4.0 ppt or even better less as the recommendations have been .004 ppt.

I live in Petersburgh NY, a mile away from the Taconic Super Fund Site which has polluted the area with PFOA/PFAS for years. Our community was informed of the contamination years after Taconic and NYSDEC and NYSDOH were aware. More and more communities are finding contamination which could be avoided if the polluters knew the MCL was moving to EPA MCL.004. Next is GenX.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Don Treasure (Doc. #1909, SBC-046284)

Currently, EPA does not have data on the health effects (if any) of this entire group, and so cannot accurately support the extremely low level of regulation. The cost of this proposal far outweigh the low if any unknown risks of this level of exposure. Both Canada and the World Health Organization have more realistic (if still not well supported by data) levels. Rescind or at least substantially raise the allowed exposure levels from the unjustified levels proposed here.

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA disagrees that it does not have "data on the health effects (if any) of this entire group." As discussed in section 4 of this *Response to Comments* document, the agency is promulgating MCLGs at zero for PFOA and PFOS, a Hazard Index MCLG of 1, and individual MCLGs for PFHxS, PFNA and HFPO-DA at 10 ppt based on the EPA's evaluation of scientific literature on human health effects. The EPA currently has sufficient data and information to promulgate standards for the PFAS regulated through this NPDWR: for additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs), 5.1.4 (for treatment considerations) and 5.2.1 (for feasibility considerations for the Hazard Index PFAS) of the EPA response in this *Response to Comments* document. Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

Ira Share (Doc. #1923, SBC-046308)

The amount of any PFAS/PFOS compound that we should be exposed to is zero. I live near Taconic Plastics in Petersburgh, NY. They have ruined our aquifer, our town water supply, our soil and most likely our food that we grow in this rural area.. We smell the emissions daily. We have no idea of the compounds they are using and releasing into the air. Are they long or short chain? Are they both? The whole class of these chemicals should be regulated, all 14,000 of them. Why should the safety of these chemicals be tested on humans? Instead of spending money on treating our diseases and filtering our water, stop these compounds from entering our bodies. Zero is the proper MCL. When one of this group gets pulled out of use, another is is waiting to take its place. Industry is way ahead of our health and safety.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2321, SBC-046304)

EPA likely only has a biostatistical link if anything to PFAS and increased risk of cancer or any disease as a result of parts per trillion level exposer to PFAS chemicals. Likely "new data" you

are aspousing is made up as is the data on CO2 contributing to climate change. Therefore EPA should not be setting standard of removal at levels of 4 PPT. Removal down to 15 PPT is more easily and economically feasible for water utilities and therefore this is the MCL that should be set rather than 4 PPT along with the other combined PFX number. We doubt you can prove any health improvements solely attributable to reducing the levels to 4 PPT rather than 15 PPT and the certainly not for the massive increase in costs to utilities to achieve removal to 4 PPT

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

June Fabre (Doc. #2430, SBC-046457)

I support the EPA's proposed new actions because no level of PFOAS exposure has been proven to be safe.

I would also like the EPA to set regulations at the limit that labs can detect if that is lower than 4 ppt for PFOA and PFOS EACH.

Health and safety are important to me as a mother, grandmother, and retired nurse. These new regulations are needed.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Anne Romney (Doc. #2557, SBC-046210)

I fully encourage the EPA to set regulations at the limit that the labs can detect rather than the proposed 4 ppt for PFOA and PFOS each.

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Laura Fontaine (Doc. #2611, SBC-046667)

Dear Administrator Regan,

Thank you for proposing health-protective limits for PFAS chemicals in drinking water that reflect the latest scientific information on their health effects.

The standard limits should be ZERO as these chemicals stay in the body forever and accumulate. There is no safe level for PFAS. We have 16 positive test results for PFAS and PFOAs in our drinking water due to release of these chemicals from the St. Gobain Plant in Merrimack NH. They are not being held accountable for the pollution of our water due to the levels registered in

our well are under the recommended NH Ambient Groundwater Quality standards. The standards need to be ZERO. We have to pay for a water system due to this infiltration of PFAS into our well water. My husband was diagnosed with Prostate Cancer last year and had to have a radical prostatectomy at age 61. He had to miss work and now has a major lifestyle change. These chemicals are not safe at any level! NH has a high rate of breast cancer. Could it be from our polluted water?

EPA should finalize these Safe Drinking Water Act regulations as quickly as possible, including the Hazard Index approach for four PFAS chemicals. Thousands of PFAS chemicals are in use and many are found in mixtures in water around the country. EPA should address the whole class of PFAS chemicals wherever possible.

All parts of EPA and the federal government need to take equally bold action to stop PFAS pollution, hold polluters accountable, and curtail uses of PFAS chemicals. Placing the burden on our communities, our drinking water, and our health is not the right way to solve the PFAS challenge.

Sincerely,

Laura Fontaine

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs or regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Wolf Creek Water and Sewer Improvement District (Doc. #2832, SBC-046612)

Thank you for the opportunity to comment on this proposed PFAS National Primary Drinking Water Regulation. I am an elected Board of Trustees member of the Wolf Creek Water and Sewer Improvement District in Eden, Utah, making this comment in that role, and as a private citizen.

Our District is a Public Water Supplier for approximately 1200 connections, and a similar number of connections for public sewer. The sewage is conveyed to a tertiary membrane bioreactor plant (MBR) and treated to a high standard. We then use the reuse water for landscape irrigation through a separate secondary water supply system. Northern Utah has many of these secondary water systems, and is increasing reuse of water.

We do not know whether we have any PFAS or GenX compounds in our water supply or sewage. Because our water supply is 3,000 year old mountain-sourced water (Utah Geological Survey Special Study 165, 2019), and we are in a fully residential setting, with no industry or fire training areas upgradient, we believe it is very unlikely that there would be PFAS etc occuring in our drinking water. However, consumer use of PFAS may well introduce them into our sewage, since we understand that toilet paper manufacturing equipment, fast food wrappers etc may contain PFAS. The removal effectiveness in our MBR plant is an unknown.

This leaves us with a situation where we may have to test for the compounds in both water streams (drinking and reuse), and if we find them, deal with the public concern that will follow.

Based on my 30 years of background in the environmental sciences (AIPG # 7148, and Registrations in KY, IN, and PA prior to retirement), I believe the value you are setting is too low. My reasoning is as follows.

*We have contacted the lab (ChemTech Ford, Salt Lake City) that provides the analyses for our water in accordance with the Utah Division of Drinking Water, which is a reflection of the Federal requirements. They are unable to provide reliable analysis below 40 ppt, even in a clean matrix sample.

*There is an extremely high probability of cross-contamination, laboratory generated outliers and other "stray" results when you push commercial laboratories down to levels of analysis below 1 part per billion.

*Further, although our water samples may be pristine, there is a very real chance of air transport cross-contamination. (Reference recent USGS analyses in soil in New Hampshire with results between 0.5 and 1 ppb in soil). Utah is a dusty place, particularly with increasing dust being transported off the Great Salt Lake, at its current low stand. There is a high probability of PFAS being present in that dust, since it is a closed basin with water from sewage treatment plants and industrial sources across densely populated Wasatch Front Area In other words the 4 nanograms/liter level proposed for PFOA and PFAS is an order of magnitude below current available services, there is a high risk of extraneous and inaccurate results, and the exposure from water sources is probably orders of magnitude below exposures from consumer goods and ingested dust.

The cost of water supply treatment, if it were deemed necessary would be extreme, due to the very low levels proposed.

We are further going to have to deal with this issue in our reuse water, with unknown complexities at this time, although the PFAS that might be therein are from consumer goods, and not from any source we can control.

In summary, this is a plea from the trenches that you reconsider setting such a low standard, and at this time set a "monitor only" standard, or a value above 50 ppt. This should remain in place until there has been more progress in removing the PFAS from consumer materials, manufacturing lubricants, and items such as recreational and racing ski wax (a local likely source). There should be a full human risk-based evaluation of the relative exposures from these sources, and the Drinking Water Primary Standard only finalized when there is concrete evidence that drinking water is a high impact to consumers through ingestion, in comparison to all the other routes of exposure. The value can be lowered from this interim value (50 ppt or higher) when there is clearer eveidence of the relative importance of drinking water as a route of exposure for consumers/humans.

We cannot afford as a country to deal with another PCB-type scare - without first dealing with the sources and primary routes of exposure. This should be tackled internationally, so that infants and children in particular are not exposed to PFAS etc from imported goods.

Thank you for your consideration

EPA Response: For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. With respect to responses on cross contamination/background contamination issues with analytical analysis, please see section 8.7 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #1944, SBC-047454)

We know these hazards through history have hardly been publicized, and when they are, it takes years to convict. If they are convicted, the company inevitably moves on to the next chemical they can get away with, due to the lack of funding in science in studying these chemicals (Rich, 2016). Following, the chemicals studied that have been made aware to those that have had the privilege of an education, are hardly regulated. People in power are now just getting to pick and choose which communities are "allowed" to be more affected than others (Erickson, 2022). Economically it makes sense as those in low-income communities can't afford lawyers to even begin to take action for themselves (Erickson, 2022).

The proposed National Primary Drinking Water Regulation does not nearly go far enough for these communities, and all communities. It's a step in the right direction, but it highlights the fact that our government will continue to do the bare minimum in order to put on a public front that they are doing something. You have a few choices. Do nothing about this, contributing to producing more fuel for angry citizens, allowing for more division in the United States. Do the bare minimum, such as setting a "maximum contaminant level" , which requires those who have the privilege of time and education to find the flaws. Or, you can actually do something and set regulations on where the problem is coming from firsthand, get rid of "maximum level" and replace it with NO levels, protecting all communities, especially vulnerable ones. Additionally directing more funding to education and science, this is the route least taken, evident in the proposed NPDWR.

With education, you know that PFAS, even in small increments, builds up in the human body, ecosystem, and other organisms over time with continual exposure (EPA, 2023). A maximum level does not mean no levels, it just means you're allowing for less exposure to occur, still resulting in the same problem just over a greater period of time. This proposal does nothing for the communities already disproportionately affected, continues to allow everyone to be exposed, and avoids the real problem. Additionally, looking at how the EPA handled the Flint water crisis, holding information from Flint citizens knowing they were using lead filled water, increases

distrust in citizens with the EPA (Bernstein, 2016). Why is it considered to be ok to have levels of anything hazardous in our drinking and bathing water and why should we trust a government agency to decide what composes safe drinking water when they have undoubtedly failed in the past?

EPA Response: For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA disagrees that the agency is doing the "bare minimum" in setting an MCL for the PFAS regulated under this NPDWR. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. The agency has conducted extensive analyses (see for example sections 3, 4, 6 and 10) and consultations (section 14) to support this final rulemaking.

Pennsylvania Chamber of Business and Industry (Doc. #1592, SBC-042796)

EPA Will Need to Provide Additional Resources to States for Compliance and Permitting Support

As discussed, the stringent MCL's being proposed will present a significant compliance burden on industry and will also present a major imposition on the staff and resources of state environmental agencies, who are already have significant challenges with respect to hiring and retaining qualified workers. This proposed rulemaking will have secondary regulatory impacts to brownfields cleanups, NPDES discharge permits, industrial stormwater permits, waste management permits for hauling, storage, and disposal at landfills, among others – all of which will require more staffing and resources for state and local agencies. States will need a substantial increase in federal funding to accommodate this mandate.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The availability of BIL funding which can be used to support implementation of the final NPDWR (please see section 2.4 for additional information). For discussion related to costs, including costs to primacy agencies, please see section 13 of the EPA response in this *Response to Comments* document. The application of MCLs in non-drinking water programs (such as water quality criteria, NPDES, or CERCLA cleanups) is beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR.

Aquarion Water Company (Doc. #1617, SBC-043374)

Much of this cost will be borne ratepayers, who are also facing increased water rates to address other important needs, such as replacing lead service lines and upgrading/replacing aging infrastructure.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The availability of BIL funding which can be used to support implementation of the final NPDWR (please see section 2.4 of the EPA response in this *Response to Comments* document for additional information). Lead service line replacements and upgrading aging infrastructure is beyond the scope of this rulemaking.

Central Valley Clean Water Association (CVCWA) (Doc. #1619, SBC-042938)

May 26, 2023

Via the Federal eRulemaking Portal

U.S. Environmental Protection Agency EPA Docket Center

Office of Ground Water and Drinking Water Docket Mail Code 2822IT

1200 Pennsylvania Avenue NW Washington, DC 20460 https://www.regulations.gov/

Re: Docket ID No. EPA–HQ–OW–2022–0114

Comment Letter — PFAS National Primary Drinking Water Regulation Rulemaking

To the U.S. EPA Office of Ground Water and Drinking Water:

The Central Valley Clean Water Association (CVCWA) appreciates this opportunity to submit comments on the PFAS National Primary Drinking Water Regulation Rulemaking and the proposed Maximum Contaminant Levels (MCLs) for PFAS that are included in the proposed rule. CVCWA is a nonprofit association of publicly-owned treatment works (POTWs) located throughout the Central Valley region, including the southern Delta, that provide wastewater collection, treatment, and water recycling services to millions of Central Valley residents and businesses. We approach these matters from the perspective of balancing environmental and economic interests consistent with state and federal law.

California's water quality planning process requires the development, adoption, and amendment of Statewide Water Quality Control Plans and Regional Water Quality Control Plans (Basin Plans) that contain water quality objectives to provide protection of the beneficial uses of California's waters. Regional Water Quality Control Boards implement Basin Plans by issuing and enforcing waste discharge requirements (WDRs), which also serve as National Pollutant Discharge Elimination System (NPDES) permits issued under federal delegation for discharges to surface water. Water quality objectives are used to set effluent limitations in NPDES permits.

State-adopted MCLs are automatically enforceable water quality objectives in Basin Plans. Federal MCLs are likely to establish the floor for California MCLs for PFAS and are likely to be incorporated as enforceable numeric water quality objectives in a Basin Plan at some point. CVCWA has evaluated the estimated impact of the U.S. EPA's proposed MCLs for PFAS and has determined that significant wastewater costs (both financial and environmental) are likely to

occur when the proposed MCLs are adopted and incorporated as effluent limits in NPDES permits for PFAS.

California POTWs have worked to comply with numerous water quality regulations that are established to ensure that beneficial uses of our water resources are reasonably protected, as required under the California Water Code. To comply with these regulations, many POTWs in recent years have upgraded their treatment processes to tertiary levels of treatment (nitrification, denitrification, and filtration). To remove PFAS to meet the proposed MCL of 4 ppt and the proposed Hazard Index, most POTWs would need to again upgrade their treatment processes to include granular activated carbon, ion exchange or, more likely, reverse osmosis. Capital costs for reverse osmosis are estimated to be $4.0 billion dollars for all the NPDES- permitted POTWs needing to upgrade to meet new PFAS limitations in California's Central Valley. Annual operation and maintenance costs are estimated to be over $360 million for POTWs in the Central Valley. In addition to these financial costs, each treatment option will result in environmental and greenhouse gas impacts and should also be considered. Importantly, the Central Valley hosts a higher proportion of disadvantaged communities than the rest of California; these lower-income communities have limited resources to adapt to the expected economic and environmental burdens. CVCWA submits these comments to emphasize the critical need to ensure that environmental and human health benefits of U.S. EPA's proposed rule is commensurate with the financial and environmental (e.g., greenhouse gas emissions) impacts associated with new treatment facilities to meet new PFAS requirements.

As U.S. EPA prepares a proposed regulation implementing proposed MCLs for PFAS, we urge you to consider the direct or indirect financial and environmental costs for POTWs associated with complying with these regulations in the overall cost analysis for the proposed MCLs. If you have any questions, or if CVCWA can be of further assistance, please contact me at (530) 268-1338 or eofficer@cvcwa.org.

Sincerely,

Debbie Mackey Executive Officer

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The application of MCLs in non-drinking water programs (such as water quality criteria, NPDES, or CERCLA cleanups) is beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR.

WaterPIO (Doc. #1624, SBC-043469)

For those of us who have worked in water for years, it's become painfully obvious that, because the EPA cannot achieve a variety of PFAS-related actions on the private polluters, it is consciously choosing to punish public water systems. The EPA cannot directly hand down

punitive actions against the private corporations that have polluted our waterways, in part of the loose regulations the EPA themselves helped set and in part because the large companies are backed by unlimited lobbying and legal resources. That's why the EPA is choosing to attack public water systems; they're the low-hanging fruit that doesn't have the staffs or the bankrolls to fight back against the EPA.

The case can also be made the EPA's goal isn't solely focused on cleaning up the nation's drinking water to safe levels because the MCLs and HI do not clearly follow PFAS-related science, as discovered by several states who have taken the time and money over the years to set their own drinking water standards. Instead, we believe the EPA is trying to create a groundswell of support for punitive actions against private polluters by slapping drinking water violations on thousands of public water systems that don't have any role in producing or illegally discharging PFAS into the nation's source waters. The systems are also not responsible for creating the millions of PFAS-laden products Americans use every day that make their way into our wastewater systems.

It must be said clearly and loudly. Not one public water system is responsible for putting PFAS in its drinking water or wastewater effluent. Not one. Yet the proposed MCLs and Hazard Index treat public water systems as if they are the polluters of the nation's source waters.

While a more-detailed public comment about the future of wastewater regulations is for another day, moves by the EPA also reveal the effort to punish public servants instead of polluters. If public wastewater service providers aren't provided exemptions under CERCLA during the drafting of new legislation, enterprising law firms will look to them as the first people to sue. After all, through the simple act of discharging effluent containing PFAS into a waterway, every wastewater system will technically become a polluter.

Again, since public water and wastewater systems won't have the legal teams and resources to fight back that the polluting corporations have, they will be the easy, first target of law firms all over the country. Public water systems will be forced to write settlement checks versus taking their cases to court because, without exemptions, they are almost guaranteed to lose in front of a judge or jury.

The total cost of these checks will likely be in the billions of dollars nationwide and public trust in their work will be devastated. After all, the settlements will make news and the dollar figures will be waved around as proof the wastewater utilities are polluters putting public health at risk. WaterPIO has sat on panels with EPA Region Administrators and lawyers from top firms and stated this as fact. No one on those panels disagreed, not in any way; we were even applauded for saying "the quiet part" out loud.

Add this potential reality to the price tags for drinking water compliance and the cost to the American consumer for basic water and wastewater services will exponentially jump to what, for many, will be unaffordable amounts.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that application of MCLs in non-drinking water programs (such as water quality criteria, NPDES, or CERCLA cleanups) is beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document or additional discussion on comments outside the scope of this NPDWR. The PFAS NPDWR is not designed to "punish" PWSs. Rather, it has been finalized to improve public health protection, consistent with the mandates and requirements of SDWA. See section III (final regulatory determinations) and IV (maximum contaminant level goals) of the preamble for this action for more information; see also section V for more information about the final rule's MCLs.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043450)

CARE Comment 4 - CARE Urges EPA to Regulate PFAS as a Class in Order to Address PFAS Contamination on a Broad Scale to Most Efficiently Protect Americans' Drinking Water

According to EPA's toxicity database, there are over 14,700 unique PFAS compounds as of August 2022. [FN52: PFAS|EPA: PFAS structures in DSSTox (update August 2022), EPA,

https://comptox.epa.gov/dashboard/chemical-lists/PFASSTRUCTV5.] EPA's proposed NPDWR only covers 6 of those chemicals. That is 0.04% of known PFAS. CARE is deeply concerned that regulating the thousands of PFAS chemicals on a case-by-case basis will take extraordinary time, effort, and resources. The time and energy wasted on EPA's current approach would likely lead to avoidable negative health effects for thousands of Americans and add burdensome and avoidable administrative costs in enacting such a multitude of individual regulations.

Furthermore, it was once believed that short-chain alternatives to long-chain, legacy PFAS were safe. [FN53: Anna Reade, PhD, The Scientific Basis for Managing PFAS as a Chemical Class, NRDC, (June 30, 2020) https://www.nrdc.org/bio/anna-reade/scientific-basis-managing-pfas-chemical-class.] Two of those short-chain alternatives include GenX Chemicals and PFBS, the very same compounds EPA holds are too dangerous at certain levels to be in our water in the current NPDWR proposal. As more and more research is conducted on PFAS, the more dangerous health effects and harms to our environment we find out. That is why sixteen PFAS experts recently published an article advocating for a robust and comprehensive classwide ban of PFAS. [FN54: Carol F. Kwiatkowski, David Q. Andrews, Linda S. Birnbaum, Thomas A. Bruton, Jamie C. DeWitt, Detlef R. U. Knappe, Maricel V. Maffini, Mark F. Miller, Katherine E. Pelch, Anna Reade, Anna Soehl, Xenia Trier, Marta Venier, Charlotte C. Wagner, Zhanyun Wang, and Arlene Blum, Environmental Science & Technology Letters 2020 7 (8), 532-543, https://pubs.acs.org/doi/10.1021/acs.estlett.0c00255.] These experts recommend eliminating the use of all PFAS save for chemicals considered essential and without safer alternatives. [FN55: Id.] They stress that "the high persistence, accumulation potential, and/or hazards (known and potential) of PFAS studied to date warrant treating all PFAS as a single class."

EPA Response: For additional discussion on alternative regulatory standards (including regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

National Chicken Council (NCC) (Doc. #1649, SBC-043217)

NCC supports efforts to protect the public health by ensuring Americans have access to safe drinking water. Water is critical to broiler chicken production and processing, and NCC member companies take great care to ensure the water they use is safe and that they return it to the environment clean. NCC also supports tailoring regulations carefully to minimize unintended consequences and unnecessary economic and nutritional impacts. We urge the Agency to consider the impact the proposed rule would have on chicken processors and other food manufacturing operations. In particular, United States Department of Agriculture (USDA) Food Safety and Inspection Service (FSIS) regulations require that processing plant water supplies meet National Drinking Water Standards. These standards set by EPA for drinking water will also affect all the nation's meat and chicken processors' ability to operate and could potentially affect food availability as well as the livelihoods of rural communities across the country.

It is important that the standards set do not inadvertently affect chicken processing plants or limit water availability for food processing, especially if, as NCC understands, the proposed standards are not based on food safety considerations. We believe that the proposed rule, as written, could negatively impact the ability for chicken producers to operate and put unnecessary strain on the food supply. As a result, should EPA proceed with this rulemaking, we urge the Agency to make the following changes to its proposal and to its process for this rulemaking:

1. EPA should work with its regulatory partners at FSIS to ensure EPA understands how EPA drinking water standards interact with FSIS regulations and, in turn, how changes to drinking water standards would impact chicken producers; develop a strategy to implement any new standards without disrupting the national food supply; and understand what, if any, food safety risks are posed by using water outside of the standards in the proposed rule in chicken processing.

2. EPA should structure any PFAS standards to apply only to water actually used for direct human consumption and not to water used in food production or other uses.

In support of these requests, we offer the following comments:

• The proposed rule directly impacts regulations governing chicken production and other food industries and has unintended consequences which would harm the chicken industry and U.S. food supply. Under FSIS regulations, 9 CFR 416.2(g), meat, poultry, and egg products establishments must have a supply of drinking water that complies with the National Drinking Water standards in 40 CFR 141. Chicken processing establishments must provide, upon request, a water report attesting to the "potability" of the water used in chicken processing.1 [FN1: 9 C.F.R. § 416.2(g)(1); see also USDA, "Public Q&A: Potable Water Certification,"

https://ask.usda.gov/s/article/What-documents-can-be-used-to-demonstrate-that-the-water-used-inthe-establishment-is-potable-fit-for-human-consumption.] Under the proposed rule, if a water source does not meet the proposed PFAS standards it would not comply with 40 CFR Part 141, and as a result, a chicken processing facility using that water source would not be able to satisfy its requirements under 9 CFR 416.2. Critically, whereas public drinking water sources may continue operating while implementing mitigation technologies – a process that can take years – and the water will remain available for drinking in the meantime, having a 40 C.F.R. Part 141-compliant water supply is a prerequisite for chicken processing establishment to operate. FSIS has numerous tools at its disposal to address regulatory noncompliances, including withdrawing inspection, which prevents a plant from operating. The proposed standard would place chicken processing establishments in an extremely precarious position, rendering them completely beholden to municipal water supplies' decisions on whether and how quickly to remediate any violations. Establishments supplied by well water face the same requirement and are equally at risk of having their fates decided by factors outside their control. It would be too much to place the burden entirely on FSIS to decide how to respond in each instance. This scenario will have major implications for the chicken industry and the U.S. food supply, and EPA should provide the necessary guidance to ensure that any National Drinking Standards do not undermine chicken processing operations and food manufacturing in general.

• It has not been determined that water with PFAS levels above the proposed threshold presents a food safety risk when used in food manufacturing. Before applying the proposed rule to chicken processing and food manufacturing, it should be determined if water with PFAS levels above the proposed threshold presents an actual food safety risk. FSIS has tested for PFAS substances in food products in the past and determined that the levels found did not present a consumer safety risk. The testing would have reflected any background levels of PFAS contributed by the facility's water supply. Given the potential disruption the proposed rule presents to the chicken industry, a robust and science-based risk assessment should be completed to fully understand whether a regulation like the proposed standard is needed to protect consumers from a legitimate food safety risk.

• Funding should be available for both city water facilities and chicken processing facilities whose water supplies are regulated by the proposed rule. The Agency discussed at both the technical meeting and the digital public hearing that state and local municipalities will have access to funding from infrastructure spending to help address needed improvements to water facilities. $1 billion in grant funding will be made available through the Infrastructure Law and an additional $5 billion through the Small or Disadvantaged Communities Grant Program, in addition to the $3.4 billion provided through the Drinking Water State Revolving Funds (SRFs) and $3.2 billion through the Clean Water SRFs. If they are affected by the proposed standard, either directly or indirectly through FSIS regulations incorporating the National Drinking Water Standards, food processing facilities should be able to access these funds to help expedite the implementation of improvements that will help ensure they have an available source of compliant water.

• NCC believes that the proposed rule will have significant economic impact on the chicken processing and food industries not fully captured by the Agency's analysis. Based on internal calculations, the costs of the proposed rule on the chicken industry would be significant. NCC estimates that PFAS water testing would cost about $1,200 per sample without considering the cost of the labor to collect the samples, the shipping of the samples, and analyzing the test results. To maintain compliance, around 112 samples are expected to be required annually per water source, meaning the testing of a single water source in a facility would cost approximately $134,000 annually. With some facilities using up to four different water sources, this cost will be significant. Laboratory capacity to handle the significant increase in testing demands simply do not exist today.

Moreover, EPA would need to consider the catastrophic effects that would follow if a chicken processing facility were shut down, temporarily or indefinitely, because it could not obtain a Part 141-compliant water source. Chicken processing facilities are expensive, capital-intensive operations. They take years to permit and build, and they are often the leading economic driver in their rural communities. Many chicken processing facilities produce millions of pounds of chicken each day. If a single chicken processing establishment's water source were to fail the proposal standard and the plant was not allowed to operate, it could negatively affect the chicken supply. Thousands of rural jobs could be lost, and the community would be unlikely to have enough jobs to reemploy those workers. Moreover, chicken processing facilities are supported by an extensive network of family farmers who raise the chickens to be processed, and those farms must be located within a reasonably close distance to the processing facility. The hundreds of family farms in that facility's live production network would lose a steady income source, and many of those farmers could go bankrupt. The lost output would significantly affect the nation's food supply, driving up protein costs and decreasing supply, placing economic and nutritional stress on American families on the on the federal and state nutrition assistance programs that rely heavily on affordable chicken to provide healthy meals.

NCC appreciates the ability to provide comments on such an important proposed rule. In consideration of the above comments, NCC asks that the Agency (1) extend the comment period for an additional 90-days, (2) engage with FSIS to ensure no unintended consequences result from the promulgation of this rule, and (3) if the proposed rule is finalized, the final rule should include an exemption for water used in food processing. These requests will help ensure that the Agency does not inadvertently undermine the food supply, food security, and the food industry while pursuing its goals for public drinking water.

Respectfully submitted,

Ashley B. Peterson, Ph.D.

Senior Vice President, Scientific and Regulatory Affairs

National Chicken Council

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The PFAS NPDWR regulate PWSs, defined as a system that provides water for human consumption to 15 or more connections or regularly serves 25 or more people daily for at least 60 days out of the year. The application of MCLs in non-drinking water programs is beyond the scope of this rulemaking; please see section 15.1 for additional discussion on comments outside the scope of this NPDWR. The EPA notes that the "the proposed standards are not based on food safety considerations" because this action does not regulate food or food safety, nor are there requirements under SDWA that the EPA should consider food safety for establishment of NPDWRs. Food and Food Safety are generally regulated by the FDA and/or the Department of Agriculture. The EPA further notes that the commenter presents a monitoring structure and associated costs that are not driven by this rulemaking. The EPA clarifies only regulated PWSs are required to monitor for the regulated PFAS in compliance with the rule. The commenter's contention that $1,200 per sample is high; the laboratory analysis per sample for the EPA method 537.1 (one of the validated methods to meet the monitoring requirements of the rule) is $309 (Method 537.1 version 2.0). See discussion in sections 8 and 13.3.4 of the EPA response in this *Response to Comments* document about the rule's mandated monitoring requirements and analytical costs, respectively. See section 17 of the EPA response in this *Response to Comments* document in regard to the request for extending the public comment period. In regard to the requested exemption for "an exemption for water used in food processing", as discussed above, this regulation directly applies to PWSs, and specifically a CWS or NTNCWS. If a food processing facility is considered a CWS or NTNCWS, then this regulation applies. If it is not, then the potential future application of other limits, including MCLs, to these systems by other regulatory agencies is beyond the scope of this rulemaking. See also the EPA response to comment Doc. #1839, SBC-046048 and Doc. #1839, SBC-047721 in section 5.1.3 in this *Response to Comments* document.

Horsham Water & Sewer Authority (HWSA) (Doc. #1686, SBC-043812)

Based on our experiences, there are a few other cases where EPA does not appear to fully appreciate the degree of impact the issues have on actual operating costs, and therefore are not adequately estimating costs appropriately. The first instance is regarding Simultaneous Compliance issues, in particular with the Lead & Copper Rule. Our state primacy agency, the Pennsylvania Department of Environmental Protection (PADEP) interpreted the Lead & Copper Rule to mandate that we had to be removed from reduced monitoring and returned to Initial Monitoring under the rule due to the installation of GAC. Having been on reduced monitoring (30 homes triennially) for years, we did not have 60 homes from our original approved sampling site list still available to us as many of the original customers have since moved. We therefore had to initiate a mass letter campaign to potentially eligible homes and then enter customer homes to sample and confirm the presence of lead solder during a pandemic. This put both our customers and our employees at risk, but we complied, nonetheless. Not surprisingly, there was no change in our 90th percentile lead and copper values. While the pandemic is over, the costs

and time of reestablishing a full Lead & Copper Rule sampling site list after being on reduced monitoring for years by canvassing customers, performing confirmation testing in homes, and then conducting two full sampling events are not inconsequential even in normal times and should not be overlooked.

EPA Response: For additional discussion on cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. Regarding responses on "simultaneous compliance challenges," please see section 12.1 of the EPA response in this *Response to Comments* document.

Citizens Campaign for the Environment (CCE) (Doc. #1710, SBC-045133)

The cost difference between treating a contaminant to the MCL and the MCLG can be significant, and when polluters can be identified, they should pay for the full cost to treat to levels where no known health effects are present.

EPA Response: For additional discussion on cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. MCLGs are public health goals and are not enforceable standards.

PFAS Regulatory Coalition (Doc. #1761, SBC-046088)

2. EPA should consider increased costs for remediation.

Under Section 121(d) of CERCLA, Superfund remedies must achieve MCLGs when remediating impacted groundwater and other drinking water sources. CERCLA 121(d)(2)(A). Further, once promulgated the MCLs would become applicable or relevant and appropriate requirements (ARARs) that Superfund remedies must attain. Id. No separate rulemaking or other process is needed. Therefore, it is this Proposal that would result in increased costs at Superfund sites, and EPA must consider those costs in this rulemaking.

The Department of Defense (DOD) PFAS remediation estimates demonstrate how significant these costs can be. As of July 2022, DOD summarized its PFAS remediation costs as follows: "Through September 30, 2021, DOD has obligated $1.46 billion to investigate and clean up PFAS. DOD anticipates obligating $409.4 million in FY 2022 and an additional $2.12 billion after FY 2022 to continue these efforts." Per- and Polyfluoroalkyl Substances (PFAS) Cleanup: Schedule, Status, and Cost Estimates, DOD Office of the Under Secretary of Defense for Acquisition and Sustainment (July 2022). DOD does not separate these costs by media, but assuming that even just half of these costs are for water/groundwater remediation leads to costs in the billions of dollars.

Further, this EPA action is likely to stimulate the adoption of PFAS cleanup standards under state law. OMB circular A-4 requires consideration of the costs of such additional state regulation as well as direct federal regulation. Circular A-4, at 6. EPA needs to address those costs for all parties anticipated to incur remediation costs. As noted elsewhere in these

comments, available estimates indicate that these new cleanup costs will amount to billions of dollars.

EPA Response: For additional discussion on cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. As required by SDWA, this rulemaking and analyses supporting the rulemaking only includes costs that "are likely to occur solely as a result of compliance with the [MCL]." Thus, the EPA's cost analyses focused on the compliance costs of meeting the MCL to PWSs that are directly subject to this regulation. The same provision expressly directs the EPA to exclude "costs resulting from compliance with other proposed or promulgated regulations." Thus, the EPA cannot consider the costs of use of the MCLs under other EPA statutes (such as CERCLA) as part of its EA because SDWA specifically excludes such consideration (42 U.S.C. § 300g-1(b)(3)(C)(i)(III)). See also City of Waukesha v. EPA, 320 F.3d 228, 243-244 (D.C. Cir. 2003) (finding that SDWA excludes consideration of the costs of, for example, CERCLA compliance, as part of the required cost/benefit analysis). For further discussion about CERCLA clean-up costs and benefits, please also see section 5.1.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1631, SBC-043434 in section 5.1.3 in this *Response to Comments* document.

Groundwater Resources Association of California (Doc. #1831, SBC-045353)

Second, National Pollutant Discharge Elimination System (NPDES) discharge sampling/reporting compliance will add costs to groundwater operations (e.g. new well construction) but will also

protect water bodies/aquifers from PFAS contamination. Third, the proposed MCLs will likely impact groundwater recharge operations and management decisions. For example, primary and even secondary MCLs are regularly adopted as thresholds for antidegradation analysis in groundwater systems or used as thresholds to assign assimilative capacity in groundwater. The addition of new MCLs for PFAS may impact past, current, and future investments in groundwater recharge and storage infrastructure, particularly where recycled water sources are used to recharge groundwater. If the proposed MCLs are adopted, they will likely be used to set new water quality objectives for PFAS in groundwater basins with subsequent restrictions on and additional costs for groundwater recharge of water containing PFAS in excess of the proposed MCLs. If MCLs are adopted as water quality objectives for groundwater, groundwater recharge projects may require treatment prior to recharge, increasing costs for groundwater recharge projects. Part of the cost-benefit analysis included inadvertent avoidance of disinfection byproducts (DBPs) due to anticipated changes in treatment type (e.g., decrease or discontinuation of chlorination and/or additional removal of organic matter). This benefit is not realized if MCLs are applied as water quality objectives in groundwater basins.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA

notes that application of MCLs in non-drinking water programs (such as water quality criteria, NPDES, or CERCLA cleanups) is beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR.

Citizens Energy Group (Doc. #1838, SBC-044853)

Washington, DC 20460

RE: PFAS National Primary Drinking Water Regulation Rulemaking Preliminary Regulatory Determination and Proposed Rule Docket Number EPA-HQ-OW-2022-0114

Dear Sir or Madam:

Citizens Energy Group ("Citizens") appreciates the opportunity to submit the following comments on the March 29, 2023, PFAS National Primary Drinking Water Regulation proposed rule, 88 Fed. Reg. 18,638. Citizens proudly serves safe and reliable drinking water to over 915,000 Hoosiers in Central Indiana and supports EPA's goal to protect public health through regulations under the Safe Drinking Water Act. Citizens offers these comments to share its perspectives and experiences as a regulated community water system.

In August 2011, Citizens acquired the assets of the drinking water system in the City of Indianapolis, Indiana and in March 2014, the assets of the drinking water system in Westfield, Indiana, and the assets of Southern Madison Utilities in 2013. Citizens' water systems reflect the mix of community water systems that will be regulated under this proposed rule, from the very small (Citizens South Madison, serving a population estimated at 65) to the very large (Citizens Water Indianapolis, serving a population estimated at 862,000).

Citizens' source of supply for its drinking water utilities is a combination of both groundwater and surface water. A network of over 100 groundwater wells provides approximately 30% of the annual finished water delivered to our customers while approximately 70% of the supply is derived from surface water sources. Surface water sources include: the White River, supplemented by Morse Reservoir; Fall Creek, supplemented by Geist Reservoir and Citizens Reservoir; and Eagle Creek Reservoir. The watershed is a mix of both agricultural and

urban/suburban development; surface waters receive the complex mix of point-source discharges from industrial facilities, stormwater discharges from MS4 systems and sheet flow runoff, and combined sewer overflows from communities upstream of the intakes on surface water.

Like many public water systems, Citizens participated in the assessment of PFAS in finished water through UCMR 3. More recently, however, Citizens has received more insight into the ubiquitous presence of PFAS in the environment through a PFAS-sampling program funded by the Indiana Department of Environmental Management ("IDEM"). Citizens has sampled the majority of its drinking water wells, the raw water intakes at four (4) surface water treatment plants and one hundred nineteen (119) groundwater wells, and a combined fourteen (14) entry points to the distribution system. In addition, Citizen has begun sampling in its water systems as required by UCMR 5.

Analytical results of samples collected under the IDEM-funded PFAS sampling program indicate low level detections of PFAS compounds, including PFBS and PFHxS, in the source of supply to our treatment plants. While Citizens understands the overarching goal of EPA's PFAS Strategic Roadmap to remedy the environmental impacts associated with the ubiquitous presence of PFAS in the environment, like other drinking water and clean water utilities, Citizens is concerned with the longer-term impacts of PFAS regulations on its operations. To that end, Citizens encourages EPA to continue to pursue a "polluter pays" model for remedying PFAS impacts on the environment, rather than shifting the financial burden to drinking water and clean water utility ratepayers.

In addition to the comments offered below, unless otherwise noted, Citizens endorses comments on this proposed rule submitted by the National Association of Clean Water Agencies ("NACWA") and the American Water Works Association ("AWWA").

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. Assigning liability for PFAS pollution is beyond the scope of this rulemaking (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion).

North American Meat Institute (Doc. #1839, SBC-046048)

May 30, 2023

Michael S. Regan, Administrator

Environmental Protection Agency

1200 Pennsylvania Avenue, N.W.

Washington, D.C. 20460

Re: Docket No. EPA-HG-OW-2022-0114; "PFAS National Primary Drinking Water Regulation Rulemaking."

Dear Mr. Administrator:

The North American Meat Institute (NAMI or the Meat Institute) appreciates the opportunity to submit these comments regarding the Environmental Protection Agency's (EPA or Agency) Preliminary regulatory determination and proposed rule; request for public comment; and notice of public hearing regarding "PFAS National Primary Drinking Water Standard," EPA-HG- OW-2022-0114, RIN 2040-AG18, 88 Fed. Reg. 18638 (March 29, 2023) ("Proposed Rule" or "PFAS Standard").

The Meat Institute is the United States' oldest and largest trade association representing packers and processors of beef, pork, lamb, veal, poultry, and processed meat products. The Meat Institute has 330 general members, operating more than 800 facilities subject to daily federal inspection by the U.S. Department of Agriculture's (USDA) Food Safety and Inspection Service (FSIS). Some of our members also operate facilities that are subject to oversight by the Food and Drug Administration (FDA). Our members include not only the largest meat and poultry processors in the United States, but also many small businesses. In fact, more than half of our members have fewer than 100 employees. NAMI also has 200 supplier members, which provide a broad range of products and services ranging from large processing equipment to laboratory testing for food safety to packaging, all to help ensure Americans enjoy a safe and abundant supply of meat and poultry products. The U.S. meat and poultry processing industry produces nutrient-dense foods that play a unique role in healthy diets and are driving solutions for the environment, farmers' livelihoods, animal care, and more.

NAMI and our members have been, and continue to be, progressive in striving to protect the environment we operate and live in. NAMI and our partners in the Protein PACT for the People, Animals & Climate of Tomorrow are committed to accelerating progress and building momentum for public commitments in each of five focus areas: the environment, animal care, food safety, nutrition, and our workforce. Protein PACT is a commitment to continuous improvement toward a common set of ambitious goals across the industry. It empowers the animal protein industry to proactively meet the needs of its customers and consumers by accelerating continuous improvement across animal agriculture, transparently verifying progress toward ambitious targets, and proactively communicating that progress. Protein PACT unites partners committed to sustaining healthy people, healthy animals, healthy communities, and a healthy environment.

To achieve its Protein PACT targets, the Meat Institute pioneered creating a sector-wide dataset and published in October 2022 the first-ever data report measuring baselines and providing a snapshot of achievements to date. In its first year, the Meat Institute's data collection effort covered an estimated 90% (by volume) of meat sold in the United States. By 2030, 100% of Meat Institute members will report on all metrics.

Our member companies rely on clean water for slaughter and processing. NAMI and our members support reasonable regulation of substances that have potential human health impacts. However, we have significant concerns about the PFAS Standard. As detailed herein, we believe

the PFAS Standard may have unintended consequences that threaten the nation's food supply as certain regulations applicable to the food industry incorporate by reference the National Drinking Water Standard ("NDWS"). We are concerned that EPA has failed to engage other agencies to assess the potential impacts of the Proposed Rule and we are concerned that EPA's cost estimates do not adequately capture the impact of the Proposed Rule because they do not factor in costs created by unintended consequences. Finally, we share in the concerns expressed more fully in comments like those submitted by the U.S. Chamber of Commerce such as, but not limited to, the processed used to develop the PFAS Standard and adherence to statutory requirements, the scientific validity of the standard, the Agency's cost benefit analysis, and the state of potential monitoring and compliance options. We fully support all of the comments submitted by the U.S. Chamber of Commerce and incorporate them by reference into our comments. All of these concerns occur against the backdrop of a nation that is only beginning to recover from a period of historic inflation of all goods, including food, and at a time when we face raising interest rates and tremendous economic uncertainty.

EPA's Rulemaking:

On March 29, 2023, EPA published in the Federal Register a National Primary Drinking Water Regulation (NPDWR) to establish for the first time Maximum Contaminant Levels (MCL's) for six PFAS chemicals in drinking water [FN1: Per- and Polyfluoroalkyl Substances (PFAS) chemicals are a group of manufactured chemicals that have been used in industry and consumer products since the 1940s. They are useful in a variety of products, including nonstick cookware, waterproof clothing, and firefighting foam. EPA has found that they break down slowly in the environment and have the potential to accumulate over time. Many PFAS chemicals have been largely phased out due to health and environmental concerns, but EPA has determined that they may still be found in the environment and may make their way into drinking water.]. The six PFAS chemicals include perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), perfluorononanoic acid (PFNA), hexafluoropropylene oxide dimer acid (HFPO-DA, commonly known as GenX Chemicals), perfluorohexane sulfonic acid (PFHxS), and perfluorobutane sulfonic acid (PFBS). EPA is also proposing "health-based, non enforceable Maximum Contaminant Level Goals (MCLGs) for these six PFAS. EPA has stated that it anticipates finalizing the regulation by the end of 2023.

EPA's own description from its website at epa.gov regarding open questions the Agency has as it continues to push forward with this extremely costly, burdensome and complex rule is telling:

[Figure 1: see docket ID EPA-HQ-OQ-2022-0114-1839]

In addition to the five areas that EPA acknowledges that it does not "fully understand," we suggest there are at least three additional questions the Agency does not fully understand: (1) the interplay of the Proposed Rule with other federal regulatory standards; (2) the extreme shock that could result to the Nation's food supply because of impacts on regulations governing the food industry; and, (3) what the path forward is to coordinate with other Agencies to make sure the Proposed Rule does not result in these unintended consequences.

EPA's overview of the MCL for each of the PFAS, as presented in the Agency's March 29, 2023 Technical Overview Presentation regarding the Proposed Rule, is as follows:

[Figure 2: see docket ID EPA-HQ-OQ-2022-0114-1839]

The Proposed Rule will require public water systems [FN2: A public water system provides water for human consumption to at least 15 connections or serves an average of at least 25 people for at least 60 days a year.] to monitor for PFAS against the extremely low and barely testable level of 4 parts per trillion [FN3: In arriving at 4 ppt, EPA used Practical Quantitation Levels, which are the lowest concentration of a contaminant that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operating conditions. EPA acknowledges that the Proposed Rule trigger levels are set at levels that are so low they are useful in determining whether the contaminant is present in a sample, but not to determine its specific concentration.], notify the public of the levels of these PFAS, and reduce the levels of the PFAS if they exceed the proposed standards. EPA has noted that PFAS can enter drinking water in numerous ways, including discharges to rivers and lakes from manufacturing and processing facilities, industrial and commercial use, or simple proximity to industrial sites, airports, military installations, and other sites where PFAS have been produced or used. EPA expects roughly 66,000 water systems to be subject to the rule, and expects approximately 3,400 - 6,300 systems to be in exceedance of one or more MCL. EPA's estimates are that the Annualized Quantified Rule Costs for public water treatment systems could be $1.2 billion at a 7% discount rate [FN4: EPA assessed costs as the expenses incurred by public water systems to monitor for the six PFAS, install and operate treatment technologies, inform consumers, and perform record-keeping and reporting responsibilities. Notably absent from the cost calculations are any attempt to quantify indirect costs to industries who may be impacted by regulations that tie their water standards to the National Primary Drinking Water Standard.]. In addition, if EPA ultimately determines that water systems must dispose of PFAS treatment as hazardous waste, EPA believes annual costs would increase by $30- $61 million per year.

Initial monitoring under the Proposed Rule must be completed in the three years between the rule promulgation date (currently expected to be the end of 2023) and the rule effective date (anticipated by the end of 2026). Initial monitoring requirements for public water systems include any combination of two or four samples collected at the system over one year, dependent on system population size and system type, or the use of recent, previously acquired PFAS drinking water data from the fifth Unregulated Contaminant Monitoring Rule, state-level drinking water occurrence monitoring, or an "other appropriate data collection program." EPA states that the initial monitoring results will determine the ongoing compliance monitoring requirements. Those requirements include quarterly monitoring as the normal frequency for all sampling locations and reduced monitoring flexibility to once or twice every three years for sampling locations where the result is below 1/3 of the MCLs. A system will be deemed in violation if monitoring results based on running annual averages exceed one of the MCLs.

If a system exceeds the MCL for one of the substances, EPA proposes that the system be required to issue public notification to consumers. The notification will be classified as a Tier 2

notification, which would require notice as soon as possible, but within 30 days of the violation. Community water systems will be required to include PFAS information in the Consumer Confidence Report distribution to customers, including the level of the regulated PFAS that is measured in their drinking water and the potential health effects of the regulated PFAS detected. Water systems with regulated PFAS above the MCLs will be required to install treatment or take other action to reduce regulated PFAS in their drinking water. EPA states that "the rule would allow water systems the flexibility to determine the best actions and approaches to their specific situation." EPA has identified granular activated carbon, anion exchange, and nanofiltration and reverse osmosis as the best available technologies, and has also noted that some water systems may be able to reduce PFAS levels without installing treatment by using an alternative source of water.

EPA Response: Please see the EPA response to comment Doc. #1839, SBC-047721 and Doc. #1649, SBC-043217 in section 5.1.3 in this *Response to Comments* document. In regard to treatment, please see section 10 of the EPA response in this *Response to Comments* document.

Regarding Figure 1 of this comment letter, which displays only a portion of the EPA's webpage "PFAS explained," the EPA is committed to providing meaningful, understandable, and actionable information on per- and polyfluoroalkyl substances – known as PFAS – to the American public. The information provided on this webpage is intended to explain some of the important background information needed to understand the details of specific actions the EPA takes to address PFAS, and not intended to relay all information pertinent to a specific rulemaking such as the NPDWR. As detailed extensively in the proposed and final rulemaking record, the EPA used the best available, peer-reviewed science related to the regulated PFAS in this action to support the regulatory determinations and the final rule, including MCLGs and feasible MCLs. See section 5.1.3 of the EPA response in this *Response to Comments* document for more information.

Regarding the commenter's three additional questions they contend the agency doesn't fully understand; the EPA disagrees with the commenter's statement that the agency has not considered the connections between this rulemaking and other federal regulatory standards and "[n]otably absent from the cost calculations are any attempt to quantify "indirect costs to industries who may be impacted by regulations that tie their water standards to the National Primary Drinking Water Standard." SDWA Section 1412(b)(3)(C)(III) states that the EPA shall consider "quantifiable and nonquantifiable costs. . . excluding costs resulting from compliance with other proposed or promulgated regulations." (emphasis added). Irrespective of the SDWA language, it is inappropriate for the EPA to consider costs to comply with other standards under a drinking water regulation, as these are separate agency actions and site-specific decisions (as applicable). Finally, the EPA notes that the agency does not estimate the costs or benefits of other agency actions. To assess these costs and benefits, the EPA would have to make assumptions about potential future, separate policy decisions under other statues. In short, these costs referred to by the commenter are beyond the scope of this regulation. Finally, the commenter asserts the agency does not fully understand "what the path forward is to coordinate

with other Agencies to make sure the Proposed Rule does not result in these unintended consequences." The EPA disagrees with this assertion, as the agency has worked with federal partners throughout the development of this regulation, including, most notably the federal agencies that participated in the Executive Order (EO) 12866 review of both the proposed and final rule and had the opportunity to provide their input during those reviews.

North American Meat Institute (Doc. #1839, SBC-047721)

Notwithstanding the huge economic impact of the Proposed Rule and its highly technical nature, EPA has allowed only a 60-day public comment period. On May 11, 2023, NAMI requested a 90-day extension of the comment period. We pointed out that the proposal raises numerous questions and seeks input on an array of complicated topics of interest to the meat industry and the food industry more generally. Given the interrelationship and potential impact of EPA's regulations with those of other federal, state and local agencies, NAMI requested additional time to allow ourselves and other stakeholders to comment effectively and in a constructive manner on this topic. Numerous other stakeholders have also requested extensions. NAMI's request for an extension was denied the next day, on May 12, 2023.

The Proposed Rule's Potential Unintended Consequences on the Meat and Poultry Industry and Related Concerns with the Agency's Cost Analysis.

Regulations Applicable to the Meat, Poultry and other Food Industries May be Impacted by the Proposed Rule

Meat [FN5: "Meat food product" means any product capable of use as human food which is made wholly or in part from any meat or other portion of the carcass of any cattle, sheep, swine, or goats, excepting products which contain meat or other portions of such carcasses only in a relatively small proportion or historically have not been considered by consumers as products of the meat food industry, and which are exempted from definition as a meat food product by the Secretary under such conditions as he may prescribe to assure that the meat or other portions of such carcasses contained in such product are not adulterated and that such products are not represented as meat food products. This term as applied to food products of equines shall have a meaning comparable to that provided in this paragraph with respect to cattle, sheep, swine, and goats. 21 U.S.C. § 601.] and poultry [FN6: Poultry is defined as any domesticated bird, whether live or dead. "Poultry product" means any poultry carcass, or part thereof; or any product which is made wholly or in part from any poultry carcass or part thereof, excepting products which contain poultry ingredients only in a relatively small proportion or historically have not been considered by consumers as products of the poultry food industry, and which are exempted by the Secretary from definition as a poultry product under such conditions as the Secretary may prescribe to assure that the poultry ingredients in such products are not adulterated and that such products are not represented as poultry products. 21 U.S.C. § 453.] establishments are subject to continuous inspection by FSIS under the authority granted to the Secretary of the U.S. Department of Agriculture (USDA) in the Federal Meat Inspection Act (FMIA) or the Poultry

Product Inspection Act (PPIA). FSIS is responsible for promulgating regulations to implement the FMIA and PPIA. One such regulation is 9 CFR 416.2, which sets standards for meat and poultry processing establishment grounds and facilities. Part 416.2(g) addresses water supply and water ice, and solution reuse and specifically requires:

(1) A supply of running water that complies with the National Primary Drinking Water regulations (40 CFR part 141), at a suitable temperature and under pressure as needed, must be provided in all areas where required (for processing product, for cleaning rooms and equipment, utensils, and packaging materials, for employee sanitary facilities, etc.). If an establishment uses a municipal water supply, it must make available to FSIS, upon request, a water report, issued under the authority of the State or local health agency, certifying or attesting to the potability of the water supply. If an establishment uses a private well for its water supply, it must make available to FSIS, upon request, documentation certifying the potability of the water supply that has been renewed at least semi-annually. (Emphasis added).

(6) Water that does not meet the use conditions of paragraphs (g)(1) through (g)(5) of this section may not be used in areas where edible product is handled or prepared or in any manner that would allow it to adulterate [FN7: The FMIA and PPIA define "adulterated" so as to include product that bears or contains any poisonous or deleterious substance which may render it injurious to health; but in case the substance is not an added substance, such article shall not be considered adulterated under this clause if the quantity of such substance in or on such article does not ordinarily render it injurious to health. 21 U.S.C. § 453(g), 601(m). The Federal Food, Drug, and Cosmetic Act similarly provides that a food is "adulterated" if it bears or contains any "poisonous or deleterious substance" which may render it injurious to human health.] edible product or create insanitary conditions.

Regarding establishments that fall under the authority of the Food and Drug Administration, [FN8: FDA generally regulates product that does not fit the definition of meat, poultry and egg products regulated by USDA.] 21 CFR 117(a) states that “Any water that contacts food, food-contact surfaces, or food-packaging materials must be safe and of adequate sanitary quality.” Though less prescriptive than FSIS regulations, it is common to demonstrate compliance by demonstrating water meets the NPDW standard.

The potential consequences on the food industry of the above-cited regulations are clear, given EPA's Proposed Rule and the new MCLs for certain PFAS chemicals. Meat and poultry establishments must have a supply of water that complies with the National Primary Drinking Water Standard. If the facility relies on water from a municipality exceeding the new PFAS MCLs, product from that facility could be deemed "adulterated" within the meaning of FSIS or FDA regulations. Once a food product is deemed adulterated, FSIS or FDA [FN9: State regulators typically have similar enforcement tools at their disposal to prevent the manufacture and distribution of "adulterated food."] have a broad array of enforcement tools, including: seizing and condemning the product; detaining imported product; enjoining persons from manufacturing or distributing the product; or requesting a recall of the product. FSIS has certain additional powers that are particularly relevant to much of the meat and poultry industry. FSIS

may suspend or withdraw federal inspection of an official establishment. Without federal inspection, an establishment may not produce or process meat or poultry products, and therefore must cease operations.

Simply put, the new PFAS MCLs could result in the destruction of food and the shuttering of a food manufacturing facility that is at the mercy of a municipal water supply that is out of compliance with the Proposed Rule. At a recent stakeholder meeting, FSIS stated there are no current plans to amend the regulations and establishments will need to ensure water meets the potable water standards set by EPA. NAMI and our members are concerned that EPA failed to adequately discuss the unintended consequences of the Proposed Rule with agencies, such as FSIS, that reference EPA standards.

It is also notable that while FSIS does not currently test water, but has tested meat and poultry products to understand whether there is a risk associated with these products for PFAS, with no findings of concern. FSIS has tested for 16 different compounds down to 0.5 ppb and is evaluating the feasibility of adding more compounds and increasing sensitivity, to align with fed partners, such as the Food and Drug Administration (FDA).

The result of this interplay between the regulatory regimes of EPA, USDA and FDA is striking -- both in its potential disruption to the nation's food supply, and in the illogical consequences it could create. As detailed earlier in these comments, there is no reason to suspect that EPA would immediately shut down a municipality's water supply on the basis of a sample that exceeds one of the MCLs. The Proposed Rule and EPA's various presentations on the topic archived at www.epa.gov make it clear that EPA will first require monitoring and public reporting, then if a water system has regulated PFAS above their proposed MCLs they will "be required to install treatment or take other action to reduce regulated PFAS levels in their drinking water and meet MCLs." EPA further states that the Proposed Rule "would allow water systems the flexibility to determine the best actions and approaches to their specific situation."

EPA at a minimum strongly implies they will work with municipalities and consider alternative actions and approaches to resolve exceedances. However, no such flexibility is expressly stated for food processing establishments that are at the mercy of public water systems for their supply of water. Moreover, EPA states that the Bipartisan Infrastructure Law provides $9 billion to invest in drinking water systems specifically affected by PFAS and other emerging contaminates and references the ability of states and communities to leverage an additional nearly $12 billion in BIL Drinking Water State Revolving Funds dedicated to making drinking water safer. Conspicuously absent is any reassurance that federal money will be available to food establishments impacted by the Proposed Rule. Some of our members treat and supply their own water for some of their plants, and when all shifts are factored in, that can add up to more than 20,000 employees using the water daily. This is a huge part of community exposure in those towns, larger than many municipal water supplies. Funds should be available to address that issue as well.

A simple example illustrates the absurd results potentially created by the interplay of the Proposed Rule and food safety regulations. A community that is home to a large meat processing plant could see that plant face repercussions as severe as FSIS pulling its federal grant of inspection and effectively shutting the plant down until either the municipality comes in compliance with the MCLs or the plant is able to source and install additional filtration in an amount sufficient to satisfy the food safety regulators that the plant had a potable water supply. That plant's employees, which could number in the thousands, would be unable to go to work. However, they would be able to drink the same tap water in their homes that caused the loss of their employment while EPA worked with the public water system to come within the MCLs. Their children could drink the same tap water in the public schools, but their school lunch program could be affected by the shock to the food supply system resulting from meat processing plants losing grants of inspection. Surely that is not the intended result of the Proposed Rule or of the FSIS and FDA regulations, but that is the reality of the black letter of the rules as currently written. We do not believe EPA adequately collaborated with other agencies to avoid such absurd results.

The Agency’s Cost Estimates are Inadequate Because They Do Not Account for Unintended Consequences.

As set forth earlier in these comments, EPA's cost estimates rest on financial costs that will be experienced by public water systems in meeting the PFAS Standard and disposing of treatment materials. NAMI believes the Agency has ignored indirect costs, which may ultimately be more significant that the direct costs to public water systems.

The study attached as Exhibit "1" from the Juday Group details some of the costs that could be borne by facilities in the food industry because of interruptions to operations or expenditures to bring incoming water into compliance with the PFAS Standard if FSIS or FDA imposed such a requirement. These costs could occur as: (1) lost revenue and sunk costs from potential temporary plant shut downs testing and compliance; (2) testing and compliance; and (3) capital outlays for new or upgraded water treatment systems. As background to this discussion, it is key to remember that these costs will not just be borne by large corporations. NAMI has members with fewer than 10 employees and whose operations can fit in a single large room. The impact of these costs could simply overwhelm a small business.

Consumer impacts are also a major concern. In addition to reduced availability of protein and higher prices at grocery stores and restaurants, the Proposed Rule could affect the operational viability of federal school nutrition programs and important federal contracts, such as those involving the Department of Defense. The Juday Group found that "without careful consideration in implementing these regulatory rules, the unintended consequences could result in a major economic disruption."

As discussed in more in the Juday Group study, the cost per day of a shutdown of a slaughter facility, varies depending on the animal involved, the size or type of plant, and the general value of wholesale meat. However, the Juday Group estimates per day costs based on a larger size

facility as follows: (1) Beef - $2 million; (2) Pork - $1.2 million; (3) Poultry - $400,000; (4) Prepared foods (further processing) - $400,000.

These numbers do not include the loss of purchased or integrator-owned animals to the plant. Unlike other manufacturing enterprises, meat and poultry processing plants involve live animals, and do not have the ability to build inventory of animals during a temporary closure and resume operations at a later date. The entire meat and poultry value chain is built to process large numbers of animals on a daily basis - - based on 2022 data, average daily slaughter was 127,037 head of cattle, 462,963 hogs, and 34.939 million broiler chickens. The sector generates economic activity and provides supplies under a just-in-time inventory system, which is necessary in handling live animals as a key input, and fresh, chilled meat as an output. These plants are not designed to house, nor feed, livestock or poultry for an extended period. In addition, animals kept on feed would continue to grow, and dependent on duration of plant closure and species, might become unsuitable for processing at the facility or for sale in the intended output market.

Through-put at a beef plant can range from 500 head per day at smaller plants, up to more than 5,000 head per day at a larger plant. Based on average livestock prices reported by USDA for 2022, the immediate loss of purchased animals delivered to the plant would be in a range from $950,000 and $9.5 million respectively. At a pork plant, daily through-put can range from 1,000 head per day up to 20,000 head per day. The immediate loss of those purchased or contracted animals would range between, $205,000 to $4.1 million.

Moving into a longer temporary shutdown lasting weeks to months, livestock losses would start to accrue to producers who lost the ability to market their animals for harvest. The effects of this dynamic were well chronicled during COVID, affecting every level from livestock producers to consumers.

In the least-worst case scenario for producers, livestock prices would drop from a lack of operational slaughter capacity. Shutdowns of smaller regional plants could have as significant an economic impact on the producers who supply it as the loss of operations at a large plant. In a worst case scenario, depending on the duration of a shutdown, producers could be forced to retain, rather than market, their animals over a period that is infeasible based on the biology of the animals they use. Hog producers particularly, due to both the biology of the animals and the physical infrastructure of the production systems, rarely have the physical capacity to maintain livestock indefinitely, which, depending on the duration of a plant shutdown could require depopulation, incurring a total economic loss.

Due to the integrated nature of the broiler chicken industry, animal loss for a temporary plant shutdown would be incurred entirely by the company. A smaller scale broiler slaughter facility may process 800,000 birds per week, at an average of 5.3 days per week. That is an average of about 151,000 birds per day. A large plan can slaughter 1.8 million birds per week, for a daily average of nearly 340,000 birds per day. Again, referencing USDA data on broiler price averaged in 2022, the daily bird losses would range between $1.2 to $2.6 million. A longer term interruption could result in a situation where contract growers would no longer receive chicks to

raise and thus lose revenue streams while still being responsible managing sunk costs and overhead in their operations.

In light of the huge economic loss that could occur in the event of plant closures, and with the uncertainty of adopting a "wait and see" approach to understand whether a public water system might have an issue that resulted in FSIS or FDA action at the processing plant, a facility might elect to do its own testing. That will represent significant costs. Water testing is an estimated $1,200 per sample. As companies will have to understand the baseline situation and attendant risk to operations, testing might have to occur frequently, such as seasonally or per quarter. Assuming baseline testing frequency of one week per quarter, four periods would result in a total testing cost of $33,600. Those cost estimates are for a single source of water. Most plants have multiple sources, ranging from four to 50 or more. The $33,600 cost estimate would be for each source, costing in aggregate between $134,400 to $1.68 million for a facility. Ongoing compliance monitoring would require sample testing based on the outcome of initial test findings. The best-case scenario would be one test per three-year compliance period, at $1,200. The worst case would be four sample testing per year for a three-year compliance period, at $14,400. Again, these costs would be felt not just by large processors, but also by small businesses.

Finally, depending on the situation with their public water system supply and Agency action, facilities might elect to install additional treatment systems. Cost estimates for treatment systems are uncertain, but empirical research suggests that treatment system costs are between $1 and $2 million. This estimate is for the system itself, not installation, retrofitting or other costs. Based on other experience within packing plants the yearly operating cost is assumed to be 50 percent of the capital investment cost of the system.

All of these costs assume supply chain availability of treatment and testing options. Supply chain constraints caused by nationwide attempts at compliance with the PFAS standard could increase these costs or the time needed to implement various measures. While the actual cost is necessarily an abstract exercise at this point and somewhat uncertain, one thing is certain: these are significant indirect costs caused by unintended consequences the Agency has failed to consider.

Consumers Will Feel the Cost of the Proposed Rule.

In addition to producer and processor impacts, again as experienced during COVID, the ultimate cost of this interruption in the supply chain would fall on consumers. The graphic from the Juday Study below helps clarify this result:

[Figure 3: see docket ID EPA-HQ-OQ-2022-0114-1839]

The magnitude of cost impacts to consumers is difficult to model given the uncertainty of what events might actually occur. However, there is ample empirical evidence from past shocks to the operational capacity of slaughter and processing which shows that major economic costs would

be incurred and felt by the consumer. What is even more apparent is that EPA has not taken these costs into account.

Conclusion

NAMI and our member companies are extremely concerned about the potential unintended consequences of the Proposed Rule and are equally concerned about what appears to be a lack of understanding by EPA of the implications of the PFAS Standard on other regulatory schemes, such as those governing the food industry. There appears to have been little or no interagency cooperation to address these concerns. We believe that USDA became aware of these concerns very late in the rulemaking process.

There are a number of steps the Agency could take to address these concerns. First, EPA should withdraw the Proposed Rule and include an express exemption or "carve out" in the PFAS component of the NDWS for water used in food processing. There is no scientific record that reducing process water to the levels envisioned by the PFAS Standard is necessary to avoid a food safety or human health issue. In fact, as mentioned earlier, FSIS has tested for PFAS in food and not found levels of concern. At a minimum, EPA should include language that a public water system that is undergoing a monitoring and remediation process in coordination with the Agency should not have its water deemed unfit for use in food processing. Second, prior to any implementation of the Proposed Rule, the Agency should engage in cooperative dialogue with FSIS, FDA and any other agencies that incorporate the NDWS by reference. This step is a minimum measure to discover and address unintended consequences and the resulting shock to the supply chain and the Nation's food supply. Dialogue between EPA and USDA and FDA would enable all agencies to better understand the correlation between potability in the various contexts those agencies regulate, could result in clear expectations and solutions for industry, and might produce useful information such as enforcement guidance for regulators and compliance guidance for all regulated entities, not just public water systems. EPA should provide more information on EPA-approved PFAS treatment options, including those that address the need for scalability of treatment technologies. Finally, public funding such as the funds outlined earlier in these documents should be made available to industries who suffer treatment costs as unintended consequences of these rules, and there should also be funding for private entity, non-transient/non-community water work systems.

NAMI appreciates the opportunity to submit these comments and stands ready to work with all agencies affected and other stakeholders to ensure that the Proposed Rule does not result in shocks to our Nation's food supply and the resultant harm to the very citizens the Proposed Rule seeks to protect.

Sincerely,

Bryan Burns

Vice President and Associate General Counsel

North American Meat Institute

Exhibit 1

Juday Group Study

Analysis: Potential Cost Impacts of EPA's Proposed PFAS/Drinking Water Rule

The potential cost impacts EPA's rule regarding per-and polyfluoroalkyl substances (PFAS) in the drinking water standards potentially would affect the meat and poultry in three ways: 1) testing and compliance, 2) capital outlays for new or upgraded water treatment systems, and 3) lost revenue and sunk costs from potential temporary shut downs. Aggregate costs could be massive and would be passed through the entire value chain both upstream to livestock producers and downstream to wholesales retailers, and ultimately consumers. Consumer impacts would also affect the cost, and even in some cases, the operational viability of federal nutrition programs. Without careful consideration in implementing these regulatory rules, the unintended consequences could result in a major economic disruption.

Temporary Plant Closure

The per day cost of a plant shut down depends on the size of the plant and the type of plant, i.e., beef, pork, or broiler chicken reflecting the general value of wholesale meat. Based on a larger capacity plant, the daily estimated cost for a plant shutdown is as follows.

Beef: $2 million Pork: $1.2 million Poultry: $400,000

Prepared Foods (further processing): $400,000

These estimates do not include loss of purchased animals delivered to the plant.

Unlike a goods manufacturing plant, meat and poultry packing and processing plants can not build nor hold inventory of livestock and birds during a temporary closure and resume operations at a later date. These plants are not designed to house, nor feed, livestock for an extended period. In sum, cattle and hog holding pens at the plant do not have the capacity to handle large volumes of animals who are not moved on to slaughter and processing. However, packing plants, and the entire livestock-meat value chain, are built to process large numbers of animals on a daily basis. The sector generates economic activity and provides supplies under a just-in-time (JIT) inventory system, which is necessary in handling live animals as a key input, and fresh, chilled meat as a major output. Industry wide, based on 2022 data, average daily slaughter was 127,037 head of cattle, 462,963 hogs, and 34.929 million broiler chickens.

Through-put at a beef plant can range from 500 head per day at smaller plants, up to more than 5,000 head per day at a larger plant. Based on average livestock prices reported by USDA for 2022, the immediate loss of purchased animals delivered to the plant would be in a range from $950,000 to $9.5 million respectively. At a pork plant, daily through-put can range from 1,000 head per day up to 20,000 head per day. The immediate loss of those purchased or contracted animals would range between, $205,000 to $4.1 million.

Moving into a longer temporary shutdown lasting weeks to months, livestock losses would start to accrue to producers who lose their ability to market animals for harvest. The effects of this dynamic were well chronicled during COVID, impacting every level of livestock producer, from grower/finishers of market ready animals back to breeders and seedstock producers.

In the least-worst scenario for producers, livestock prices would drop from a lack of operational slaughter capacity. It is important to note that shutdowns of smaller regional plants could have as significant an economic impact on the producers who supply it as the loss of operations at a large plant.

Under a worst case scenario, depending on the duration of a shutdown, producers could be forced to retain, rather than market, their animals, over a period that is infeasible based on the biology of the animals they raise. Hog producers particularly, due to both the biology of the animals and the physical infrastructure of the production systems, often do not have the physical capacity to maintain livestock indefinitely, which, depending on the duration of a plant shutdown could require depopulation, resulting in a total economic loss.

For the same reasons that scenario could also unfold in the poultry sector. Moreover, , due to the integrated nature of the broiler chicken industry, animal loss for a temporary plant shut down would be incurred entirely by the company. Contract growers would no longer receive chicks to raise and thus lose revenue streams while still being responsible managing sunk costs and overhead in their operations.

A smaller scale broiler slaughter facility may process 800,000 birds per week; at an average of 5.3 days per week. That is an average of about 151,000 birds per day. A large plant can slaughter 1.8 million birds per week, for a daily average of nearly 340,000 birds per day. Again, referencing USDA data on broiler price averages in 2022, the daily bird losses could range between $1.2 to $2.6 million.

Finally, again as experienced during COVID, down stream consumers would bear significant addition costs from an interruption in the supply chain caused by an indeterminant plant shutdown.

[Figure 4: see docket ID EPA-HQ-OQ-2022-0114-1508]

The scope and magnitude of cost impact is difficult to model for both up and down stream cost pass through but there is ample empirical evidence from past shocks to the operational capacity of slaughter and processing which support the proposition that major economic costs would be incurred.

EPA estimates there are 66,000 water systems in the country which would be subject to its proposed rule; the agency further assumes that 3,400 to 6,300 – or between 5 to 9.5 percent of all water systems – would initially prove out of compliance. Thus, it is feasible, if not likely, one or several meat or poultry plants would be serviced by a water system exceeding the proposed maximum containment level (MCL).

Assuming such a plant – or plants - was a major, or significant sized processor, and further assuming its operations may be offline for 3 to 6 months to source and install a new treatment system, the supply of meat produced (pork or beef) could be reduced by 5 to 10 percent. Such a dramatic shock to supply would be passed on to consumers in the form of significantly higher prices. Further, the inflationary impact would not be limited to the specific species harvested and processed at the plant where operations were suspended. Higher beef prices would influence pork and poultry prices; likewise higher pork prices would lead to higher beef and poultry prices. Based on estimated cross-price elasticities observed over time, up to one-third of the price inflation in one species could be passed on to another.

Treatment Systems

Cost estimates for treatment systems are uncertain, but empirical research suggests that treatment system costs are between $1 and $2 million. This estimate is for the system itself, not installation, retrofitting or other costs. Based on other experience within packing plants the yearly operating cost is assumed to be 50 percent of the capital investment cost of the system.

Testing and Compliance

Water testing is an estimated $1,200 per sample. As companies will have to understand the baseline situation and risk before compliance, testing would have to be conducted seasonally, each quarter. Assumed baseline testing is one week per quarter, or 7 days during four periods for a total testing cost of $33,600. Those cost estimates are for a single source of water. Most plants have multiple sources, ranging from four to 50 or more. The $33,600 cost estimate would be for each source, costing in aggregate between $134,400 to $1.68 million.

On going compliance monitoring would require sample testing based on the outcome of initial test findings. The best case scenario would be one test per three-year compliance period, at $1,200. A worst case would be four sample testing per year for a three-year compliance period, at $14,400.

EPA Response: Regarding the public comment period for this rulemaking, please see section 17.1 of the EPA response in this *Response to Comments* document. For additional discussion on cost considerations for the final MCLs, please section 5.1.3 of the EPA response in this *Response to Comments* document.

This commenter discusses the requirements or expectations under the United States Department of Agriculture's (USDA) and FDA's authorities to have a supply of running water that complies with the NPDWRs (40 CFR part 141). As detailed in the EPA response to comment Doc. #1839, SBC-046048 in section 5.1.3 in this *Response to Comments* document, costs associated with compliance with other regulations are outside the scope of this rulemaking. Further, in cases where the meat or poultry facility is itself a CWS or NTNCWS (i.e., a regulated entity under this rulemaking), the EPA has estimated the costs to PWSs associated with complying with the NPDWR, including implementation, monitoring, and treatment or non-treatment actions to comply with the rule, where applicable. In this case that would include costs to the facility to comply with the NPDWR. In cases where the meat or poultry facility is not a PWS and receives its water from a regulated PWS, the EPA reasonably anticipates that like all customers of PWSs, the meat and poultry facility will receive water compliant with all federal regulations, including the PFAS NPDWR. In the latter case, costs to supply water compliant with the standard will be incurred by the PWS but may be passed on to their customers. Again, this cost has been quantified and included in the EPA's cost analysis.

Regarding the commenter's claims of potential shutdowns, destruction of food, and other potential indirect impacts, enforcement actions by Food Safety and Inspection Service (FSIS) and FDA are outside of the scope of this rulemaking. Costs associated with these enforcement actions are likewise outside of the scope of this rulemaking. However, the EPA notes that in the final rule, the EPA is exercising its authority under SDWA § 1412(b)(10) to implement a nationwide capital improvement extension to comply with the MCL. All systems must comply with the MCLs by five years after the date of the promulgation. All systems must comply with all other requirements of the NPDWR, including initial monitoring, by three years after the date of promulgation. The EPA expects that customers of PWS, including meat and poultry facilities, will have information about PFAS occurrence at the PWS they are served by three years after the rule is promulgated due based on the monitoring schedule for the final rule. The five-year timeframe to comply with the MCLs is reasonably anticipated to provide sufficient opportunity for meat and poultry plants to obtain water compliant with the NDPWR.

Regarding funding, if, as provided by example by the commenter, the meat or poultry facility is a regulated PWS, there is no reason to think the water system would exclude from the BIL potential funding source. For concerns regarding BIL funding, please see section 2.4 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter's statements regarding the potential costs of sampling water, which the commenter states is $1,200 per sample and further suggests that a facility would test once a quarter for four years at a cost of $33,600. First, the EPA clarifies only regulated PWSs are required to sample in compliance with the rule. This commenter suggests that meat and poultry facilities may elect to do so while not being compelled by the NPDWR to better understand their water quality. Elective sampling at these facilities is not required under the rule and therefore not included in EPA's cost analysis. Further, the commenter overstates the potential costs of this elective sampling were it to be done. The commenter's cost per sample far

exceeds EPA estimates as well as estimates provided by public commenters, see section 13.3.4 of the EPA response in this *Response to Comments* document for more information and it is unclear how the commenter derived this estimate, as no supporting information or citations were included. Additionally, the commenter provides no justification for their estimated frequency of sampling described, the EPA expects that far fewer sampling results would provide a reasonable understanding of water quality from a given source, particularly, as in the hypothetical case described by the commenter.

Regarding the impact of supply chain issues on costs to comply with the rule, see section 13.3.3 of the EPA response in this *Response to Comments* document. Regarding EPA's work with federal partners, see the EPA response to comment Doc. #1839, SBC-046048 in section 5.1.3 in this *Response to Comments* document. EPA disagrees with the commenter's recommendation that the agency should withdraw the rule and include an exemption to "carve out" water used for food processing. EPA disagrees with this recommendation, as it is both not permissible under SDWA and further inconsistent with the agency's requirements for public health protection under SDWA. Specifically, SDWA does not include provisions under which the EPA could exempt water systems that serve certain industries from meeting the standard. The EPA also disagrees with the recommendation that "[a]t a minimum, EPA should include language that a public water system that is undergoing a monitoring and remediation process in coordination with the agency should not have its water deemed unfit for use in food processing," as EPA cannot dictate enforcement actions of other agencies and this recommendation is outside of the scope of this rulemaking. Please also see the EPA response to comment Doc. #1649, SBC-043217 in section 5.1.3 in this *Response to Comments* document.

Groundwater Resources Association of California (Doc. #1831, SBC-045351)

Groundwater is also a primary source for domestic wells and agricultural irrigation. Hence, the cost, benefit, and risk evaluations should give due consideration to the nation's groundwater resources and supplies (including untreated groundwater used for potable and non-potable purposes). For example, PFAS contamination can impact domestic wells (pumping from shallow groundwater systems) that are not part of PWS. Contaminated groundwater can also impact agricultural produce, in turn posing health risks to human populations consuming such produce. It is unclear if occurrence in and risks to groundwater resources was included in EPAs assessment. The following are additional cost-benefit-risk considerations that should be given to the direct and indirect impacts (costs and benefits) of the proposed MCLs on groundwater systems.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The agency did consider occurrence data from both groundwater and surface water systems (as well as ambient water quality data) in the agency's occurrence analysis. The agency then evaluated finished drinking water to inform the agency's analysis on cost and benefits. Please see sections 7 (occurrence) or 13 (HRRCA) of the EPA response in this *Response to Comments* document.

Vermont PFAS/Military Poisons Coalition (Doc. #2715, SBC-047424)

The EPA should do what the European Chemicals Agency (ECHA) has done this year. ECHA proposes to ban PFAS production and the import of over 10,000 forms of PFAS chemicals in the European Union (EU). 108 European companies have committed to phasing out PFAS chemicals from products and processes and have joined in calling for comprehensive laws to deal with PFAS.

The proposed EU ban on PFAS is extensive, as opposed to the EPA's approach of regulating a few PFAS at a time. The EPA's proposal to regulate PFAS doesn't even include all of the 26 most common forms of PFAS found in drinking water. There are no pending proposed standards for 20 of these and 12 of these PFAS are not included in current monitoring. Three of these PFAS fall outside the "working definition" for PFAS that the EPA adopted without any outside review. Why would the EPA summarily adopt a definition that leaves out thousands of PFAS? Finally, the law won't even take effect until 2026.

The EPA and all US government agencies need to start using the Precautionary Principle, especially in regards to PFAS. Before a product goes on the market, a company must prove it is safe for our health and the environment. All ingredients must be listed and known to consumers. If there is any doubt, we must err on the side of caution and logical scientific assumptions and not allow the product on the market. Thank you.

EPA Response: For additional discussion on alternative regulatory standards (including regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The commenter does not provide information about the "26 most common forms of PFAS found in drinking water" or which PFAS the commenter believes these to be. EPA is regulating six PFAS with this NPDWR with specific Chemical Abstract Service Registry Number (CASRN) identifiers and does not specify a specific definition for PFAS. The definition that the commenter is referencing is used under the EPA's Toxic Substances Control Act (TSCA) and is outside the scope of this rulemaking. Additionally, the agency notes that consumer product regulation is beyond the scope of this regulation. Please see also the EPA response to comment Doc. #1638, SBC-043451 in section 5.1.3 in this *Response to Comments* document and section 5.1.3 of the EPA response in this *Response to Comments* document in regard to European limits.

Layla Cable (Doc. #2776, SBC-046243)

The precursors that turn into forever chemicals need to be addresses as well. Firefighting foam and military based release many more. Please include all PFAS and others turn into them in substances that need control.

EPA Response: For additional discussion on alternative regulatory standards (including regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Tracy Frisch (Doc. #2119, SBC-047418)

In addition, EPA should require Total Organic Fluroine be measured as a PFAS Hazard Index, until validated health data on individual chemicals determines an acceptable health risk to the public.

Next EPA should act with haste to address the unchecked emissions of these and other PFAS chemicals from industrial sites and consumer products. It must halt the approval of new PFAS chemicals, ban the production of all PFAS and use of PFAS in new products and as a manufacturing aid, restrict dumping of PFAS waste into the wastewater system, limit pollution caused by biosolids/sludge fertilizers, and set health-based limits for PFAS in subsistence fish and other wild foods.

EPA Response: For additional discussion on alternative regulatory standards (including regulation of PFAS as an entire class), please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that actions related to "approval of new PFAS chemicals, ban the production of all PFAS and use of PFAS in new products and as a manufacturing aid, restrict dumping of PFAS waste into the wastewater system, limit pollution caused by biosolids/sludge fertilizers, and set health-based limits for PFAS in subsistence fish and other wild foods" are beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional information.

Michigan Farm Bureau (MFB) (Doc. #1562, SBC-043361)

Additional Regulatory Impacts from MCLs

While MCLs fall under the statute and rules of the Safe Drinking Water Act, [FN18: 42 U.S.C. §300f, et. seq., 1974] setting MCLs and the science underpinning health impacts from contaminants crosses over into other regulatory programs, including the Clean Water Act. [FN19: 33 U.S.C. §1251, et. seq., 1972.] Pollutants regulated under the Clean Water Act, effluent limits, water quality standards set by states and approved by EPA all must consider and include human health parameters. Setting MCLs for PFAS, and the human health impacts affecting those regulatory standards, is thus an important step toward establishing water quality criteria for designated uses, National Pollutant Discharge Elimination Program (NPDES) effluent limits and other discharge regulations, and contaminated site cleanup.

All of these programs are vital to protecting the nation's waters, but all come at a cost of compliance. For instance, Michigan has used health data underpinning its MCLs among other studies including aquatic life, recreational activities, fish consumption and other designated uses to set water quality values for PFOS at 11 ppt for water used for drinking and 12 ppt for water not used for drinking, and for PFOA at 66 ppt for water used for drinking and 170 ppt for water not used for drinking. [FN20: Michigan Department of Environment, Great Lakes, and Energy. 2022. EGLE Establishes New Surface Water Values for Two PFAS Chemicals. Retrieved from: https://www.michigan.gov/egle/newsroom/mi-environment/2022/07/27/egle-establishes-new-

surface-water-values-for-two-pfas-chemicals.] Wastewater utilities are required to sample effluent and biosolids for PFOA and PFOS, meeting surface water quality values for discharges of effluent and meeting a limit of 125 ppb for biosolids land application. Industrial pre-treatment is required for facilities discharging to any wastewater facility with biosolids concentrations higher than 20 ppb of PFOS. [FN21: Michigan Department of Environment, Great Lakes, and Energy. 2022. Land Application of Biosolids Containing PFAS: Interim Strategy. Retrieved from: https://www.michigan.gov/pfasresponse/-/media/Project/Websites/egle/Documents/Programs/WRD/Biosolids/PFAS-Biosolids-Interim-Strategy-2022.pdf?rev=ef886f1fb9e047ab8c73f15c2c7d8c35&hash=D97B285D327B4906E22CADDE75B2BD5C.] These are necessary steps but also incur significant cost to regulated facilities: wastewater facilities are reporting additional compliance costs in the tens of millions of dollars each in capital costs, staff, testing, laboratory analysis, treatment, and disposal to address the PFAS requirements imposed at the state level. [FN22: Personal communication with members of the Michigan Water Environment Association, March 2023.]

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that application of MCLs in non-drinking water programs (such as water quality criteria, NPDES, or CERCLA cleanups) is beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

Illinois Farm Bureau (IFB) (Doc. #1630, SBC-043138)

[The most glaringly overlooked and/or underestimated data includes:]

• The Safe Drinking Water Act requires consideration of the costs and benefits. The estimated annualized costs for a proposed MCL of 4 ppt for PFOA and PFOS are approximately $1.8 billion annually and are more than twice as much as the EPA estimated costs in their economic analysis. The significant costs and impacts and their connection to other elements of the PFAS Strategic Roadmap, such as the proposed hazardous substance designation under CERCLA require further analysis and consideration.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that application of MCLs in non-drinking water programs (such as water quality criteria, NPDES, or CERCLA cleanups) is beyond the scope of this rulemaking; please see section 15.1 for additional discussion on comments outside the scope of this NPDWR. The EPA has carefully considered all public comments regarding the cost analysis and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to EPA's cost analysis

for the file rule are detailed in sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. At a two percent discount rate, the EPA estimates the quantifiable annual costs of the final rule will be $1,548.64 million per year and the quantifiable benefits of the rule will be $1,549.40 million per year. For further discussion about CERCLA clean-up costs and benefits, please also see section 5.1.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1631, SBC-043434 in section 5.1.3 in this *Response to Comments* document.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043485)

[They have identified the following areas of concern regarding the agency's development of this rule:]

• The Safe Drinking Water Act requires consideration of the costs and benefits. The estimated annualized costs for a proposed MCL of 4 ppt for PFOA and PFOS are exorbitant. The significant costs and impacts and their connection to other elements of the PFAS Strategic Roadmap, such as the proposed hazardous substance designation under CERCLA, require further analysis and consideration.

EPA Response: Please see the EPA response to comment Doc. #1630, SBC-043138 in section 5.1.3 in this *Response to Comments* document. For further discussion about CERCLA clean-up costs and benefits, please also see section 5.1.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1631, SBC-043434 in section 5.1.3 in this *Response to Comments* document.

Pennsylvania Municipal Authorities Association (Doc. #1832, SBC-045784)

[PMAA's specific comments on the Proposal are as follows:]

8. EPA's PFAS Strategic Roadmap, which lays the groundwork for EPA's response to various PFAS issues, focuses on a number of principles, one of which is to "Hold Polluters Accountable." However, directly contrary to the principles of the PFAS Strategic Roadmap, the Proposal will have severe consequences for PMAA member authorities that have absolutely no role in producing or placing PFAS chemicals into the stream of commerce; rather they are merely passive receivers of PFAS chemicals. Notwithstanding the aforementioned, EPA now seeks to impose significant additional technical and management costs on PMAA member authorities and their ratepayers/customers related to, among other things, the use of filtration and the management of biosolids. What justifies these additional costs, and did EPA specifically consider such costs in the Proposal? Moreover, why is EPA shifting costs to public entities, such as PMAA member municipal authorities, to address PFAS-related initiatives, when such "shifting of costs" is contrary to EPA's own principles set forth in EPA's PFAS Strategic Roadmap?

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. Discussion on the EPA's cost estimates can be found in sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. Topics related to assigning liability for PFAS pollution or addressing sources of PFAS contamination are beyond the scope of this rulemaking (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion).

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046001)

Section 8.12: Additional factors

EPA should focus its final analyses on the issues raised in these comments. AMWA believes that EPA's time and resources would be better spent by updating its cost analysis to reflect today's economic reality more accurately. EPA should work to portray the actual cost increases for labor, water treatment chemicals, lab analyses, materials, and construction that have been exacerbated since 2021. Additionally, the agency must include the social costs of carbon and additional energy usage and GHG emissions for GAC, IX, and RO treatments.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA has carefully considered all public comments regarding the cost analysis and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to EPA's cost analysis for the file rule are detailed in sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. At a two percent discount rate, the EPA estimates the quantifiable annual costs of the final rule will be $1,548.64 million per year and the quantifiable benefits of the rule will be $1,549.40 million per year.. Please also see section 13.11 of the EPA response in this *Response to Comments* document for additional discussion on the social costs of carbon.

Millie Garcia-Serrano (Doc. #1803, SBC-044285)

EPA needs to consider implementation of the proposed regulation, which poses financial, technological, logistical, and communication challenges that are of significant concern to the ASTSWMO membership, as follows:

1. Cost Concerns: EPA's cost analysis does not include costs that will be incurred under CERCLA or other remediation programs, which are likely to be significant. For example, for Superfund-financed sites, where there are no viable responsible parties, States will be responsible for cost-sharing obligations for remedial actions as well as 100% of the costs for long-term operation and maintenance of the remedies in perpetuity. Additionally, with this proposed

regulation, the number of sites to be remediated is likely to increase significantly, requiring additional resources for States to perform and/or oversee the remedial activities.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. See also the EPA response to comment Doc. #1630, SBC-043138 in section 5.1.3 in this *Response to Comments* document. The EPA has carefully considered all public comments regarding the cost analysis and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to EPA's cost analysis for the file rule are detailed in sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. As required by SDWA, this rulemaking and analyses supporting the rulemaking only includes costs that "are likely to occur solely as a result of compliance with the [MCL]." Thus, the EPA's cost analyses focused on the compliance costs of meeting the MCL to PWSs that are directly subject to this regulation. For further discussion about CERCLA clean-up costs and benefits, please also see section 5.1.3 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1631, SBC-043434 in section 5.1.3 in this *Response to Comments* document.

Plymouth Village Water & Sewer District (Doc. #1827, SBC-044562)

[Please carefully consider the following points to help inform the pending rulemaking on this class of pervasive and persistent PFAS chemicals:]

• Public water system customers already face both real and perceived affordability issues. The substantial costs required to meet the proposed 4 ppt MCL will adversely impact individual and regional economies, especially in more financially disadvantaged communities. As noted above, EPA has underestimated the full life-cycle costs of treating PFAS to the proposed MCLs.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA has carefully considered all public comments regarding the cost analysis and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to EPA's cost analysis for the file rule are detailed in sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. For additional discussion on funding concerns and BIL, particularly for disadvantaged communities, please see section 2.4 of the EPA response in this *Response to Comments* document.

New Hampshire Water Works Association, Inc. (NHWWA) (Doc. #1576, SBC-042455)

Public water system customers already face both real and perceived affordability issues. The substantial costs required to meet the proposed 4 ppt MCL will adversely impact individual and regional economies, especially in more financially disadvantaged communities. As noted above, EPA has underestimated the full life-cycle costs of treating PFAS to the proposed MCLs.

EPA Response: Please see the EPA response to comment Doc. #1827, SBC-044562 in section 5.1.3 in this *Response to Comments* document.

Groundwater Resources Association of California (Doc. #1831, SBC-045354)

An assessment of these groundwater-related costs and available funding sources to offset costs should be included in determining the economic feasibility of the proposed MCLs. The justification for costs cites investments in the Infrastructure Investment and Jobs Act, but funds allocated under the Act are specifically for the Drinking Water State Revolving Funds (SRF), the Drinking Water SRF for Emerging Contaminants, and the Small, Underserved, and Disadvantaged Communities Grants. Groundwater management agencies that may not be directly associated with potable water treatment systems yet manage the critical drinking water source, may not be eligible for these funds but will incur significant costs due to the proposed MCLs.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA has carefully considered all public comments regarding the cost analysis and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to EPA's cost analysis for the file rule are detailed in sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. For additional discussion on funding concerns and other funding sources outside of BIL, please see section 2.4 of the EPA response in this *Response to Comments* document.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043480)

May 30, 2023

Submitted via www.regulations.gov

Alexis Lan

Office of Ground Water and Drinking Water Environmental Protection Agency 1200 Pennsylvania Avenue, N. W.

Washington, DC 20460

Submitted via www.regulations.gov

Re: Docket ID No. EPA-HQ-OW-2022-0114, Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

The undersigned agricultural organizations appreciate the opportunity to submit these comments to the U.S. Environmental Protection Agency (EPA) in response to its proposed rule to set National Primary Drinking Water Regulations (NPDWR) for six PFAS chemicals [FN1:"Perfluoroalkyl or polyfluoroalkyl substance" (PFAS) means a non-polymeric

perfluoroalkyl or polyfluoroalkyl substance that contains at least 2 sequential fully fluorinated carbon atoms, excluding gases and volatile liquids, that is a hazardous substance (as defined in section 101 of the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (42 U.S.C. 9601))], including perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS). (March. 14, 2023).

Our organizations represent farm and ranch families working together to build a sustainable future of safe and abundant food, fiber and renewable fuel for our nation and the world. We support EPA's underlying goal of addressing widespread contamination of the environment caused by historic use of PFOA and PFOS. Unfortunately, EPA's proposed Maximum Contaminant Level (MCLs) of 4 ppt for PFOA and PFOS and the designation of a hazard index for PFNA, PFHxS, Gen X, and PFBS overlook potential widespread unintended consequences.

At the onset, it is worth emphasizing our shared concerns regarding the health impacts of PFAS exposure, even as research continues to examine claims of causation. This is personal for our membership, rural families that live near to or in the approximately 140,000 small communities in the US with drinking water systems. [FN2: United States Environmental Protection Agency, Small Drinking Water Systems Research and Development, fact sheet, updated February 2020, https://www.epa.gov/sites/default/files/202002/documents/scienceinaction_small_systems_research_2020.pdf] There are many factors that must be considered when developing regulatory limits and these comments will outline the challenges that we foresee with setting the drinking water MCL for PFOA and PFOS at the very low level of 4ppt, which is out-of-step with limits recommended by international standard-setting bodies. We fear that the enormous costs, estimated to be at least $5.2 billion annually, and implementation roadblocks outlined below will have a ripple effect throughout our economy, potentially hitting rural communities the hardest.

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA has carefully considered all public comments regarding the cost analysis and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to EPA's cost analysis for the file rule are detailed sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document.

U.S Conference of Mayors, National League of Cities and National Association of Counties (Doc. #1733, SBC-043891)

While we appreciate the recent significant investments in our nation's water infrastructure from BIL, it unfortunately is not enough to protect the health of our residents in the manner the Agency is attempting. We have serious concerns that not only will local governments be unable to afford the required costs to comply with this regulation, but also that the Agency has underestimated the cascading impacts this regulation will have on local communities, primarily in the form of higher water bills.

In general, local governments will be responsible, directly or indirectly, for a wide array of associated compliance costs, including for testing, monitoring and installing treatment. The proposed Maximum Contaminant Level (MCL) of 4 ppt will require 3,400-6,000 systems across the country to take action, significantly more than are currently doing so based on state-level standards or that would need to do so if the MCL was set at a higher level such as 10 ppt. Many of the roughly 66,000 water systems that will be subject to the regulation are small systems for which compliance will be even more challenging and the financial impacts more severe. Moreover, as the Agency moves forward with rulemakings designating PFOS and PFOA or other PFAS as hazardous substances under CERCLA, these costs will only increase as local governments will also be responsible for the appropriate removal and transport of hazardous chemicals.

As providers of public water, providing safe, clean and affordable drinking water to our communities is of utmost importance to local governments. It is worth emphasizing that local governments have limited financial resources to comply with a host of new and existing water-related mandates, including but not limited to testing for lead, removing lead service lines, upgrading cybersecurity and replacing aging infrastructure. Consequently, local utilities may be forced to fund the compliance costs associated with this new regulation by cutting back on infrastructure replacement and maintenance, reducing operational resiliency and reducing other expenditures that would otherwise benefit public health and access to clean and safe drinking water.

As local governments are forced to bear the brunt of the financial burden, an increase in water rates in communities across the nation is a near certainty. Indeed, this rising consumer cost for utilities to comply with the proposed MCL will be felt most harshly by the low-income households and small business community. The U.S. Census reports that local governments spent $80 billion in 2020 on water supply utilities. A $2.5-$3.2 billion new unfunded federal mandate will require a 3.125-4% increase in national spending that will be passed on to consumers through rate increases and long-term debt, particularly where advanced treatment is required for compliance. Given this regulation will currently impact approximately 3,400-6,000 systems, the burden on those communities will be dramatically higher. Many communities and residents are already experiencing significant and widespread financial burdens, and this proposed regulation will add to that burden.

Because of this, we urge the Agency to reconsider the financial impact this proposed regulation will have on individual consumers, particularly on environmental justice and disadvantaged communities. These communities are often disproportionately impacted by both increased costs for their water bills and risk exposure to emerging contaminants. In examining the financial impacts this regulation could impose upon individual households, costs will vary depending on several factors, such as the size of the public water system. In scenarios where new treatment facilities would need to be installed and operated, individual households may see increases in the amounts of hundreds of dollars to their water bills. For systems serving smaller communities, this number extends into the thousands, according to an AWWA study.

EPA Response: For additional discussion on cost considerations for the final MCLs and alternative MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. EPA disagrees with commenter that the cost of the rule will be between $2.5-$3.2 billion per year. See the economic analysis for further discussion. For discussion related to household cost of the rule, please see section XII of the FRN and section 13.10 of the EPA response in this *Response to Comments* document. Additionally, EPA notes the availability of federal funding that can help offset some of the costs of implementing this regulation. For further discussion, see section 2.4. The EPA has carefully considered all public comments regarding the cost analysis and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to EPA's cost analysis for the file rule are detailed in sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. The are also significant quantified and non-quantifiable benefits as a result of implementing this NPDWR.

U.S Conference of Mayors, National League of Cities and National Association of Counties (Doc. #1733, SBC-043889)

May 30, 2023

The Honorable Radhika Fox Assistant Administrator Office of Water

U.S. Environmental Protection Agency 1200 Pennsylvania Avenue NW Washington, DC 20460

RE: Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation, Docket ID No. EPA-HQ-OW-2022-0114

Dear Assistant Administrator Fox,

On behalf of the nation's mayors, cities and counties, we appreciate the opportunity to submit comments on the U.S. Environmental Protection Agency's (EPA) Proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation (NPDWR). Local leaders are dedicated to the health, well-being and safety of their residents and communities and are therefore highly interested and concerned regarding the public health impact that PFAS substances may have on our drinking water supplies and systems.

We appreciated the opportunity to submit comments to EPA in response to the Agency's Federalism Consultation briefing last year. However, we are disappointed to see that our recommendations are not reflected in this proposed regulation. Given this, we urge EPA to move forward cautiously, consult with local governments, gather and utilize additional and updated scientific data, and reexamine the cost-benefit analysis to best inform this regulation. Specifically, should EPA move forward, we ask that the Agency:

• Provide maximum flexibility for local governments, including longer compliance timeframes;

• Reconsider regulatory alternative Option 1 c, which would establish a higher MCL at 10 parts per trillion (ppt) for PFOS and PFOA; and

• Provide additional direct funding for local governments to comply with the proposed regulation to avoid creating an unfunded mandate that will disproportionately impact low- income residents and communities.

These measures are important to ensuring that local governments, water utilities and ratepayers are not unduly burdened in trying to fix a problem they did not create.

Our organizations represent the nation's 3,069 counties, 19,000 cities and the mayors of the 1,400 largest cities throughout the United States. For the past several years, all levels of government, including the counties and cities we represent, have become increasingly concerned about drinking water contamination from PFAS. Created by private industry for use in a variety of sectors and applications around the globe, these chemicals have made their way into drinking water systems across the country and are heavily concentrated in communities near military installations or industrial sites.

The presence of these human-made chemicals has spurred action by state and local governments across the country. We continue to urge the federal government to take holistic and comprehensive action to address PFAS contamination through pollution prevention, cleanup, research and development, scientific and public health analysis, and prevention of further exposure.

As passive receivers of materials containing PFAS, local water systems neither caused nor contributed to the pollution. We urge EPA to adhere to the polluter pays model and provide sufficient direct funding to comply with this regulation. Additionally, in developing this regulation, EPA should provide local governments with maximum flexibility and a longer compliance timeframe to avoid overburdening communities and ratepayers.

As coregulators in implementing federal statutes, including the Safe Drinking Water Act, and as partners in protecting public health, it is important that federal, state and local governments work together to craft reasonable and practicable rules and regulations to address PFAS contamination. In order to achieve these goals, it is essential that EPA provide local governments with a clear understanding of the rules' and regulations' requirements and a full and complete cost-benefit analysis.

In general, our organizations support provisions in the 1996 Amendments to the Safe Drinking Water Act that requires drinking water standards to be based on sound science, public health protection and the occurrence of contaminants in drinking water supplies at levels of public health concern in order to reduce risk while also balancing costs. Consequently, we believe the NPDWR for PFAS, and any regulatory or legislative initiative addressing PFAS in drinking water, should balance public health and environmental priorities with technological and economic feasibility. Any federal mandate on local governments should include additional federal financial resources, as well as offer local water systems flexibility in implementation and compliance options. Further, our organizations support programs for public education regarding safe drinking water and innovative solutions that approach this problem beyond traditional command and control.

Local governments fund the majority of water infrastructure investments

Local governments fund over 98 percent of all capital, operations and maintenance investment in drinking water and wastewater infrastructure in the United States, primarily through user fees and bonds. The most recent U.S. Census data shows that local governments spent over $142 billion on water and wastewater in 2020 alone, and, between 1993 and 2019, spent over $2.38 trillion, not adjusted for inflation. Even with this significant investment by and commitment from local governments, many communities struggle to upgrade their drinking water and wastewater systems.

During this same time period, the federal government only appropriated approximately $2 billion annually for both the Clean Water and Drinking Water State Revolving Loan Fund (SRF) programs. The SRF programs provide grants to states which, in turn, provide local governments with loans that must be repaid.

While we are pleased that the bipartisan Infrastructure Investment and Jobs Act (also known as the Bipartisan Infrastructure Law or BIL) provided record-high levels of funding for our nation's water infrastructure, including $10 billion over five years for grants to address PFAS and other emerging contaminants in drinking water and wastewater, this funding is insufficient for local governments to meet the requirements of this proposed regulation and/or other rules that the Agency is considering.

At a minimum, it must be acknowledged that the timelines for the availability of funding under BIL, which is through FY 2026, and the likely compliance dates for a new NPDWR for PFAS do not align. Therefore, it is uncertain if local governments will be able to use BIL funding specifically for compliance with this forthcoming regulation or for future rulemakings pertaining to PFAS.

Taking a holistic approach toward drinking water regulations

Considering EPA is simultaneously undergoing other rulemaking processes that pertain to local drinking water and wastewater infrastructure management, among others, it is important that these rules and regulations are not developed in silos within the Agency. We urge the Agency to take a holistic and integrated approach and consider the cumulative impacts that the rules and regulations will have on local governments in terms of costs, compliance, and implementation timelines. Additionally, EPA should examine other related consequences of proposed rules, such as the impact on efforts to reduce greenhouse gas emissions.

Specifically, we are concerned that the Agency's rulemakings around NPDWR for PFAS, Lead and Copper Rule Improvements, and regulating PFAS under CERCLA and RCRA will individually and combined, create additional unfunded mandates on local governments that will be economically significant and, in many communities, unaffordable. If EPA moves forward with these proposed rules and regulations, new funding sources must be created to assist local governments with compliance and implementation. Even with the increased funding from BIL for the SRF programs, as well as for reducing lead in drinking water and addressing PFAS

drinking water contamination, local governments will still face a significant water infrastructure needs gap that would exacerbate affordability and equity concerns for the many fixed- and low-income households that already spend a disproportionate amount of their income on water bills.

EPA Response: Please see the EPA response to comment Doc. #1733, SBC-043891 in section 5.1.3 in this *Response to Comments* document. With respect to BIL and funding concerns, please see section 2.4 of the EPA response in this *Response to Comments* document. The EPA notes that actions taken under other EPA programs (such as CERCLA and RCRA) and the Lead and Copper Rule Improvements (LCRI) are beyond the scope of this rulemaking.

Arizona Corporation Commission (ACC) (Doc. #1735, SBC-045179)

BEFORE THE UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

PFAS National Primary)

Drinking Water) Docket No. EPA–HQ–OW–2022–0114

Regulation Rulemaking)

COMMENTS OF THE ARIZONA CORPORATION COMMISSION

INTRODUCTION

The Arizona Corporation Commission ("ACC") appreciates the opportunity to provide the following observations regarding the Environmental Protection Agency's ("EPA" or "Agency") PFAS National Primary Drinking Water Regulation Rulemaking. The following responses address comments posed by the rulemaking that will impact Arizona's water companies and citizens.

The ACC is the state regulatory body responsible for the regulation of Arizona's public utilities, including utilities providing water service to the residents of Arizona. The ACC has broad authority over public service corporations under Article XV of the Arizona Constitution and Arizona Revised Statutes, Title 40.

COST OF COMPLIANCE

The Environmental Protection Agency's proposed per- and polyfluoroalkyl substances ("PFAS") rule will have various impacts on the utilities regulated by the ACC associated with the sampling, treatment, and disposal of PFAS. The ACC and its regulated utilities are greatly concerned about the potential costs and liabilities associated with the proposed rule. Respectfully, the ACC believes the EPA's estimates for national costs are extremely low and not supported by rigorous evaluations. The ACC suggests the EPA revisit its calculations. In view of the extensive testing and treatment costs that will be imposed on customers, it will be important for the EPA to conduct a thoughtful assessment of the economic consequences of its decision.

EPA Response: For additional discussion on cost considerations for the final MCLs and alternative MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA has carefully considered all public comments regarding the cost analysis and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to EPA's cost analysis for the file rule are detailed sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. The are also significant quantified and non-quantifiable benefits as a result of implementing this NPDWR.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043163)

B. Favorable Trends in Declining PFAS Levels and Ongoing Industrial Source Reduction Efforts Further Support a Phased Approach to Water System Upgrades

As EPA is aware, extensive human health PFOA/PFOS data is available from the Centers for Disease Control and Prevention and the Food and Drug Administration. Fortunately, there are declining trend lines over 20 years of actual blood PFOA and PFAS levels as depicted in the chart below. The much improved and presumably still improving situation as compared to the situation only 20 years ago may further support reasons to phase-in treatment upgrades beginning with higher priority facilities, i.e., those experiencing relatively higher PFAS concentrations rather than all facilities with concentrations greater than the proposed MCLs.

[Figure 1: See Docket ID: EPA-HQ-OW-2022-0114-1657]

* Average = geometric mean

Data Source: Centers for Disease Control and Prevention. National Report on Human Exposure to Environmental Chemicals, Biomonitoring Data Tables for Environmental Chemicals. Atlanta, GA: U.S. Department of Health and Human Services, Centers for Disease Control and Prevention.

See ASTDR, PFAS in the U.S. Population, available at https://www.atsdr.cdc.gov/pfas/health-effects/us-population.html (last visited May 15, 2023).

It is unclear to what degree if any and in what manner EPA has directly considered human health impacts from areas around the Nation where there have been long-term PFAS exposure.

EPA is aware of situations where people in the U.S. have been exposed to levels of PFOA/PFOS for many years or decades at levels orders of magnitude higher than EPA's proposed MCLs. Known examples of source water contamination include the Parkersburg/Vienna, West Virginia area and the Wilmington, North Carolina (Cape Fear) area, where Chemours (formerly DuPont) facilities discharged PFAS chemicals for extended periods of time, as EPA is well aware.

These types of situations are especially concerning and may be instructive for regulatory development purposes. However, the MCL proposal does not appear to identify any health effect clusters as a result of these "hot spot" exposures, which presumably would be highly observable

given far lower levels of the proposed MCLs that EPA proposes are necessary to protect public health.

During an online Town Hall meeting regarding PFAS-related issues, we understand that North Carolina's health agency represented that it was not aware of any PFAS-related health effect clusters, despite what is believed to be long-term, high-concentration discharges of PFAS chemicals.

EPA Response: For additional discussion on alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA considered human health impacts in high exposure communities where peer-reviewed human health effects studies were available for those communities. Multiple peer reviewed studies of the C8 Health Project, which focused on a high-exposure PFOA community in the United States, reported significantly increased risks of multiple health effects with elevated exposure to PFOA including elevated serum liver enzyme levels indicative of liver damage (Gallo et al. 2012 and Darrow et al., 2016) as well as kidney and testicular cancers (Barry, 2013,; Vieira, 2013). Further, the commenter referenced an exposure scenario in North Carolina that was recently uncovered; the EPA is not aware of any peer reviewed epidemiological studies studying adverse health effects in this community. Moreover, the EPA's occurrence analysis demonstrates that there is a substantial likelihood that the PFAS regulated through this NPDWR occurs and co-occurs in drinking water (see section 6 for additional discussion). The agency also disagrees that a "phased-in" MCL approach is necessary in light of the health effect concerns for PFAS; please see section 12.1 of the EPA response in this *Response to Comments* document for additional discussion.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043398)

Favorable Trends in Declining PFAS Levels and Ongoing Industrial Source Reduction Efforts Further Support a Phased Approach to Water System Upgrades

As EPA is aware, extensive human health PFOA/PFOS data is available from the Centers for Disease Control and Prevention and the Food and Drug Administration. State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045123)

Comments on EPA PFAS MCL by the Vermont Department of Health concerning Toxicity Assessment and Proposed Maximum Contaminant Level Goal for Perfluorooctanoic Acid (PFOA) in Drinking Water (referred to as "document").

Comment: The Department of Health suggests that EPA provide a regulatory approach that is consistent with short-term exposures during pregnancy. Please explain how a regulation based on running annual average is protective of the developing fetus.

Explanation: The document describes the concerning developmental toxicity outcome of low birth weight, based on human studies. The points of departure from these studies are environmentally relevant serum levels, and as appropriate for human studies, the uncertainty factor used for reference dose derivation is 10.

EPA states the PFOA reference dose is applicable to both short-term and chronic risk assessment scenarios. This is at odds with the decision to regulate PFOA based on a running annual average. Doing so would expose a person who is pregnant during their entire gestation period. As pregnancy would be considered a short-term, rather than chronic situation, the decision to allow exposure throughout the pregnancy is not consistent with the agency's conclusion that the reference dose is applicable to short- term assessments. developing fetus.

EPA Response: While the EPA has characterized developmental effects, including immune impacts, associated with developmental PFAS exposure (i.e., during pregnancy and/or childhood) in addition to health effects that occur after chronic exposure (i.e., exposure over many years), the developmental and chronic effects associated with exposure to PFAS are not known to represent immediate acute health effects based on the currently available information. Exceedances for contaminants in other NPDWRs (such as nitrate, nitrite, or total nitrate and nitrite) can result in immediate life-threatening health impacts for infants (i.e., methemoglobinemia); this has not been demonstrated for the PFAS regulated in this NPDWR. The agency explains in CFR § 141.903(e) that in cases where there is elevated exposure scenarios such that a sampling result is high enough to cause the RAA to exceed an MCL (i.e., if the result is greater than four times the MCL), the systems is out of compliance immediately. Therefore, the agency finds the RAA appropriate for use in determining compliance with the MCLs. States and PWSs have to meet the requirements of the NPDWR however SDWA allows a state with primacy to require more stringent monitoring, compliance and PN requirements (e.g., such as more frequent sample collection or more stringent compliance calculations) if they deem necessary. For instance, if there are regional factors that suggest more frequent sampling is warranted by particular PWSs, the rule provides that primacy agencies may increase the required monitoring frequency, where necessary, to detect variations within the system (e.g., fluctuations in concentrations due to seasonal use or changes in water source). Finally, once the rule is finalized, the EPA will develop appropriate implementation guidance to assist in the understanding of violations and PN, among other rule requirements. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on alternative regulatory standards (including lower PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion on the MCLGs for PFOA and PFOS, please see section 4 of the EPA response in this *Response to Comments* document.

WateReuse Association (Doc. #1712, SBC-043517)

May 30, 2023

The Honorable Michael S. Regan Administrator

U.S. Environmental Protection Agency William Jefferson Clinton Building 1201 Pennsylvania Avenue, N.W. Washington, D.C. 20460

Re: Docket ID No. EPA–HQ–OW–2022–0114

Dear Administrator Regan:

On behalf of the WateReuse Association (WateReuse), I am pleased to submit our comments on EPA's preliminary regulatory determination and proposed rule to establish Maximum Contaminant Levels (MCLs) for certain per- and polyfluoroalkyl substances (PFAS).

The WateReuse Association is a not-for-profit trade association for water utilities, businesses, non-profit organizations, and research entities that advocate for policies and programs to advance water recycling. WateReuse and its state and regional sections represent nearly 250 water utilities serving over 60 million customers, and over 200 businesses and organizations across the country.

Water reuse, also known as water recycling, is the process of intentionally capturing wastewater, stormwater, saltwater or graywater and cleaning it as needed for a designated beneficial freshwater purpose, such as drinking, industrial processes, groundwater replenishment, and watershed restoration. The fundamental principle of water reuse is using the right water for the right purpose, everywhere and all the time. By advancing water reuse, we protect and enhance public health and the environment while helping communities build resilience to drought, flooding, and other impacts of climate change. Across the country, water, wastewater, and stormwater managers have shown that water recycling can be a central feature in innovative, integrated approaches to solving water management challenges.

One common application of water recycling is the production of drinking water, either through indirect potable reuse or through direct potable reuse. In both cases, advanced treatment is typically used to meet drinking water standards. Through the use of technologies such as reverse osmosis (RO) and granular activated carbon (GAC), advanced water recycling projects are helping to remove PFAS from drinking water.

While water recycling facilities are helping to address PFAS contamination through the use of advanced treatment such as RO and GAC, the ubiquitous nature of PFAS contamination necessitates a strong focus by EPA and other government agencies on source control. We recommend that EPA take more proactive measures to identify where PFAS are originating and to control their introduction into commerce, as prevention is more cost-effective than attempting to clean up pollution later. A source control approach also maintains the polluter pays principle.

Advancing regulatory actions that provide source water protection will reduce the number of systems with PFAS contamination above the proposed drinking water standards. We therefore urge EPA and other federal agencies to work toward limiting the production and introduction of PFAS into commerce.

Sincerely,

Patricia Sinicropi

Executive Director

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. With respect to responses on potable water reuse, the agency notes that NPDWRs apply to PWSs and does not pose direct standards or requirements for wastewater treatment facilities and advanced treatment facilities for potable reuse unless the water is for direct distribution (in this circumstance, these systems generally would be classified as PWSs). Typically, the process of using treated wastewater for potable water reuse involve a series of treatment steps after conventional wastewater treatment which then may get discharged to a surface water body, used for groundwater augmentation, or go directly to a PWS for additional treatment and distribution. At this last step, the PWS must meet the federal requirements outlined in the NPDWR. The agency's cost analysis specific for PWSs and primacy agencies implementing the PFAS NPDWR is further described in section 13.3 of the EPA response in this *Response to Comments* document. The EPA further notes that topics related to assigning liability for PFAS pollution or addressing sources of PFAS contamination are beyond the scope of this rulemaking (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion). For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document. For general concerns around treatment discharges and waste residuals, as well as concern around water recovery or water reuse applications, please see section 10.4 of the EPA response in this *Response to Comments* document.

Florida Section American Water Works Association - Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044489)

• Other Facility Operations

In addition to direct costs, other facility operations with permits containing MCL references could face cost increases. For example, some water reuse permits in the state of Florida reference MCLs and the facilities may need to change current treatment processes. Florida is a national leader in water reuse production with over 900 million gallons a day (please see https://floridadep.gov/water/domestic-wastewater/documents/2021-reuse-inventory-report). However, the time allowed for comments on EPA's proposed rule did not allow us to quant if y these potential cost estimates.

EPA Response: Please see the EPA response to comment Doc. #1712, SBC-043517 in section 5.1.3 in this *Response to Comments* document.

Los Angeles County Sanitation Districts (Doc. #1756, SBC-044515)

Implementation of the proposed MCLs could impede water recycling efforts in areas such as Southern California. Considering the interdependence of recycled water and drinking water for many public water systems, it is imperative that EPA evaluate the impacts of the proposed MCLs on the production and use of recycled water. This is increasingly true throughout the United States as water recycling is considered a climate-resilient water supply and is being implemented in an increasing number of areas. In California, for example, treated wastewater used for indirect or direct potable reuse projects must meet federal and state MCLs, so new federal MCLs for PFAS will apply to recycled water used for these purposes. While some potable reuse projects employ advanced treatment processes that may already reduce or remove PFAS, not all do. Moreover, unless designed to meet regulatory requirements for PFAS removal, these systems may not achieve newly adopted MCLs for PFAS, and new or modified treatment processes may still be necessary. The new MCLs may also affect the options available for management of the treatment residuals, as mentioned above. As an example, for groundwater replenishment projects, recycled water must meet MCLs before application to spreading basins that overlie the aquifer, and water reclamation plants (which typically have tertiary treatment that do not remove PFAS) will likely require new treatment technologies if and when they are required to meet the proposed PFAS MCLs, unless such treatment is already in place. The economic ramifications of these capital projects are enormous: multiple new technologies and treatment trains may be required at each water reclamation plant as one or more pretreatment steps prior to filtration or adsorption may be required. The energy requirements associated with the use of these technologies to treat tens of thousands of acre-feet of wastewater per year are also potentially huge and could include power for high-pressure pumping and other pumps, raw material manufacture and transport, thermal energy for regeneration/reactivation, and waste handling and transport. The energy consumption and associated greenhouse gas emissions of these technologies draw into question their sustainability and use for wastewater treatment. The high energy and financial costs of complying with low MCLs may discourage water recycling efforts and may deter or significantly delay expansion of existing projects and/or implementation of new projects. This would reduce these important climate resilient local water supplies. It is evident that the EPA has not fully considered nor evaluated the costs or energy and greenhouse gas impacts stemming from recycled water compliance with the proposed MCLs. The Sanitation Districts urge the EPA to address the impacts of the MCLs on water reuse and develop the appropriate regulatory frameworks that govern the operation of these projects while still promoting the use of this sustainable climate-resilient local water resource.

EPA Response: Regarding the agency's consideration for greenhouse gas impacts for the rule, please see section 13.11 of the EPA response in this *Response to Comments* document. For additional discussion on water reuse applications, please see the EPA response to comment Doc. #1712, SBC-043517 in section 5.1.3 in this *Response to Comments* document.

Water Replenishment District (WRD) (Doc. #1754, SBC-044220)

May 30, 2023

Administrator Michael S. Regan

United States Environment Protection Agency 1200 Pennsylvania Avenue, NW

William Jefferson Clinton Bldg Room; EPA East Room 1309 Washington, DC 20004

RE: Public Comment on EPA's Proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation (Docket ID: EPA-HQ-OW-2022-0114)

Dear Administrator Regan,

In response to the Environmental Protection Agency's (EPA) request for public comments regarding the proposed National Primary Drinking Water Regulation for per- and polyfluoroalkyl substances (PFAS), the Water Replenishment District (WRD) is submitting this letter to provide our comments regarding the proposed regulation. We believe that implementing the proposed limits without accompanying accessible remediation funding mechanisms could inhibit some local water purveyors (i.e., groundwater pumpers) from providing safe and affordable drinking water to their communities.

The Water Replenishment District (WRD) is the largest groundwater agency by population in the State of California, managing and protecting local groundwater resources for four million residents. WRD's service area covers a 420-square-mile region of southern Los Angeles County, the most populated county in the United States. WRD is committed to managing and protecting the Central Basin and West Coast Basin, two of the most utilized urban groundwater basins in the nation.

We urge you to carefully consider the issue of effective and accessible funding as you finalize the rule. While it is important to protect public health from PFAS contamination, it is also vital to ensure the human right to water. It has been our experience that the existing California funding programs are often inaccessible and unnecessarily cumbersome which leaves many smaller water purveyors at a disadvantage, even though the State of California statutorily recognizes that "every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes."

Detailed herein is information regarding our agency, our efforts to date to address PFAS contamination in local groundwater, and the anticipated financial impacts of the proposed regulation without an effective means of funding for PFAS remediation projects.

WRD BACKGROUND

WRD was formed in 1959 by a vote of the people and our mission is to provide, protect, and preserve safe and sustainable groundwater supplies within the Central Basin and West Coast Basin. The 43 cities in our service area, including a portion of the City of Los Angeles, and other

unincorporated parts of Los Angeles County use about 220,000 (72 billion gallons) of groundwater annually which accounts for nearly half of the region's water supply needs.

WRD owns three water treatment facilities: two advanced water treatment facilities and a groundwater desalter. Through the operation of WRD's two advanced water treatment facilities, WRD provides supplemental replenishment water for delivery to two Los Angeles County Public Works infrastructure systems: the Montebello Forebay Spreading Grounds located in the northeast portion of the Central Basin and the Seawater Barrier Project injection wells located along the coast. Traditionally, imported water from the Colorado River or Northern California Bay-Delta was used to supplement these systems. However, through technological and regulatory advancements, recycled water can now be used for 100 percent of replenishment purposes, supplemented by imported water only as needed to maintain barrier demands.

By utilizing local replenishment alternatives, WRD has secured groundwater sustainability and reliability while using water that would have otherwise flowed unused to the ocean. Additionally, costs remain affordable to ratepayers and energy savings from using less imported water yields a valuable environmental benefit of reduced carbon emissions.

WRD PFAS REMEDIATION PROGRAM

WRD has a legacy of identifying and treating unwanted substances before they spread in groundwater. Since its establishment in 1991, WRD's Safe Drinking Water Program (SDWP) and Disadvantaged Communities Program (DAC) provides financial and technical assistance to drinking water purveyors seeking to remediate their production wells. Through these programs, WRD has secured millions in State grant funding for well remediation and other water system projects. WRD established the PFAS Remediation Program in August 2020, and builds on the tremendous success of SDWP and DAC.

The PFAS Remediation Program is one of the first of its kind in California to award grant funding to treat PFAS-impacted drinking water wells. There are 1,740,000 residents in WRD's service area who are served by public water systems that have PFOA or PFOS levels above the current state Response Level. Furthermore, 35-45% of this population, or roughly 700,000 people, live within census tracts that are classified as disadvantaged or severely disadvantaged. As WRD's service area includes about 4 million residents, nearly 45% of the WRD population is affected by PFAS-impacted wells.

With a current Program budget of over $60 million that was funded by local water purveyors in the Central Basin and West Coast Basin, WRD's PFAS Remediation Program provides either grants for pumpers to install their own treatment systems, or for WRD to design and construct treatment systems for them. The purpose of the Program is to ensure remediation projects could be implemented immediately to prevent unnecessary closures of wells and ensure continued access to low-cost, high-quality groundwater by preventing the spread of PFAS contamination. Thus far, a total of 14 groundwater pumpers have applied for funding from the Program, and funding agreements have been executed between WRD and six (6) pumpers, for a total funding amount of over $27 million.

WRD assists groundwater pumpers with applications for grant funding from the State and other sources for their PFAS remediation projects. In many cases, water purveyors that serve economically disadvantaged communities lack the resources to prepare and submit successful applications for grant funding. In addition, it is not uncommon for the total cost of the remediation project to exceed the funding amount that can be provided from WRD's PFAS Program, and therefore the water purveyor requires additional funding to offset the cost of their project.

IMPACTS OF THE PROPOSED PFAS REGULATION

Perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS) have been detected at concentrations greater than the proposed Maximum Contaminant Levels (MCLs) in drinking water wells, particularly those located in the northeast portion of the Central Basin, referred to as the Montebello Forebay (see attached Figure 1). The Montebello Forebay is critical to WRD's groundwater replenishment operations because it is a region where surface and recycled water infiltrate into the subsurface to directly recharge multiple unconfined drinking water aquifers. Contaminants in groundwater within this region can spread easily and quickly both laterally and vertically due to the nature of the underlying geology.

At the time when California established Response Levels (RLs) for PFAS, approximately 45% of the drinking water wells in the WRD service area exceeded the RLs. If the new MCLs are adopted, which are significantly lower than the RLs, the number of impacted drinking water wells would jump to approximately 70%, bringing the total of impacted wells to approximately 98 drinking water wells. Based on WRD's estimates, it would cost approximately $160 million (capital costs only) to remediate all 98 impacted drinking water wells. Without State or Federal funding assistance to offset remediation costs, it is cost prohibitive for many water purveyors in WRD's service area.

While the WRD PFAS Remediation Program offers a remedy for some of the water purveyors in the Central Basin and West Coast Basin, the funding for the Program places an undue and unsustainable burden on the groundwater pumping community. The pumping community came together and voluntarily contributed to a PFAS fund despite having no responsibility for the PFAS contamination. Furthermore, many of the impacted drinking water wells are located within Disadvantaged Communities (DACs) and Severely Disadvantaged Communities (SDACs), as depicted in the attached Figure 1.

CONCLUSION

WRD is concerned that without effective and accessible funding mechanisms for PFAS treatment in our service area, the proposed MCLs will likely result in the unintended consequence of prohibiting smaller water purveyors, especially those that serve DACs and SDACs, the use of the local groundwater supply and force them to rely on expensive and unsustainable imported water supplies.

Since WRD and its pumping community are not the responsible entities for contaminating the groundwater basins with PFAS, and presently no other party has been held accountable, it is critical that WRD and the pumping community receive timely funding assistance to address this very serious risk to basin water quality. Furthermore, to be effective, funding programs need to be streamlined to be accessible so that smaller water purveyors that are under resourced can receive funding in an expeditious manner.

WRD respectfully urges the EPA to consider the need for streamlined and accessible funding programs to implement in tandem with the proposed regulation. Without this funding structure in place, an undue burden will be placed on our most underserved and economically fragile communities. WRD appreciates and supports the EPA's commitment to protecting public health and leveraging the best available science to establish nationwide, health-protective standards for PFAS in drinking water.

Sincerely,

Stephan Tucker, MBA, PE, PMP

General Manager, Water Replenishment District

Attachment: Figure 1

Figure 1. PFOA/PFOS Detections in Drinking Water Wells in the Central Basin and West Coast Basin

[Figure 1: See docket ID EPA-HQ-OW-2022-0114-1754]

EPA Response: For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional considerations on funding and BIL, please see section 2.4 of the EPA response in this *Response to Comments* document.

WaterPIO (Doc. #1624, SBC-043473)

(Of course, landing on 4ppt each makes the health advisories look even more ridiculous. The EPA set the HAs at parts per quadrillion (ppq) levels, 4 ppq for PFOA and 20 ppq for PFOS. The agency clearly ignored the error rate for testing at ppq levels; it can be as high as FIFTY percent. Because the numbers are so unreliable, ppq testing results are unreportable to the public, even when water systems could show their customers they are in the clear for PFAS.

Again, the EPA put public water in a position to fail.)

EPA Response: The EPA notes that the final MCLs consider feasibility: The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA

response in this *Response to Comments* document. Please see section 7 of the EPA response in this *Response to Comments* document for additional discussion on validated analytical methods to meet the monitoring requirements of this NPDWR. The commenter did not provide further explanation nor supporting information regarding claims that "the agency clearly ignored the error rate for testing at ppq levels; it can be as high as FIFTY percent." Further, HAs are beyond the scope of this action. HAs are not regulations and should not be construed as legally enforceable federal standards.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043657)

APPENDIX-B

Rate Impacts of BWWB's Ongoing and Emerging Compliance and Infrastructure Needs

(Excluding the PFAS Rule)

BWWB believes that USEPA's cost analysis was considered in a vacuum without addressing the impact of other compliance and infrastructure needs, such as:

• LCRR compliance

• Risk reduction and aging infrastructure (AWIA)

• Non-revenue water (NRW) control

The financial conditions of BWWB can be briefly described using three metrics: annual capital budget, annual O&M budget and planned annual revenue. Table B1 presents the baseline of BWWB's financial conditions. A preliminary estimate for the compliance and aging infrastructure costs in the next 5 years resulting from the three regulations mentioned above was added on the baseline to calculate the rate increase and affordability challenges BEFORE the proposed PFAS Rule. The results are presented in Table B1 on the subsequent page.

Table B1. Baseline Capital and O&M Budget with additional LCRR, AWIA and NRW Control Compliance Costs

[Table B1: See Docket ID EPA-HQ-OW-2022-0114-1602]

Table B2 below summarizes the impacts on BWWB's ratepayers in the next 5 years resulting from the ongoing and emerging compliance and infrastructure needs. Please refer to the Executive Summary Letter for the detailed explanation of Table B2.

Table B2. Impacts on ratepayers and BWWB by LCRR, AWIA and NRW Control Compliance

[Table B2: See Docket ID EPA-HQ-OW-2022-0114-1602]

EPA Response: For additional discussion on cost considerations for the final MCLs and alternative MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA has carefully considered all public comments regarding the cost analysis

and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to EPA's cost analysis for the file rule are detailed in the sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. The agency also notes significant quantified and non-quantifiable benefits as a result of implementing this NPDWR. Evaluating aging water infrastructure and non-revenue water control are not part of routine compliance sampling in drinking water regulations and thus are not accounted for in the EPA's cost analysis. Moreover, SDWA section 1412(b)(3)(C)(i)(III) requires that EPA include quantifiable and non-quantifiable costs that are likely to occur solely as a result of compliance with the MCL. Therefore, actions taken in other rules (such as the Lead and Copper Rule Revisions) and other programs (replacement of aging water infrastructure) are beyond the scope of this rulemaking.

Water Works Operators' Association of Pennsylvania (WWOAP) (Doc. #1604, SBC-042827)

April 21, 2022

Environmental Quality Board

P.O. Box 8477

Harrisburg, PA 17105-8477 eComments

RegComments@pa.gov

RE: Regulation #7-569: Safe Drinking Water PFAS MCL Rule

Dear Environmental Quality Board:

The Water Works Operators' Association (WWOAP) (www.wwoap.org) is a nonprofit group of members dedicated to increasing the knowledge and expertise of those working at all levels and in all sectors of Pennsylvania's water supply industry. We provide information regarding public water supply design, construction, treatment, and management. For nearly a century, WWOAP has existed to help strengthen and promote the water industry.

The WWOAP supports the proposed rulemaking which will improve public health protection by setting maximum contaminant level goals (MCLG) and maximum contaminant levels (MCL) for two per- and polyfluoroalkyl substances (PFAS) – perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS).

The proposed amendments are intended to protect public health by setting state MCLs for contaminants in drinking water that are currently unregulated at the federal level. If the proposed amendments were adopted, Pennsylvania would move ahead of the federal Environmental Protection Agency (EPA) in addressing PFOA and PFOS in drinking water and join a small group of states that have set MCLs for select PFAS in drinking water.

In addition, the EPA is also moving forward with the MCL process as outlined in the federal Safe Drinking Water Act (SDWA) for perfluorooctanoic acid (PFOA) and perfluorooctane

sulfonate (PFOS). EPA expects to publish a proposed rule by Fall 2022 with a final rule expected Fall 2023. Therefore, Pennsylvania may need to adjust this proposed rulemaking if the EPA were to put forth its own rulemaking with conflicting or more stringent MCLs for PFOA and PFOS.

On July 29, 2021, a pre-draft version of the proposed rulemaking was presented to the Public Water System Technical Assistance Center (TAC) Board of which WWOAP is a member. The TAC unanimously voted to support the Department of Environmental Protection (DEP) moving forward in the rulemaking process to present a proposed PFAS Rule to the EQB. [FN1: Minutes of the July 29, 2021, Meeting – Public Water System Technical Assistance Center (TAC) Board https://files.dep.state.pa.us/PublicParticipation/Advisory%20Committees/AdvCommPortalFiles/TAC/2022/Draft_Minutes_Ju l_29_2021_TAC_meeting.pdf.]

Currently, EPA's health advisory limit (HAL) is 70 parts per trillion (ppt) for the combined concentrations of PFOS and PFOA. Since PFAS are unregulated, there is no MCL. However, our ability to detect has outpaced our ability to understand the significance.

DEP conducted a statewide sampling plan which began in June 2019. DEP identified 493 public water system sources as potential sampling sites because they met the criterion of being located within a half mile of a potential source of PFAS contamination, such as military bases, fire training sites, landfills, and manufacturing facilities.

Of those, DEP tested 372 targeted sites and 40 additional sites (for a total of 412) that were not located within a half mile of a potential source of PFAS contamination to establish a baseline.

Of the PFAS chemicals sampled, PFOS and PFOA were most common, being detected at 103 and 112 sites, respectively. Of the sites with detections, only eight PFAS were detected. The eight PFAS that were detected are: PFOS, PFOA PFNA, PFHxS, PFHpA, PFBS, Perfluorohexanoic acid (PFHxA), and Perfluoroundecanoic acid (PFUnA). Results were non-detect for the other 10 PFAS that were tested.

Of the 412 total samples, two of the results were above the EPA's HAL of 70 ppt for the combined concentrations of PFOS and PFOA: State of the Art, Inc. in Centre County, and Saegertown Borough in Crawford County.

The proposed rulemaking includes a proposed PFOA MCL of 14 ppt that is a 90% improvement in health protection as compared to the current EPA HAL of 70 ppt.

In addition, the proposed rulemaking includes a proposed PFOS MCL of 18 ppt that is a 93% improvement in health protection as compared to the current EPA HAL of 70 ppt.

Public water systems can treat source water with granular activated carbon (GAC), anion exchange (IX), and reverse osmosis (RO) (e.g., high-pressure membrane systems) to remove PFOS and PFOA from drinking water.

According to DEP's Table 16 (GAC Treatment Costs), "the average capital cost for the GAC treatment was $3,457,110 per million gallons per day (MGD) per entry point (EP) with an average annual operation and maintenance (O&M) cost of $171,970 per MGD per EP." [FN2:

Proposed Rulemaking – Safe Drinking Water PFAS MCL Rule, pg. 36, Table 16. GAC Treatment Costs http://www.irrc.state.pa.us/docs/3334/AGENCY/3334PRO.pdf]

Moreover, DEP's Table 17 (IX Treatment Costs), "the average capital cost for the IX treatment was $3,284,360 per MGD per EP with an average annual O&M cost of $155,666 per MGD per EP." [FN3: Proposed Rulemaking – Safe Drinking Water PFAS MCL Rule, pg. 36-37, Table 17. IX Treatment Costs http://www.irrc.state.pa.us/docs/3334/AGENCY/3334PRO.pdf]

In addition to treatment costs, the proposed rulemaking also imposes significant compliance monitoring costs. Specifically, the proposed rule requires initial quarterly monitoring for community and nontransient noncommunity systems serving a population of more than 350 persons beginning January 1, 2024. It also will require repeat compliance monitoring on a quarterly basis for any EPs at which either PFOA or PFOS is detected at a level above its respective minimum reporting limit (MRL), including those EPs at which one or both MCLs are exceeded. If the quarterly repeat monitoring results are reliably and consistently below the MCLs, the frequency of repeat monitoring may be reduced from quarterly monitoring to annual monitoring. Table 15 on page 35 of the proposed rulemaking summarizes the overall cost estimates for compliance monitoring costs in each of the first four years of rule implementation. According to DEP, "the average annual monitoring costs over the first four years are $4,397,916." [FN4: Proposed Rulemaking – Safe Drinking Water PFAS MCL Rule, pg. 35, Table 15. Compliance Monitoring Costs http://www.irrc.state.pa.us/docs/3334/AGENCY/3334PRO.pdf]. WOAP recommends that DEP consider accepting UCMR5 sampling results which begin in January, 2023 for many water systems. The UCMR5 sampling results should be accepted as the initial monitoring with reduced monitoring, as appropriate, beginning with the effective date of this regulation. Systems that do not detect PFAS or that have demonstrated through UCMR5 sampling to be consistently and reliably below the proposed MCLs should be able to discontinue quarterly sampling for another year after the UCMR5 sampling is completed. This would be a considerable cost saving to systems for compliance monitoring.

The WWOAP is concerned that the cost for monitoring and treatment will ultimately be much higher than those estimated for the proposed MCLs of 14 ppt for PFOA and 18 ppt for PFOS. The WWOAP is also concerned with the potential impact that the actual costs will have on community water systems, particularly small systems which make up the majority of our members. Therefore, it is imperative that the "Compliance Assistance Plan" [FN5: Compliance Assistance Plan, page 38 http://www.irrc.state.pa.us/docs/3334/AGENCY/3334PRO.pdf] be adequately funded to help community water systems offset the costs of this proposed rulemaking.

The WWOAP appreciates the opportunity to present these comments on this proposed rulemaking and respectfully requests the EQB's consideration.

Respectfully submitted,

Serena A. DiMagno

Legislative/Regulatory Affairs Committee Chairman

EPA Response: For additional discussion on cost considerations for the final MCLs and alternative MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. With respect to the agency's cost analysis, the EPA has carefully considered all public comments regarding the cost analysis and made numerous changes to the costs analyses as recommended by commenters. Specific changes made to EPA's cost analysis for the file rule are detailed in sections 13.3.1 through 13.3.6 of the EPA response in this *Response to Comments* document. The EPA notes that the agency did not propose standards (nor alternative MCLs) for PFOS at 14 or 18 ppt and subsequently did not consider these alternative thresholds in the EPA's cost analyses. With respect to funding concerns, please see section 2.4 of the EPA response in this *Response to Comments* document. Finally, considerations for international and state drinking water standards is further discussed in section 5.1.5 of the EPA response in this *Response to Comments* document.

Superfund Settlements Project (SSP) and RCRA Corrective Action Project (RCAP) (Doc. #1631, SBC-043434)

EPA failed to consider the costs of the Proposal at CERCLA and RCRA Corrective Action sites.

The SDWA requires EPA to conduct a Health Risk Reduction and Cost Analysis when proposing a NPDWR. [FN40: 42 U.S.C. § 300g-1(b)(3)(C)(i).] EPA is relying on its Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation [FN41: EPA-822-P-23-001 (March 2023).] (the "Economic Analysis") to fulfill this statutory mandate. The Economic Analysis, however, fails to consider a direct and substantial cost that will follow from the Proposal: costs in connection with remediation of contaminated

sites under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 ("CERCLA") [FN42: 42 U.S.C. §§ 9601 et seq.] and the Resource Conservation and Recovery Act. [FN43: 42 U.S.C. §§ 6901 et seq] Relatedly, the Economic Analysis fails to consider and recognize the very limited environmental benefit that would result from the Proposal.

CERCLA Section 121(d) requires that on-site remedial actions attain or waive federal environmental Applicable or Relevant and Appropriate Requirements ("ARARs"), or more stringent state environmental ARARs, upon completion of the remedial action. [FN44: 42 U.S.C. § 9621(d) et seq.] The 1990 National Oil and Hazardous Substances Pollution Contingency Plan also requires compliance with ARARs during removal and remedial actions at Superfund sites to the extent practicable. [FN45: 40 C.F.R. §300.400(g).] For water that is to be used for drinking, MCLs are clearly ARARs. [FN46: 40 C.F.R. § 300.430(e)(2)(i); see also USEPA, CERCLA Compliance with Other Laws Manual: Interim Final, EPA/540/G-89/006 at 4-8 (August 1988).] In addition, MCLs are relevant and appropriate as in situ cleanup standards where either surface water or ground water is or may be used for drinking water, which includes where an aquifer is considered to have any potential for use as drinking water but where no such use is currently occurring, planned, necessary or reasonably anticipated. [FN47:Id] In addition, to account for the potential future usability option, an MCL can come into play even for "unusable" groundwater (e.g., highly saline or having high total dissolved solids).

Consistent with CERCLA, the RCRA corrective action program bases cleanup levels on the maximum potential beneficial use of the groundwater. Thus, cleanup levels are generally set at a level that would be protective for drinking water use, with EPA adopting existing cleanup standards, generally MCLs or state drinking water standards. [FN48: See, e.g., 61 Fed. Reg. 19449.]

There are more than 1,300 Superfund sites and 3,700 RCRA corrective action sites. The Proposed Rule fails to identify these entities as affected; [FN49: See 88 Fed. Reg. 18642.] however, the sites would clearly be affected by the Proposal and the cost would be significant. Adding treatment of PFAS to the levels set forth in the Proposal will result in increased operating costs as well as longer remediation times, yet there would be no health risk reduction benefit. EPA already can set site-specific health-based clean up criteria. [FN50: See, e.g., National Contingency Plan, 40 C.F.R. Part 300; USEPA, Handbook of Groundwater Protection and Cleanup Policies for RCRA Corrective Action, EPA530-R-04-030 (April 2004).] Where the costs so expansively outweigh the benefit, a regulatory action cannot be justified.

This imbalance between cost/benefit is particularly troublesome at sites where PFAS had not been manufactured, used, disposed or discharged. It is reasonable to believe that, given that PFAS are ubiquitous, PFAS will be detected at numerous Superfund and RCRA corrective action sites and, at many of these sites, there would have been no manufacturing, use, disposal or discharge of PFAS at the site itself. By requiring responsible parties to remediate PFOA and PFOS at these Superfund and RCRA corrective action sites to the proposed MCLs, EPA will essentially be asking them to clean up to below background levels while nearby areas exhibit

similar levels at ambient conditions. The cost to treat groundwater to the proposed MCLs will have a substantial impact on remediation costs, costs EPA failed to consider in its Economic Analysis.

Importantly, for those sites where responsible parties are essentially cleaning up background PFAS groundwater contamination, there will be little to no environmental benefit since the site may essentially become an island in a sea of low-level PFAS contamination. Particularly at CERCLA sites, because of CERCLA's liability scheme, these extremely low MCLs will result in delays of the overall site cleanup such that these levels will be a detriment rather than benefit to the environment. Where a hazardous substance is present, CERCLA liability can attach, regardless of concentration. [FN51: See, e.g., A&W Smelter & Refiners V. Clinton, 146 F.3d 1107, 1110 (9th Cir. 1989).] CERCLA further creates a strict liability scheme that imposes liability regardless of whether the Potentially Responsible Party's ("PRP's") actions at the time of disposal were negligent, in accordance with the regulations in place at the time, or consistent with industry best practices. CERCLA also provides for joint and several liability: if there is more than one PRP, any one of those PRPs may be held liable for the entire site cleanup regardless of the number of other PRPs. [FN52: See Burlington Northern and Santa Fe Ry. Co. v. United States, 556 U.S. 599 (2009).] Nor is CERCLA temporally limited: although federal laws are generally not interpreted as having retroactive application absent an explicit statement that they should be applied retroactively, CERCLA has been interpreted to apply to both current and former PRPs and for past releases. [FN53: See, e.g., Commonwealth Edison Co. v. United States, 271 F.3d 1327, 1350-51 (Fed. Cir. 2001); United States v. Monsanto Co., 858 F.2d 160, 174 (4th Cir. 1988); United States v. Northeastern Pharm. & Chem Co., 810 F.2d 726, 734 (8th Cir. 1986). Note, however, that no court has considered whether Section 102(a) can be applied retroactively, an open question given the general position that retroactivity is not favored by the law. See, e.g., Bowen v. Georgetown Univ. Hosp., 488 U.S. 204, 208-09 (1988).]

EPA typically pursues a few "deep pocket" PRPs for whom they seek strict, joint and several liability. [FN54: Probst, Katherine N., Superfund at 40: Unfulfilled Expectations, Chapter 6, at 232 ("Unfairness can result from the way EPA implements the law as well. PRPs complain in particular that EPA often picks a subset of PRPs to target with a notice letter and ask to enter into a settlement at a site.")] EPA then leaves it to those PRPs to gain cooperation from others, and, when cooperation is not forthcoming, CERCLA provides a right to pursue contribution. [FN55: See 42 U.S.C. § 9613(f).] Where significant costs will be incurred to address substances for which no PRP is responsible, however, gaining cooperation will be extremely challenging. That, in turn, will result in delays in addressing contamination. The impact of setting MCLGs and MCLs at levels far below those needed for public health protection are especially concerning since a CERCLA "release" giving rise to such liability for a site surrounded by anthropogenic, ambient elevated concentrations will require significant investigation and remediation, all the while adding no further health benefit to the communities that the MCL was intended to protect.

The same is true for RCRA corrective action sites. While some of the same concerns regarding liability and allocation may not apply, RCRA corrective action has its own long arm and the

concerns regarding addressing contamination unrelated to a site and/or at ambient levels are the same. RCRA corrective action is required for all releases of hazardous waste or constituents from any solid waste management unit, whether permitted or not, on-site or off-site, and regardless of when the release occurred. [FN56: 42 U.S.C. § 6924(u), (v).]

EPA, at the discretion of the Administrator, may establish less stringent MCLs if achieving the MCL could result in an increase in health risks from other contaminants. [FN57: 42 U.S.C. § 300g-1(b)(5).] While this section is not directly applicable, this is the case here in connection with contaminated sites requiring remediation, and EPA should have considered this in its Economic Analysis.

If EPA finalizes the Proposal (whether in part or in whole), SSP and RCAP urge EPA to consider granting a nationwide variance to contaminated remediation sites using either SDWA Section 1415 or 1416 [FN58: 42 U.S.C. §§ 300g-4, 300g-5.] where site groundwater is not used for drinking water and adequate drinking water supply is present and reasonably expected to be present in the future. Alternatively, while not the purview of the Office of Water, another alternative way to address these significant issues would be to issue a blanket ARAR waiver at Superfund sites and similar policy for RCRA corrective action sites.

EPA Response: For additional discussion on cost considerations for the final MCLs and alternative MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. SDWA § 1416(a) and (b)(2)(C) describe how the EPA or states may also grant an exemption for PWSs meeting specified criteria that provides an additional period for compliance. Regarding exemptions, please see section 12.1 of the EPA response in this *Response to Comments* document. Further, the EPA notes that application of MCLs in non-drinking water programs (such as water quality criteria, NPDES, or CERCLA cleanups) is beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR.

Inland Empire Utilities Agency (IEUA), California (Doc. #1666, SBC-043391)

EPA also fails to acknowledge that these proposed MCLs may be considered when developing wastewater effluent limits as health-based water quality standards to protect water quality of receiving water that have municipal or domestic supply beneficial use or groundwater recharge opportunities.

As result, IEUA believes that EPA's economic assessment is incomplete and does not adequately capture increasing capital and operational costs for water, wastewater, and water recycling agencies required to meet compliance.

EPA Response: For additional discussion on cost considerations for the final MCLs and alternative MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that application of MCLs in non-drinking water programs (such as water quality criteria, NPDES, or CERCLA cleanups) is beyond the scope of this rulemaking;

please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043725)

There will also be increased energy demand as more treatment facilities are constructed and treatment material regeneration facilities are needed. Both activities will increase coal mining, which will have its own environmental impacts and should be considered in EPA's cost estimates.

EPA Response: For additional discussion on cost considerations for the final MCLs and alternative MCLs, please see section 5.1.3. The EPA has considered the costs or electricity usage and energy demand. For the EPA's response on greenhouse gas emissions associated with the rule, see section 13.11 in this *Response to Comments* document.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043805)

Limits in any media, including drinking water, should be set with the understanding that it exists in the background of the environment and everyday life. To impose limits on the water industry to address PFAS, which is only a passive receiver of these compounds, while allowing the other industries that also use and provide products containing PFAS to consumers and the environment, is unbalanced and incomplete.

Humans and the environment as exposed to PFAS in many other media, and in much greater quantities. Therefore, the cost-benefit to achieve these regulatory requirements in the water industry needs to be weighed against the cost-benefit of removing it from food packaging, personal care products, clothing, and other direct and indirect exposure routes.

EPA Response: For additional discussion on cost considerations for the final MCLs and alternative MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA notes that removing PFAS in consumer products is beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion on comments outside the scope of this NPDWR.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045907)

EPA has seriously underestimated the costs of the proposed rule on regulated entities, and, by the Chamber's and others' estimates, the costs are expected to be significant. The significant costs of this rulemaking indicate EPA has failed to satisfy the SDWA requirements for feasibility in regulation, by failing to demonstrate that the proposed MCLs are as close to the MCLGs as "feasible" and that the combination of technology, treatment techniques, or other means required to meet the MCLs are not "more stringent than is feasible." EPA cannot finalize the rule as proposed without addressing these SDWA requirements.

EPA Response: The EPA disagrees with the commenter that the agency did not address SDWA requirements in setting the MCLs as close as feasible to the MCLG. Please see sections 5.1.2 (laboratory considerations, including capacity and capability), section 5.1.3 (cost considerations and alternative MCLs), and 5.1.4 (treatment considerations) of the EPA response in this *Response to Comments* document. Additionally, please see section 13 of the EPA response in this *Response to Comments* document.

Metropolitan Water District of Southern California (Doc. #1777, SBC-045437)

Since the proposed MCLs are almost certain to have a significant economic impact, Metropolitan recommends that EPA first decide whether to issue a final determination to regulate PFHxS, GenX chemicals, PFNA, and PFBS, in addition to PFOA and PFOS (see comment #1). If EPA decides to regulate some or all of these PFAS, it should then follow the required process of conducting an economic feasibility assessment for any proposed MCL(s) and consider all comments received in this NPDWR rulemaking and any future related rulemakings.

EPA Response: The EPA followed SDWA requirements in setting the MCLs as close as feasible to the MCLG. Please see sections 5.1.2 (laboratory considerations, including capacity and capability), section 5.1.3 (cost considerations and alternative MCLs), and 5.1.4 (treatment considerations) of the EPA response in this *Response to Comments* document. Regarding EPA's regulatory determinations for PFHxS, PFNA, HFPO_DA and mixtures of these three PFAS and PFBS, please see section 3 of this *Response to Comments* document.

5.1.4 Treatment Considerations

Summary of Major Public Comments and EPA Responses

Many commenters agree with the EPA's determination that feasible technologies exist to treat to the final MCLs based on their experience of full-scale use and/or existing case studies while some contend that feasible technologies are not available to support implementation of the final MCLs. With respect to the agency's feasibility analysis as it pertains to treatment technologies, the EPA evaluates the availability and performance of BATs for treating water to minimize the presence of the contaminant as well as the costs of applying those BATs to large metropolitan water systems when treating to that level (1412(b)(4)(E) and (5)). The definition of "feasible" means feasible with the use of best technology…"which includes consideration of the analytical limits of the best available treatment technology." *See* S. Rep. No. 169, 104th Cong., 1st Sess. (1995) at 3. To designate technologies as BATs, the EPA evaluated each technology against six BAT criteria, including whether there is a reasonable cost basis for large metropolitan water systems. The EPA evaluated whether the technologies are currently being used by systems, whether there were treatment studies available with sufficient information on design assumptions to allow cost modeling, and whether additional research was needed (USEPA, 2024e). In considering the results of this information, the EPA determined that these costs are reasonable to large metropolitan water systems. Please see section X of the final rule preamble and section 10 of the EPA's *Response to Comments* document for additional discussion on treatment technologies including BAT identification and evaluation.

Pursuant to SDWA § 1412(b)(4)(E)(ii), the agency also evaluated "technolog[ies], treatment technique[s], or other means that is affordable" for small PWSs. In this evaluation, the agency determined that the costs of SSCTs to reach 4.0 ng/L are affordable for households served by small drinking water systems. Additionally, the EPA notes that SDWA § 1412(b)(4)(D) states that "granular activated carbon is feasible for the control of synthetic organic chemicals" which

the agency lists as a BAT for this rule (section X). All PFAS, including PFOA and PFOS, are Synthetic Organic Chemicals (SOCs), and therefore, GAC is BAT as defined by the statute. For additional discussion on BATs and SSCTs, please see section X of the final rule preamble.

Individual Public Comments

Michigan Farm Bureau (MFB) (Doc. #1562, SBC-043357)

The WHO reported [FN10: World Health Organization. 2022. PFOS and PFOA in Drinking Water: Background Document for Development of WHO Guidelines for Drinking-water Quality, Version for Public Review issued 29 September, 2022. WHO/SDE/WSH/XXXXXX. Retrieved from: https://www.cmbg3.com/library/WHO-Draft-Drinking-Water-Document.pdf] on PFAS levels in drinking water from the Unregulated Contaminant Monitoring Rule third round update (UCMR-3), noting that in 2013-2015, average concentration of treated drinking water from groundwater sources was 45 ppt of PFOA and 199 ppt of PFOS, and from mixed groundwater/surface water sources was 33 ppt of PFOA and 47 ppt of PFOS. For comparison, the State of Michigan has regulated seven PFAS chemicals since 2020, setting MCL limits of:

• PFOA: 8 ppt

• PFOS: 16 ppt

• PFNA: 6 ppt

• PFHxS: 51 ppt

• PFBS: 420 ppt

• GenX: 370 ppt

• PFHxA: 400,000 ppt (this is not a chemical being proposed for MCL in EPA's rule)

The Michigan PFAS Action Response Team (MPART), a multi-agency work group tasked with coordinating on PFAS monitoring at a range of sources, reported utility treated drinking water mean concentrations across the state: [FN11: Means calculated from: Michigan PFAS Action Response Team. 2023. Statewide PFAS Survey of Public Water Supplies. Retrieved from: https://www.michigan.gov/pfasresponse/drinking-water/statewide-survey.]

• PFOA: 10.45 ppt (range: non-detect to 780 ppt)

• PFOS: 13.64 ppt (range: non-detect to 740 ppt)

• PFNA: 5.86 ppt (range: non-detect to 14 ppt)

• PFHxS: 9.81 ppt (range: non-detect to 67 ppt)

• PFBS: 9.85 ppt (range: non-detect to 230 ppt)

• GenX: no results reported

• PFHxA: 7.09 ppt (range: non-detect to 79 ppt)

This demonstrates that even with robust water treatment requirements already in place, some drinking water utilities will struggle to meet EPA's proposed PFAS MCL limits. MPART's surface water sampling in locations across the state also had significant variation in PFAS concentrations, with mean concentrations of: [FN12: Means calculated from: Michigan PFAS Action Response Team. 2023. PFAS Surface Water Sampling. Retrieved from: https://www.michigan.gov/pfasresponse/investigations/sites-aoi.]

• PFOA: 13.55 ppt (range: 0.19 to 7,700 ppt)

• PFOS: 46.37 ppt (range 0.28 to 11,000 ppt)

• PFNA: 1.00 ppt (range: non-detect to 97 ppt)

• PFHxS: 4.49 ppt (range: non-detect to 549 ppt)

• PFBS: 2.45 ppt (range: non-detect to 83.5 ppt)

• GenX: 1.33 ppt (range: non-detect to 14 ppt)

• PFHxA: 5.59 ppt (range: non-detect to 690 ppt)

While sampled surface water sites are weighted heavily toward site investigations with known or suspected PFAS sources entering the surface water, it is crucial to note that first, these results include sampling done after drinking water, surface water, and groundwater regulatory limits have already been set, and second, that particularly the concentrations of PFOA and PFOS are in some samples much higher than MCLs, making background or raw water concentrations of PFAS including PFOA and PFOS to be a significant challenge to treat to MCL levels of 4 ppt.

EPA Response: Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. Regarding how the EPA considers state data, the agency relied on multiple data sources, including UCMR 3 and state finished water data, to evaluate the occurrence of PFOA, PFOS, PFHxS, PFNA, and HFPO-DA and probability of co-occurrence of these PFAS and PFBS. The EPA also incorporated both the UCMR 3 and some state data into a Bayesian hierarchical model which supported exposure estimates for select PFAS at lower levels than were measured under UCMR 3. The specific modeling framework used to inform this regulatory action is based on the peer-reviewed model published in Cadwallader et al. (2022). The EPA acknowledges that the available data were collected under varying circumstances; for example, targeted vs. non-targeted monitoring (i.e., monitoring not conducted specifically in areas of known or potential contamination). The EPA primarily considers finished drinking water data in the agency's occurrence analysis as this is the most reflective of conditions to determine whether a contaminant is known to occur or there is a substantial likelihood that the contaminant will occur in PWSs with a frequency and at levels of public health concern. A comprehensive discussion of all the available state PFAS drinking water occurrence data is

included in the *Occurrence Technical Support Document* (USEPA, 2024a). For additional discussion on internal and state drinking water standards and guidelines, please see section 5.1.7.

The EPA acknowledges responses that while it may be challenging for some systems to treat to the MCL, the history of full-scale use of the designated BATs provide evidence that the BATs could treat to or below the MCL. Section 1412(b)(4)(E) of SDWA requires that the agency "list the technology, treatment techniques, and other means which the Administrator finds to be feasible for purposes of meeting [the MCL]," which are referred to as BATs. The EPA examined the following criteria for identifying feasible BATs: 1) The capability of a high removal efficiency; (2) a history of full-scale operation; (3) general geographic applicability; (4) reasonable cost based on large and metropolitan water systems; (5) reasonable service life; (6) compatibility with other water treatment processes; and (7) the ability to bring all the water in a system into compliance. Please see section 10 of the EPA response in this *Response to Comments* document for additional discussion on treatment technologies.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045036)

Treatment Technologies

An analysis of NJDEP records shows that facilities can reliably and consistently achieve levels of PFNA, PFOA, and PFOS close to or below detection levels (0.53 ppt to 5 ppt) through carefully designed and operated PFAS treatment. All detections of PFOA or PFOS were below New Jersey's MCLs of 14 ppt for PFOA and 13 ppt for PFOS for both GAC and AIX treatment technologies.

In addition to the 24 facilities with permanent treatment for PFAS, permits have been submitted to NJDEP for installation of PFAS treatment at approximately 90 additional facilities. These facilities are in various stages of completing the permitting process and constructing PFAS treatment. Records indicate that these facilities are designing their treatment systems to achieve finished water levels of PFOA and PFOS ranging from less than 1 ppt to 40 ppt.

EPA Response: The EPA acknowledges commenter's statement that, based on NJDEP records, "facilities can reliably and consistently achieve levels of PFNA, PFOA, and PFOS close to or below detection levels (0.53 ppt to 5 ppt) through carefully designed and operated PFAS treatment." Regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of this of the EPA response in this *Response to Comments* document. For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

Environmental Working Group (EWG) (Doc. #1721, SBC-045412)

EPA's proposed MCLS are feasible.

SDWA requires an MCL to "be as close to the maximum contaminant level goal as is feasible" and defines feasibility as, "feasible with the best technology…and other means which the

Administrator finds, after examination of efficacy under field conditions… are available."[FN47: 42 U.S.C. [sec] 300g-1(b)(4)(D).] SDWA further specifies that "granular activated carbon is feasible for the control of synthetic organic chemicals" and that any other technology "must be at least as effective …as granular activated carbon." [FN48: Id.]

EPA Response: The EPA agrees that the MCLs for this regulatory action are set as levels as close as feasible to the MCLG. Regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046103)

ii. EPA's Proposed PFOA and PFOS MCLs are Feasible Using Readily Available Detection and Treatment Technologies

EPA's proposed PFOA and PFOS MCLs are "as close . . .as is feasible" to those chemicals' MCLGs, as required by the SDWA. [FN65: 42 U.S.C. § 300g-1(b)(4)(B).] The SDWA defines feasibility as "feasible with the use of the best technology" that has been tested under "field conditions" and is "available." [FN66: 42 U.S.C. § 300g-1(b)(4)(D).] When it amended the SDWA in 1986, Congress specified that "granular activated carbon is feasible for the control of synthetic organic chemicals," like PFAS. [FN67: Pub. L. No. 99-339, 100 Stat. 642, 644-645 (June 19, 1986) (currently codified at 42 U.S.C. § 300g–1(b)(4)(D)).] Congress added that "other means found to be the best available for the control of synthetic organic chemicals must be at least as effective in controlling synthetic organic chemicals as granular activated carbon." [FN68: Id.]

Here, EPA correctly found that granular activated carbon ("GAC"), anion exchange, and high pressure membranes such as those used in reverse osmosis systems "can achieve [PFAS] concentrations less than 4 [ppt]" and may "exceed >99 percent [PFAS removal]." [FN69: Proposed Rule, 88 Fed. Reg. at 18,684–86.] Those technologies are not only readily available, but they have been deployed and proven effective in communities across the country. The Cape Fear Public Utility Authority reported no PFAS detections in water treated by granular activated carbon at a Wilmington, NC drinking water treatment plant, despite high levels of PFAS in the water before treatment. [FN70: See WECT News, CFPUA: No PFAS Found in Water Treated by GAC Filters (Oct. 11, 2022), https://www.wect.com/2022/10/11/cfpua-no-pfas-found-water-treated-by-gac-filters/.] In nearby Brunswick County, another utility used reverse osmosis to reduce PFOA and PFOS to non- detectable levels. [FN71: Brunswick Cnty. Gov. Complex, Brunswick County Commissioners Receive Final Report Showing PFAS Not Detected in LPRO Treated Water (Apr. 17, 2018), https://www.brunswickcountync.gov/brunswick-county-commissioners-receive-final-report- showing-pfas-not-detected-in-lpro-treated-water/; CDM Smith, Advanced Treatment Options for the Northwest Water Treatment Plant: Brunswick County, App'x A (Apr. 2018), https://www.brunswickcountync.gov/wp-

content/uploads/2018/04/CDM-Smith-Brunswick- Final-Report-April-2018.pdf.] The use of granular activated carbon treatment in New Jersey yielded similar results:

Seven different GAC treatment plants operating for years . . . removed PFOA, PFOS, and other PFAS chemicals to nondetectable levels. Three of those GAC plants were treating groundwater with concentrations of PFOA or PFOS of >500 ppt to nondetectable levels. Since 2019, 12 New Jersey plants, seven that use GAC and five that use IEX, have been achieving nondetectable levels of PFOA and PFOS in >99.9% of treated water with detection limits ranging from 0.53 to 5 ppt. [FN72: Elizabeth Southerland & Linda S. Birnbaum, What Limits Will the World Health Organization Recommend for PFOA and PFOS in Drinking Water, 57 Env't Sci. & Tech. 7103, 7103–7105 (2023), https://doi.org/10.1021/acs.est.3c02260; N.J. Drinking Water Quality Inst., Treatment Subcomm., Recommendation on Perfluorinated Compound Treatment Options for Drinking Water, at 6–8 (June 2015), https://www.nj.gov/dep/watersupply/pdf/pfna-pfc-treatment.pdf.]

EPA Response: The EPA agrees that the PFOA and PFOS MCLs are as close as feasible to the MCLG. Regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document . For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

Environmental Working Group et al. (Doc. #1810, SBC-044690)

Under EPA's proposal, drinking water utilities will be required to test water for PFOA, PFOS, GenX, PFBS, PFNA, and PFHxS and install treatment technologies to reduce the concentrations of these chemicals to the level of EPA's proposed "maximum contaminant levels" or lower. Fortunately, proven technology is available that will not only reduce the presence of the six PFAS in EPA's proposal, but will also improve protection against other PFAS compounds and common contaminants.

EPA Response: The EPA agrees that treatment technology is available to reduce the six regulated PFAS to levels below their MCLs and that this regulation will also improve protection against other PFAS and non-PFAS contaminants. Please see section 5.1.4 o of the EPA response in this *Response to Comments* document for more information about the agency's evaluation of feasible treatment technologies for the final NPDWR. For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

Lance Freeman (Doc. #2132, SBC-047306)

The idea of lowering the amount of PFAS in water is inherently good in a vacuum. Fewer people dying because of dangerous chemicals in their drinking water is ideal. However, my concern does not come from the dislike of this idea, it comes from the uncertainty of logistics. The biggest question I have is if it is feasible technology-wise to effectively remove PFAS to this

level? That would be the first thing to determine. The EPA did state they were looking for comments on if it is feasible and what methods and technology would work best, I feel that the answers they get from those comments should be the top priority and even when they receive those answers they should be triple verified to make sure they work properly. Without the ability to remove PFAS effectively, it is unreasonable to assume this limit can be placed. Any water with PFAS in it would be unfit to be used as a resource and given that a large portion of the United States is experiencing water shortages as is, the removal of drinking water because it doesn't meet the new requirements might hurt more than it helps.

EPA Response: Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document. The EPA agrees that protecting public health and the environment by reducing PFAS contamination is important and that finalizing this NPDWR is an important step toward accomplishing that objective. After considering public comment, EPA reaffirms that there are feasible treatment technologies to remove PFAS to levels below the MCLs in this final regulation.

Anonymous (Doc. #2569, SBC-047292)

I have worked in the water treatment industry for nearly 30 years and to see such a drastic reduction to the proposed MCL of 4 ppt when the previous health advisory was 70 ppt seems unwarranted. This is in light of the fact that the FDA released a study in 2019 which identified PFAs was present in every food they tested, most of the time containing PFAs levels over 100 ppt and sometimes in the thousands. I work in a highly efficient treatment plant with multiple GAC contactors and we are able to get our levels down around 4 ppt. Most treatment plants will not be able to do that and will have to incur exorbitant capital costs to remove something that is already in the food supply. Since PFAs are already consumed daily, the level in the water can be 0 and everyone who eats will still consume hundreds if not thousands of ppt of PFAs every day. It doesn't make sense to have such stringent (4 ppt) number given the costs involved.

EPA Response: Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. This final NPDWR is informed by the current and best available peer-reviewed science. For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document. For additional discussion on how costs were considered in setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. EPA has considered the RSC in informing the MCLGs for this regulation: please see sections 4.2.5 and 4.3.3 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044025)

8. EPA seeks comment on its PFOA and PFOS evaluation of feasibility for the proposal, including analytical measurement and treatment capability, as well as reasonable costs, as defined by SDWA.

a. An MCL of 4.0 ppt for PFOA and PFOS is not broadly feasible due to treatment installation costs, available treatment technologies and materials, product supply availability, manufacturing and disposal limitations, labor shortages and laboratory limitations.

EPA Response: Please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document. For additional discussion on extensions and exemptions, please see section 12.1 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045038)

NJDEP agrees and notes that of the 216 samples submitted by the 11 treatment plants that utilized GAC, only eight samples had detectable levels of PFOA (ranging between 2.1 ppt to 9.4 ppt, and no samples had detectable levels of PFOS. These facilities were able to reduce their levels of PFOA and PFOS to below the detection levels in 93% to 100% of samples. Detection limits for these samples ranged from 0.47 ppt to 5 ppt. All systems that have installed treatment for PFNA in New Jersey are utilizing GAC. These systems have reported non-detect for PFNA since the installation of treatment.

NJDEP notes that although the proposed MCLs seem to be achievable by treatment such as GAC, media changeouts may occur at an increased frequently as water systems look to meet the lower proposed MCLs.

EPA Response: Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045022)

EPA requested comment on whether PWS can feasibly treat PFOA and PFOS to 4.0 ppt or below. Based on NJDEP's experience in implementing New Jersey's state-specific MCLs, water systems have demonstrated the ability to treat for PFOA, PFOS, and PFNA to 4.0 ppt. Based on NJDEP records, permits have been submitted to NJDEP for installation of PFAS treatment at approximately 90 additional facilities. These facilities are in various stages of completing the permitting process and constructing PFAS treatment. Twenty four facilities in New Jersey have installed permanent treatment for removal of PFAS. Of these, 11 facilities have utilized granular

activated carbon (GAC) treatment and 13 facilities have utilized anion exchange (AIX) treatment. Regulated drinking water systems began submitting standardized compliance data to the Department for PFOA and PFOS in January 2019. These compliance samples are collected post-treatment, prior to entering the water distribution system. Between January 23, 2019 and May 22, 2023, over 300 samples were submitted for PFOA and PFOS by the 24 facilities utilizing permanent PFAS treatment. An analysis of these data shows that these facilities were able to achieve levels of PFOA and PFOS below detection in the vast majority of treated water samples (>95%). Detection limits for these samples ranged from 0.47-5 ppt.

EPA Response: Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

Tyson Foods, Inc. (Doc. #1750, SBC-043901)

May 30, 2023

VIA ELECTRONIC SUBMISSION (www.regulations.gov)

Alexis Lan,

Office of Ground Water and Drinking Water

Standards and Risk Management Division

Mail Code 4607M

Environmental Protection Agency

1200 Pennsylvania Avenue NW

Washington, DC 20460

RE: PFAS National Primary Drinking Water Regulation Rulemaking [EPA– HQ–OW–2022–0114]; 88 Fed. Reg. (60): 18638 (March 29, 2023)

Dear Ms. Lan,

Tyson Foods, Inc. (Tyson Foods) is one of the world's largest food companies and a recognized leader in protein. As the world's population continues to grow and as we face a potential global food shortage, we need a food system that can support this population by providing nutritious protein and sustains our planet. This will require the global agriculture industry to become more efficient, productive, resilient, and sustainable – while keeping food affordable, nutritious, and accessible.

We appreciate the opportunity to comment on the Environmental Protection Agency' (EPA) proposed rule, PFAS National Primary Drinking Water Regulation Rulemaking (Proposed Rule or Proposal).

The Proposal as written poses a myriad of significant challenges to the meat and poultry industry. For instance, there is genuine concern based on available empirical data and analyses that the proposed levels cannot be achieved with existing treatment technology. Additionally, the draft rule proposes levels below those that can be reliably detected using existing EPA methods.

EPA Response: Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

responsesColorado Water Utility Council (CWUC) (Doc. #1622, SBC-044026)

9. EPA seeks comment on its evaluation of feasibility for the proposed HI MCL finding, including analytical measurement and treatment capability, as well as reasonable costs, as defined by SDWA.

a. Removal technologies for PFHxS may not be the same as what effectively removes PFOA and PFOS. Either way, EPAs cost estimates for PFAS removals are grossly underestimated.

EPA Response: Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. This final NPDWR is informed by the current and best available peer-reviewed science. For additional discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document. For additional discussion on how costs were considered in setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

COMM Water Department (Doc. #1577, SBC-042446)

EPA needs to rapidly work toward finding permanent destruction technologies or we will continue to face the prospect of a never-ending cycle of moving PFAS around our environment.

EPA Response: Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. The EPA notes that destruction technologies for PFAS is discussed in the updated *Interim Destruction and Disposal Guidance*. The interim guidance outlines the current state of the science on techniques and treatments that may be used to destroy or dispose of PFAS and PFAS-containing materials. However, the interim guidance is beyond the scope of this rulemaking.

Marlene Ladderbush (Doc. #1612, SBC-042922)

EPA needs to rapidly work toward finding permanent destruction technologies or we will continue to face the prospect of a never-ending cycle of moving PFAS around our environment.

EPA Response: Please see the EPA response to comment Doc. #1577, SBC-042446 in section 5.1.4 in this *Response to Comments* document.

Town of Lincoln Water Department (Doc. #1613, SBC-043034)

EPA needs to rapidly work toward finding permanent destruction technologies or we will continue to face the prospect of a never-ending cycle of moving PFAS around our environment.

EPA Response: Please see the EPA response to comment Doc. #1577, SBC-042446 in section 5.1.4 in this *Response to Comments* document.

Water Supply District of Acton (Doc. #1662, SBC-043665)

EPA needs to rapidly work toward finding permanent destruction technologies or we will continue to face the prospect of a never-ending cycle of moving PFAS around our environment.

EPA Response: Please see the EPA response to comment Doc. #1577, SBC-042446 in section 5.1.4 this *Response to Comments* document.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043209)

• EPA is requesting comment regarding PFAS treatment technologies.

o The Department regulates not only public drinking water systems but wastewater facilities as well. The identification of RO/NF as best available technologies (both full scale treatment and POUs) should be accompanied with a strong recommendation to evaluate the impact on wastewater treatment plant effluent and sludges due to the concentrated waste stream.

EPA Response: Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. Regarding the impact of disposal of PFAS containing waste from RO/NF, see the EPA response to comment Doc. #1577, SBC-042446 in section 5.1.4 in this *Response to Comments* document for a discussion of the EPA's *Interim Destruction and Disposal Guidance*. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation.

City of Thornton, Colorado (Doc. #1748, SBC-044789)

Thornton is also concerned that an increase in landfill disposal of spent treatment media containing concentrated PFAS has a high potential to increase contamination of source waters or lead to contamination of new sources. Leachate from these landfills should be addressed by the EPA without leading to increased disposal costs for utilities.

EPA Response: Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. The agency notes that addressing leachate from landfills is beyond the scope of this rulemaking (please see section 15.1 of the EPA response in this *Response to Comments* document for additional information). For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Fairfax Water (Doc. #1789, SBC-045302)

Water Utilities Need a Comprehensive Understanding of EPA's PFAS Regulatory Framework to Support Decision Making for Capital Intensive Infrastructure

The drinking water treatment process results in several residual streams including process water from filter backwashes, sediments that are removed from source waters, and spent filter media. Utilities need to have clarity on the entire EPA PFAS regulatory structure, from source water to residuals, to make informed and cost-effective decisions on behalf of their ratepayers. EPA needs to provide clarity on how and when it will regulate sources of PFAS in the environment. There is currently no EPA regulatory mechanism to eliminate a PFAS source in a drinking water supply. EPA should reprioritize its PFAS regulatory focus so that sources are eliminated at the polluter's expense instead of PFAS remediation becoming the financial burden of the public.

EPA Response: Please see the EPA response to comment Doc. #1729, SBC-043581 in section 5.1.4 in this *Response to Comments* document for a discussion of how EPA's PFAS Strategic Roadmap sets timelines for specific actions. Regarding the impact of disposal of PFAS containing waste treatment residuals, see the EPA response to comment Doc. #1577, SBC-042446 in section 5.1.4 in this *Response to Comments* document for a discussion of the EPA's *Interim Destruction and Disposal Guidance*. Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. Topics related to assigning liability for PFAS pollution or addressing sources of PFAS contamination are beyond the scope of this rulemaking (please see section 15.11 of the EPA response in this *Response to Comments* document for additional discussion).For additional discussion on the management of treatment residuals, please see section 10.4 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044190)

Additionally, NCDEQ requests that EPA continue its research into PFAS treatment, such as the planned PFAS demonstration projects by the Agency's Office of Research and Development (ORD), waste disposal technologies, additional investment into the capacity development program, and enhanced investment into the state agencies' programs who will oversee and implement this regulation.

EPA Response: Under EPA's PFAS Strategic Roadmap, the Office of Research and Development is evaluating and developing technologies for reducing PFAS in the environment to inform decisions on drinking water and wastewater treatment, contaminated site cleanup and remediation, air emission controls, and end-of-life materials management. Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. With respect to responses regarding PFAS treatment and residuals management, please see section 10.4.1 of the EPA response in this *Response to Comments* document. For concerns on funding and BIL, please see section 2.4 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044104)

Additionally, ASDWA requests that EPA continue its research into PFAS treatment, such as the planned PFAS demonstration projects by the Agency's Office of Research and Development (ORD), waste disposal technologies, additional investment into the capacity development program, and enhanced investment into the primacy agencies' programs which will oversee and implement this regulation. Primacy agencies and systems will also need in-depth guidance and training on PFAS mitigation techniques before the final rule's compliance date.

EPA Response: Please see the EPA response to comment Doc. #1652, SBC-044190 in section 5.1.4 in this *Response to Comments* document.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043581)

The EPA should also reexamine its PFAS Strategic Roadmap and consider the chronology and speed of regulatory decision-making so that those subjected to new rules have sufficient time to adapt at each stage. EPA needs to clarify preferred and effective disposal and destruction procedures for spent materials used to remove PFAS from water and how to scale in an economic manner. PFAS in sewer systems needs to be addressed. Biosolids deserve consideration too since systems came to rely on them as a source of revenue, but now for many, they have turned into an additional expense. These actions should simultaneously help to clarify liability so that those undertaking improvements in treatment are not potentially subject in the future to avoidable legal risks particularly as EPA considers parameters for designating PFAS compounds as "hazardous substances" under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). If these efforts require additional research or

changes in law, we urge EPA to include that in communications such as budget requests with federal legislators so they can appropriate the resources necessary or legislate policy changes accordingly.

EPA Response: Reexamination of EPA's PFAS Strategic Roadmap, PFAS in sewer systems, biosolids, and the designation of hazardous substances under CERCLA is beyond the scope of this rulemaking. Please see the EPA response to comment Doc. #1577. SBC-042446 in section 5.1.4 in this *Response to Comments* document for a discussion of the *EPA's Interim Destruction and Disposal Guidance*. Regarding responses regarding the agency's evaluation of feasible treatment technologies for the final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document. Topics related to assigning liability for PFAS pollution or addressing sources of PFAS contamination are beyond the scope of this rulemaking (please see section 15.1 of the EPA response in this *Response to Comments* document for additional discussion).For additional discussion on the management of treatment residuals, please see section 10.4 of the EPA response in this *Response to Comments* document.

Paul Eldredge (Doc. #2770, SBC-047458)

EPA should also reexamine its PFAS Strategic Roadmap and consider the chronology and speed of regulatory decision making so that those subjected to new rules can have sufficient time to adapt at each stage. EPA needs to clarify preferred and effective disposal and destruction procedures for spent materials used to remove PFAS from water and how to scale in an economic manner. These actions should simultaneously help to clarify liability so that those undertaking improvements in treatment are not potentially subject in the future to avoidable legal risks particularly as EPA considers parameters for designating PFAS compounds as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). If these efforts require additional research or changes in law, we urge EPA to include that in communications such as budget requests with federal legislators so they can appropriate the resources necessary or legislate policy changes accordingly.

This is especially pertinent at a time when wastewater agencies are still overcoming the compounding difficulties caused by workforce shortages, lingering supply chain issues, and inflation. Public works professionals balance public health and environmental concerns with doing what is best in the communities where we live and serve.

Thank you for your time and consideration of these comments.

EPA Response: Please see the EPA response to comment Doc. #1728, SBC-043581 in section 5.1.4 in this *Response to Comments* document.

American Public Works Assocation (APWA) (Doc. #1584, SBC-042394)

EPA should also reexamine its PFAS Strategic Roadmap and consider the chronology and speed of regulatory decision making so that those subjected to new rules can have sufficient time to

adapt at each stage. EPA needs to clarify preferred and effective disposal and destruction procedures for spent materials used to remove PFAS from water and how to scale in an economic manner. Biosolids deserve consideration too since systems came to rely on them as a source of revenue, but now for many they have turned into an additional expense. These actions should simultaneously help to clarify liability so that those undertaking improvements in water treatment are not potentially subject in the future to avoidable legal risks particularly as EPA considers parameters for designating PFAS compounds as "hazardous substances" under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). If these efforts require additional research or changes in law, we urge EPA to include that in communications such as budget requests with federal legislators so they can appropriate the resources necessary or legislate policy changes accordingly.

EPA Response: Please see the EPA response to comment Doc. #1729, SBC-043581 in section 5.1.4 in this *Response to Comments* document.

California Farm Bureau Federation (Doc. #1704, SBC-045079)

EPA's PFAS Strategic Roadmap only committed to meeting its statutory deadline of December 2023. This proposed drinking water standard of 4 ppt will require drinking water providers to treat drinking water sources for PFOA and PFOS and thus create more of a need for the management of treatment residues. Additionally, the Roadmap did not identify plans to address PFOA and PFOS under the Resource Conservation and Recovery Act (RCRA), which, among other things, would have required EPA to conduct a rulemaking to establish management, treatment, and disposal standards thmat would apply to all RCRA-regulated PFOA and PFOS waste anywhere in the United States. The absence of regulatory requirements, or at least clear guidance on management, treatment, disposal, and destruction guidelines, hampers the ability of drinking water utilities to develop the management infrastructure needed to address PFOA and PFOS contamination. Additionally, responsible parties lack places to send contaminated materials for appropriate management and disposal.

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1704]

EPA Response: Actions identified in the PFAS Strategic Roadmap regarding other agency programs (such as RCRA) are beyond the scope of this rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document. That said, the EPA PFAS Strategic Roadmap reference RCRA actions. In the Roadmap, the agency identified various authorities including the RCRA. The EPA also disagrees with the comment on the availability of disposal options. Disposal options and guidance on management of treatment residuals for PFAS containing waste currently exist; please see section 10.4 of the EPA response in this *Response to Comments* document for additional discussion on the management of treatment residuals. Also see the EPA response to comment Doc. #1577, SBC-042446 in section 5.1.4 in this *Response to Comments* document for a discussion of the EPA's *Interim Destruction and Disposal Guidance.* Regarding responses regarding the agency's evaluation of feasible treatment technologies for the

final NPDWR, please see section 5.1.4 of the EPA response in this *Response to Comments* document.

5.1.5 International and State Drinking Water Standards and Guidelines

Summary of Major Public Comments and EPA Responses

Many commenters compared the proposed MCLs to existing state and international standards, regulations and guidelines. In particular, these commenters reference several states who have conducted their own rulemakings to promulgate MCLs and use it as a point of comparison for the EPA's analysis. Further, some of these commenters ask the EPA to explain why certain states' cost-benefit analyses supported their respective levels and why the EPA's analysis is different. The EPA notes that potential differences in conclusions could arise from several factors, including from differences in the number of entities included in the analysis, baseline levels of PFAS contamination, estimation of health risk reduction benefits, and the estimation of costs. EPA's HRRCA for the proposal was based on the best available and peer-reviewed science, using data collected by accepted methods or best available methods, and the Administrator determined at proposal that the benefits of the rule justify its costs. For the EPA response to comments on the EPA's HRRCA, see section 13 in this *Response to Comments* document.

Regarding state PFAS regulations, some commenters point to state-led actions as a point of comparison for EPA's action and state that the agency's analysis is inconsistent with the approaches taken by states. While some states have promulgated drinking water standards for various PFAS prior to promulgation of this NPDWR, this rule provides a nationwide, health protective level for PFOA and PFOS (as well as other PFAS) in drinking water and reflects regulatory development requirements under SDWA, 'including requirements that EPA's action be based on the best available, peer-reviewed science; available drinking water occurrence, treatment, and evaluation of feasibility, including consideration of costs.. The state adopted MCLs identified by commenters were adopted prior to EPA's proposal and were adopted pursuant to relevant state authorities at the time. The fact that states have adopted less stringent MCLs under state law prior to EPA's proposal is not relevant to EPA's determination that its MCLs met applicable SDWA requirements. After the MCLs takes effect, SDWA requires primacy states to have a standard that is no less stringent than the MCLs.

The EPA notes that the EA for this rulemaking accounts for existing state standards at the time of analysis. Specifically, to estimate the costs and benefits of the final rule, the EPA assumed that occurrence estimates exceeding state limits are equivalent to the state-enacted limit. For these states, the EPA assumed that the state MCL is the maximum baseline PFAS occurrence value for all Entry Point to the Distribution Systems (EPTDSs) in the state. Additionally, while states may establish drinking water regulations or guidance values absent federal regulation as they deem appropriate, the presence of state regulations does not preclude the EPA from setting federal regulations under the authority of SDWA that meets that statute's requirements.

Regarding international PFAS guidelines and standards, some commenters point to these actions as a point comparison for the EPA's action and state that the agency's analysis is inconsistent with the approaches taken by international organizations. While some international entities (such as Australia, Japan, the United Kingdom and the European Union) have developed drinking water guidelines and standards for some PFAS, this NPDWR reflects the regulatory development requirements under SDWA, including requirements that the EPA's action be based on the best available, peer-reviewed science; available drinking water occurrence, treatment, and evaluation of feasibility, including consideration of costs. The international guidelines and state standards identified by commenters are relevant to those international authorities at that time. The fact that international organizations have adopted PFAS standards and guidelines is not relevant to the EPA's determination that its MCLs met applicable SDWA requirements.

Several commenters reference the World Health Organization's (WHO) Guidelines for Drinking Water Quality. The EPA notes that WHO provided a draft document that was offered for public comment in the fall of 2022 and that the WHO received a number of comments on that draft document. In the WHO's response to comments on the provisional draft value for PFOA and PFOS assessment, the WHO wrote the following. "The provisional guideline value of 100 ng/L for PFOA and PFOS proposed in the draft background document is not a health-based value and the draft background document does not suggest this is a safe level of exposure. Therefore, the WHO's proposed provisional guideline value should not be compared to health-based values established by other agencies. The draft background document found that high pressure membrane processes, adsorption and ion-exchange can reduce PFOS and PFOA contamination levels by ≥ 90 percent, and that these technologies can consistently and reliably reduce PFAS-contaminated waters to below 100 ng/L. However, the draft background document did not intend to suggest that these technologies couldn't reduce PFOS and PFOA contamination to concentrations lower than 100 ng/L. Therefore, the provisional guideline value should not be interpreted as the lowest concentrations of PFOA and PFOS that can be achieved with available treatment technologies; in fact, it is expected that well-operated treatment processes designed for PFAS removal are able to achieve concentrations well below this value." The WHO review and assessment of the PFAS group of substances is an ongoing process. The EPA does not believe it is appropriate to use the WHO's approach for determining PFOA and PFOS or other PFAS MCLs because it is inconsistent with the statutory requirements of the SDWA. The language in the SDWA is clear: the EPA must set the MCL as close as feasible to the health-based MCLG. In setting the MCLG, the EPA uses established systematic review practices (USEPA, 2022b) to identify, evaluate, synthesize, integrate, and quantify evidence in a chemical database. These protocols have been repeatedly peer-reviewed and improved upon over time. Other health agencies, including the WHO, do not follow these same practices and, as a result, may arrive at different conclusions. The EPA then considers non-health-based factors (such as analytic and treatment feasibility) when setting the MCL as close as feasible to the MCLG. For more information, please see section 4.2.6 of the EPA response in this *Response to Comments* document. Additionally, the WHO has stated, "In light of comments received and to ensure that the latest evidence is taken into account since the background document was drafted, WHO will

continue its review of PFAS. The updated assessment will consider, inter alia, the International Agency for Research on Cancer's (IARC's) carcinogenicity assessment on PFOS and PFOA," (https://www.who.int/teams/environment-climate-change-and-health/water-sanitation-and-health/chemical-hazards-in-drinking-water/per-and-polyfluoroalkyl-substances) indicating that their conclusions are subject to change.

With respect to the how the EPA considered other agencies' (including states') assessments and why the agency's health conclusions may have differed, please see section 4.2.6 of the EPA response in this *Response to Comments* document.

Individual Public Comments

Massachusetts Municipal Association (MMA) (Doc. #1800, SBC-043761)

Impacts of the Proposed NPDWR and Areas of Concern

The EPA's proposed regulation would establish legally enforceable thresholds, or maximum contaminant levels (MCLs), of 4 parts per trillion (ppt) for PFOA and 4 ppt for PFOS. This introduces a much stricter approach than the sum currently being utilized in the Commonwealth, which does not require specific action for one chemical's result unless the 20 ppt threshold is surpassed.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043874)

Regarding treatment, Eps in Pennsylvania would fall into three categories:

(i) Eps where levels of PFOA, PFOS, PFHxS, GenX, PFNA PFBS are below both the state rule MCLs and the proposed HI criteria in the NPDWR. Such systems would not need to implement water treatment under either state or federal regulations.

(ii) Eps with levels of PFOA and PFOS are below the state MCL, but where PFOA, PFOS, PFHxS, GenX, PFNA PFBS levels are above the proposed values in the NPDWR. As noted in the previous section, approximately 700 Eps in the Commonwealth of Pennsylvania are likely to fall into this category. Such systems would need to comply with the proposed federal rule in the same manner and under the same schedule as all other PWSs in the USA that exceed PFAS levels set in the NPDWR. However, they are not disadvantaged by the pre-existing state regulations. Indeed, due to the early availability of the monitoring data, these systems will identify the issues and will be able to plan accordingly.

(iii) EPs with levels of PFOA and/or PFOS that exceed the Pennsylvania MCL rules (and therefore also the proposed NPDWR). These approximately 200 EPs are required to treat the water in accordance with the Pennsylvania PFAS MCL and will have started setting up and

possibly running treatment processes for compliance with the less strict Pennsylvania rule by the time the federal regulations are in place. Some commenters on the Pennsylvania PFAS regulations questioned whether these facilities will be able to address compliance with the more strict NPDWR. However, as clearly stated in the Pennsylvania PFAS MCL rule, that concern is invalid; the PA-DEP expects that "[i]f the EPA's MCLs are more stringent, those PWSs that have installed treatment as required by this final-form rulemaking may need to make relatively minor operational adjustments, such as changing out the media more frequently, but large-scale design changes are not expected." [FN19: 53 Pa.B. 345.] The PFAS treatment methodologies endorsed by the PA-DEP are the ones certified by the EPA for addressing this contamination in drinking water. [FN20: See id. at 368.] These technologies have been tested and determined by the EPA to be capable of removing PFOA, PFOS and other PFAS(including those in the proposed NPDWR) to non-detectable levels [FN21: EPA, Per- and Polyfluoroalkyl Substances, https://tdb.epa.gov/tdb/contaminant?id=11020 (last visited May 24, 2023).] The equipment installed by the approximately 200 Pennsylvania entry points that are required by the Pennsylvania PFAS MCL rule to remove PFAS can therefore comply with the proposed federal requirements with only "minor operational adjustments."

EPA Response: The EPA does not disagree with commenter's classification of entry points in Pennsylvania. The EPA agrees that this regulation will require PFOA and PFOS be treated to lower levels than would have otherwise been required solely by the Pennsylvania drinking water rules. Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. For additional discussion on PFAS treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045954)

Several states and countries have implemented regulatory limitations of certain PFAS that differ significantly with EPA proposed limits. Some examples are Michigan, New Jersey, New Hampshire, Massachusetts, and Vermont, among several others. States must go through rigorous and thorough reviews of the science and data available to propose and finalize PFAS regulation. EPA's proposed MCLs are significantly lower than every state that has regulated PFOA and PFOS by at least half. This discrepancy makes it difficult to communicate whether water treated to these existing state standards is currently safe, and AMWA asks EPA to further explain why these states' cost-benefit analyses supported their respective levels and why EPA's analysis is different. Water systems must be able to explain to ratepayers why they are paying more for water after the implementation of this NPDWR, and having these differences complicates that task.

Other countries, such as Australia and Japan, as well as the United Kingdom (UK) and European Union (EU), have also approved limits on PFAS in drinking water that are higher than those the EPA has proposed. EPA's proposed limits are still much lower than every one of these. These countries have access to the same research that EPA does. In the UK, samples above 10 ppt

require more investigation if actions are needed, while samples over 100 ppt require immediate action [FN2: Drinking Water Inspectorate. (2022, July 7). Water Supply (Water Quality) Regulations 2016 (2018 in Wales) for Poly and Perfluorinated Alkyl Substances (PFAS). https://dwi-content.s3.eu-west-2.amazonaws.com/wp-content/uploads/2023/01/13123351/IL_03-2022_PFAS_Guidance-4-1.pdf.] Japan sets a provisional target of less than 50 ppt for PFOA and PFOS combined [FN3: The Mainichi. (2023 February 4). Japan must grasp full picture of chemical pollution amid PFAS detection.https://mainichi.jp/english/articles/20230204/p2a/00m/0op/008000c#:~:text=Since%202010%2C%20Japan%20has%20also,each%20of%20PFOS%20and%20PFOA.]

Australia similarly sets guidelines at 70 ppt for PFOA and PFOS combined [FN4: Australian Government National Health and Medical Research Council. (2023, April 28). Australian Drinking Water Guidelines. https://www.nhmrc.gov.au/about-us/publications/australian-drinking-water-guidelines.] AMWA supports regulation based on sound science and data and asks EPA to further explain how it came to different conclusions than every other state and country currently addressing PFAS in drinking water.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science and meet the statutory requirements under SDWA. EPA has described, in detail, how it developed the MCLG and what science was used, in section IV of the final rule preamble. The EPA has described, in detail, how it determined the MCL in section V of the final rule preamble. Additional analyses outlined in the support documents used to inform these sections of the preamble go into greater detail; see for example: *Economic Analysis for the Final Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation and Appendices, Framework for Estimating Noncancer Health Risks Associated with Mixtures of Per- and Polyfluoroalkyl Substances (PFAS), Maximum Contaminant Level Goals (MCLGs) for Three Individual Per- and Polyfluoroalkyl Substances (PFAS) and a Mixture of Four PFAS, OW Final Maximum Contaminant Level Goals (MCLGs) for Perfluorooctanoic Acid (PFOA) and Perfluorooctane Sulfonic Acid (PFOS) in Drinking Water, Best Available Technologies and Small System Compliance Technologies for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water, Technical Support Document - Technologies and Cost for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water, and Per- and Polyfluoroalkyl Substances (PFAS) Occurrence & Contaminant Background Support Document for the Final PFAS National Primary Drinking Water Regulation*. Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For additional discussion on PFAS risk communications, please see section 1.2 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046089)

3. EPA's analysis is inconsistent with the approaches taken by states that have been issuing standards.

Several states have conducted their own rulemakings to establish MCLs or similar drinking water standards. None of these states justified standards at the PQL levels proposed by EPA. The most recent state to adopt standards, Pennsylvania, conducted a robust cost/benefit analysis and promulgated MCLs of 14 ppt for PFOA and 18 ppt for PFOS, which are three to five times greater than what EPA is proposing. 53 Pa.B. 333, Jan. 14, 2023; available at: https://www.pacodeandbulletin.gov/Display/pabull?file=/secure/pabulletin/data/vol53/53-2/46.html. EPA's Proposal is inconsistent with the conclusions reached by Pennsylvania and the other states that have established their own MCLs.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science and meet the statutory requirements under SDWA. Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1738, SBC-045954 in section 5.1.5 this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043871)

b. Enacting the proposed PFAS NPDWR in Pennsylvania is technically and economically feasible.

Compliance with the proposed federal PFAS regulations would not only be feasible, but also easier for states like Pennsylvania that already have existing regulations, even if their current regulations are less stringent.

There is a discrepancy between the Commonwealth's Safe Drinking Water PFAS MCL Rule of 2022 and the proposed NPDWR: Pennsylvania set the MCLs for PFOA and PFOS at values much higher than the proposed 4 ppt in the NPDWR (14 ppt and 18 ppt, respectively) [FN11: 53 Pa.B. 362.]. Moreover, the Pennsylvania regulation does not restrict levels of any other PFAS compounds in drinking water.

Similarly, the MCLs set in other states for PFOA and PFOS are higher than the proposed values in the NPDWR (see for example New York [FN12: NY State Health Dep't, Public Water Systems and NYS Drinking Water Standards for PFAS and Other Emerging Contaminants, https://www.health.ny.gov/environmental/water/drinking/Emerging_pfas_publicwater.htm (last updated Oct. 2022).]). In addition, to the best of our knowledge none of the states use the HI approach proposed by the EPA for other PFAS species. Either they set MCLs (see for example Michigan [FN13: Mich. PFAS Action Response Team, Maximum Contaminant Levels (MCLs), https://www.michigan.gov/pfasresponse/drinking-water/mcl (last visited May 24, 2023).]), or they define a maximum for the sum concentrations of several species (for example,

Massachusetts set a maximum of 20 ppt for the sum of PFOS, PFOA, PFHxS, PFNA PFHpA and PFDA [FN14: MassDEP, Per- and Polyfluoroalkyl Substances (PFAS), https://www.mass.gov/info-details/per-and-polyfluoroalkyl-substances-pfas#drinking-water-standards-and-health-information- (last visited May 24, 2023).]).

The differing standards can raise the question of whether the existence of state-level PFAS regulations for drinking water will impede compliance with the proposed federal rule. Indeed, a number of public comments submitted to PA-DEP on the Pennsylvania MCL PFAS rule raised this question. Yet, such concerns are invalid. States where some regulations already exist are better prepared, rather than less, to comply with the proposed NPDWR. As stated in the PA-DEP response in the final Pennsylvania rule:

However, when a final Federal rule is published, the regulations will go into effect 3 years after they are finalized. During this 3-year period, the Department will review the Federal rule and evaluate the supporting documentation to determine how the Federal rule compares to the Department's regulations. If the Federal rule is more stringent, the Department will follow the Commonwealth's rulemaking process to revise its regulation to address any discrepancies and to ensure the Department's regulations meet at least the minimum Federal requirements [FN15: 53 Pa.B. 345 (emphasis added).].

The testing methods required in the Pennsylvania PFAS rule (EPA Method 533, EPA Method 537.1 or EPA Method 537 Version 1.1) are the same as those certified by EPA and noted in the NPDWR. [FN16: Id. at 366; 88 Fed. Reg. 18750.] Tests required by PA-DEP will therefore be applicable for the initial monitoring requirements in the NPDWR [FN17: 88 Fed. Reg. 18683.]. This is also the case in other states where testing is required as part of a PFAS drinking water regulation (e.g. MA, MI, NY, NJ, NH, ME), as well as in states where some testing is required even though no MCLs for drinking water have been set there as yet (e.g. California [FN18: Cal. Water Res. Control Bd., Section on PFAS, Drinking Water Resources, https://www.waterboards.ca.gov/pfas/drinking_water.html (last updated Mar. 1, 2023).]).

EPA Response: The EPA agrees that the MCLs in this PFAS NPDWR are feasible. Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 10 on extensions and exemptions.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045464)

State regulation – The development of the proposed rule needs to consider how the MCLs relate to and affect the patchwork of state drinking water PFAS regulations that have emerged, particularly those that are less stringent.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science and meet the statutory requirements

under SDWA. Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For additional discussion on PFAS risk communications, please see section 1.2 of the EPA response in this *Response to Comments* document.

City of Concord Water Treatment Plant, New Hampshire (Doc. #1499, SBC-042568)

April 14, 2023

United States of America

Environmental Protection Agency

Subject: Proposed PFAS National Primary Drinking Water Regulation

EPA,

New Hampshire (NH) has been at the forefront of PFAS contamination since 2016.

NH established MCLs for PFOA, PFOS, PFHxS and PFNA in 2019. New Hampshire Department of Environmental Services (NHDES) had to consider the extent to which the contaminants are found in NH, the ability to detect them in public water systems, the ability to remove the contaminant from drinking water, and the costs and benefits to affected parties that will result from establishing the standard, and then develop a MCL for each compound that is protective of the most sensitive population at all life stages.

Included with the final rule making process, NHDES provided a summary technical report on the development of the drinking water standards (MCLs) including an explanation of the health risk assessment for each compound and information on cost, benefit, occurrence, and ability to detect and treat these chemicals.

The City of Concord believes that NHDES through its very thorough scientifically based process has set the appropriate MCL for PFOA at 12 ppt, and PFOS at 15 ppt.

We would ask that EPA set the proposed standards at the same limits that NH has established.

Respectfully,

Marco Philippon

Water Treatment Superintendent

Concord Water Treatment Plant

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

Daniel Varon (Doc. #1518, SBC-042723)

I highlight these facts to emphasize the uncertainty behind PFAS, and question whether the proposed regulation if the most efficient means to reduce PFAS containment in humans, or if the high standards proposed by the EPA are too stringent. The proposed MCL is 4.0 ng/L for PFOA and PFOS, and 1.0 ng/L for a combination of PFNA, PFHxS, PFBS, and HFPO-DA on all drinking water sources. [FN16: PFAS National Primary Drinking Water Regulation Rulemaking, 88 Fed. Reg. 60 (proposed Mar. 29, 2023) (to be codified at 40 C.F.R. pt. 141 & 142).] This is a calling for an enforceable minimum of 5% of what the EPA currently suggests is an allowable level. In determining the amount of PFAS in drinking water across the country, the EPA used a threshold amount of 30 ng/L, 20 ng/L, and 90 ng/L for PFHxS, PFNA, and PFBS respectively. Two of which numbers are still below the current EPA recommended level. [FN17: Id.] The EPA then found ranges of detectable PFAS from 0.1% to 38% across different states. [FN18: Id.] This is once again evidence that PFAS do not have an equal impact across the country, and all the reason that a blanket ruling, especially with such a high threshold, could overcorrect the situation and not maximize economic resources. Combine this with the fact that there are other sources of PFAS pollutants, such as food, that may have a large impact on human exposure and yet are not being addressed with this proposed action.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. The agency is clarifying for the commenter that the NPDWR applies to PWSs and does not regulate "all drinking water sources." The commenter incorrectly points out "threshold amounts of 30 ng/L, 20 ng/L, and 90 ng/L for PFHxS, PFNA, and PFBS respectively"; these are not the MCLs that the EPA proposed for regulation nor were they thresholds the EPA evaluated in the EPA's HRRCA.

New Hampshire Water Works Association, Inc. (NHWWA) (Doc. #1576, SBC-042448)

May 25, 2023

Email: Office of Water Dockets: OW-Docket@epa.gov

Comments: https://www.regulations.gov/commenton/EPA-HQ-OW-2022-0114-0027

Mail:

U.S. Environmental Protection Agency

EPA Docket Center

Docket ID: EPA-HQ-OW-2022-0114

Mail Code 28221T

1200 Pennsylvania Ave., NW

Washington, DC 20460

Subject: Docket ID: EPA-HQ-OW-2022-0114; proposed PFAS drinking water standards

Dear EPA Office of Water:

Our Association supports, represents, and advocates for public drinking water systems in New Hampshire. Our sector is committed to providing clean, safe, and affordable public water, using sound science to create practical policies that protect human health. As a national leader in the discovery, definition, regulation, treatment, and funding to reduce threats caused by PFAS chemicals, we are providing important input to EPA's proposed MCLs for six PFAS compounds.

New Hampshire has been at the forefront of this issue in the past decade, having experienced significant contamination issues with firefighting foam at a former airbase on the Seacoast and with a manufacturing facility in Merrimack. The New Hampshire Department of Environmental Services (NHDES) took a pro-active approach with sampling, outreach, community engagement and regulatory action. They have not only had public water systems sample for PFAS but have performed extensive testing of private wells, landfills, and other impacted sites (see where PFAS chemicals are found across the state [Link: https://nhdes.maps.arcgis.com/apps/View/index.html?appid=66770bef141c43a98a445c54a17720e2&extent=-73.5743%2C42.5413%2C-69.6852%2C45.4489]). NHDES requires regulated public water systems to continue monitoring for PFAS, with sampling frequencies based on initial occurrence analysis.

Effective October 1, 2019, NHDES has had science- and health-based, enforceable standards for PFOA (12 parts per trillion; ppt), PFOS (15 ppt), PFNA (11 ppt), and PFHxS (18 ppt). To develop a MCL for each compound protective of the most sensitive population at all life stages NHDES considered: the extent to which the contaminants are found in NH; the ability to detect and quantify PFAS in drinking water; the ability to remove the contaminant from drinking water; and the costs and benefits to affected parties that result from establishing the standard. NHDES provided a summary technical report [Link: https://www.des.nh.gov/sites/g/files/ehbemt341/files/documents/r-wd-19-29-final.pdf] on the MCL development that included a health risk assessment for each compound and information on cost, benefit, occurrence, and ability to detect and treat these chemicals. Based on this thorough and science- and health-based approach, in the state that leads the country in PFAS investigation and remediation, we suggest that EPA set the proposed standards at the same limits that NHDES has established.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

WaterPIO (Doc. #1624, SBC-043472)

The EPA states their proposed MCLs and HI are tied to various studies, but those studies – which were also considered by the states over the years – somehow enabled the EPA to conveniently land where the states didn't, on the absolute lowest levels that public water can accurately test for today. While some would say we can test down to two parts per trillion with certainty, four ppt is where 100% confidence is agreed upon across the Water World. So that's where the EPA set its proposed MCLs.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043396)

2. WHETHER THE PROPOSED MCLS ARE SET AT APPROPRIATE LEVELS

A. EPA's Proposal Is Much More Stringent Than PFAS Values Approved by the World Health Organization and Other Nations

EPA's proposed PFAS MCLs are so low as to raise questions as to their appropriateness considering they appear to be far out of step with than other prominent health agencies such as the following:

• World Health Organization – WHO set a provisional guidance value in September 2022 of 100 ppt for PFOA/PFOS (compared to EPA's MCLs of 4 ppt). WHO had the benefit of EPA's science when it adopted its value. This is a 25-fold difference between two of the world's two preeminent health organizations.

• United Kingdom & European Union – The Europeans have set their PFAS regulatory framework as follows:

<10 ppt = no issue; 10 - 100 ppt = research; and >100 ppt = action required.

• Australia – This nation set a standard of PFOS plus PFHxS at <70 ppt and PFOA <560 ppt (2022).

• Japan – This nation set a standard for PFOS plus PFOA of <50 ppt.

These dramatic differences between and among EPA and other respected health organizations (much higher levels approved by the others) warrant consideration by EPA, including in connection with the health-based phased implementation approach we suggest below.

MAMWA is also concerned that adopting such low levels as MCLs will send a message to millions of Americans that their water is not safe to drink.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. For additional discussion on risk communications, please see section 1.2 of the EPA response in this *Response to Comments* document. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044906)

Several states and countries have implemented regulation of certain PFAS, with PFOA and PFOS commonly targeted. Some examples are Michigan, New Jersey, New Hampshire, Massachusetts, Vermont and several others. States also must go through rigorous and thorough reviews of the science and data available to propose and finalize PFAS regulation. EPA's proposed MCLs are significantly lower than every state that has regulated PFOA and PFOS by at least half. This makes it difficult to communicate whether water treated to these existing state standards is currently safe. Cleveland Water asks EPA to further explain why these states' cost-benefit analyses supported their respective levels and why EPA's analysis is different. Water systems need to be able to explain to ratepayers why they are paying more for water, and having these discrepancies does not make that an easy task.

Other countries, such as Australia, Japan, and the United Kingdom (UK) as well as the European Union (EU) have also approved limits on PFAS in drinking water. EPA's analysis is still much lower than every one of these. These countries have access to the same research that EPA does. In the UK, samples above 10 ppt require more investigation to determine if actions are needed, while samples over 100 ppt require immediate action [FN2: https://dwi-content.s3.eu-west-2.amazonaws.com/wp-content/uploads/2023/01/13123351/IL_032022_PFAS_Guidance-4-1.pdf]. Japan sets a provisional target of less than 50 ppt for PFOA and PFOS combined [FN3: https://mainichi.jp/english/articles/20230204/p2a/00m/0op/008000c#:~:text=Since%202010%2C%20Japan%20has%20also,each%20of%20PFOS%20and%20PFOA]. Australia similarly set guidelines at 70 ppt for PFOA and PFOS combined [FN4: https://www.nhmrc.gov.au/about-us/publications/australian-drinking-water-guidelines]. Cleveland Water supports regulation based on sound science and data and asks EPA to further explain how it came to different conclusions than every other state and country currently addressing PFAS in drinking water.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

Arlington County Virginia (Doc. #1603, SBC-043005)

Our concerns, detailed in the following paragraphs can be summarized as:

1. The proposed enforceable Maximum Contaminant Level (MCL) is imprudent

EPA Response: Please see the EPA response to comment Doc. #1603, SBC-043009 in section 5.1.5 in this *Response to Comments* document.

Arlington County Virginia (Doc. #1603, SBC-043009)

Proposed MCL Level

The proposed regulatory levels for the 6 PFAS compounds in drinking water are far more stringent than respected international health organizations and are orders of magnitude below levels which are observed in other exposure pathways.

The World Health Organization in September of 2022 set a provisional guidance value of 100 ppt for PFOA & PFAS, a value 25 times higher than the EPA's proposed MCL. The European Union and UK have established a regulatory framework of 100 ppt mandating response, with levels below 10 ppt deemed non-issues. Australia and Japan have likewise established limits that are substantially higher than the EPA's proposed 4 ppt.

Further, PFAS has been widely reported in organic pasta sauce at levels 5,000 times the proposed regulatory limit, plus similar or higher level in many common food packaging materials. Similarly, sampling of interior dust consistently finds levels of PFAS several orders of magnitude higher than the level proposed in drinking water.

There is currently insufficient science to understand the relative importance of various ingestion paths such as inhalation, food consumption, drinking water, and transdermal methods. However, the available science indicates that the concentrations of PFAS in dust, food and food packaging, and household products are several orders of magnitude greater than the levels proposed for drinking water.

By setting regulatory limits drastically below those of respected international health agencies and magnitudes lower than what consumers are exposed to in their environments, the proposed regulation will lead consumers to develop a misleading sense of the exposure and risks associated with PFAS from drinking water. Such confusion will serve to undermine confidence in public drinking water systems, which are recognized as pillars of public health.

EPA Response: The agency disagrees that the regulation "will lead consumers to develop a misleading sense of the exposure and risks associated with PFAS from drinking water." The MCLs promulgated in this NPDWR will establish national-level regulations for six PFAS in drinking water that are reflective of the best available, peer-reviewed science and supporting studies (please see section 5.1.5 of the EPA response in this *Response to Comments* document for additional discussion on considerations for international and state drinking water standards and guidelines). For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

Fairfax Water (Doc. #1789, SBC-045295)

Risk Communication Challenges

EPA proposes MCL's for PFOA and PFOS that are lower than levels established by any state to date. They are also lower than proposed guidance from the European Union and the World Health Organization. All of these bodies have conducted their own rigorous analysis of scientific studies on potential health impacts of these compounds. It will be challenging for utilities to explain to the public the incremental health benefits provided by EPA's proposed standards relative to the lowest of the existing state standards, and further to explain the capital intensive treatment required to meet that marginally lower MCL. This will be particularly true for utilities that have already made capital investments as a result of a previously established state drinking water regulation for PFAS.

EPA Response: For additional discussion on considerations for international and state drinking water standards and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. For additional discussion on risk communications, please see section 1.2 of the EPA response in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044660)

VIII. EPA is out of step with other health organizations around the world who have evaluated PFAS health issues.

As we noted at the outset, our members seek to serve the public in an affordable and cost-effective manner. We don't try to avoid necessary and appropriate requirements. To the contrary, we embrace them and prioritize them within our other infrastructure and operational requirements. However, EPA's proposed PFAS MCLs are so low that they give us pause – especially as we consider the fact that PFAS levels in our environment (and bodies) have been dropping dramatically and will plummet further given the intense focus on ending the use of these chemicals.

With this perspective, we are troubled that EPA's criteria are so much lower than other prominent health agencies. For example, the World Health Organization set a provisional guidance value in September 2022 of 100 ppt for PFOA/PFOS and 500 ppt for all other PFAS. WHO had the benefit of EPA's science when it adopted criteria five orders of magnitude higher for PFOA and four orders of magnitude for PFOS. This is an incredible difference between the world's two preeminent world health organizations.

WHO has not been alone in its repudiation of EPA's interim health advisory levels and now proposed MCLs. For example:

• The United Kingdom and European Union set their PFAS regulatory framework as follows:

<10ppt = no issue;

< 100ppt = research; and

>100ppt = action required.

• Australia set a standard of PFOS + PFHxS at < 70ppt and PFOA a < 560ppt (2022).

• Japan's standard for PFOS+PFOA is < 50 ppt.

• Canada's Guidelines for Canadian Drinking Water Quality, released in September 2022, show 600 ppt for PFOS and 200 ppt for PFOA. The application guidelines indicate the sum of PFOS and PFOA should not exceed 200 ppt. This remains much higher than the EPA proposal.

These are dramatic and, potentially, unprecedented differences between the PFAS standards of prominent health organizations and EPA's, which warrant significant caution on EPA's part. These differences also support our suggested phased implementation approach.

EPA Response: For discussion on considerations for international and state drinking water standards and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1816, SBC-044682 in section 5.1.3 this *Response to Comments* document.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044638)

VIII. EPA is out of step with other health organizations around the world who have evaluated PFAS health issues.

As we noted at the outset, our members seek to serve the public in an affordable and cost-effective manner. We don't try to avoid necessary and appropriate requirements. To the contrary, we embrace them and prioritize them within our other infrastructure and operational requirements. However, EPA's proposed PFAS MCLs are so low that they give us pause – especially as we consider the fact that PFAS levels in our environment (and bodies) have been dropping dramatically and will plummet further given the intense focus on ending the use of these chemicals.

With this perspective, we are troubled that EPA's criteria are so much lower than other prominent health agencies. For example, the World Health Organization set a provisional guidance value in September 2022 of 100 ppt for PFOA/PFOS and 500 ppt for all other PFAS. WHO had the benefit of EPA's science when it adopted criteria five orders of magnitude higher for PFOA and four orders of magnitude for PFOS. Westport Harbor Water Association (Doc. #2855, SBC-047295)

The limits as set for our system are a hardship and we ask that the limits remain at the 20 parts per trillion for smaller systems that serve less than 500 people as set by the Massachusetts DEP. We also question the cost per lives saved as estimated by the EPA for the entire program. Our engineers and testing laboratory find the proposed limits as onerous to even measure on an accurate basis nor have we found any reasonable information as to harm caused by low levels of PFAS/PFOS.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. For additional discussion on alternative regulatory standards (including higher PFOA and PFOS MCLs), please see section 5.1.3 of the EPA response in this *Response to Comments* document. Please also see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043161)

2. WHETHER THE PROPOSED MCLS ARE SET AT APPROPRIATE LEVELS

A. EPA's Proposal Is Much More Stringent Than PFAS Values Approved by the World Health Organization and Other Nations

EPA's proposed PFAS MCLs are so low as to raise questions as to their appropriateness considering they appear to be far out of step with than other prominent health agencies such as the following:

• World Health Organization – WHO set a provisional guidance value in September 2022 of 100 ppt for PFOA/PFOS (compared to EPA's MCLs of 4 ppt). WHO had the benefit of EPA's science when it adopted its value. This is a 25-fold difference between two of the world's two preeminent health organizations.

• United Kingdom & European Union – The Europeans have set their PFAS regulatory framework as follows:

<10 ppt = no issue;

10 - 100 ppt = research; and >100 ppt = action required.

• Australia – This nation set a standard of PFOS plus PFHxS at <70 ppt and PFOA <560 ppt (2022).

• Japan – This nation set a standard for PFOS plus PFOA of <50 ppt.

These dramatic differences between and among EPA and other respected health organizations (much higher levels approved by the others) warrant consideration by EPA, including in connection with the health-based phased implementation approach we suggest below.

VMDWA is also concerned that adopting such low levels as MCLs will send a message to millions of Americans that their water is not safe to drink.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. For additional discussion on risk communications, please see section 1.2 of the EPA response in this *Response to Comments* document. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation.

David Dow (Doc. #2631, SBC-046603)

I am Dr. David Dow from East Falmouth, Ma. For over 30 years I have been engaged in the Superfund/Safe Drinking Water Act cleanup at Joint Base Cape Cod. In recent times the Air Force Civil Engineer Center added the Ma. DEP PFAS6 to the toxic contaminants of concern. This state mcl requires that the sum of 6 PFAS chemicals can't exceed 20 ng/l. The proposed EPA mcl contains many of the same isomers, but has different criteria for implementation which I don't fully understand. Recently EPA sought public comments under CERCLA to add additional PFAS chemicals for regulatory oversight.

The Fire Training Area-1 plume underlies the Yearling Meadows development where I reside and pollutes groundwater in Falmouth and Mashpee. This has required Granular Activated Carbon Filters on Public Drinking Water Wells in the two Cape Cod towns. The sources of the FTA-1 plume include the former fire training area and water/sediments of Ashumet and Johns Ponds. In addition, a PFAS6 plume from a former Massa. Army National Guard Training Range threatens Well #2 on the Upper Cape Water Supply Reserve (which lies on the northern 15,000 acres at JBCC). A recent EPA Region1 study of the UCWSR reported toxic chemical threats from the Massa. Army National Guard's proposed Multi-purpose Machine Gun Range. Falmouth and Sandwich receive public drinking water from the UCWSR as a replacement for Town Public Drinking Water Wells which had to be shut down because of JBCC Superfund plumes.

Given this situation, I wanted to know whether the EPA PFAS mcl was more protective of public health for sensitive populations than Ma. DEP's PFAS6 mcl. In addition, since JBCC and the local Mashpee Wampanoag Tribe appear on the Masaa. Executive Office of Energy & Environmental Affairs Environmental Justice Population maps, how will the proposed EPA mcl address these EJ concerns for drinking water and consumption of fish from the kettle hole ponds adjacent to JBCC which are contaminated at unsafe levels for sensitive populations (according to Massa. Dept of Public Health) ? EPA's Region1 Safe Drinking Water Act Branch explores toxic threats to the UCWSR, while its Superfund Branch deals the AFCEC cleanup of PFAS pollution sources and off base plumes. Ma. DEP has a similar complex regulatory approach which creates confusion amongst the concerned public and activists (some of whom I advise). Since the JBCC cleanup is being conducted under CERCLA/SDWA, which PFAS chemicals will be regulated by EPA Region 1 ?

It is hard for me to see the big picture solution strategy in addressing our local PFAS drinking water challenges

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. The EPA acknowledges that some states, like Massachusetts, have established drinking water regulations for some PFAS prior to the PFAS NPDWR proposal. At the time of submission of this comment, the agency notes that PFAS NPDWR was a proposal for public comment. As such, the proposal did not require any actions for drinking water systems at that time and as such, a comparison of public health protection for sensitive populations cannot be ascertained. When the final NPDWR goes into effect, states will be required to have a standard that is no less strict than the NPDWR. For environmental justice considerations and the EPA's consultation with Indian Tribal governments for the final NPDWR, please see sections 14.10 and 14.6 of the EPA response in this *Response to Comments* document, respectively. The agency further notes that CERCLA actions are beyond the scope of the current rulemaking; please see section 15.1 of the EPA response in this *Response to Comments* document for further information. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation.

Association of State and Territorial Solid Waste Management Officials (ASTSWMO) (Doc. #1583, SBC-042399)

Consistency with State Standards: More than a dozen States have promulgated groundwater and drinking water protection standards for one or more PFAS. Some State standards use a similar "hazard index" approach for combinations of PFAS and regulate PFAS not included in the proposed MCLGs. EPA should confirm that the proposed federal MCLGs do not affect the applicability of State standards, in the context of their use as "Applicable or Relevant and Appropriate Requirements" (ARARs) in CERCLA cleanups.

EPA Response: The EPA notes that application of MCLs in non-drinking water programs (such as water quality criteria, NPDES, or Applicable, or Relevant and Appropriate Requirements for CERCLA cleanups) is beyond the scope of this rulemaking; please see section 15.1 for additional discussion on comments outside the scope of this NPDWR. Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

Pennsylvania Chamber of Business and Industry (Doc. #1592, SBC-042793)

417 Walnut Street

717 255-3252 / 800 225-7224 FAX 717 255-3298 www.pachamber.org

VIA ELECTRONIC FILING

The Honorable Michael Regan, Administrator

May 26, 2023

Environmental Protection Agency

1200 Pennsylvania Avenue, NW

Washington, DC 20460

RE: Proposed PFAS National Drinking Water Regulation (Docket ID: EPA-HQ-OW2022-0114)

Dear Administrator Regan,

On behalf of the Pennsylvania Chamber of Business and Industry, the largest, broad-based business advocacy organization in the Commonwealth, thank you for the opportunity to present comments with respect to the United States Environmental Protection Agency's (EPA) proposed National Primary Drinking Water Regulation for six PFAS compounds: PFOA, PFNA, HFPODA, PFHxS, and PFBS.

The PA Chamber represents nearly 10,000 members of all sizes and industry sectors. The PA Chamber and our members recognize that the development, use and stewardship of the water resources are essential to the health, success and vitality of every community, industry and enterprise. With that recognition, we understand that stewardship of our water resources requires a delicate, but essential, balancing of environmental and economic considerations.

With this in mind, we respectfully offer the following comments for your consideration.

1. EPA Should Recognize the Substantial Challenge a Federal Approach Will Present to Industry in States that Have Already Established an MCL for These Compounds

On January 14, 2023 the Pennsylvania Department of Environmental Protection published a final rulemaking establishing state drinking water maximum contaminant levels for PFOA at 14 ng/L and PFOS at 18 ng/L. These MCL's were established after an extensive, multi-year statewide sampling across hundreds of drinking water sources in the state, and, importantly, after a multiyear regulatory development process that, per state law, requires a demonstration that the regulation is effective with respect to costs and benefits. A federal MCL beneath these levels will, by our state environmental regulator's own evaluation, result in costs in excess of benefits for the state. Further, a federal MCL that is more stringent than Pennsylvania's will also result in significant challenges for the disposal of PFAS compounds, as well as challenges for industry with stormwater and discharge permits and the remediation and reuse of industrial sites. Such challenges will impede the stated policy goals of the administration and Congress to reshore and expand domestic manufacturing.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document.

For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Millie Garcia-Serrano (Doc. #1803, SBC-044287)

3. Consistency with State Standards: More than a dozen States have promulgated groundwater and drinking water protection standards for one or more PFAS. Some State standards use a similar "hazard index" approach for combinations of PFAS and regulate PFAS not included in the proposed MCLGs. EPA should confirm that the proposed federal MCLGs do not affect the applicability of State standards, in the context of their use as "Applicable or Relevant and Appropriate Requirements" (ARARs) in CERCLA cleanups.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. For additional discussion on cost considerations for the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document. The EPA further notes that application of MCLs in non-drinking water contexts (such as

Applicable, or Relevant and Appropriate Requirements under CERCLA) are beyond the scope of this rulemaking.

U.S. Poultry & Egg Association et al. (Doc. #1765, SBC-044547)

3. EPA has not appropriately addressed the inconsistent messaging regarding PFAS human health risks across EPA program offices, other U.S. federal agencies, state agencies, and international agencies.

Chemical-specific toxicity information developed by EPA is often used not only across agency program offices, but also by other federal and state agencies. In fact, beginning with the initial EPA Risk Assessment Guidance for Superfund, agency guidance recommends selecting toxicity criteria based on the most recent data (USEPA 1989, p. 7-15). This recommendation has since been implemented in numerous EPA directives (USEPA 1993, 2003) that further establish a hierarchy and process for selecting toxicity criteria, all of which rely on the most recent and peer-reviewed source of information. It may be considered by some that the technical support documentation for the proposed MCLs represents the "most recent" assessment by the agency, and peer-review by the Science Advisory Board allows these values to be used across federal and state government agencies. Therefore, it is imperative that the Office of Water consider such additional applications of the toxicity information supporting its proposed drinking water regulations. Specifically, the oral noncancer toxicity values (reference doses, or RfDs) and cancer toxicity values (cancer slope factors or CSFs) for PFOA and PFOS are likely to be incorporated into the Regional Screening Level tables for CERCLA, and may be considered for wastewater discharge, effluent limitation guidelines or National Pollutant Discharge Elimination System permits. Additionally, many state-level remediation, property redevelopment, stormwater, and wastewater programs rely on toxicity information from EPA. The agency needs to clarify how the underlying toxicity information developed as supporting information for the proposed MCLs should and should not be used by other U.S EPA program offices and related state agencies. For public drinking water, states will be required to establish standards that are as strict as the federal regulations. It is not clear how other agencies and programs will incorporate this information.

In addition to EPA, several other federal agencies have authority over statues governing public health, such as the Food and Drug Administration (FDA), U.S. Department of Agriculture (USDA), and the Centers for Disease Control and Prevention (CDC). Statements made by EPA regarding human health risks associated with exposure to PFOA and PFOS present inconsistencies with current positions by some of these agencies. It is not clear how EPA has coordinated its potential PFOA/PFOS risk information across the federal agencies. The deliberations during interagency review should be more transparent to the public. For example, when the FDA finds a detectable level of PFAS in the food supply, the agency conducts an assessment to evaluate whether the level detected presents a possible human health concern and warrants further FDA action. Currently, the FDA is using toxicity information from a mix of the Agency for Toxic Substances and Disease Registry (ATSDR) and EPA [FN3:

https://www.fda.gov/food/process-contaminants-food/testing-food-pfas-and-assessing-dietary-exposure]. Based on information from these sources, the FDA has made public determinations that extremely low levels of certain PFAS detected in food items does not present a risk to public health. However, EPA states in the agency's public FAQ document that "there is no level of these contaminants that is without a risk of adverse health effect." (Proposed PFAS National Primary Drinking Water Regulation FAQ for Drinking Water Primacy Agencies, p. 3). EPA must clarify that its specific statements apply to assumptions related to drinking water exposure and the agency must work with other federal agencies to ensure consistent and science-based messaging.

EPA has not taken into consideration the unintended consequences of such stringent and inconsistent messaging regarding potential human health risks associated with PFOA and PFOS. In addition to other U.S. federal agencies, EPA's position regarding health risks associated with PFAS is inconsistent with other international authoritative bodies, including Health and Environment Canada, Australia Department of Health, Food Standards Australia New Zealand, and the United Kingdom Committee on Toxicity [FN4: See the International portion of the ITRC PFAS "Water Table" factsheet found here: https://pfas-1.itrcweb.org/fact-sheets/]. The substantial inconsistency in human health risk estimates may pose significant problems when it comes to the import and export of items such as food commodities. This has economic implications and presents challenges for global companies with respect to corporate policies and risk management strategies. EPA needs to explicitly consider the implications related to inconsistencies within the public health and regulatory agencies within the U.S. and worldwide. Coordination across federal and state regulatory and public health agencies, and consideration of global impacts, has either not occurred or has not been transparent to the public.

EPA Response: Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see sections 5.1.5 and 4.2.6 of the EPA response in this *Response to Comments* document. The EPA notes that applications of MCLs (or the toxicity assessments that underpin the MCLGs promulgated in this NPDWR) in non-drinking water contexts or other agency programs is beyond the scope of this rulemaking. Regarding the coordination with other Federal Agencies on PFAS, EPA participates in the cross government IPC convened by the Council of Environmental Quality to share information and collaborate on new policy strategies to support research, remediation, and removal of PFAS in communities across the nation. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For additional discussion on PFAS risk communications, please see section 1.2 of the EPA response in this *Response to Comments* document. Regarding commenter concerns with any potential economic implications and challenges to the "import and export of items such as food commodities", any such concerns is not relevant to the EPA's determination that its MCLs met applicable SDWA requirements.

5.1.6 Considerations for Future Science

Summary of Major Public Comments and EPA Responses

Many commenters express concern with "MCLs changing over time" in light of new science and updated information (e.g., improvements in analytical methods, toxicity and/or future occurrence information including UCMR 5) and some contend that the EPA should "review and reduce" the MCLs as science improves. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science and meet the requirements of SDWA. The EPA agrees with commenters that the agency should periodically review promulgated standards. The EPA is required to review NPDWRs every six years and determine which, if any, need to be revised (i.e., the Six-Year Review Process). The purpose of the review is to evaluate current information for regulated contaminants and to determine if there is any new information on health effects, treatment technologies, analytical methods, occurrence and exposure, implementation and/or other factors that provides a health or technical basis to support a regulatory revision that will improve or strengthen public health protection. This process allows the agency to consider these and other information as appropriate in deciding whether existing NPDWRs should be identified as candidates for revision as required SDWA. For additional discussion on MCLGs, please see section 4 of the EPA response in this *Response to Comments* document; for additional discussion on occurrence, please see section 6 of the EPA response in this *Response to Comments* document; and for additional discussion on analytical methods, please see section 7 of the EPA response in this *Response to Comments* document.

Individual Public Comments

A. O. Smith Corporation (Doc. #1674, SBC-043694)

The Company does appreciate that acting on high concentration levels of PFAS chemicals in the nation's drinking water is critically important and a matter of public health. As the EPA is aware, many States acted under the color of their own authority to regulate PFAS in their drinking water systems prior to the EPA's proposed PFAS NPDWS. Some of those states overlap with the drinking water sampling data that was provided to the EPA as part of its analysis. These states and their respective PFAS MCLs include the following:

[Table: See Docket ID EPA-HQ-OW-2022-0114-1674]

Recognizing that the MCLs established by these states, as well as others, including some that were in development prior to the EPA issuing its proposed PFAS NPDWS, were all promulgated through a combination of legislative and regulatory processes. Those processes, among other things, examined medical literature, toxicological reports, state-based occurrence data, and the technical and cost feasibly of their public water systems to treat drinking water supplies to and none found an MCL at 4 ppt for PFOA and PFOS to be justified. Therefore, while the Company is not in a position to empirically state what the appropriate MCL level for PFOA and PFOS should be at this time, it would recommend that the EPA reconsider setting its value at 4 ppt

taking into consideration the dearth of health-effect data analyzing long-term human exposure at 4 ppt in drinking water and the pending review of UCMR5 occurrence data, which will assist in a potential revision of the cost-effectiveness analysis of setting the MCL at 4 ppt. [FN12: The Company recognizes that the EPA examined a 5 and 10 ppt option for the MCL, which may be more appropriate, but given the lack of toxicology analysis at these levels in humans for long exposure periods as well as occurrence data, the Company still cannot empirically state these are more appropriate levels than those independently promulgated by Maine, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont.]

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document. The EPA's record for this action supports finalizing the MCLs for PFOA and PFOS at 4.0 ng/L. However, because of supply chain and labor challenges that may affect the compliance timeline, the agency has promulgated a two-year extension of the compliance date for the MCLs. See section 12.1 of the EPA response in this *Response to Comments* document for further information. The EPA currently has sufficient data and information to promulgate standards for the PFAS regulated through this NPDWR and is not required under the statute to wait for another round of UCMR data to be collected before finalizing the regulation. Nonetheless, based on public comment and interest, the agency considered UCMR 5 data released as of July 2023 (USEPA, 2024l). While these data were not available for this rule's proposal and not a basis for informing the agency's decisions for the final rule, the EPA notes that they generally confirm the extensive occurrence analyses the agency has conducted: namely, that all six regulated PFAS occur in finished drinking water and that the six regulated PFAS co-occur with one another. For additional details, please see the *Occurrence Technical Support Document* (USEPA, 2024a) and section 6.8 of the EPA response in this *Response to Comments* document.

Richard Gelderman (Doc. #2820, SBC-047330)

2) There is no safe level of exposure to PFOA or PFOS. For that reason, the EPA must review and reduce the maximum contaminant level (MCL) for PFOA and PFOS as testing technologies advance.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Nancy Bouldin (Doc. #2822, SBC-047471)

Dear Assistant Administrator Fox,

I live in Monroe County in southern WV, where we are blessed with clean headwater streams, but significant karst terrain that makes our public and private drinking water sources highly vulnerable to surface contaminants.

Regarding EPA's proposed National Primary Drinking Water Regulation for six per- and polyfluoroalkyl substances (PFAS), I support the EPA's proposal to set strong, science-based drinking water standards and commend the EPA's recognition that both individual PFAS and chemical mixtures of PFAS threaten human health.

My husband grew up in Charleston and when I first went there in the 1970s, the Kanawha River and air were both polluted. Things seemed to improve but now are sliding back as the silent problems of PFAs have made their way into WV waters across the state. This is a critical and long overdue step to protect our public health.

I urge the EPA to consider the following comments to strengthen the proposed rule to further protect and prioritize public health:

1. As recognized by the EPA, there is no safe level of exposure to PFOA or PFOS. For that reason, the EPA must review and reduce the maximum contaminant level (MCL) for PFOA and PFOS as testing technologies advance.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Melda Clark (Doc. #2823, SBC-047473)

Dear Assistant Administrator Fox,

WV has very little clean drinking water. What is left of drinkable water in WV needs protection. MVP is also after WV. They own Land air and water straight through the middle of our state. MVP has 201 injection wells on the eastern side of Braxton County WV. Our water is greatly at risk. 5 million GALs of clean water, turns to fracked water with no one wanting the cancer causing waste. Don't let WV hold the waste of natural gas. Stop MVP and others from polluting our water .

Thank you for the opportunity to comment on the EPA's proposed National Primary Drinking Water Regulation for six per- and polyfluoroalkyl substances (PFAS). I support the EPA's proposal to set strong, science-based drinking water standards and commend the EPA's recognition that both individual PFAS and chemical mixtures of PFAS threaten human health. PFAS-contaminated water has harmed the health of West Virginians for decades; this is a critical and long overdue step to protect our public health.

I urge the EPA to consider the following comments to strengthen the proposed rule to further protect and prioritize public health:

1. As recognized by the EPA, there is no safe level of exposure to PFOA or PFOS. For that reason, the EPA must review and reduce the maximum contaminant level (MCL) for PFOA and PFOS as testing technologies advance.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Karen Valentine (Doc. #2834, SBC-047475)

Dear Assistant Administrator Fox,

Thank you for the opportunity to comment on the EPA's proposed National Primary Drinking Water Regulation for six per- and polyfluoroalkyl substances (PFAS). I support the EPA's proposal to set strong, science-based drinking water standards and commend the EPA's recognition that both individual PFAS and chemical mixtures of PFAS threaten human health. PFAS-contaminated water has harmed the health of West Virginians for decades; this is a critical and long overdue step to protect our public health.

I urge the EPA to consider the following comments to strengthen the proposed rule to further protect and prioritize public health:

1. As recognized by the EPA, there is no safe level of exposure to PFOA or PFOS. For that reason, the EPA must review and reduce the maximum contaminant level (MCL) for PFOA and PFOS as testing technologies advance.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Monty Fowler (Doc. #2836, SBC-047477)

Dear Assistant Administrator Fox,

I support the EPA's proposal to set strong, science-based drinking water standards and commend the EPA's recognition that both individual PFAS and chemical mixtures of PFAS threaten human health. PFAS-contaminated water has harmed the health of West Virginians for decades; this is a critical and long overdue step to protect our public health.

I urge the EPA to consider the following comments to strengthen the proposed rule to further protect and prioritize public health:

1. As recognized by the EPA, there is no safe level of exposure to PFOA or PFOS. For that reason, the EPA must review and reduce the maximum contaminant level (MCL) for PFOA and PFOS as testing technologies advance.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Steven Cole (Doc. #2837, SBC-047479)

Dear Assistant Administrator Fox,

Thank you for the opportunity to comment on the EPA's proposed National Primary Drinking Water Regulation for six per- and polyfluoroalkyl substances (PFAS). I support the EPA's proposal to set strong, science-based drinking water standards and commend the EPA's recognition that both individual PFAS and chemical mixtures of PFAS threaten human health. PFAS-contaminated water has harmed the health of West Virginians for decades; this is a critical and long overdue step to protect our public health.

I urge the EPA to consider the following comments to strengthen the proposed rule to further protect and prioritize public health:

1. As recognized by the EPA, there is no safe level of exposure to PFOA or PFOS. For that reason, the EPA must review and reduce the maximum contaminant level (MCL) for PFOA and PFOS as testing technologies advance.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

John Doyle (Doc. #2840, SBC-047481)

Dear Assistant Administrator Fox,

Thank you for the opportunity to comment on the EPA's proposed National Primary Drinking Water Regulation for six per- and polyfluoroalkyl substances (PFAS). I support the EPA's proposal to set strong, science-based drinking water standards and commend the EPA's recognition that both individual PFAS and chemical mixtures of PFAS threaten human health. PFAS-contaminated water has harmed the health of West Virginians for decades; this is a critical and long overdue step to protect our public health.

I urge the EPA to consider the following comments to strengthen the proposed rule to further protect and prioritize public health:

1. As recognized by the EPA, there is no safe level of exposure to PFOA or PFOS. For that reason, the EPA must review and reduce the maximum contaminant level (MCL) for PFOA and PFOS as testing technologies advance.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Laurine Yates (Doc. #2900, SBC-047483)

Dear Assistant Administrator Fox,

Thank you for the opportunity to comment on the EPA's proposed National Primary Drinking Water Regulation for six per- and polyfluoroalkyl substances (PFAS). I support the EPA's proposal to set strong, science-based drinking water standards and commend the EPA's recognition that both individual PFAS and chemical mixtures of PFAS threaten human health.

PFAS-contaminated water has harmed the health of West Virginians for decades; this is a critical and long overdue step to protect our public health.

I urge the EPA to consider the following comments to strengthen the proposed rule to further protect and prioritize public health:

1. As recognized by the EPA, there is no safe level of exposure to PFOA or PFOS. For that reason, the EPA must review and reduce the maximum contaminant level (MCL) for PFOA and PFOS as testing technologies advance.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Mass comment campaign submitted by Jill Fischer (Doc. #3070, SBC-047485)

Dear Assistant Administrator Fox,

Thank you for the opportunity to comment on the EPA's proposed National Primary Drinking Water Regulation for six per- and polyfluoroalkyl substances (PFAS). I support the EPA's proposal to set strong, science-based drinking water standards and commend the EPA's recognition that both individual PFAS and chemical mixtures of PFAS threaten human health. PFAS-contaminated water has harmed the health of West Virginians for decades; this is a critical and long overdue step to protect our public health.

I urge the EPA to consider the following comments to strengthen the proposed rule to further protect and prioritize public health:

1. As recognized by the EPA, there is no safe level of exposure to PFOA or PFOS. For that reason, the EPA must review and reduce the maximum contaminant level (MCL) for PFOA and PFOS as testing technologies advance.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Wagner Engineering (Doc. #3072-9, SBC-047360)

Is it EPA’s intention to reduce the MCL in the future as testing capabilities improve, and the minimum detection limit decreases? If so, what assurances can EPA provide to the impacted water systems that the technologies being recommended and utilized today will meet future requirements, and not require additional capital expense that will have to be passed on to ratepayers?

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Three Rivers Waterkeeper (3RWK) (Doc. #1689, SBC-044974)

III. 3RWK supports the strong MCLs for PFOS and PFOA, but notes that future developments in testing technology could render an MCL of 4.0 ppt obsolete.

The EPA's proposal to set the Maximum Contaminant Level Goal (MCLG) for PFOS and PFOA at zero is critical to protecting the health of our nation's waterways and the people who rely on them. PFOS and PFOA are already subject to restrictions and bans in a number of State and international jurisdictions due to the strength of the evidence suggesting their association with serious health impacts. 3RWK supports the EPA's decision to set a strong, cautious standard protecting public health.

3RWK believes that the enforceable MCL should be set as close as possible to the unenforceable MCLG. The EPA says that 4.0 ppt is the current limit at which PFOS and PFOA are reliably detectable, and that lower MCLs would likely lead to laboratory capacity issues. However, if there is no safe amount of PFOS and PFOA, then it follows that any detectable amount is unacceptable. As new monitoring technology becomes available and tests become more sensitive, the MCL of 4.0 ppt becomes obsolete. Furthermore, the limit of 4.0 ppt essentially tells communities that if PFAS is detected at the strength that 2023's testing equipment is capable of showing, then they have no recourse, even if they are likely exposed to a harmful concentration of PFAS.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046105)

Despite acknowledging that existing technologies can reduce PFOA and PFOS levels below 4 ppt, EPA proposed a 4 ppt MCL based on those chemicals' practical quantitation levels ("PQL"), or the lowest level that can be detected "by capable analysts at 75 percent or more of the laboratories using a specified analytical method[.]" [FN73: Proposed Rule, 88 Fed. Reg. at 18,666–67.] Because no laboratories can currently measure PFOA or PFOS levels down to the 0 ppt MCLG and not all labs can reliably measure those chemicals below the PQL, "EPA often bases the MCL on the PQL." [FN74: EPA, EPA 810-R-16-002, Development of Estimated Quantitation Levels for the Third Six- Year Review of National Primary Drinking Water Regulations (Chemical Phase Rules), Off. of Water, at 1-3 (Oct. 2016), https://www.epa.gov/sites/default/files/2016- 12/documents/810r16002.pdf.] EPA's latest six-year review of National Primary Drinking Water Treatment Standards identified at least 14

contaminants for which EPA set MCLs based on the PQL, including benzo[a]pyrene, PCBs, and 2,3,7,8-Tetrachlorodibenzo-p-Dioxin. [FN75: Id. at 1-3 – 1-4.] Similarly, setting the PFOA and PFOS MCLs at the PQL is consistent with the SDWA and with EPA's past practice.

As testing technologies advance, however, EPA must review and reduce those MCLs. The SDWA provides that "not less often than every 6 years," EPA must "review and revise, as appropriate, each national primary drinking water regulation promulgated under this subchapter." [FN76: 42 U.S.C. § 300g–1(b)(9).] As EPA acknowledges, laboratory testing capacity "can improve over time," and "the Six-Year Review process is an opportunity to evaluate whether new information . . . shows that PQLs for carcinogens can be reduced, which introduces the possibility of reducing the MCLs[.]" [FN77: EPA, EPA 810-R-16-002, Development of Estimated Quantitation Levels for the Third Six- Year Review of National Primary Drinking Water Regulations (Chemical Phase Rules), at 1-2.] Many labs already have the ability to measure PFOA and PFOS well below the MCLs, and some emerging technologies can detect PFOA, PFOS, GenX, and PFBS in the parts- per-quadrillion range. [FN78: Phenomenex, Achieving Low Parts-per-Quadrillion Detection Limits for PFAS Analysis in Drinking Water (TN-1316), at 1, https://www.phenomenex.com/documents/2022/09/29/17/52/achieving-low-partsperquadrillion- detection-limits-for-pfas-analysis-in-drinking-water-tn1316.] EPA should reassess laboratories' PFOA and PFOS detection capacity during each six-year review period and decrease the MCL whenever new information supports a lower PQL.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see 5.1.2 of the EPA response in this *Response to Comments* document.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043503)

It is also worth noting that the World Health Organization (WHO) has recommended a limit of 100 ppt, individually, of either PFOA or PFOS in drinking water and a total cap of 500 ppt for combinations of up to 30 PFAS. When formulating this limit, the WHO looked at the same basic data that EPA evaluated in crafting this proposed rule—but reached very different conclusions. These guidelines represent the position of the United Nations regarding PFAS in drinking water and are likely to be adopted by many countries around the world. Meanwhile, the EPA has rushed to release proposed MCLs that will be extremely challenging to meet.

Conclusion

We strongly encourage the EPA to reevaluate the proposed MCLs for these six PFAS chemicals to ensure that it is an achievable standard and isn't unnecessarily burdensome to families

nationwide in the form of higher rates and entirely beyond reach – to implement or afford – for rural communities. The challenges that we have outlined in these comments regarding the feasibility of this rule mirror those of the thousands of small, rural drinking water utilities throughout the country. We hope that you will consider our concerns as you continue to work to make our drinking water safer, yet accessible for all American families.

U.S. Poultry & Egg Association

United Egg Producers

EPA Response: The EPA does not believe it is appropriate to use the WHO's approach for determining PFOA and PFOS or other PFAS MCLs because it is inconsistent with the statutory requirements of the SDWA. The language in the SDWA is clear: the EPA must set the MCL as close as feasible to the health-based MCLG. In setting the MCLG, the EPA uses established systematic review practices (USEPA, 2022b) to identify, evaluate, synthesize, integrate, and quantify evidence in a chemical database. These protocols have been repeatedly peer-reviewed and improved upon over time. Other health agencies, including the WHO, do not follow these same practices and, as a result, may arrive at different conclusions. The EPA then considers non-health-based factors (such as analytic and treatment feasibility) when setting the MCL as close as feasible to the MCLG. For more information, please see section 4.2.6 of the EPA response in this *Response to Comments* document. Additionally, the WHO has stated, "In light of comments received and to ensure that the latest evidence is taken into account since the background document was drafted, WHO will continue its review of PFAS. The updated assessment will consider, inter alia, the IARC's carcinogenicity assessment on PFOS and PFOA," (https://www.who.int/teams/environment-climate-change-and-health/water-sanitation-and-health/chemical-hazards-in-drinking-water/per-and-polyfluoroalkyl-substances) indicating that their conclusions are subject to change. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the

requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see 5.1.2 of the EPA response in this *Response to Comments* document.

Illinois Farm Bureau (IFB) (Doc. #1630, SBC-043144)

It is also worth noting that the World Health Organization ("WHO") has recommended a limit of 100 ppt, individually, of either PFOA or PFOS in drinking water and a total cap of 500 ppt for combinations of up to 30 PFAS. When formulating this limit, the WHO looked at the same basic data that EPA evaluated in crafting this proposed rule— but reached very different conclusions. These guidelines represent the position of the United Nations regarding PFAS in drinking water and are likely to be adopted by many countries around the world. Meanwhile, the EPA has rushed to release proposed MCLs that will be extremely challenging to meet.

Conclusion

In light of the uncertain benefits and the economic hardships a new standard would cause to farmers in Illinois, the Illinois Farm Bureau encourages the EPA to continue to reevaluate the proposed MCLs for these six PFAS chemicals.

IFB appreciates your thoughtful consideration of these comments. If you wish to discuss any of these concerns or suggestions, please contact Lauren Lurkins, Director of Environmental Policy, at llurkins@ilfb.org or (309) 557-3153.

Sincerely,

Richard L. Guebert, Jr.

President

Illinois Farm Bureau®

1701 Towanda Avenue

Bloomington, IL 61701-2050

EPA Response: Please see the EPA response to comment Doc. #1642, SBC-043503 in section 5.1.6 in this *Response to Comments* document.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-042767)

Comments by Washington Suburban Sanitary Commission:

Docket ID: EPA-HQ-OW-2022-0114

PFAS National Primary Drinking Water Regulation Rulemaking

1. Maximum Contaminant Levels

Hazard Index approach:

EPA is proposing an MCL for mixtures of PFHxS, HFPO-DA, PFNA, and PFBS expressed as a Hazard Index (HI). WSSC Water is concerned that regulating a group of contaminants in this complex manner will make future compliance incrementally difficult as additional PFAS chemicals that exhibit similar dose-additive health impacts are identified. This approach would practically lower the allowable Health Quotient for individual chemical each time new contaminants are added and regulated in the group. In contrast, under the Stage 2 DBP Rule, EPA successfully regulated a group of co-occurring contaminants by setting an implementable MCL supported by available analytical and treatment technologies. WSSC Water suggests that EPA explore an alternative approach to regulate PFAS chemicals as a class, in a sustainable and consistent manner. We also recognize that developing such a novel approach will require a significant amount of time, and urge that EPA set aside adequate amount of time for soliciting input from stakeholders and experts to ensure the legitimacy of the approach.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document. With respect to the 60-day public comment process and comment period extensions, please see 17.1 of the EPA response in this *Response to Comments* document. For additional discussion on the feasibility of the hazard index MCL, please see section 5.2 of the EPA response in this *Response to Comments* document. For additional discussion on alternative MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Oregon Health Authority (OHA) (Doc. #1582, SBC-042759)

However, OHA encourages EPA to continue research to hopefully incorporate more species of PFAS into this HI class approach as toxicity information becomes available.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Citizens Campaign for the Environment (CCE) (Doc. #1710, SBC-045132)

As technology for water treatment and testing improves, MCL's can and should be strengthened to match MCLG's, thus treating drinking water to a level that is truly safe for consumption.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1711, SBC-044467)

[The Agency's proposal suffers from the following significant shortcomings –]

• The Agency's choice of regulatory alternatives does not provide a reasonable basis for comparison of the possible regulatory approaches.

ACC urges the Agency to withdraw its preliminary regulatory determination and proposed standard for the four PFAS until its has collected additional information on the national occurrence of these substances.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document. The EPA disagrees with commenter that the agency needs to wait for additional information on the national occurrence of these substances in order to finalize the NPDWR at this time. The EPA currently has sufficient data and information to make a regulatory determination for the PFAS regulated through this NPDWR: for additional discussion on the EPA's regulatory determinations, please see section 3; for additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs), 5.1.4 (for treatment considerations) and section 6 (for occurrence) of the EPA response in this *Response to Comments* document.

Environmental Working Group (EWG) (Doc. #1721, SBC-045419)

EPA should periodically update the MCLs and health-based water concentrations as new science emerges and detection methods improve.

SDWA requires that the EPA "shall, not less often than every 6 years, review and revise, as appropriate, each national primary drinking water regulation."[FN86: 42 U.S.C. [sec] 300g–1(b)(9).] As part of this six-year review, and more frequently if needed, the EPA should review both health data and laboratory capacity and adjust the MCLS appropriately.

The EPA proposed the 4 ppt MCL for PFOA and PFOS as the closest feasible MCL to the MCLG of 0 ppt based on the practical quantitation levels ("PQL") for those two PFAS. The PQL is the lowest level detectable "by capable analysts at 75 percent or more of the laboratories using a specified analytical method."[FN87: PFAS National Primary Drinking Water Regulation Rulemaking, 88 Fed. Reg. 18638, 18666 (March 29, 2023).] However, as the EPA acknowledges, "the overwhelming majority of laboratories with the necessary instrumentation to support PFAS monitoring" can detect PFOA and PFOS below the PQL of 4 ppt and "49 out of 54 laboratories seeking EPA approval included a lowest PFAS calibration standard level at 1 ppt or lower."[FN88:Id.]

Because most laboratories can detect PFOA and PFOS well below the PQL it may only be a short matter of time before the PQL is below 4 ppt. Furthermore, many labs can also detect the four HI PFAS at levels well below the HBWCs assigned to each PFAS. We suggest the EPA

reassess the toxicity thresholds for the HBWCs as it prepares the final rule, but also continue to reassess those thresholds as new science emerges and as testing technologies advance.

Furthermore, because so many labs can detect PFAS below the PQLs and HBWCs, utilities should report all measurable detections when monitoring for PFAS. The EPA should not treat detections below the PQL as non-detects, especially when consumers have an interest in knowing about all measurable PFAS detections in their drinking water.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document. For additional discussion on CCRs and reporting of detected values, please see section 9.1 of the EPA response in this *Response to Comments* document. For monitoring and compliance requirements and use of values below the PQL, please see section 8.8 of the EPA response in this *Response to Comments* document. For additional discussion on PQLs, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

West Virginia Rivers Coalition (Doc. #3072-21, SBC-047370)

These MCLs are a necessary step in the work to safeguard public health from PFAS contamination. However, these rules must be adaptive to technology as it advances. The MCLs are currently set at a detectable level, but detection technology will continue to advance throughout the coming years. We need rulemaking that can swiftly evolve alongside advances in science. These MCLs must be regularly reviewed and updated.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

West Virginia Rivers (Doc. #3072-70, SBC-046384)

Thank you for the opportunity to speak this evening. My name is Maria Russo and I am the Clean Water Campaign Coordinator for the West Virginia Rivers Coalition. As we know, PFAS are carcinogens and exposure affects the immune and cardiovascular systems, as well as human development. When exposed over time, PFAS can lead to kidney cancer, pancreatic cancer, and death. I am from the eastern panhandle of West Virginia and it has been proven that my community, people I love, have been exposed to PFAS through contaminated drinking water. In a recent study completed by the United States Geological Survey, in cooperation with the West Virginia Department of Environmental Protection, along with other partners, at least one type of PFAS was detected at levels exceeding health advisories in 130 of our community water systems. My region in the eastern panhandle has some of the highest concentration of PFAS in raw water across the state of West Virginia. Blue Ridge Elementary School, which is less than 10 miles from my house, has PFOA and PFOS levels exceeding 14.8 parts per trillion. It is critical that we start addressing PFAS at the source such as product manufacturing so that we can make our collective work easier in addressing this massive public health issue. The EPA states that it is committed to using and advancing the best available science to tackle PFAS pollution and

protect public health to provide safe drinking water for all. While I recognize the EPA is proposing individual MCLs of 4.0 parts per trillion due to current technology, I urge EPA to continue to revisit those standards frequently as the technology continues to improve. I support the EPA setting the Maximum Contaminant Level Goals, MCLG, for PFOA and PFOS at zero. I hope that we can make that goal of zero a reality. The longer we wait to lower these standards, the longer our communities will continue to be exposed to these life-threatening forever chemicals. Thank you.

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Prince William County Service Authority (Doc. #1609, SBC-042834)

Water Utilities Need a Comprehensive Understanding of the Future PFAS Regulatory Framework to Support Decision Making for Capital Intensive Infrastructure

The drinking water treatment process results in several residual streams including process water from filter backwashes, sediments that are removed from source waters, and spent filter media. Utilities need to have clarity on the entire EPA PFAS regulatory structure, from source water to residuals, to make informed and cost-effective decisions on behalf of their ratepayers. EPA needs to provide clarity on how and when it will regulate sources of PFAS in the environment. There is currently no EPA regulatory mechanism to eliminate a PFAS source in a drinking water supply. EPA should reprioritize its PFAS regulatory focus so that sources are eliminated at the polluter's expense instead of PFAS remediation becoming the financial burden of the public.

The proposed rule states that other PFAS compounds may be added to the proposed HI in the future. EPA also indicates that the MCLs for PFOA and PFOS could be lowered in future regulatory actions. EPA is moving forward with actions such as designating certain PFAS compounds as hazardous waste under CERCLA, which further introduces risk to utility ratepayers. EPA has been considering rules on PFAS in biosolids from wastewater treatment plants .

EPA Response: The EPA's PFAS Strategic Roadmap lays out EPA's whole of agency approach to tackling PFAS. The PFAS Strategic Roadmap describes how EPA will get upstream of the problem and bring deeper focus to preventing PFAS from entering the environment in the first place—a foundational step to reducing the exposure and potential risks of future PFAS contamination. The EPA notes that the other actions to address sources of PFAS are highlighted in the agency's PFAS Strategic Roadmap including the CERCLA hazardous waste designation are beyond the scope of this rulemaking (please see section 15.1 of the EPA response in this *Response to Comments* document for additional information). For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Prince William County Service Authority (Doc. #1609, SBC-042848)

7. Utilities need a comprehensive understanding of EPA's proposed regulatory structure for PFAS from sources of supply to residuals in order to make cost effective decisions and reduce rate impacts to our customers.

The Prince William County Service Authority appreciates the opportunity to comment on EPA's PFAS National Primary Drinking Water Regulation Rulemaking.

Sincerely,

Calvin D. Farr, Jr., P.E.

General Manager/CEO

EPA Response: Please see the EPA response to comment Doc. #1586, SBC-042384 in section 1.3 in this *Response to Comments* document.

Three Rivers Waterkeeper (3RWK) (Doc. #1689, SBC-044977)

V. The scientific understanding of PFAS and the legislative frameworks are in flux, necessitating an approach that can be adapted to changing circumstances.

Indeed, two of 3RWK's criticisms of the Pennsylvania DEP's PFAS regulations were the decision to not propose MCLs for PFAS other than PFOS and PFOA, and the decision to allow for unusually high cumulative MCLs for PFOS and PFOA.

Both government agencies and the industries that rely on PFAS must prepare for the eventual total phasing out of PFAS. The more the health effects of PFAS become clear, and the more we understand these chemicals, the more regulation of certain individual PFAS registers as insufficient. Recent studies for example have shown the importance of accounting for precursor chemicals as well, which are not addressed in this proposed rule. [FN18: Bridger J. Ruyle et al., Centurial Persistence of Forever Chemicals at Military Fire Training Sites, 57 Environmental Science and Technology 8096, 8103-04, May 15, 2023, https://pubs.acs.org/doi/10.1021/acs.est.3c00675. See also Paul Karoff, EPA's New PFAS Rules Don't Account for Major Source of Drinking Water Contamination, Harvard John A. Paulson School of Engineering and Applied Sciences News, May 15, 2023, https://seas.harvard.edu/news/2023/05/epas-new-pfas-rules-dont-account-major-source-drinking-water-contamination.] As mentioned previously, States such as Minnesota are passing increasingly strict PFAS rules, and the international community is pondering the possibility of banning them all. As important as PFAS have been to America's industrial history, there are alternatives that lack the extreme health and environmental impacts. [FN19: Cheryl Hogue, How to Say Goodbye to PFAS, 97 Chemical & Engineering News 47, Nov. 20, 2019, https://cen.acs.org/environment/persistent-pollutants/say-goodbye-PFAS/97/i46#.]

EPA Response: For discussion on how the EPA considers future science, please see section 5.1.6 of the EPA response in this *Response to Comments* document. Regarding considerations for existing state and international PFAS standards, regulations and guidelines, please see section 5.1.5 of the EPA response in this *Response to Comments* document. For additional discussion on regulation of additional PFAS, including PFAS precursors, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

5.1.7 Significant Figure Usage

Summary of Major Public Comments and EPA Responses

The EPA received several comments related to significant figure usage in the rule proposal for MCLs, MCLGs, and HBWCs. Some commenters stated EPA's proposal regarding significant figure usage was unclear and/or displayed inconsistently throughout the proposed rule. The agency clarifies for these commenters that in the rule proposal the agency intended to express the PFOA and PFOS MCLs, as well as the Hazard Index MCLG and MCLs and the respective HBWCs for the four Hazard Index PFAS, to the tenths place in ppt (ng/L) (e.g., 4.0 ppt for PFOA MCL, 1.0 for the Hazard Index MCL and MCLG, and 10 ppt for the PFNA HBWC). In the proposal, the agency specifically requested comment on significant figure use when calculating both the Hazard Index MCLG and MCL using two significant figures (i.e., 1.0). For comments and a discussion on significant figure usage for the Hazard Index MCL and MCLG, HBWCs for the Hazard Index PFAS, and the individual MCLs and MCLGs for PFHxS, PFNA and HFPO-DA, which are all being finalized with one significant figure, please see the final rule preamble section IV.B.1.b and section 4.3.4 of the EPA response in this *Response to Comment*s document.

Commenters asked the EPA to clarify the use of significant figures concerned that results may affect compliance (i.e., RAA) calculations. These commenters note that sample results that are rounded to one versus two significant figures may affect compliance determinations particularly when the MCL is set at the PQL. The EPA agrees that the number of significant figures required and process for mathematical rounding can impact the compliance result but as described below, the agency maintains that it is establishing the most appropriate number based on available information and statutory requirements. For PFOA and PFOS, the EPA is finalizing MCLs using two significant digits. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and will consider implementation topics (such as compliance calculations) as the agency develops implementation materials for the final NPDWR.

For all regulated PFAS, including the individual PFAS MCLs and the Hazard Index MCL, the EPA is finalizing the number of significant figures based on consideration of the precision of the analytical methods for the regulated PFAS and the precision of the underlying parameters used to derive the health-based values (i.e., MCLGs and HBWCs). Furthermore, under SDWA, the agency must set the MCL as close as feasible to the MCLG. EPA guidance states that all MCLs should be expressed in the number of significant digits permitted by the precision and accuracy

of the specified analytical procedure(s) and that data reported should contain the same number of significant digits as the MCL (USEPA, 2000b). Additionally, EPA methods 533 and 537.1, those authorized for use in determining compliance with the final PFAS MCLs, state that "[c]alculations must use all available digits of precision, but final reported concentrations should be rounded to an appropriate number of significant digits (one digit of uncertainty), typically two, and not more than three significant digits" (USEPA, 2009 and USEPA, 2019). Consequently, the EPA has determined that both methods 533 and 537.1 provide sufficient analytical precision to allow for two significant digits for all PFAS analyzed under these methods with the use of two significant digits being the most appropriate number given analytical uncertainty in allowing for more digits.

Specifically, regarding consideration of the derivation of the PFOA and PFOS MCLGs, as previously discussed in section IV of the final rule preamble, the health-based MCLGs for PFOA and PFOS are being finalized as zero because these two PFAS are likely human carcinogens. Based on EPA's MCL feasibility determination under SDWA described in section V.A of the final rule preamble, the MCLs for PFOA and PFOS cannot be set identical to these MCLGs. Therefore, unlike the PFHxS, PFNA, and HFPO-DA MCLs and the Hazard Index MCL where the underlying health information drove the decision for one significant figure for the MCLGs and HBWCs and the MCL must be set as close as feasible to the MCLG (see section IV.B.1.b and section 4.3.4 of the EPA response in this *Response to Comment*s document), the use of two significant figures for the PFOA and PFOS MCLs (i.e., 4.0 ng/L each) is the most appropriate number provided that both the precision of the analytical methods allows for this and this level is as close as feasible to the MCLGs (i.e., use of one significant figure (4 ng/L) would not be as close as feasible to the MCLG). This approach of using two significant figures is also consistent with other MCLs the EPA has set with carcinogenic contaminants with MCLGs of zero, including arsenic and bromate.

Individual Public Comments

PFAS Regulatory Coalition (Doc. #1761, SBC-046093)

The American Petroleum Institute (API) members are concerned that the commercial drinking water analytical laboratories may not have sufficient sensitivity and reporting precision to meet the proposed MCLs, HI, MCLGs, and trigger levels. API retained Environmental Standards, Inc. (Environmental Standard) to survey the commercial analytical laboratories accredited by The NELAC Institute (TNI) to perform PFAS analyses in drinking water utilizing the US EPA Methods 533, 537, and/or 537.1 to understand the analytical sensitivity and reporting precision currently being provided.

2.0 Brief on Environmental Standards

Environmental Standards is a consulting firm founded in 1987. Environmental Standards was acquired by Montrose Environmental Group in 2022. Environmental Standards' specialty consulting offerings include environmental chemistry, geosciences, environmental data

management, emergency response quality assurance oversight, and environmental health and safety auditing support.

Environmental Standards' chemistry staff includes B.S. through Ph.D. Chemists, six national Registry of Certified Chemists – Certified Environmental Analytical Chemists and one American Society of Quality – Certified Quality Auditor.

With respect to Environmental Standards' long rich history in fluorochemistry, our Chemists have been retained by several Future 500 Companies to provide chemistry quality assurance support for their perfluorinated compound (PFC, now PFAS) projects dating back to 2000. These projects have generated tens of thousands of commercial laboratory sample data representing drinking water, groundwater, surface water, wastewater, sediment, soil, tissues, and various other matrices (e.g., articles of commerce, fire debris, windshield washer fluid to name a few).

3.0 Surveyed Laboratories

Environmental Standards utilized the TNI Laboratory Accreditation Management System (LAMS) (https://lams.nelac-institute.org/) to search for environmental laboratories that are accredited to analyze PFAS analytes in drinking water by US EPA Methods 533, 537, and/or 537.1. Environmental Standards identified 51 facilities as being accredited to analyze drinking water for PFAS analytes by US EPA Methods 533, 537, and/or 537.1. Environmental Standards provided a survey to gather information on method detection limits (MDLs), practical quantitation limits (PQLs), lowest calibration standard concentration, and reporting significant figures. Environmental Standards received responses that represent 14 of the 51 facilities.

Environmental Standards noted that even though laboratories have retained TNI accreditation for US EPA Method 537, none of the 14 responding facilities offered this analysis to clients and provided US EPA Method 537.1 analysis instead. Of the 14 responding facilities, 12 of the facilities offer US EPA Method 533 analyses. A listing of the MDLs, PQLs and lowest calibration standard concentration is provided on Table 1.

4.0 Comments on Commercial Laboratory Sensitivity

Environmental Standards evaluated the provided information to understand if the commercial laboratory facilities can provide sufficient sensitivity and reporting precision (e.g., significant figures) to support/meet the proposed MCLs, HI MCLGs, and trigger levels.

Both US EPA Methods 533 and 537.1 indicate the laboratory must establish a minimum reporting level (MRL). The MRL is the lowest analyte concentration that meets data quality objectives and are generally equivalent to the lowest initial calibration standard concentration. US EPA Method 533 Section 12.2 specifies that the laboratory must report only those values that fall between the MRL (i.e., lowest calibration standard concentration) and the highest calibration standard.

Environmental Standards has summarized the MCLs, HBWCs, and trigger levels along with the lowest and highest MDLs, PQLs, and lowest initial calibration standards provided by the responding laboratories on Table 2.

Environmental Standards observed that the laboratory-provided PQLs for PFOA and PFOS were below the proposed MCLs of 4 ppt. However, in all cases, the PQLs reported were higher than the proposed trigger level of 1.3 ppt.

While MDL reporting is not acceptable for Methods 533 and 537.1, one of the laboratories had Method 537.1 MDLs for PFOA and PFOS that were above the proposed trigger level. In addition, Facility 350539 utilized only one significant figure (e.g., 2 ppt) for reporting results < 10 ppt and would not be able to provide sufficient significant figures to report to the proposed trigger level, which requires at least two significant figures (e.g., 1.3 ppt).

Based on the laboratory survey responses, under the current configuration, none of the commercial laboratories that responded will not be able to meet the sensitivity and reporting precision needed to comply with the US EPA-proposed MCL trigger levels. Even if MDL reporting allowed for future reporting, the prospect of reporting estimated data for trigger value compliance purposes is arguably unacceptable by any measure.

As a remedy, the hypothetical lowering of concentration of the lowest initial calibration standard may seem trivial; however, the measurements near the MDL are highly imprecise. As a practical matter, attempts to improve sensitivity of the analysis can be impacted by trace-contaminants in sample containers, reagents, laboratory equipment, and materials. Obtaining a sufficiently clean resource may become a challenge. On a final note, any such alterations to improve sensitivity will increase analytical costs, the number of repeated analysis due to quality control failures and will, accordingly, lengthen the time from sample receipt to reporting.

Published literature, as well as TNI, recommends that PQLs be approximately 3-times the calculated MDL. As such, commercial laboratories may be required to perform and potentially have to manipulate additional MDL studies to rationalize reported lower PQLs. Significant additional time and cost will be required to alter procedures, determine new MDLs. Technically achieving lower MDLs and PQLs will require revised/enhanced support system for sample handling, purchased reagents/standards, and protocols for laboratory equipment decontamination - this all with a currently, severely stressed PFAS analysis capacity issue.

The US EPA individual HBWC for PFHxS, HFPO–DA, PFNA, and PFBS were easily achieved based on the survey responses. The US EPA is proposing a health-based HI MCLG for PFHxS, HFPO–DA, PFNA, and PFBS of 1 (unitless). The proposed HI MCLG utilizes the following equation for the calculation.

HI MCLG = (HFPO-DA/10 ppt) + (PFBS/2000 ppt) + (PFNA/10 ppt) + (PFHxS/9 ppt)

Utilizing the lowest Method 533 or for Method 537.1 PQLs for PFHxS, HFPO–DA, PFNA, and PFBS (see Table 1 and Table 2), the calculated HI MCLG would be 0.600 ppt.

Utilizing the highest Method 533 PQLs for PFHxS, HFPO–DA, PFNA, and PFBS (see Table 1 and Table 2), the calculated HI MCLG would be 0.802 ppt. Utilizing the highest Method 537.1 PQLs for PFHxS, HFPO–DA, PFNA, and PFBS (see Table 1 and Table 2), the calculated HI MCLG would be 1.67 ppt.

The current PQLs for PFHxS, HFPO–DA, PFNA, and PFBS for some of the surveyed laboratories may be sufficiently sensitive to support the proposed HI MCLG; however, Environmental Standards anticipates that other laboratories will be required to adjust instrument calibration to meet reporting expectations based on the survey responses.

5.0 Concluding Statements

The surveyed laboratory responses indicated that the current laboratory sensitivity and reporting precision can meet the US EPA-proposed MCLs for PFOA and PFOS for drinking water. The surveyed laboratory response indicated that the current laboratory sensitivity and reporting precision will not be met by all accredited facilities for the US EPA-proposed trigger levels for PFOA and PFOS.

The surveyed laboratory responses indicated that the current laboratory sensitivity and reporting precision can meet the US EPA-proposed HBWCs for PFHxS, HFPO–DA, PFNA, and PFBS. The surveyed laboratory responses indicated that the current sensitivity demonstrated by the accredited laboratories may not be sufficient to meet the US EPA-proposed HI MCLG for combined PFHxS, HFPO–DA, PFNA, and PFBS.

Environmental Standards noted that Method 533 and 537.1 accredited commercial laboratories will require revised/enhanced support system for sample handling, purchased reagents/standards, and protocols for laboratory equipment decontamination - this all with a currently, severely stressed PFAS analysis capacity issue.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. Specifically pertaining to the commenter's claim that a laboratory would not be able to provide reported values to two significant figures, the agency disagrees because the standards and methods used for the analysis of the regulated PFAS are capable of including at least two significant figures and there is no rationale for not incorporating more than one digit of uncertainty. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA notes that after evaluation of public comment, the NPDWR finalizes rule trigger levels at one-half the MCLs which is different from one-third of the MCLs that the EPA proposed. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. Additionally, the EPA clarifies for the commenter that the Hazard Index MCLG and Hazard Index MCL are both equal to 1 (unitless), not 1 ppt. As the commenter provides and the EPA confirms, laboratories can achieve the PQLs for the Hazard Index PFAS (PFBS, HFPO-DA, PFHxS, and PFNA) which are all at least one-half lower than the respective HBWCs for each of the four PFAS and at least half lower than the respective individual MCLs for PFHxS, PFNA and HFPO-DA; therefore, the Hazard Index MCL and MCLG, as well as the PFHxS, PFNA and HFPO-DA MCL and MCLGs, are feasible. With respect to the EPA's discussion on the validated analytical methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042978)

However, in the case of analytical results the additional significant figure does represent a level of implied precision which has not been demonstrated by laboratories conducting EPA-approved drinking water analytical methods.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042883)

Source Water and Analytical Variability:

Through the years of sampling that has been conducted by Massachusetts PWS, it is not uncommon for different labs to report a difference of several parts per trillion +/- in PFAS when analyzing the exact same source water. We question whether we are pushing the sensitivity of

the equipment to a point where it cannot be reliably quantified. A sample is considered valid at +/-30%. When discussing regulatory compliance levels in the low parts per trillion, this is quite concerning. As a point of illustration, the following are split sample results for a utility in Massachusetts. On a sample date of 12/11/2020, lab A's result was 12.7 ppt, while lab B's result was 20.56 – both were valid results, yet the swing was 7.86 ppt. This analytical variability is well over what EPA proposes as the MCL, so PWS could be subject to noncompliance and enforcement actions due to analytical variability alone. For this reason, we also do not recommend going to two significant figures to determine compliance values. MassDEP was initially going to count values below the Method Reporting Limit toward compliance with the MMCL but dropped that approach in its final rule. We recommend that EPA consider all results below the Practical Quantification Limit be considered 0 ppt.

Some Massachusetts PWS have seen +/- parts per trillion variability in PFOS and PFOA concentrations when collecting monthly samples. Even a 1-2 ppt variation can represent over 40% variability when close to the MDL. It is difficult to tell if this variability is attributable to changes of PFOS and PFOA concentrations in the source water or if it is linked to the variability of the analytical method (+/- 30%). Having a proposed Rule Trigger Level of 1/3 the PFOS and PFOA MCL or Hazard Index may have PWS and primacy agencies fluctuating back and forth on whether the PWS is eligible for a monitoring waiver. These variations may also impact the running annual average calculation. This uncertainty creates unnecessary complexity, increased level of effort, and possible erosion of public confidence. Importantly, the proposed approach to use results below the PQL, which are unreliable with questionable accuracy and not available to all PWSs due to the lab capacity, is inappropriate to determine reduced monitoring eligibility. This sets a precedent for using results that are inaccurate and not equally achievable for driving regulatory decisions. MWWA recommends following the Standard Monitoring Framework (SMF) where all results below the PQL are considered 0 ppt.

We are also aware of several instances where it was found that lab instrumentation was not properly cleaned between sample runs, resulting in erroneous detections. It is paramount that labs are not conducting cross matrix analysis on instruments that analyze drinking water samples.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. With respect to implementation concerns relative to variability around sample results, the agency notes that the commenter is comparing +/- 30 percent QC criteria for accuracy to the evaluation of the precision of two reported results for the same sample analyzed at two separate laboratories. There are numerous factors that may contribute to high or low bias in a measurement result at any individual laboratory, and these factors are not unique to PFAS analysis or exclusive to low level measurement. The EPA further notes that compliance with the MCL is determined by RAAs where an individual sample result will not cause a system to be out of compliance (unless that result is 4x above the MCL in which they are in violation immediately). For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help

operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding laboratory or background contamination considerations, please see section 8.7 of the EPA response in this *Response to Comments* document. The EPA further notes that results below the PQLs will be considered 0 ppt for compliance determination purposes but note the use of results below the PQL can be useful in determining analyte presence/absence. For discussion of rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. For discussion of monitoring waivers, which are not allowed under the final rule, please see section 8.5 of the EPA response in this *Response to Comments* document.

Marlene Ladderbush (Doc. #1612, SBC-042915)

Our experience in Massachusetts has shown that there can be a wide range in results when different labs analyze the same source water. PWS professionals question whether we are pushing the sensitivity of the equipment to a point where it cannot be reliably quantified. A sample is considered valid at +/-30%, when discussing regulatory compliance, or Maximum Contaminant Levels

(MCL), in the low parts per trillion, this is concerning. The analytical variability we routinely see in Massachusetts can be well over what EPA proposes as the MCL so PWS could be subject to noncompliance and enforcement actions due to analytical variability alone. For this reason, EPA should not go to two significant figures to determine compliance values.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1612, SBC-042915 and #1601, SBC-042883 in section 5.1.7 in this *Response to Comments* document with respect to implementation concerns around variability surrounding sample results.

Town of Lincoln Water Department (Doc. #1613, SBC-043027)

Our experience in Massachusetts has shown that there can be a wide range in results when different labs analyze the same source water. PWS professionals question whether we are pushing the sensitivity of the equipment to a point where it cannot be reliably quantified. A sample is considered valid at +/-30%, when discussing regulatory compliance, or Maximum Contaminant Levels (MCL), in the low parts per trillion, this is concerning. The analytical variability we routinely see in Massachusetts can be well over what EPA proposes as the MCL so PWS could be subject to noncompliance and enforcement actions due to analytical variability alone. For this reason, EPA should not go to two significant figures to determine compliance values.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1612, SBC-042915 and Doc. #1601, SBC-042883 in section

5.1.7 in this *Response to Comments* document with respect to implementation concerns around variability surrounding sample results. For additional discussion on the EPA's feasibility analysis with respect to analytic and laboratory considerations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For background PFAS contamination concerns, please see section 9.7 of the EPA response in this *Response to Comments* document.

COMM Water Department (Doc. #1577, SBC-042439)

Our experience in Massachusetts has shown that there can be a wide range in results when different labs analyze the same source water. PWS professionals question whether we are pushing the sensitivity of the equipment to a point where it cannot be reliably quantified. A sample is considered valid at +/-30%, when discussing regulatory compliance, or Maximum Contaminant Levels (MCL), in the low parts per trillion, this is concerning. The analytical variability we routinely see in Massachusetts can be well over what EPA proposes as the MCL so PWS could be subject to noncompliance and enforcement actions due to analytical variability alone. For this reason, EPA should not go to two significant figures to determine compliance values.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1612, SBC-042915 and Doc. #1601, SBC-042883 in section 5.1.7 in this *Response to Comments* document with respect to implementation concerns around variability surrounding sample results. For additional discussion on the EPA's feasibility analysis with respect to analytic and laboratory considerations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For background PFAS contamination concerns, please see section 9.7 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-042519)

Finally, laboratories must be able to show the ability to reliably and consistently report results to two significant figures if the final MCL includes two significant figures. As discussed previously, this has not been demonstrated by at least 75% of the labs nationwide as the UCMR5 MRL was set with one significant figure. The effect of setting the MCL at two significant figures and to four decimal places, instead of one significant figure and to three decimal places, is water systems being out of compliance at 0.0041 µg/L with two significant figures or 0.005 µg/L with one significant figure. For systems with PFAS at these low levels, such a difference due to significant figures could mean a significant difference from a true value that could result in significant expense if they are required to install and maintain treatment.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. Specific to the UCMR 5 MRLs having one significant figure, the agency disagrees with the commenter that for the purposes of determining the MCLs for PFOA and PFOS that two significant figures have not

been demonstrated by at least 75 percent of laboratories nationwide because the UCMR 5 MRLs were determined under a multi-laboratory study which calculated the MRLs for all regulated PFAS to each have more than one significant figure (USEPA, 2020b). However, for the particular application of the UCMR program these MRLs are rounded to one significant figure though the agency notes that data is accepted from laboratories at or above the MRL which would include data at 4.0 ng/L (or 0.0040 ug/L) due to the precision of the methods and laboratory precision. Based on the considerations discussed in the EPA response 5.1.7, this same rounding would not be appropriate. Additionally, the EPA notes the commenter is incorrect in the examples they provide. Using the commenter's example for PFOA or PFOS (assuming an average of four quarterly samples): with one significant figure, a system is exceeding at 0.0045 µg/l and with two significant figures this exceedance occurs at 0.00405 µg/l. The numbers provided are both exceedances but they're not the cut-offs to which you exceed or not exceed. The EPA further notes that compliance with the MCL is determined by RAAs where individual sample results will not cause a system to be out of compliance (unless that result is 4x above the MCL in which they are in violation immediately).

Water Supply District of Acton (Doc. #1662, SBC-043662)

Our experience has shown that there can be a wide range of results when different labs analyze the same source of water. We question whether we are pushing the sensitivity of the equipment to a point where analyte values cannot be reliably quantified. Additionally, the interference of non-drinking water samples being processed on the same equipment at the lab, along with other chemicals and constituents in the water, may cause inaccurate results that overstate the PFAS concentrations in samples. These overstatements cause costly treatment upgrades, premature media replacement, and erosion in the public trust of public water systems. The analytical variability we routinely see in Massachusetts can be well over what EPA is proposing as the MCL. PWS could be subject to noncompliance and enforcement actions due to analytical variability alone. For this reason, EPA should not go to two significant figures to determine compliance values.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1612, SBC-042915 and Doc. #1601, SBC-042883 in section 5.1.7 in this *Response to Comments* document with respect to implementation concerns around variability surrounding sample results. For additional discussion on the EPA's feasibility analysis with respect to analytic and laboratory considerations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For background PFAS contamination concerns, please see section 9.7 of the EPA response in this *Response to Comments* document.

Town of Tewksbury, Massachusetts (Doc. #1637, SBC-043245)

Our experience in Massachusetts has shown that there can be a wide range in results when different labs analyze the same source water. PWS professionals question whether we are

pushing the sensitivity of the equipment to a point where it cannot be reliably quantified. A sample is considered valid at +/-30%, when discussing regulatory compliance, or Maximum Contaminant Levels (MCL), in the low parts per trillion, this is concerning. The analytical variability we routinely see in Massachusetts can be well over what EPA proposes as the MCL so PWS could be subject to noncompliance and enforcement actions due to analytical variability alone. For this reason, EPA should not go to two significant figures to determine compliance values.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. Please also see the EPA response to comment Doc. #1612, SBC-042915 and Doc. #1601, SBC-042883 in section 5.1.7 in this *Response to Comments* document with respect to implementation concerns around variability surrounding sample results. For additional discussion on the EPA's feasibility analysis with respect to analytic and laboratory considerations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For background PFAS contamination concerns, please see section 9.7 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044891)

• DEP has several concerns with laboratory capacity considerations:

o Because there does not appear to be an initial compliance monitoring schedule identified in the proposed rulemaking, systems will likely wait until the last minute to complete their monitoring requirements, which will impact overall lab capacity. Therefore, DEP does not believe that it is safe to assume that lab capacity will be evenly spread out over initial monitoring.

O Because labs will be expected to meet very low reporting limits, the incidence of QA/QC failures will likely increase. This will result in a greater number of samples that will need to be resampled and reanalyzed. This adds to the burden on the laboratory and further reduces its capacity for additional samples.

O Many laboratories hold secondary accreditation in states other than the state in which they primarily conduct business. Those labs with secondary capacity are not able to accurately determine what percentage of their total capacity will be available to their state. This complicates the ability to estimate lab capacity.

O As noted previously, many labs will need to purchase standards in order to meet the significant figures required by the proposed rulemaking. This poses two complicating factors to overall lab capacity. One, the standards are very expensive, and two, there are a limited number of vendors from which to purchase those standards.

O Analysis of overall laboratory capacity needs to consider not only the additional drinking water compliance monitoring samples, but also performance monitoring for additional treatment systems that will be required , and monitoring of other environmental matrices that will likely increase as a result of this proposed rulemaking.

EPA Response: For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. For initial monitoring requirements and timing, please see section 8.1.1 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. With respect to performance monitoring, the EPA anticipates that many water systems will conduct a pilot test before implementing a full-scale treatment installation and that the operational results from the pilot test will be a sufficient indicator of performance; therefore, water systems should not have to collect large amounts of performance samples indefinitely during the full-scale operation of treatment technologies. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for additional details on how these considerations were factored into the EPA's cost estimates.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044889)

Laboratory and Analytical Method Considerations

• Regarding significant figures and decimal places, since the reporting limits are not clearly defined and appear to be missing from the proposed rulemaking, as already noted, DEP cannot comment on the missing information and can only make assumptions and comment on those assumptions. Since the PQLs for PFOA and PFOS and the four PFAS included in the HI have one decimal place (i.e., two significant figures), laboratories will need to be able to report to two decimal places (i.e.#.## ppt). This further means that laboratories will need to be able to read results to three decimal places. Labs will likely need to purchase the appropriate standards in order to meet the required number of significant figures, since they are not likely to be able to make their own standards. DEP notes that availability of standards for purchase, and the availability of vendors to supply those standards, are likely to be a limiting factor in laboratories' ability to read to this level.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. The EPA also clarifies for the commenter that it does include information in the proposed rule 40 CFR141.902(9) on the levels that regulated PFAS must be reported. The EPA also disagrees with the commentor regarding the necessity of laboratories to purchase "the appropriate standards in order to meet the required number of significant figures, since they are not likely to be able to make their own standards." A fundamental responsibility of any analytical chemist is to accurately perform appropriate dilutions of certified reference standard solutions when following an analytical test method to measure ppt levels of PFAS.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043710)

The proposed rule uses two significant figures for PFOA, PFOS and for the HI MCLs and MCLGs. Aurora Water suggests the use of one significant figure for PFOA, PFOS and HI MCLs and MCLGs.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044362)

• EPA requests comment on significant figure use when calculating both the HI MCLG and the MCL. EPA has set the HI MCLG and MCL using two significant figures (i.e., 1.0). EPA requests comment on the proposed use of two significant figures for the MCLG when considering underlying health information and for the MCL when considering the precision of the analytical methods (pg. 18666 Federal Register Volume 88, Number 60).

O Based on the PQLs promulgated by EPA for PFOA and PFOS, it is not appropriate to use two significant figures for an MCL that is set at the PQL (e.g., the proposed MCL for PFOA would be 4.0 ppt with a PQL of 4.0 ppt). The PQLs set by EPA indicates that the order of magnitude at which laboratories can produce measurements with adequate precision is at the ppt level. Therefore, significant figures at orders of magnitude below the ppt level cannot be reliably determined by analytical methods and should not be reported or used in compliance determinations. Compliance determinations are made based on averages of those measurements that are compared to the MCL. Averages of measurements cannot have significant figures at orders of magnitude lower than the least precise measurement. Therefore, the measurements and the averages calculated from them cannot be produced with sufficient precision for the MCL and MCLG to have significant figures below the ppt level.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis with respect to analytic and laboratory considerations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. With respect to the use of values below the PQL for the purposes of compliance determinations, see section 8.2 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044363)

o Additionally, EPA should reconsider the significant figures used in the PQLs for these contaminants. As discussed above, a PQL of 4.0 ppt for PFOA and PFOS is inappropriate and should rather be 4 ppt.

o However, if there is much greater and widespread precision in laboratory measurement capabilities than the PWL would suggest, EPA should consider revising the PQLs and providing

a comparative analysis of how the use of one or two significant figures for the HI MCLG and the MCLs would impact costs and public health protection associated with the new rules. Without such a comparative analysis, the commenters are unable to provide adequate feedback on the benefits or drawbacks of using two significant figures for the HI MCLG and the MCLs.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis with respect to analytic and laboratory considerations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. With respect to the use of values below the PQL for the purposes of compliance determinations, see section 8.2 of the EPA response in this *Response to Comments* document. Finally, the agency considered a reasonable range of regulatory alternatives and disagrees that an analysis of one or two significant figures for the Hazard Index MCLG is needed to provide adequate feedback on the MCLs. The number of significant figures for the MCLG is based on the analytical precision of the method(s) as well as the magnitude of precision of the underlying health values used to inform the MCLG. The MCLs are then set as close a feasible to the MCLGs considering the analytical precision of the method(s). Thus, a comparative analysis of costs and public health protection is not a part of the determination of significant figures but rather that is considered in the cost-benefit analysis of the regulatory standard. Please see section 13 and section 5.1.3 of the EPA response in this *Response to Comments* document for additional discussion.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044092)

ASDWA recommends that EPA revise the use of significant figures to ensure accuracy and consistency throughout the proposed rule.

The proposed rule uses inconsistent significant figures for the proposed MCLs. For example, the footnote in the table at 141.50(b) states correctly that the HBWC for HFPO-DA is 10.0 ppt, but the formula used for the Hazard Index in that same footnote uses 10. This inconsistency continues for PFBS and PFNA. EPA should ensure that all references to the MCLs use the correct number of significant figures. ASDWA's members have also noted this issue in EPA's presentations and fact sheets. EPA should ensure that all materials the Agency releases use the correct number of significant figures.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044179)

2. NCDEQ recommends that EPA revise the use of significant figures to ensure accuracy and consistency throughout the proposed rule.

The proposed rule uses an inconsistent number of significant figures for the proposed MCLs. For example, the footnote in the table at 141.50(b) states correctly that the health-based water concentration (HBWC) for HFPO-DA is 10.0 ppt, but the formula used for the hazard index in that same footnote uses 10. This inconsistency continues for PFBS and PFNA. EPA should ensure that all references to the MCLs use the correct number of significant figures. Additionally, this same issue has been found in EPA's presentations and fact sheets. EPA should ensure that all materials the Agency releases use the correct number of significant figures.

EPA Response: Regarding usage of significant figures for the final NPDWR, please see section 5.1.7 of the EPA response in this *Response to Comments* document.

5.2 PFAS Hazard Index: PFHxS, HFPO-DA, PFNA, and PFBS

5.2.1 General

Summary of Major Public Comments and EPA Responses

The EPA received many comments supporting the use of the Hazard Index approach and regulation of additional PFAS. Consistent with these comments, through this action, the agency is establishing drinking water standards for PFHxS, PFNA, HFPO-DA, and PFBS (as well as PFOA and PFOS) to provide health protection against these contaminants found in drinking water. The EPA considered PFAS health effects information, evidence supporting dose additive health concerns from co-occurring PFAS, as well as national and state data for the levels of multiple PFAS in finished drinking water.

Several commenters disagreed that the EPA's determination to set the MCL for the Hazard Index PFAS at the same level as the MCLG reflects what is feasible. Some of these commenters assert that technologies to remove the Hazard Index PFAS are not the same as those that effectively remove PFOA and PFOS. A couple of commenters were concerned that meeting the Hazard Index MCL may require more frequent media change-outs (e.g., GAC), thereby increasing operating costs such that the Hazard Index MCL of 1 is not feasible. The agency disagrees with these commenters that the BATs do not support the conclusion that those BATs could treat to at or below the Hazard Index MCL based on the history of full-scale use as documented in the BAT/SSCT document, the information in the proposed and final rule preambles, as well as in the comments that provided full-scale data as well as case studies. The best available treatment technologies available for PFOA and PFOS are the same for the PFAS regulated through the Hazard Index: all of the BATs (described in more detail in section 10 of the EPA response in this *Response to Comments* document and in the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water;* USEPA, 2024e) have all been demonstrated to be effective in removing all six PFAS finalized for regulation as part of this rulemaking albeit to differing degrees. Additionally, the process integration for all BATs is similar. As described above in 5.1 of this section, the agency similarly considered feasibility as defined by SDWA for PFHxS, PFNA, HFPO-DA, individually and for mixtures of these three PFAS and PFBS. First, the EPA established a Hazard Index MCLG as a Hazard Index of 1 for

mixtures of two or more of PFHxS, PFNA, HFPO-DA, and PFBS. As part of setting the Hazard Index MCLG, the agency defined an HBWC for PFHxS, PFNA, HFPO-DA, and PFBS used in the calculation (see discussion in section IV of the final rule preamble). The EPA does agree that several site-specific factors will dictate the appropriate strategy for treatment and recommends pilot testing to aid in determining the best solution for a given location. The EPA further acknowledge that external factors such as limited space may dictate a different treatment train than the optimal engineering approach. For additional discussion on best available treatment technologies, please see USEPA (2024e). In considering the feasibility of setting the MCLs as close as feasible to the MCLG, the EPA first evaluated the (1) the availability of analytical methods to reliably quantify levels of the contaminants in drinking water and (2) the lowest levels at which contaminants can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions using the approved methods (i.e., the PQLs). The EPA determined that there are available analytical methods approved to quantify levels below these HBWC levels. In addition, the PQLs for PFHxS, PFNA, HFPO-DA, and PFBS (between 3.0 to 5.0 ng/L) are all lower than the respective HBWCs used in setting the Hazard Index MCLG for each of these PFAS (10 ng/L for PFHxS, PFNA, and PFHxS, and 2000 ng/L for PFBS). Thus, the PQLs are not a limiting factor in determining the MCL. Second, the EPA evaluated the availability and performance of BATs for treating water to minimize the presence of these contaminants consistent with the MCLGs (see section X of the final rule preamble and section 10 of the EPA response in this *Response to Comments* document for additional discussion on BATs) as well as the costs of applying those BATs to large metropolitan water systems when treating to that level. The EPA has found the same technologies identified for PFOA and PFOS are also both available and have reliably demonstrated PFAS removal efficiencies that may exceed >99 percent and can achieve concentrations less than the proposed Hazard Index MCL for mixtures of two or more of PFHxS, PFNA, HFPO-DA, and PFBS, and that the cost of applying those technologies is reasonable for large metropolitan water systems. For contaminants where the MCLG is higher than the PQL, the EPA sets the MCL at the MCLG if treatment is otherwise feasible because the PQL is not a limiting factor. In consideration of the availability of feasible treatment technologies, approved analytical methods to reliably quantify levels of the contaminants in drinking water, the EPA's cost analysis, and the fact that the PQLs are below the HBWCs used in setting the Hazard Index MCLG, the agency determines that setting the MCL at the same level as the MCLG for mixtures of PFHxS, PFNA, HFPO-DA and PFBS is feasible. Thus, the EPA is setting the Hazard Index MCL of 1 for mixtures of PFHxS, PFNA, HFPO-DA, and/or PFBS. For additional discussion and considerations surrounding BATs, please see section X.A of the final rule preamble and section 10 of the EPA response in this *Response to Comments* document. For more information about the EPA's cost estimates, please see section XII of the final rule preamble and 13.3 of the EPA response in this *Response to Comments* document.

The EPA notes additional detailed responses on the following topics as it relates to feasibility of the MCL within this section of the EPA response in this *Response to Comments* document: For additional discussion on feasibility with respect to laboratory capacity, capability, or other

analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. With respect to comments related to practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. With respect to cost considerations when setting the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis as it relates to treatment considerations, please see section 5.1.4 of the EPA response in this *Response to Comments* document.

The agency also disagrees with commenters that the Hazard Index does not set a "level" as contemplated by the statute and that the Hazard Index approach is inconsistent with the SDWA mandate that MCLs be only as close as feasible to the MCLG. The statute does not dictate that the MCLG take a particular form; however, it must represent a "level" that meets the MCLG statutory definition. Given that the MCL must be "as close as feasible" to the MCLG, and that the MCL is defined as the "maximum permissible level of a contaminant in water which is delivered to any user of a public water system," the MCLG can take any form so long as it is a maximum level of a contaminant in water. SDWA defines an MCL as "the maximum permissible level of a contaminant in water which is delivered to any user of a public water system." Like the MCLG, SDWA does not dictate that the MCL take a particular form; however, given this definition, an MCL establishes a "maximum permissible level of a contaminant in water" and as a practical matter the identified "level" must be capable of being validated so that it can be determined whether that PWSs are delivering water to any user meeting or exceeding that "level." The EPA's MCL of 1 establish a "maximum permissible level of contaminant in water" because it is a limit for a mixture with PFAS components that must be met before the water enters the distribution system. PWSs use their monitoring results as inputs into the Hazard Index equation to determine whether they are delivering water to any user that meets the MCL.

Many commenters support excluding PFOA and PFOS from the Hazard Index MCL. The EPA agrees with these commenters as there are analytical limitations that would complicate including PFOA and PFOS in the Hazard Index. As discussed in section IV of the final rule preamble of the Hazard Index approach, individual PFAS hazard quotients (HQs) are calculated by dividing the measured concentration of each component PFAS in water (e.g., expressed as ng/L) by the corresponding HBWC for each component PFAS (e.g., expressed as ng/L). The HBWC is akin to an MCLG in that they reflect a level below which there are no known or anticipated adverse effects over a lifetime of exposure, including for sensitive populations and life stages, allowing an adequate margin of safety. Since PFOA and PFOS are likely human carcinogens, the MCLG (and if included in the Hazard Index, the HBWC) for each contaminant is zero. The only feasible way to represent PFOA and PFOS in the Hazard Index approach would be to only consider values for PFOA and PFOS at or above the PQL of 4.0 ng/L, however the level at which no known or anticipated adverse effects on the health of persons would occur is zero, which is well below the PQL. The Hazard Index is intended to capture the aggregate risks of the Hazard Index PFAS in a mixture when the monitored concentration of each mixture component is above the

PQL but below the HBWC. These risks are not relevant to mixtures with PFOA and PFOS given their PQLs. Because of the PQL considerations discussed in the preceding section V.A of the final rule preamble and section 5.1 of the EPA response in this *Response to Comments* document, the EPA is not including PFOA and PFOS in the final rule Hazard Index. Therefore, the EPA is finalizing individual MCLs for PFOA and PFOS but not including these contaminants in the Hazard Index addressing mixtures.

A few commenters provided feedback on the EPA's request for comment regarding the usage of significant figures to express the MCLs. See discussion on this issue in section 4.3.4 of the EPA response in this *Response to Comments* document. In summary, after considering public comment, the EPA agrees that one (1) significant digit is appropriate for the individual PFAS for PFHxS, PFNA and HFPO-DA (i.e., 10 rather than 10.0), and Hazard Index MCL (i.e., 1 rather than 1.0). For additional discussion on significant figure usage, please see section 4.3.4 and 5.1.7 of the EPA response in this *Response to Comments* document.

Some commenters asked about inclusion of other PFAS in the NPDWR (such as including in the Hazard Index) in future revisions. Although this final rule only addresses mixtures of the four PFAS, the agency believes the Hazard Index approach can be an adaptive and flexible framework for considering additional PFAS. As discussed above, the EPA is required to review NPDWRs every six years and determine which, if any, need to be revised (i.e., the Six-Year Review Process). The purpose of the review is to evaluate current information for regulated contaminants and to determine if there is any new information on health effects, treatment technologies, analytical methods, occurrence and exposure, implementation and/or other factors that provides a health or technical basis to support a regulatory revision that will improve or strengthen public health protection. This process allows the agency to consider these and other information as appropriate in deciding whether existing NPDWRs should be identified as candidates for revision as required by SDWA. The EPA notes that SDWA specifies a process that the agency follows to identify and list unregulated contaminants that may lead to the development of a NPDWR in the future. This listing currently includes PFAS as a structural class. Additionally, the EPA anticipates that the completed UCMR 5 dataset will be informative for considering potential future regulatory action regarding the 23 additional UCMR 5 PFAS that are not directly included in this final rule. The CCL listing and UCMR5 monitoring results may inform whether EPA should initiate a rulemaking process to develop an NPDWR for any specific contaminant in the future.

To understand the totality of national-level cost impacts for the Hazard Index MCL, the EPA considered both the contribution of PFHxS (estimated as part of the national level cost analysis), as well as the costs for PFNA, HFPO-DA, and PFBS (estimated in the Appendix N sensitivity analysis). Together, these provide information on the costs for the Hazard Index MCL and the individual MCLs for PFHxS, PFNA, and HFPO-DA, as a whole. Please see sections 5.1.2 and 13.3 of the EPA response in this *Response to Comments* document for additional discussion. Additionally, for more information on the agency's methodology, findings, and limitations of the

EPA's updated analysis of costs associated with compliance with the Hazard Index, please see Appendix N.3 of the EA (USEPA, 2024c).

Individual Public Comments

WaterPIO (Doc. #1624, SBC-043460)

Founded in 2017, WaterPIO is a public communications firm dedicated to helping water and wastewater utilities of all sizes improve their customer, media, and crisis communications. The company is now helping water providers in more than a dozen states, including several who called on us following discoveries of PFAS compounds in their drinking water. WaterPIO has conducted PFAS-related public communications in North Carolina, South Carolina, Georgia, Alabama, Illinois, Kentucky, Tennessee, Virginia, Ohio, Indiana, West Virginia, New York, Pennsylvania, Maryland, and Vermont.

After working as a DC-based national and local news producer for a decade, WaterPIO's President Mike McGill has led public communications for water utilities for 16 years. Before creating WaterPIO, he served as the former chief spokesperson for what is now WSSCWater and the former Chief Communications Officer for the Cape Fear Public Utility Authority (CFPUA), the water provider at the heart of the GenX discovery made during the mid-to-late 2010s.

During McGill's time at CFPUA, his counsel to notify the public about the results of Dr. Detlef Knappe's groundbreaking study – which CFPUA had fully cooperated with while McGill worked for the organization – went unheeded by its General Manager at the time. As a result, when the Wilmington StarNews report titled, "Toxin Taints CFPUA Drinking Water" hit the public space, CFPUA's reputation with its customers instantly hit an all- time low. McGill was re-hired to appear live on local newscasts, write op-eds, and develop public education campaigns to help the utility explain its PFAS-related actions.

News organizations from across the country came to Wilmington with the belief that it had become the next Flint, Michigan, a city with undrinkable tap water. Fortunately, thanks to the actions taken after the article, the Cape Fear Region did not get permanently tagged with such a distinction. And now, thanks to new management, an empowered staff, and a $43 million granular activated carbon project, CFPUA is fast becoming the drinking water industry's example of what to do when faced with a significant PFAS discovery.

CFPUA's roller-coaster of a response is a proper place to start for our comment because it clearly shows the years of reputation-related challenges PFAS discoveries can create for public water systems. CFPUA's failure wasn't due to the work of its employees; they had actually helped Dr. Knappe find the GenX in the Cape Fear River. The failure was due to their poor reaction to the initial discovery and horrific public communication-related decisions.

This comment is written more in an op-ed style because we work with leading water organizations who are making the scientific arguments far better than we can. What our comment hopes to achieve is a greater understanding of the impacts the EPA's proposed

Maximum Contaminant Levels (MCLs) and Hazard Index will have on the public after thousands of water systems across the country receive almost-certain notices of violations.

Simply put, what EPA is proposing is no less than the end of the nation's confidence in its drinking water. This is not hyperbole. This is fact. The public will never look at their tap water the same way again.

Based on our experience working with public water systems across the country that have been impacted by PFAS discoveries, WaterPIO believes the EPA's proposed MCLs and Hazard Index pose no less than eight, nearly impossible challenges for service providers, even if they don't have any PFAS detections in their drinking water:

1. The proposed MCLs were set at the lowest confirmable levels when the science on their impact on public health at numbers that low is not settled. In addition, the first-time use of a convoluted Hazard Index for drinking water will be difficult for water systems to meet and nearly impossible to explain to the public.

EPA Response: The commenter provides a claim that the regulation will be "no less than the end of the nation's confidence in its drinking water." The EPA finds the opposite to be true: promulgating a nationwide NPDWR will reduce exposures to these compounds which may cause harmful human health effects. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. The agency also disagrees that the "proposed MCLs were set at the lowest confirmable levels when the science on their impact on public health at numbers that low is not settled." The science is clear on PFAS human health effects based on the weight of evidence reviewed by the agency in promulgating the health-based MCLGs; please see section 4 for more information. Additionally, the MCLs (for PFOA and PFOS) are set at their practical quantitation limits and the MCLs for the Hazard Index PFAS includes individual HBWCs that are well above their respective PQLs. For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. Please also see section 5.1.2 of the EPA response in this *Response to Comments* document for more information on PQLs, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations. Regarding risk communication concerns. The EPA notes that after finalization of the PFAS NPDWR, the EPA intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation; please see section 1.2 of the EPA response in this *Response to Comments* document for more information.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-053343)

The Hazard Index approach is inconsistent with SDWA because it sets a limitation on a group of chemicals rather than the individual chemicals, and it does not set a "level" as contemplated by

the statute. The Hazard Index approach is not a "level" at all—it is a sum of component HQs, calculated by dividing the measured regulated PFAS component contaminant concentration in water by the associated health-based water concentration. A sum of those quotients greater than 1 constitutes an exceedance of the MCL. EPA thus transforms the typical MCL or MCLG into a complex mathematical equation that leaves uncertainty regarding compliance, absent additional efforts to measure, calculate, and combine fractions of each individual contaminant. Indeed, the Hazard Index is a highly variable equation that can change over time as inputs change (as the health-based water concentration may change).

This approach is also inconsistent with the SDWA mandate that MCLs be only as close as feasible to the MCLG [FN63: 42 U.S.C. [sec] 300g-1(b)(4)(B).]. Under the Hazard Index approach, it would be impossible to fulfill this requirement as the proposed MCL and MCLGs have the same unitless value [FN64: This novel approach to calculating a Hazard Index for a mixture of chemicals is not a treatment technique authorized by SDWA. See 42 U.S.C. [sec] 300g-1(b)(7)(A).].

EPA Response: The EPA disagrees that the Hazard Index is "inconsistent with SDWA because it sets a limitation on a group of chemicals rather than the individual chemicals." Section 1401(6) defines the term ''contaminant'' to mean ''any physical, chemical or biological or radiological substance or matter in water.'' A mixture of two or more ''contaminants'' qualifies as a ''contaminant'' because the mixture itself is ''any physical, chemical or biological or radiological substance or matter in water.'' Additionally, SDWA 1401(3) defines the term "maximum contaminant level" to mean "the maximum permissible level of a *contaminant* in water which is delivered to any user of a public water system" (emphasis added). Therefore, the Hazard Index approach, which captures mixtures of two or more of PFHxS, PFNA, HFPO-DA and PFBS, constitutes as a contaminant and a MCL with Hazard Index value of 1 sets the maximum permissible level of that contaminant.

The agency also disagrees that the Hazard Index does not set a "level" as contemplated by the statute and that the Hazard Index approach is inconsistent with the SDWA mandate that MCLs be only as close as feasible to the MCLG. The statute does not dictate that the MCLG take a particular form; however, it must represent a "level" that meets the MCLG statutory definition. Given that the MCL must be "as close as feasible" to the MCLG, and that the MCL is defined as the "maximum permissible level of a contaminant in water which is delivered to any user of a public water system," the MCLG can take any form so long as it is a maximum level of a contaminant in water. SDWA defines an MCL as "the maximum permissible level of a contaminant in water which is delivered to any user of a public water system." Like the MCLG, SDWA does not dictate that the MCL take a particular form; however, given this definition, an MCL establishes a "maximum permissible level of a contaminant in water" and as a practical matter the identified "level" must be capable of being validated so that it can be determined whether that PWSs are delivering water to any user meeting or exceeding that "level." The EPA's MCL of 1 establish a "maximum permissible level of contaminant in water" because it is a limit for a mixture with PFAS components that must be met before the water enters the

distribution system. PWSs use their monitoring results as inputs into the Hazard Index equation to determine whether they are delivering water to any user that meets the MCL.

The agency also disagrees that dividing an exposure metric over a health metric constitutes a "complex mathematical equation." This calculation is also not mathematically different (i.e., summing up numbers and dividing) than a RAA calculation which is used frequently for compliance calculations for NPDWRs. Regardless, to assist in the calculation of these values, the agency is developing a calculator tool to easily determine your hazard index result. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. With respect to responses that the Hazard Index reflects a "variable equation that can change over time as inputs change," the EPA notes that the MCL is not variable. The inputs (i.e., exposure concentration) varies but that is analogous to any other NPDWRs regulated by an MCL where concentrations can change over time. Nonetheless, the MCL will be 1 unless or until the NPDWR changes. The agency is required to review NPDWRs every six years and determine which, if any, need to be revised. This review (i.e., the Six-Year Review Process) is not unique to this PFAS NPDWR. For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's regulatory determination for mixtures of PFAS, please see section 3.2 of the EPA response in this *Response to Comments* document. For additional discussion on the Hazard Index MCLG, please see section 4 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045898)

C. The Hazard Index approach is inconsistent with SDWA's statutory requirements for setting MCLs

For each contaminant that EPA determines to regulate, it must either issue an MCL or, "if it is not economically or technologically feasible to so ascertain the level of such contaminant," use a treatment technique [FN59: 42 U.S.C. [sec] 300g-1(b)(7)(A).]. The novel Hazard Index approach is neither an MCL nor a treatment technique. Therefore, EPA's use of this approach to regulate PFNA, PFBS, HFPO-DA, and PFHxS violates SDWA.

1. SDWA contemplates setting individual levels for each contaminant

The term "maximum contaminant level" means "the maximum permissible level of a contaminant in water which is delivered to any user of a public water system." [FN60: 42 U.S.C. [sec] 300f(3).] Notably, SDWA contemplates setting MCLs and MCLGs for each contaminant [FN61: 42 U.S.C. [sec] 300g-1(b)(E) ("For each contaminant that the Administrator determines to regulate under subparagraph (B), the Administrator shall publish maximum contaminant level goals and promulgate, by rule, national primary drinking water regulations under this subsection." (emphasis added)). See also City of Portland, Oregon v. EPA, 507 F.3d 706 (D.C. Cir. 2007): "[The SDWA] requires EPA to set a 'maximum contaminant level goal' (MCLG) for

each identified contaminant at a level at which no known adverse health consequences will occur" (emphasis added).] individually and with a specific level so that regulated entities can understand the levels that must be achieved for compliance. In this proposal, EPA proposes an MCL and MCLG for PFNA, PFHxS, PFBS, and HFPO-DA as a mixture and uses a Hazard Index approach rather than a specific concentration level (ppm or ppt). SDWA does not contemplate setting MCLs for a mixture, let alone using a complex equation. The term "mixture" appears only twice in the statute, and it is related to drinking water studies of complex mixtures [FN62: 42 U.S.C. [sec] 300j-18(b)(3).]. The statutory text thus reflects that Congress never intended for EPA to regulate mixtures of contaminants, rather than the individual contaminants themselves, using MCLs.

EPA Response: With respect to responses regarding why the EPA can use the Hazard Index to calculate an MCL/MCLG under SDWA, please see the EPA response to comment Doc. #1713, SBC-053343 in section 5.2.1 in this *Response to Comments* document. A mixture is a "contaminant" for purposes of the statute (please see section 3.2 of the *Response to Comments* document for additional discussion). The definition of a contaminant does not specify that a contaminant is only a singular chemical. The SDWA definition is very broad, specifically stating that a contaminant is "*any* physical, chemical or biological or radiological substance or matter" (emphasis added), with no specific description or requirement for how it is formed. Matter for example, by definition, is comprised of either pure substances or mixtures of pure substances. A pure substance is either an element or compound, which would include "any PFAS chemical. The statute encompasses "matter" which is a broad term that includes mixtures and therefore definitionally includes PFAS mixtures, comprised of a combination of PFAS (chemical substances), as itself qualifying as a "contaminant" under SDWA. Moreover, other provisions of the statute, would be restricted in a manner inconsistent with Congressional intent if the EPA were to adopt the cabined approach to "contaminant" suggested by some commenters. For example, Section 1431 of SDWA, provides important authority to the EPA to address imminent and substantial endangerment to drinking water supplies posed by "a contaminant" that is present in or threatened those supplies. Congress clearly intended this authority to be broad and remedial, but it would be significantly hampered if the EPA would be restricted to only addressing individual chemicals and not mixtures threatening a water supply. For these reasons, the EPA's interpretation of the definition of contaminant is the only reading that is consistent with the statutory definition and use of the term in context and at to the extent the definition of contaminant is ambiguous, the EPA's interpretation represents the best interpretation of that term.

Finally, even if a mixture is considered a group, as some commenters suggest, Congress clearly contemplated that the EPA could regulate contaminants as groups. See A Legislative History of the SDWA, Committee Print, 97th Cong. 2d Sess.(February 1982) at 542-3) (noting the tens of thousands of chemical compounds in use commercially, with many more added each year, of which many will end up in "the nation's drinking water and finding that "[i]t is, of course, impossible for EPA to regulate each of these contaminants which may be harmful to health on a contaminant-by-contaminant basis. Therefore, the Committee anticipates that the

Administrator will establish primary drinking water regulations for some groups of contaminants, such as organic and asbestos.") Thus, the EPA has the authority to regulate a mixture as a contaminant under SDWA.

Commenter states that the "mixture" appears only twice in the statute in 42 U.S.C. [sec] 300j-18(b)(3). EPA disagrees with commenter's assertion that this textual reference to mixture "thus reflects that Congress never intended for EPA to regulate mixtures of contaminants, rather than the individual contaminants themselves, using MCLs." Instead, the statute's reference to "mixture" is evidence that Congress understands that drinking water contains mixtures as a contaminant. Please see section 3.2 for more information on the EPA's rationale to regulate mixtures.

Clean Air Council, et al. (Doc. #1731, SBC-043844)

Introduction

The Environmental Protection Agency ("EPA") issued in March 2023 a proposed National Primary Drinking Water Regulation ("NPDWR") and health-based Maximum Contaminant Level Goals ("MCLG") for six per- and polyfluoroalkyl substances ("PFAS") compounds and their mixtures: Perfluorooctanoic acid ("PFOA"), perfluorooctane sulfonic acid ("PFOS"), perfluorohexane sulfonic acid ("PFHxS"), hexafluoropropylene oxide dimer acid ("HFPO–DA") and its ammonium salt (also known as "GenX" chemicals), perfluorononanoic acid ("PFNA"), and perfluorobutane sulfonic acid ("PFBS"). For PFOA and PFOS, EPA proposes MCLGs of zero nanograms per liter ("ng/L") or parts per trillion ("ppt"). Based on technical feasibility EPA proposes enforceable Maximum Contaminant Levels ("MCLs") of 4.0 ppt for PFOA and 4.0 ppt for PFOS.

EPA Response: With respect to the EPA's regulation of additional PFAS through a Hazard Index MCL, please see the section 5.2.1 of the EPA response in this *Response to Comments* document. With respect to the EPA's regulation of PFOA and PFOS, please see the section 5.1 of the EPA response in this *Response to Comments* document. With respect to additional individual PFAS MCLs for PFHxS, HFPO-DA and PFNA, please see section 5.3 of the EPA response in this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043856)

Summary of Comments

1. PFAS levels that exceed the proposed federal standards are prevalent in the Commonwealth of Pennsylvania, and Pennsylvania's compliance with the proposed federal standards is feasible.

a. PFAS are prevalent in Pennsylvania drinking water at levels above the proposed MCLs and HI.

b. Enacting the proposed PFAS NPDWR in Pennsylvania is technically and economically feasible.

2. The proposed PFOA and PFOS MCLs and the HI are reasonable and protective of public health, and their implementation is feasible.

a. The proposed stand-alone PFOA and PFOS MCLs of 4.0 ppt are appropriate for the protection of public health.

EPA Response: With respect to the EPA's regulation of additional PFAS through a Hazard Index MCL, please see the section 5.2.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. With respect to additional individual PFAS MCLs for PFHxS, HFPO-DA and PFNA, please see section 5.3 of the EPA response in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-045387)

If a cumulative approach is taken by EPA using the Hazard Index, the potential for drinking water noncompliance from the presence of individual PFAS in single-digit ppt levels may also impose significant operational challenges for running PFAS treatment systems. Increased spent adsorptive media will be generated, requiring disposal or incineration from more frequent change-outs. With adsorptive media technologies that are commonly used for PFAS treatment, such as granular activated carbon (GAC) and anion exchange (AIX) resin systems, water is sampled from the different media bed depths to detect a breakthrough of PFAS, along with monitoring of the finished water level. When the breakthrough of the media is approaching the PFAS limit, the system requires a change-out with new media. Media change- outs are costly (although hopefully infrequent in well-designed systems), and therefore should be based on accurate analytical results. NEWWA is concerned that low parts-per-trillion accuracies will be difficult to achieve and may cause inefficient use of resources such as requiring an excessive number of PFAS samples to ensure accurate results.

EPA Response: For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. For more information on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042735)

If a cumulative approach is taken by EPA using the Hazard Index, the potential for drinking water noncompliance from the presence of individual PFAS in single digit ppt levels may also impose significant operational challenges for running PFAS treatment systems. Increased spent adsorptive media will be generated requiring disposal or incineration from more frequent

change-outs. With adsorptive media technologies that are commonly used for PFAS treatment, such as granular activated carbon (GAC) and anion exchange (AIX) resin systems, water is sampled from the different media bed depths to detect a breakthrough of PFAS, along with monitoring of the finished water level. When the breakthrough of the media is approaching the PFAS limit, the system requires a change-out with new media. Media change-outs are costly (although hopefully infrequent in well-designed systems), and therefore should be based on accurate analytical results. NEWWA is concerned that low parts per trillion accuracy will be difficult to achieve and may cause inefficient use of resources such as requiring an excessive number of PFAS samples to ensure accurate results.

EPA Response: Please see the EPA response to comment Doc. #1836, SBC-045387 in section 5.2.1 in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042886)

If a cumulative approach is taken by EPA using the Hazard Index, the potential for drinking water noncompliance from the presence of individual PFAS in single digit ppt levels will impose significant operational challenges for running PFAS treatment systems. Increased spent adsorptive media will be generated requiring disposal or incineration from more frequent change-outs. With adsorptive media technologies that are commonly used for PFAS treatment, such as granular activated carbon (GAC) and anion exchange (AIX) resin systems, water is sampled from the different media bed depths to detect breakthrough of PFAS, along with monitoring of the finished water levels. When breakthrough of the media is approaching the PFAS limit, the system requires a change-out with new media. Media change-outs are costly, and therefore should be based on accurate analytical results. MWWA is concerned that low parts per trillion accuracies will be difficult to achieve and may cause inefficient use of resources such as requiring an excessive number of PFAS samples to ensure accurate results.

EPA Response: Please see the EPA response to comment Doc. #1836, SBC-045387 in section 5.2.1 in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046078)

4. Even accredited laboratories are not all able to meet the sensitivity and reporting precision required by the Proposal.

The concerns raised above regarding laboratory accuracy and capacity are further underscored by a laboratory survey recently conducted by Environmental Standards, Inc. for the American Petroleum Institute. Environmental Standards Survey, May 2023. Environmental Standards identified and surveyed 51 accredited laboratories for US EPA Methods 533, 537, and/or 537.1 and received responses from 14 of this facilities (27%). The results indicated that while the current laboratory sensitivity and reporting precision can meet the US EPA-proposed MCLs for PFOA and PFOS for drinking water, the current laboratory sensitivity and reporting precision

will not be met by all accredited facilities for the US EPA-proposed trigger levels for PFOA and PFOS.

Further, the current laboratory sensitivity and reporting precision can meet the US EPA-proposed HBWCs for PFHxS, HFPO–DA, PFNA, and PFBS, but the current sensitivity demonstrated by the accredited laboratories may not be sufficient to meet the US EPA-proposed Hazard Index MCLG for combined PFHxS, HFPO–DA, PFNA, and PFBS. This further demonstrates that the Proposal is technically infeasible with current laboratory capabilities.

EPA Response: The agency disagrees there is insufficient laboratory capability and capacity to support the monitoring requirements of this NPDWR. Using data submitted as part of the UCMR 5 LAP as a reference point, the EPA notes that 47 of 53 laboratories (89 percent) that applied for UCMR 5 approval generated a MRL confirmation at 2 ng/L (one-half the proposed MCLs for PFOA and PFOS) or less for Method 533. This suggests the majority of laboratories with the necessary instrumentation to support PFAS monitoring have the capability to provide screening measurement results at the revised trigger level of one-half of the MCL. For responses regarding feasibility with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For responses regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please also see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. EPA clarifies for the commenter that MCLGs are non-enforceable and are not required to be achieved by water systems, only MCLs are legally enforceable standards. Additionally, the EPA clarifies for the commenter that the Hazard Index MCLG and Hazard Index MCL are both equal to 1 (unitless), not 1 ppt.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045207)

8. CT DPH agrees with EPA's PFOA and PFOS evaluation of feasibility for the proposal and the feasibility for the proposed Hazard Index (HI) Maximum Contaminant Level (MCL) finding with respect to the analytical measurement and treatment capability. CT DPH agrees that setting the MCL at the Practical Quantitation Level (PQL) for PFOA and PFOS is implementable and feasible, as all laboratories certified by the CT DPH Environmental Laboratory Certification Program (ELCP) are calibrating to concentrations less than 4.0 ppt and have demonstrated their ability to justifiably report to concentrations below 4.0 ppt. CT DPH agrees that the HI MCL is feasible, as all laboratories certified by the CT DPH ELCP are calibrating to concentrations well below the Health Based Water Concentration (HBWC) that is used in the calculation. The best available technologies that EPA has described are proven to be effective at removing the proposed PFAS in drinking water.

Thank you for the opportunity to provide these comments regarding the EPA's preliminary determination.

Sincerely,

Lori J. Mathieu

Public Health Branch Chief

Environmental Health and Drinking Water Branch Connecticut Department of Public Health

C: Lisa M. Morrissey, MPH, Deputy Commission–r - DPH Graham Stevens, DEEP

EPA Response: The EPA acknowledges commenter's agreement that the PFOA, PFOS, and Hazard Index MCLs are all feasible. With respect to the EPA's regulation of additional PFAS through a Hazard Index MCL, please see the section 5.2.1 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. With respect to additional individual PFAS MCLs for PFHxS, HFPO-DA and PFNA, please see section 5.3 of the EPA response in this *Response to Comments* document.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043037)

Maximum Contaminant Levels and Hazard Index

DEQ recommends consistency in the use of significant figures in the proposed rule.

In different places in the proposed rule, an inconsistent number of significant figures is used for the proposed MCLs. For example, the footnote in the table at 141.50(b) states correctly that the Health-Based Water Concentration for HFPO-DA is 10.0 ppt, but the formula used for the Hazard Index in that same footnote uses 10. EPA should ensure that all references to the MCLs use a consistent number of significant figures.

EPA Response: With respect to responses on significant figure usage for PFOA and PFOS, please see section 5.1.7 of the EPA response in this *Response to Comments* document. With respect to significant figure usage for the Hazard Index PFAS and individual PFAS MCLGs and MCLs (PFHxS, HFPO-DA and PFNA), please see section 4.3.4 of the EPA response in this *Response to Comments* document. With respect to rounding and compliance calculations, please see section VIII.B.3 of the final rule preamble. Please see also the EPA response to comment Doc. #1726, SBC-045150 in section 5.2.1 in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045026)

EPA requests comment on the use of two significant figures (i.e., a value of 1.0) for the HI. NJDEP believes two significant figures would be appropriate for reporting and should not result in issues that could be caused due to precision of the analytical methods.

NJDEP notes that the use of one versus two significant figures (i.e., 1 versus 1.0) may impact implementation of an MCL based on the HI. An HI of 1 would not be exceeded unless the HI is calculated to be 1.5 or above, while an HI of 1.0 would be exceeded when the HI is calculated to be 1.05 or above. Also related to this point, it is noted that there is inconsistency in the presentation of the numerical values for the Health Based Water Concentrations (HBWCs) for the four PFAS with preliminary regulatory determinations throughout the rule proposal, and that EPA should clarify whether the HBWCs are intended to include a decimal point, since this can have important implications in implementation of these values.

EPA Response: With respect to responses on significant figure usage for PFOA and PFOS, please see section 5.1.7 of the EPA response in this *Response to Comments* document. With respect to significant figure usage for the Hazard Index PFAS and individual PFAS MCLGs and MCLs (PFHxS, HFPO-DA and PFNA), please see section 4.3.4 of the EPA response in this *Response to Comments* document. With respect to rounding and compliance calculations, please see section VIII.B.3 of the final rule preamble. Please see also the EPA response to comment Doc. #1726, SBC-045150 in section 5.2.1 in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045088)

Section V – Maximum Contaminant Level Goal

1) Significant figures: In the presentations/guidance to states and operators, when assessing compliance with the Hazard Index for PFHxS, PFNA, PFBS, and GenX the respective health-based water concentrations are 10 ppt, 2000 ppt, 10 ppt, and 9.0 ppt. This creates confusion and complexity due to rounding and whole vs. decimal numbers. It also does not accurately reflect the regulation in that there are no decimals provided in any of the health-based water concentrations. Reference to the standards needs to be precise and guidance on how to round based on decimals must be provided.

EPA Response: Please see the EPA response to comment Doc. #1726, SBC-045150 in section 5.2.1 in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045150)

EPA should revise the use of significant figures to ensure accuracy and consistency throughout the proposed rule and supporting materials.

The proposed rule uses an inconsistent number of significant figures for numeric values in the proposed rule. For example, the footnote to the table at 40 CFR § 141.50(b) shows the Health-Based Water Concentration (HBWC) for HFPO-DA as "10.0" ppt (three significant figures), but the formula used for the HI in that same footnote uses "10" (one significant figure). This inconsistency also occurs for PFBS ("2000.0" followed by "2000"). EPA's June 21, 2022, FR notice for the HAs upon which these HBWCs are based uses "10" (one significant figure) for GenX (HFPO-DA) and "2,000" (one significant figure) for PFBS. The same issue arises in the footnote to the table in § 141.61(c) where, in addition to the above examples, the HBWC for PFNA is shown as "10.0" and "10." EPA should ensure that all references to numeric values in the rule and all supporting materials, including presentations and fact sheets, use a consistent number of significant figures. As different labs may report results with different numbers of significant figures, it is important that EPA establish a consistent regulatory standard so that when results are used for compliance, appropriate rounding practices are applied. Compliance is often determined on a fine line between one value and another and will be even more so in this NPDWR as the MCL is being set so close to the limit of analytical capabilities.

EPA Response: With respect to responses on significant figure usage for PFOA and PFOS, please see section 5.1.7 of the EPA response in this *Response to Comments* document. The EPA notes that the PFOA and PFOS MCLs are finalized with two significant figures. With respect to significant figure usage for the Hazard Index PFAS and individual PFAS MCLGs and MCLs (PFHxS, HFPO-DA and PFNA), please see section 4.3.4 of the EPA response in this *Response to Comments* document. The EPA notes that the Hazard Index PFAS MCL and the individual MCLs for PFNA, PFHxS, and HFPO-DA are set to one significant figure. The EPA further notes that with respect to rounding in compliance calculations, any necessary rounding does not occur until the end of the calculation for an individual MCL, per § 141.903(f)(1)(i) of the regulations. For the Hazard Index, no rounding occurs until after the RAA Hazard Index is calculated, per section § 141.903(f)(2)(i) of the regulations. With respect to rounding and compliance calculations, please see section VIII.B.3 of the final rule preamble.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045200)

May 30, 2023

Via: Federal eRulemaking Portal: https://www.regulations.gov/

SUBJECT: Docket ID Number EPA-HQ-OW-2022-0114, PFAS National Primary Drinking Water Regulation Rulemaking

Dear Administrator Regan:

The Connecticut Department of Public Health (CT DPH) submits these comments in response to the United States Environmental Protection Agency's (EPA) Proposed PFAS National Primary Drinking Water Regulation (NPDWR). CT DPH is the primacy agency responsible for enforcing the federal Safe Drinking Water Act (SDWA) for the State of Connecticut and looks forward to

the implementation of the final PFAS NPDWR. CT DPH is supportive of the EPA's Proposed PFAS NPDWR as it will provide a framework for CT DPH to implement actions in Connecticut's Interagency PFAS Action Plan.

CT DPH has reviewed EPA'S Proposed PFAS NPDWR and respectfully provides detailed comments (attached) for EPA's consideration. Critical recommendations offered are outlined as follows:

1. CT DPH recommends EPA provide more details when explaining the significant figure use in the Hazard Index (HI) calculation. It is particularly important that EPA clarify this point because the Hazard Index is calculated as a sum of four ratios, which provides many more places where rounding can be done than in the traditional screening-level-based Maximum Contaminant level (MCL) approach, which is a single value. If rounding is done at multiple places in the HI calculation, it could have a significant impact on the result (and the determination of compliance with the MCL).

EPA Response: Please see the EPA response to comment Doc. #1726, SBC-045150 in section 5.2.1 in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045209)

2. EPA requests comment on significant figure use when calculating both the HI MCLG and the MCL. EPA has set the HI MCLG and MCL using two significant figures (i.e., 1.0). EPA requested comment on the proposed use of two significant figures for the MCLG when considering underlying health information and for the MCL when considering the precision of the analytical methods.

CT DPH agrees that at least two significant figures need to be used when calculating the individual Hazard Quotients and the total Hazard Index. However, EPA should provide more details when explaining the significant figure use in the HI calculation. It is particularly important that EPA clarify this point because the HI is calculated as a sum of four ratios, which provides many more places where rounding can be done than in the traditional screening-level-based MCL approach, which is a single value. If rounding is done at multiple places in the HI calculation, it could have a significant impact on the result (and the determination of compliance with the MCL). Specifically, 1) USEPA should clarify whether the same level of precision (two significant figures) also applies to the PFAS drinking water analytical results when they are divided by the HBWC for HQ calculation (e.g. if the analytical result of PFHxS concentration is 4.2 ppt in the drinking water, should the HQ[PFHxS] be 4.2 ppt/ 10 ppt=0.42 or 4 ppt/ 10 ppt=0.4; and similarly, if the analytical result of PFBS concentration is 1981 ppt, should the HQ[PFBS] be 1981 ppt/ 2000 ppt= 0.99 or 2.0E+3 ppt/ 2000 ppt= 1.0). 2) USEPA should explicitly state whether the "two significant figures" refers to not just the HI but also the rounded HQ for each PFAS. CT DPH encourages EPA to incorporate the requirement on significant figure use into each relevant step of its HI calculation guidance.

EPA Response: Please see also the EPA response to comment Doc. #1726, SBC-045150 in section 5.2.1 in this *Response to Comments* document.

Corix Infrastructure Inc. (Doc. #1834, SBC-045366)

4. With regards to the specific items EPA has requested comment on, Corix provides below:

• We support the use of two significant figures when calculating both the HI MCLG and the MCL.

EPA Response: With respect to responses on significant figure usage for PFOA and PFOS, please see section 5.1.7 of the EPA response in this *Response to Comments* document. With respect to significant figure usage for the Hazard Index PFAS and individual PFAS MCLGs and MCLs (PFHxS, HFPO-DA and PFNA), please see section 4.3.4 of the EPA response in this *Response to Comments* document. With respect to rounding and compliance calculations, please see section VIII.B.3 of the final rule preamble.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044410)

Page 18730. Section V – Maximum Contaminant Level Goal.

EPA requests comment on significant figure use when calculating both the HI MCLG and the MCL. EPA has set the HI MCLG and MCL using two significant figures (i.e., 1.0). EPA requests comment on the proposed use of two significant figures for the MCLG when considering underlying health information and for the MCL when considering the precision of the analytical methods.

• DOH supports using all digits of precision in calculations, but rounding to two significant figures for the final reported value. Using the significant figure only changes how we round before an HI MCL is reached. A system would exceed the MCL with a RAA of 1.05 instead of 1.5 ppt.

EPA Response: Please see also the EPA response to comment Doc. #1726, SBC-045150 in section 5.2.1 in this *Response to Comments* document.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042977)

Regarding EPA's proposed requirement to report to tenths of a part per trillion for the MCLGs, as well as the MCLs, EGLE DWEHD recognizes both the benefits and issues associated with this approach. By including this additional significant figure, RAA calculations may be compared to MCLs and associated trigger levels without the need for extra rounding, resulting in more straightforward compliance determinations.

EPA Response: Please see also the EPA response to comment Doc. #1726, SBC-045150 in section 5.2.1 in this *Response to Comments* document.

A. O. Smith Corporation (Doc. #1674, SBC-043692)

The Company does however have concerns related to the HI approach that the EPA is taking regarding mitigating four other PFAS compounds (e.g., PFHxS, HFPO–DA and its ammonium salt (also known as GenX chemicals), PFNA, and PFBS) in the context of the potential utilization of POU or POE solutions for small water systems. As a general proposition the HI is an approach that has not been utilized under the SDWA. Hence, while in theory the structure may be achievable the Company foresees potential execution and implementation challenges given no precedent exists in the drinking water context. Compounding the challenges is the inclusion of GenX chemicals in the HI. GenX chemicals in particular present a specific challenge for POU and POE manufacturers as a new consensus test method will need to be developed to address the new HI generally and specifically developing an effective treatment technology that takes into consideration GenX as compared to solely targeting PFOA, PFOS, PFNA, and PFBS. It is unclear if the HI will pose a challenge to large public water systems to implement considering the EPA is focused on treating incoming water down to the HI. However, for POU and POE manufacturers the current third-party NSF/ANSI test protocol considers 90th percentile occurrence data, which may have an impact on the effectiveness of treatment technology to address the mix of PFAS that the HI is attempting to address. A. O. Smith would recommend that the EPA remove GenX from the HI approach until a robust review of the pending GenX occurrence data from UCMR5 survey is completed.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. With respect to point-of-use (POU) and point-of-entry (POE) devices, EPA is currently not listing them as best available treatment technologies and SSCTs because the MCLs require treatment to concentrations below the current National Sanitization Foundation International/American National Standards Institute (NSF/ANSI) certification standard for POU device removal of PFAS. The EPA is aware that the NSF/ANSI Drinking Water Treatment Unit Joint Committee Task Group is in the process of updating their standards; should these future standards meet the NPDWR, the EPA could revise the SSCT list to include POE/POU. For additional discussion on small system compliance technology identification and evaluation, please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA also disagrees that the inclusion of HFPO-DA poses a specific challenge because the EPA's record demonstrates that the same technologies which remove the other chemicals can remove HFPO-DA (see USEPA, 2024l). The agency disagrees that the EPA

should wait for UCMR 5 to be completed before regulation. For considerations and use of pending and future science and for additional discussion on UCMR 5, please see sections 5.1.6 and 6.8, respectively, of the EPA response in this *Response to Comments* document.

Superfund Settlements Project (SSP) and RCRA Corrective Action Project (RCAP) (Doc. #1631, SBC-052848)

The SDWA definition of primary drinking water regulation requires EPA to specify "for each such contaminant" an MCL or treatment technique [FN11: 42 U.S.C. § 300f(1).]. The MCLG "shall be set at the level at which no known or anticipated adverse effects on the health of persons occur and which allows an adequate margin of safety." [FN12: 42 U.S.C. § 300g-1(b)(4)(A).]. For a contaminant for which an MCLG is established, EPA shall specify a MCL which is as close to the MCLG as feasible. [FN13: 42 U.S.C. § 300g-1(b)(4)(B).] The HI approach cannot meet these requirements. The HI does not specify "for each such contaminant" a single level but rather a sliding level that depends on the concentration of other substances. This has the practical effect of resulting in an HI exceedance of a combination of the four substances even where none individually is detected in concentrations that exceed the individual health-based water concentration ("HBWC") for any of the substances. Further, the end result would be inequitable: one water system with a certain concentration of one of the substances would have a treatment requirement while another with the same concentration of that substance would not.

EPA Response: The EPA disagrees with this comment. See the EPA response to comment Doc. #1713, SBC-053343 in section 5.2.1 in this *Response to Comments* document.

California Farm Bureau Federation (Doc. #1704, SBC-045067)

[For example, the U.S. Chamber analysis highlights the following:]

• The hazard index approach is problematic. The hazard index approach for PFNA, PFHxS, Gen X, and PFBS has never been used in setting an MCL, and it presents both technical and legal questions about how it would be implemented.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. As an example, the EPA intends to publish an on-line calculator tool to easily determine your Hazard Index result. For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document.

Uttara Jhaveri (Doc. #1778, SBC-045445)

UNREGULATED CONTAMINANT MONITORING RULE (UCR)

The Fifth Unregulated Contaminant Monitoring Rule [FN15: Environmental Protection Agency, Fifth Unregulated Contaminant Monitoring Rule, (2021), https://www.epa.gov/dwucmr/fifth-unregulated-contaminant-monitoring-rule] requires sample collection for thirty chemical contaminants between 2023 and 2025 using analytical methods to provide EPA and other interested parties with scientifically valid data on the national occurrence of these contaminants in drinking water. [FN16: Id.] Many of the chemicals listed in the Monitoring Rule are PFAS and the EPA should consider including the other PFAS from the Unregulated Contaminant Monitoring Rule such as perfluorodecanoic acid (PFDA), perfluorododecanoic acid (PFDoA), perfluoro (2-ethoxyethane) sulfonic acid (PFEESA), and perfluoroheptanesulfonic acid (PFHpS). [FN17: Id.] Depending on the rate of occurrence and considering the negative ramifications on human health, their inclusion would promote public safety.

EPA Response: See section 6.8 of the EPA response in this *Response to Comments* document with respect to additional considerations for UCMR5. For discussion on potential regulation for additional PFAS in the future, please see the EPA section 5.2.1 and section 4.3.5 of the EPA response in this *Response to Comments* document.

responsesCalifornia-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045270)

2. EPA should seek public stakeholder input on the proposed Hazard Index (HI) approach and consider other methods to address PFAS mixtures.

CA-NV AWWA appreciates EPA's effort to attempt to address the potential cumulative health effects of PFAS mixtures, but we see multiple problems with the use and application of the Hazard Index (HI) to regulate perfluorohexane sulfonic acid (PFHxS), hexafluoropropylene oxide dimer acid (HFPO–DA) and its ammonium salt (also known as GenX chemicals), perfluorononanoic acid (PFNA), and perfluorobutane sulfonic acid (PFBS), and mixtures of these PFAS contaminants. The Hazard Index is overly stringent, confusing, and not supported by research or experience. Issuance of the proposed HI MCLs and MCLGs will create significant risk communication challenges for water systems, and confusion in the public. We support the recommendation [FN1: EPA-SAB-22-008. Transmittal of the Science Advisory Board Report titled, "Review of EPA's Analyses to Support EPA's National Primary Drinking Water Rulemaking for PFAS." August 2022] of the Science Advisory Board to use the HI approach as a "screening method and decision-making tool" instead of the proposed MCL and MCLG approach. The HI framework, as a Primary National Drinking Water Regulation needs further evaluation, research on the use and application of such an approach, and appropriate risk-based communication guidance before it can be implemented.

We strongly suggest eliminating the proposed HI-based MCLs and MCLGs for PFHxS, HFPO-DA, PFNA, and PFBS. We encourage EPA to work closely with water systems, including small water systems, and other stakeholders to fully consider this and other options for a useable mixture-based approach that can be practically applied. We support EPA's continued efforts to evaluate, prioritize, and develop MCLs for other high-risk individual PFAS compounds based on known toxicity, occurrence, and technical and economic feasibility. We also ask for transparency and early inclusion in efforts to address potential PFAS mixture concerns in drinking water.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. Please also see section 1.2 for additional discussion on PFAS risk communications. Regarding the use of the Hazard Index as more than screening tool, please see section 4.3.1 of the EPA response in this *Response to Comments* document.

WaterPIO (Doc. #1624, SBC-043470)

Back to the proposed MCLs and Hazard Index, and how they will wreck the American people's confidence in their drinking water.

While the PFAS health advisories will be technically eliminated by the creation of MCLs and Hazard Index, the negative public perception they created will remain. Even if water providers meet the new MCLs and HI, because the health advisory language will still be out there in the Internet's permanent ink, systems will still find themselves accused of having drinking water containing PFAS at "unsafe" levels.

Far too many articles were written about the health advisories for them to simply go away following the imposition of the MCLs and HI. Heck, several pieces were written that stated the HAs were enforceable drinking water standards. Looking to the future using our experience as former network and local news producers, the press, activists, elected officials, and concerned customers will package the health advisories together with the MCLs and HI proposal to deliver a "double whammy" against public confidence in drinking water.

EPA Response: The HAs for PFOA, PFOS, HFPO-DA (GenX chemicals) and PFBS are beyond the scope of this rulemaking. The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For discussion on

feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. Please also see section 1.2 of the EPA response in this *Response to Comments* document for additional discussion on PFAS risk communications.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-047686)

Hazardous Index MCL

CARE welcomes EPA's innovative move in regulating PFAS as a class. EPA's proposal to regulate PFNA, GenX, PFHxS, and PFBS is through a group based MCL called a Hazardous Index (HI). EPA did not include PFOA and PFOS in the HI because their individual proposed MCLGs are zero. [FN9: Id. at 18639.] The combined approach of the HI is due to the chemicals' additive toxic effects and likely co-occurrence in drinking water. [FN10: Id.] EPA's Science Advisory Board opined that a HI methodology is a valid and reasonable approach for estimating the potential aggregate health hazards from associated chemicals with similar health risk (health endpoints) when the chemicals regularly or easily mix in environmental media. [FN11: Id. at 18654.] This dose additivity means that low levels of multiple PFAS, that individually would not likely result in adverse health effects, are expected to result in adverse health effects when combined in a mixture. [FN12: Id. at 18639; 18647.]

Due to their widespread use and persistence, many PFAS are known to co-occur in drinking water and the environment—meaning that these compounds are often found together and in different combinations as mixtures. [FN13: Id.] EPA has determined that there is a substantial likelihood that PFHxS, HFPO–DA, PFNA, and PFBS, individually and as mixtures, will occur and co-occur with a frequency and at levels of public health concern in PWSs based on EPA's evaluation of the best available occurrence information. [FN14: Id. at 18647.] This preliminary determination is based on the most recent publicly available data, which includes UCMR 3 data and more recent PFAS drinking water data collected by several states. In general, the most recent state data using newer analytical methods than UCMR 3 show widespread occurrence of PFOA, PFOS, PFHxS, PFNA, and PFBS in multiple geographic locations. [FN15: Id. at 18648.]

For the proposed HI level, EPA developed Health Based Water Concentrations (HBWCs) for PFHxS, HFPO– DA, PFNA and PFBS. [FN16: Id. at 18645.] These HBWCs are defined as a level protective of health effects over a lifetime of exposure, including sensitive populations and life stages. In reaching the HBWCs, EPA utilized research from the Agency for Toxic Substances and Disease Registry (ATSDR) that viewed animal toxicity studies. [FN17: Id.]

These studies found that oral exposure to PFHxS, HFPO–DA, PFNA, and PFBS, individually and in a mixture, may result in adverse health effects including disruption of several biological systems including the endocrine, cardiovascular, developmental, immune, and hepatic systems. [FN18: Id.] These PFAS and their mixtures are also anticipated to affect common target organs, tissues, or systems to produce dose-additive effects from co-exposures. [FN19: Id.]

Economic Analysis for the Proposed PFAS NPDWR

In conjunction with the proposed PFAS NPDWR, EPA's Office of Management and Budget prepared an Economic Analysis (EA) that reviewed both the proposed rule and the Health Risk Reduction and Cost Analysis reports prepared by EPA. [FN20: Office of Water, Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation, EPA, 1-2 (March 2023), https://www.epa.gov/system/files/documents/2023-03/Proposed%20PFAS%20NPDWR%20EA_final_03_09_2023_0.pdf.] The EA compared the proposed MCL and HI levels against several regulatory alternative MCLs that were less stringent than the proposed 4ppt for PFOA and PFOS. EPA also compared the quantifiable and nonquantifiable health benefits expected against the costs from the proposed levels.

EPA determined that a final rule promulgation and implementation of the proposed NPDWR would reduce PFAS concentrations in drinking water distributed by PWS and result in reduced frequency of cardiovascular disease, bladder cancer, birth weight, and renal cell carcinoma. [FN21: Id. at 1-2; 6-6.] EPA also anticipates that the nonquantifiable human health benefits are substantial and may reasonably exceed the benefits the Agency was able to quantify for this regulatory proposal. [FN22: Id. at 1-3.] Quantified benefits include those likely to occur from reductions in co-occurring compounds that would be treated as a result of the identified effective treatment technologies required by the proposed NPDWR. [FN23: Id. at 1-4.]

Costs include expenses incurred by PWSs to 1) monitor for PFAS, 2) inform customers, 3) install and operate treatment technologies, and 4) perform record-keeping and reporting to comply with the NPDWR. [FN24: Id. at 1-2.] Install and operation costs include costs associated with engineering, installing, operating, and maintaining PFAS removal treatment technologies, including treatment media replacement and spent media destruction or disposal. [FN25: Id. at 5-9.] The EA also looked at certain non-treatment actions that some PWSs might take in lieu of treatment, such as constructing new wells in an uncontaminated aquifer or interconnecting with and purchasing water from a neighboring PWS. Lastly, costs incurred by states or other primary agencies to implement the rule, such as time spent to read and understand the rule, internal training for implementation, and reporting to EPA, were also examined. [FN26: Id. at 5-36.] Following a comparison of the associated benefits and costs to the proposed NPDWR, the Administrator determined that the quantified and nonquantifiable benefits justify the costs. [FN27: Id. at 7-7.]

After considering all these factors, CARE supports EPA's determination that the six PFAS and the mixtures listed in the HI should be regulated as contaminants under SDWA. CARE believes these determinations will protect human health and the environment and that the proposed MCLs are within EPA's statutory and regulatory authority prescribed by the Safe Drinking Water Act. CARE also welcomes EPA's first step in addressing PFAS as a class but, as explained in Issue IV, encourages EPA to broaden the HI to include more PFAS in future rulemakings. CARE wishes to underscore that the proposed NPDWR protects our drinking water at levels that are based on current feasibility limits and scientific knowledge while also asserting EPA should readdress the proposed levels as feasibility and scientific data evolve.

EPA Response: For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. The commenter supports the feasibility of the final Hazard Index MCL. The EPA is clarifying that the agency conducted and analyzed quantifiable and non-quantifiable costs and benefits of the regulation (and not the Office of Management and Budget); please see section 13 of the EPA response in this *Response to Comments* document for additional discussion on the agency's HRRCA. With respect to potential inclusion of additional PFAS compounds in the future, please see the section 5.1.6 of the EPA response in this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043846)

For PFHxS, HFPO–DA and its ammonium salt, PFNA, and PFBS, EPA is proposing using a Hazard Index ("HI") approach to account for their additive toxicity. Specifically, EPA is proposing Health Based Water Concentration ("HBWCs") of 9.0 ppt for PFHxS, 10.0 ppt for HFPO–DA; 10.0 ppt for PFNA; and 2000 ppt for PFBS. The sum of the individual hazard quotients (concentration in the water divided by the HBWC) yields the HI, where HI of 1.0 defines the MCL for these four PFAS.

The proposed NPDWR reflects current evidence regarding toxicity and health impacts of PFAS compounds. In particular, the HI addresses their confirmed dose-additivity, namely the cumulative effect when there is exposure to multiple PFAS species. Although the proposed MCLs and HBWCs are stricter than those in most of the states that have current regulations for PFAS in drinking water, this does not pose a conflict: States with existing PFAS drinking water standards will be well-positioned to meet the proposed NPDWR.

Commenters strongly support the proposed regulation as a strong step to ensuring public health and safety. The MCLs and HI/HBWC are adequate to protect public health based on current data, and are feasible for both testing and treatment. Commenters urge EPA to follow updated research and adjust the MCLs and NBWC values periodically and add more PFAS species to the HI to reflect new data.

EPA Response: For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. The commenter supports the feasibility of the final Hazard Index MCL. With respect to potential inclusion of additional PFAS compounds in the future, please see the section 5.1.6 of the EPA response in this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043882)

c. Laboratory detection methods can accurately measure the regulated PFAS species at the proposed PQL, MCLs, and HBWCs, and the proposed trigger levels are appropriate.

The proposed MCLs and HBWCs are well above the minimum detection limit ("MDL") of the leading EPA PFAS testing methods (533 and 537.1) as summarized in the table below. These

methods are broadly used by certified laboratories and accepted by current state regulations [FN56: See, e.g., 53 Pa.B. 343. Commercial laboratories also consider these to be accepted methods. See, e.g., Eurofins, PFAS Analysis, https://www.eurofinsus.com/media/1713837/pfas-user-Guide_221.pdf (last visited May 26, 2023); Assent, PFAS Guidance on Risk Assessment for Manufacturers, https://www.assent.com/resources/pfas-compliance/ (last visited May 26, 2023); Garden State Laboratories, Analytical Services, https://www.gslabs.com/?gclid=EAIaIQobChMIwb7n6ZLX_gIVi8vjBx1qBgrcEAAYAiAAEgLEL_D_BwE (last visited May 30, 2023).] Newly-developed methods such as EPA's method 1633 will also be able to determine the relevant PFAS compounds at the proposed levels [FN57: Draft Method 1633, supra note 46, at Table 6.]. Therefore, reliably identifying EPs where the regulated PFAS compound levels are above the values set by the proposed NPDWR is feasible.

EPA Response: For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. The agency acknowledges the comment supporting the feasibility of the final Hazard Index MCL. The agency notes that EPA Method 1633 is not a drinking water method and is not approved to meet the monitoring requirements of this final NPDWR for PFAS. For additional discussion on validated analytical methods, please see section VII of this *Response to Comments* document.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043864)

Hazard Index MCL

EPN agrees that EPA's HI MCL of one is implementable and feasible, and we commend EPA for setting the MCL equal to the MCLG.

EPA Response: The commenter support the Hazard Index MCLG and MCL. For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce (Doc. #1537, SBC-042647)

[Accordingly, we are planning to provide comments to EPA and will request that the agency withdraw the proposal and should await the results of the UCMR 5 process:]

The novel hazard index approach. The hazard index approach for the PFAS other than PFOA and PFOS has never been used in setting an MCL, and it presents both technical and legal questions about how it would be implemented.

EPA Response: For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. For additional discussion on the agency's legal authority to regulate mixtures of PFHxS, PFNA, HFPO-DA and PFBS and discussion of the Hazard Index approach, please see section 3.2 of the EPA response in this *Response to Comments* document.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043483)

[They have identified the following areas of concern regarding the agency's development of this rule:]

• The novel hazard index approach. The hazard index approach for PFNA, PFHxS, Gen X, and PFBS has never been used in setting an MCL, and it presents both technical and legal questions about how it would be implemented.

EPA Response: Please see the EPA response to comment Doc. #1537, SBC-042647 in section 5.2.1 in this *Response to Comments* document.

Oregon Health Authority (OHA) (Doc. #1582, SBC-042760)

Section VI – Maximum Contaminant Level

• EPA requests comment on its proposal of using an HI approach for PFHxS, HFPO-DA, PFNA, and PFBS, including whether it can be clearly implemented and achieves the goal of protecting against dose additive noncancer health effects.

OHA believes the HI approach, while a new concept in drinking water, is implementable at the state level.

EPA Response: For discussion on feasibility considerations for the Hazard Index PFAS, please see the section 5.2.1 of the EPA response in this *Response to Comments* document.

Safe Healthy Playing Fields, Inc. (Doc. #1621, SBC-042945)

The preliminary determination to regulate PFNA, PFBS, PFHxS and GenX as mixtures is a welcome first step. However, the concept of unitless actual measurements of summed fractions is not easily understood by the majority of the general population. It gives the appearance of creative bookkeeping that even the Wall Street Journal [Link: https://www.wsj.com/articles/epa-standards-miss-many-chemicals-in-drinking-water-study-says-eb748826] wasn't able to parse.

It is a generally accepted practice to write to a seventh grade level when providing health information. The National Institutes of Health [Link: https://www.nih.gov/institutes-nih/nih-office-director/office-communications-public-liaison/clear-communication/clear-simple] notes:

"People with health literacy challenges are found among all ethnicities, races, and classes but there is a link between literacy and education and income levels. Many of the same populations at risk for limited health literacy also suffer from disparities in health status, illness (including heart disease, diabetes, obesity, HIV/AIDS, oral disease, cancer deaths, and low birth weight), and death."

The Health Index for PFNA, PFBS, PFHxS and GenX is unclear, instills fear and indicates a compromise with the chemical industry allowing them to continue to pollute both people and planet for multiple generations without a right to know or informed consent.

EPA Response: For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. The agency disagrees that dividing an exposure metric over a health metric will not be easily understood. This calculation is also not mathematically different (i.e., summing up numbers and dividing) than a RAA calculation which is used frequently for compliance calculations for NPDWRs. Regardless, to assist in the calculation of these values, the agency is developing a calculator tool to easily determine your hazard index result. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. The commenter provides no explanation for its statement that a hazard index approach "instills fear and indicates a compromise with the chemical industry [by] allowing them to continue to pollute both people and planet for multiple generations without a right to know or informed consent." The EPA's final rule represents data-driven drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. For additional discussion on risk communications as well as SDWA Right-to-Know requirements in the final NPDWR (including CCRs and PN), please see section 1.2 and 9, respectively, of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044414)

Page 18730. EPA requests comment on its proposal of using an HI approach for PFHxS, HFPO–DA, PFNA, and PFBS, including whether it can be clearly implemented and achieves the goal of protecting against dose additive noncancer health effects.

• The HI approach is reasonable for regulating PFAS with additive toxicity. This will be challenging to implement as proposed due to the tracking of multiple compounds and automating this into existing data systems. DOH has limited IT resources to prepare for migration to SDWIS state. Timing will be a key consideration for successful implementation of this area of the

proposed PFAS rule. As written, this approach will have a considerable resource impact on compliance activities.

EPA Response: For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. With respect to data management systems, the EPA agrees that appropriate data management solutions are needed to effectively comply with SDWA requirements; however, the agency does not believe these systems must be available at the time of rule promulgation. Additionally, while beyond the scope of this rulemaking itself, the EPA is actively working on PFAS data management solutions, such as updating the SDWIS suite of applications to manage data

reported from this rule (please see section 11 of the EPA response in this *Response to Comments* document).

Washington State Department of Health (DOH) (Doc. #1665, SBC-044399)

(2) Specific Comments

Page 18639. Executive Summary: EPA is proposing to use a Hazard Index (HI) approach to protecting public health from mixtures of four PFAS: PFHxS, HFPO-DA, PFNA and PFBS because of their known and additive toxic effects and occurrence and likely co-occurrence in drinking water.

• Effective implementation and data system support is needed to implement the HI.

EPA Response: Please see the EPA response to comment Doc. #1665, SBC-044414 in section 5.2.1 in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045025)

Regarding implementation, although a HI approach may be unfamiliar to non-toxicologists, this approach and its application to PFAS detected in drinking water are clearly explained in the proposed rule and are not conceptually difficult to understand. EPA has stated that it will post an online calculator that will determine the HI from the detected concentrations of the four PFAS considered in the HI. This online calculator will assist in the implementation of an MCL based on the HI.

EPA Response: For discussion on feasibility considerations for the Hazard Index PFAS, please see the EPA section 5.2.1 of the EPA response in this *Response to Comments* document. As the commenter notes, to assist in the calculation of these values, the agency is developing a calculator tool to easily determine your Hazard Index result. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation.

Missouri Department of Natural Resources (Doc. #1563, SBC-042526)

EPA requests comment on its proposed decision to establish stand- alone MCLs for PFOA and PFOS in lieu of including them in the HI approach. EPA requests comment on whether establishing a traditional MCLG and MCL for PFHxS, HFPO–DA, PFNA, and PFBS instead of, or in addition to, the HI approach would change public health protection, improve clarity of the rule, or change costs.

The Department agrees with the EPA decision to establish stand-alone MCLs for PFOA and

PFOS. At this time, the Department believes it is premature to establish MCLs for the other four PFAS.

EPA Response: For discussion on feasibility considerations for the Hazard Index PFAS, please see the section 5.2.1 of the EPA response in this *Response to Comments* document. For discussion on PFOA and PFOS MCLs, please see section 5.1 of the EPA response in this *Response to Comments* document.

Oregon Health Authority (OHA) (Doc. #1582, SBC-042758)

OHA supports excluding PFOA and PFOS from this HI approach since their proposed Maximum Contaminant Level Goals (MCLGs) are so much lower than the other four PFAS species proposed for regulation.

EPA Response: With respect to the EPA's decision to exclude PFOA and PFOS from the Hazard Index approach, please see section 5.2.1 of the EPA response in this *Response to Comments* document.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042976)

Additionally, EGLE DWEHD requests that EPA further speak to the proposed use of a general hazard index for the four PFAS chemicals versus multiple target organ toxicity-specific indexes, and that EPA speak to the exclusion of PFOA and PFOS from hazard index calculations.

EPA Response: With respect to the EPA's decision to exclude PFOA and PFOS from the Hazard Index approach, please see the EPA response in 5.2.1 of the EPA response in this *Response to Comments* document. With respect to the agency's discussion on the application of the target organ specific hazard index approach, please see section 4.3.1 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044366)

• EPA requests comment on its proposed decision to establish stand-alone MCLs for PFOA and PFOS in lieu of including them in the HI approach (pg. 18671 Federal Register Volume 88, Number 60).

o The commenters agree with EPA's decision to establish stand-alone MCLs for PFOA and PFOS in lieu of including them in the HI approach. The justification provided by EPA in their analysis is convincing because including PFOA and PFOS in the HI approach would not provide additional public health protection for those contaminants over setting MCLs at the PQL. Based on the co-occurrence data for PFOA, PFOS, and the HI PFAS, it is clear that including PFOA and PFOS in the HI approach would increase public health protection for the HI PFAS, but it would also significantly increase costs and the number of water systems required to treat for PFAS.

EPA Response: With respect to the EPA's decision to exclude PFOA and PFOS from the Hazard Index approach, please see section 5.2.1 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044415)

Page 18730. EPA requests comment on its proposed decision to establish stand- alone MCLs for PFOA and PFOS in lieu of including them in the HI approach.

• DOH supports this approach to compliance in the PFAS rule. Establishing MCLs is consistent with the current nationwide Standard Monitoring Framework implementation.

• EPA has set the MCLs for PFOS and PFOA at what the Agency determined are the PQLs for these compounds. Given that, it doesn't make sense to consider an approach where lower concentrations would contribute to the HI of a mixture.

EPA Response: With respect to the EPA's decision to exclude PFOA and PFOS from the Hazard Index approach, please see the section 5.2.1 of the EPA response in this *Response to Comments* document.

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044308)

Hazard Index (HI) Approach:

Vancouver supports the decision to establish stand-alone MCLs for PFOA and PFOS in lieu of including them in the HI approach.

EPA Response: With respect to the EPA's decision to exclude PFOA and PFOS from the Hazard Index approach, please see section 5.2.1 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045023)

EPA requested comments on its proposed decision to establish standalone MCLs for PFOA and PFOS in lieu of including them in the HI approach. Since the proposed MCLs for PFOA and PFOS are set at the analytical minimal reporting levels, any detection of these PFAS above the minimal reporting limits of 4.0 ppt would result in an MCL exceedance, whether or not they are included in the HI approach.

EPA Response: With respect to the EPA's decision to exclude PFOA and PFOS from the Hazard Index approach, please see section 5.2.1 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045099)

4) EPA requests comment on its proposed decision to establish stand-alone MCLs for PFOA and PFOS in lieu of including them in the Hazard Index approach:

If EPA were to add PFOA and PFOS to the existing Hazard Index would be challenging and require additional supporting data and information due to the impact any reported level will have when compared with the respective health advisory number. Adjustment to the Hazard Index standard of 1.0 would need to be justified.

EPA Response: With respect to the EPA's decision to exclude PFOA and PFOS from the Hazard Index approach, please see section 5.2.1 of the EPA response in this *Response to Comments* document.

Missouri River Public Water Supplies Association (MRPWSA) (Doc. #1581, SBC-042410)

Use of the Hazard Index Approach to Regulate PFHxS. HFPO-DA. PFnA. and PFBS — MRPWSA does not support the use of the Hazard Index as proposed for regulating PFAS in drinking water and recommends the development of drinking water regulations that follow the MCL approach once data to support such action is available.

EPA Response: With respect to the EPA's regulation of additional PFAS through a Hazard Index MCL, please see the section 5.2.1.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045492)

Moreover, the agency is proposing to regulate the four PFAS chemicals under the novel HI approach. Many small entities and their representatives have expressed concerns about the validity of this approach. Advocacy encourages the agency to address the concerns raised by stakeholders on this topic.

EPA Response: With respect to the EPA's regulation of additional PFAS through a Hazard Index MCL, please see the section 5.2.1 of the EPA response in this *Response to Comments* document. The EPA has considered all public comments provided on the proposed NPDWR, including comments on the hazard index.

Austin Water (AW), Austin, TX (Doc. #1688, SBC-044454)

In addition to the proposal to regulate perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS) with individual maximum contaminant levels (MCLs), the proposed PFAS NPDWR uses a "Hazard Index" approach for four substances: perfluorohexane sulfonic acid (PFHxS), GenX chemicals, perfluorononanoic acid (PFNA), and perfluorobutane sulfonic acid (PFBS). This proposal is the first time the Hazard Index (HI) approach has been applied to drinking water regulations for public water systems under the SDWA framework. EPA has set

legal limits on over 90 contaminants in drinking water without using the HI approach. The HI approach differs considerably and is more nuanced and complex than regulations for MCLs or treatment technique (TT) requirements. Over the last four decades, community public water systems have developed a historical understanding of EPA's regulatory methodology employed under SDWA and the implementation of MCL and TT compliance requirements. The unforeseen introduction of a HI approach requires more time for water system staff to review and understand of the basis for and implementation of this application within our industry. As AW and other water systems are currently dedicating resources to meeting other new drinking water regulatory requirements, it is important to give water systems at least until the spring of 2024 to comprehend and incorporate the science behind the HI approach fully. This includes planning for potential impacts on compliance with proposed NPDWR regulations and being prepared to communicate with the public as needed. With these factors existing, it will be beneficial to allow additional time for further review and feedback on the use and effectiveness of the HI approach.

EPA Response: With respect to the EPA's regulation of additional PFAS through a Hazard Index MCL, please see the section 5.2.1 of the EPA response in this *Response to Comments* document. Regarding responses on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. While the agency acknowledges that the Hazard Index has not been used under SDWA to set an enforceable MCL, the Hazard Index approach has been used successfully by the EPA in other programs. The EPA further notes that the Hazard Index value is the MCL which represents the maximum level allowed of a contaminant or group of contaminants in water which can be delivered to any user of a PWS. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation.

Michigan Farm Bureau (MFB) (Doc. #1562, SBC-043352)

However, we have significant concerns about the feasibility of implementation and compliance with the proposed Maximum Contaminant Limits (MCLs) for six PFAS: 4 parts per trillion (ppt) for perfluorooctanoic acid (PFOA), 4 ppt for perfluorooctane sulfonic acid (PFOS), combined Health Index value for the total combined concentrations of up to 2000 ppt of perfluorobutane sulfonic acid (PFBS), 9 ppt of perfluorohexane sulfonate (PFHxS), 10 ppt of hexafluoropropylene oxide dimer acid and its ammonium salt (HFPO-DA, also known as GenX), and 10 ppt of perfluorononanoic acid (PFNA).

As EPA moves forward with its strategic plan and this important set of regulations, we urge the agency to carefully consider the impacts of setting these MCLs. EPA needs to ensure they are using the most recent, most accurate, and most transparent science in setting those regulatory limits. The agency needs to understand the larger impacts of drinking water regulations, not only because drinking water standards and the science behind them forms the basis of all other

regulatory standards for water, including surface and groundwater quality standards and designated uses, permitted discharge standards for NPDES and other program compliance, and contamination clean-up thresholds.

EPA Response: The EPA believes the MCLs are feasible and this is demonstrated by the Administrative record for this action. See sections 5.2.1., 5.1.2, and 5.1.4 of the EPA response in this *Response to Comments* document for further discussion. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and are driven by the requirements of SDWA. In the administrative record, the EPA has described, in detail, how it developed the final rule's MCLs. See section V of the preamble for this NPDWR for information supporting development of the MCLs. With respect to commenter concerns on impacts of the NPDWR in non-drinking water contexts, such as NPDES or other permitting standards, these issues are beyond the scope of the current rulemaking. For additional discussion, please see section 5.1.3 and section 15.1 for the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045601)

First, AWWA notes that EPA's novel use of the hazard index approach in the proposal is not clearly permissible under the SDWA. The SDWA is designed for an individual assessment of contaminants and an individualized assessment of appropriate MCLG and MCL, as the statute uses the singular "contaminant" when defining "maximum contaminant level." [FN17: 42 U.S.C. § 300f(3).] The proposal runs counter to this statutory focus by a Hazard Index approach rather than a specific concentration level for proposing an MCL and MCLG for PFNA, PFHxS, PFBS, and HFPO-DA.

The Hazard Index approach is also arguably inconsistent with SDWA because it is not a "level" but instead a calculated sum of component hazard quotients using a highly variable equation that can change over time.

EPA Response: With respect to the EPA's regulation of additional PFAS through a Hazard Index MCL, please see the EPA response to comment Doc. #1713, SBC-053343 in section 5.2.1 in this *Response to Comments* document. Regarding EPA's statutory authority to regulate mixtures, please see section 3.2 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044875)

Based on the substantial science and data used by DEP to promulgate our state PFAS maximum contaminant level (MCL) rule, DEP supports the decision to establish standalone MCLs for perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS), instead of including them in the hazard index (HI) approach. Additional comments relative to the proposed MCLs for PFOA and PFOS and the combined HI approach for additional PFAS are provided later in this letter.

EPA Response: Regarding the EPA's decision to exclude PFOA and PFOS from the Hazard Index MCL, please see section 5.2.1 of the EPA response in this *Response to Comments* document.

5.3 Individual PFAS MCLs: PFHxS, HFPO-DA, PFNA, and PFBS

5.3.1 General

Summary of Major Public Comments and EPA Responses

Commenters were mixed on the EPA's request for public comment on the establishment of stand-alone MCLs in lieu of or in addition to the Hazard Index MCL. Many of the comments were related to risk communications and messaging to consumers. While several commenters favored stand-alone MCLs in lieu of the Hazard Index to improve communications to their customers, several other commenters recommended stand-alone MCLs in addition to the Hazard Index MCL to achieve this purpose. Several commenters opposed individual MCLs for some or all of the PFAS because they believe it may complicate risk communication. Some commenters assert that the Hazard Index is novel and may confuse the public. The EPA notes that while the Hazard Index has not been used under SDWA to set an enforceable MCL, it has been validated and successfully used by other parts of the EPA as an effective approach to minimizing public health risks. After consideration of public comment, the agency agrees that risk communication is an important focus for water systems and primacy agencies, and the EPA believes that finalizing individual MCLGs and MCLs in addition to the Hazard Index framework to address mixtures may help support risk communication efforts because utilities and the public may be more familiar with individual MCLs when one contaminant is occurring. At the same time, since those individual MCLs do not address additional risks from mixtures of co-occurring PFAS, the EPA is finalizing a Hazard Index MCL to address dose additive health concerns associated with mixtures of PFHxS, PFNA, HFPO-DA, and PFBS that co-occur in drinking water. For additional discussion on the Hazard Index approach and other mixture-based approaches (e.g., TOSHI), please see section IV of the final rule preamble. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For additional discussion on PFAS risk communications, please see section 1.2 of the EPA response in this *Response to Comments* document.

In the final NPDWR, the EPA is promulgating individual MCLs for PFHxS, PFNA and HFPO-DA at the same level as their respective MCLGs (which are equivalent to the HBWCs). The EPA is finalizing individual MCLs as follows: HFPO-DA MCL = 10 ng/L; PFHxS MCL = 10 ng/L; and PFNA MCL = 10 ng/L. Concurrent with this action, the EPA is making the required determinations to support both the individual MCLs for PFHxS, PFNA, and HFPO-DA as well the Hazard Index MCL for mixtures of PFHxS, PFNA, HFPO-DA and PFBS (please see section III of the final rule preamble and section 3 of the EPA response in this *Response to Comments* document for additional discussion on the EPA's regulatory determinations).

The agency considered feasibility as defined by SDWA and notes that EPA's feasibility justification for these individual PFHxS, PFNA and HFPO-DA MCLs are the same as the Hazard Index MCL discussed in section 5.2 of the EPA response in this *Response to Comments* document and section V.B of the final rule preamble. The EPA further notes that the Hazard Index MCLG applies to the entire mixture but the EPA's technical justification for the underlying values (i.e., HBWCs) are the same as the individual MCLGs in this rule. In summary, the EPA has determined that it is feasible to set the individual MCLs at the MCLGs for PFHxS, PFNA and HFPO-DA current BATs can remove each contaminant to a level equal to or below their respective MCLGs. In addition, there are analytical methods available for these contaminants and the PQL for each contaminant is below the level established by the MCLG. The EPA also considered costs and determined that establishing an individual MCL of 10 ng/L for PFHxS, PFNA, and HFPO-DA is reasonable based on consideration of the costs to large metropolitan water systems. These considerations support a determination that individual MCLs of 10 ng/L for PFHxS, PFNA, and HFPO-DA are feasible and therefore the EPA is setting the MCL at the same level as the MCLG. For additional discussion regarding the derivation of the individual HBWCs and MCLGs, please see section III and IV of the final rule preamble.

In light of finalizing the individual MCLs for PFHxS, PFNA, and HFPO-DA, the EPA has separately presented national level marginal costs associated with the individual MCLs for PFHxS, PFNA and HFPO-DA in the absence of the Hazard Index MCL; for more information, please see sections 5.1.2 and 13.3 of the EPA response in this *Response to Comments* document. Additionally, please Chapter 5.1.3 and Appendix N.4 of the HRRCA.

Individual Public Comments

Pennsylvania Chamber of Business and Industry (Doc. #1592, SBC-042798)

EPA's Novel and Unprecedented Hazard Index Approach for PFAS Presents Significant Questions and Should be Reconsidered

In stark contrast to how all other MCLs have been established, which is determined in reference to health advisory limits, EPA is proposing in this rulemaking to regulate four PFAS combinations using a hazard index that may produce subjective determinations with conflicting interpretations between utilities and regulators. It is likely this approach will produce significant uncertainty to regulated communities and may be inconsistently applied across the country and not well understood by the public. As such, EPA should develop a workable MCL using traditional approaches.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. The agency disagrees that it is likely that the Hazard Index approach will produce "significant uncertainty" to regulated communities, "may be inconsistently applied across the country" and "may product subjective determinations with conflicting interpretations between utilities and regulators" because the MCL of 1 is the

maximum level allowed of a contaminant in water which is delivered to any user of a PWS The hazard index calculation is not mathematically different (i.e., summing up numbers and dividing) than a RAA calculation which is used frequently for compliance calculations for NPDWRs. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. The EPA disagrees with commenter's assertions regarding MCLs and HAs. HAs and NPDWRs are different actions with different purposes that are conducted pursuant to different statutory authorities.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044017)

1. EPA requests comment on its preliminary regulatory determination for PFHxS and its evaluation of the statutory criteria that supports the finding. EPA also requests comment on if there are additional data or studies EPA should consider that support or do not support the Agency's preliminary regulatory determination for PFHxS, including additional health information and occurrence data.

a. PFHxS will likely become the PFAS problem for many utilities in their efforts to keep the HI below 1. This compound has been observed to breakthrough treatment media before PFOA and PFOS. PFHxS has a reference value of 9 in the new rule. CWUC is curious if EPA's treatment cost models are based on only PFOA and PFOS or all six compounds targeted in the new rule? CWUC recommends that the PFHxS reference value be re-evaluated and raised if possible (or consider establishing MCLs over the HI approach).

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. With respect to the commenter's question on if the cost models account for PFOA and PFOS, or all six compounds (specifically PFHxS), the EPA's cost models do account for PFHxS occurrence and removal. SafeWater Multi-Contaminant Benefit Cost (MCBC) calculates bed life using a system of equations that considers the percent removal required for each PFAS that occurs at an entry point and has an MCL or other limit in the regulatory option, even if the contaminant occurs at a concentration below the regulatory limit. See the EPA response to comment Doc. #1709, SBC-053307 in section 13.3.2 in this *Response to Comments* document about consideration of PFAS competition in the EPA's bed life equations. Further, please see Appendix N.3 of the EA (USEPA, 2024c) and section 13.3.2 of the EPA response in this *Response to Comments* document for discussion on the Hazard Index and individual MCLs for PFNA, PFHxS, and HFPO-DA costs at the national level. The EPA notes that in the final regulation, EPA has adjusted the MCL for PFHxS to 10 ng/L from 9.0 ng/L (please see the EPA response to comment Doc. #1774, SBC-045656 in section 4.3.3 in this *Response to Comments* document).

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-052953)

• The health effects required language for PN for an HI MCL exceedance in Appendix A to Subpart O of Part 141 will be confusing to the public. The required language does not sufficiently explain the HI and is likely to cause confusion and fear.

• The health effects required language for CCR reporting for the HI MCL in Appendix A to Subpart Q of Part 141 will be confusing to the public. The required language does not sufficiently explain the HI.

• DEP believes that communication of the HI MCL to the public will be a significant implementation challenge of the proposed rulemaking. As noted above, the required health effects language does not adequately explain the HI, how it is determined, what the significance is, or why it is unitless. This is likely to cause confusion and fear in the public. Communication to the public in a way that does not incite fear and misunderstanding is critical. One key point that will be important to communicate is the relative source contribution of drinking water and the numerous other potential routes of exposure to PFAS. For a public that is concerned about very low detected levels of PFAS in their drinking water, it is important to educate them on other ways to reduce their exposure, since drinking water is only considered a 20% relative source contribution to overall exposure.

• DEP notes that on page 18690 of the preamble to the proposed rulemaking, EPA states that it "has not separately quantified the benefits and costs for the alternative approach to regulate PFHxS, PFNA, PFBS, and HFPO-DA with individual MCLs instead of the HI." In other words, EPA did not show whether it is more cost effective or more feasible to regulate these four PFAS with traditional MCLGs and MCLs instead of the HI, and it did not clearly articulate the costs and benefits associated with regulating these four PFAS in a more traditional manner. As a result, it is not clear what impact eliminating the HI and regulating the four HI PFAS with traditional MCLGs and MCLs would have on overall costs. DEP believes that this missing information is critical in the evaluation of this proposed rulemaking and in determining the best way to regulate these PFAS, particularly since - as our previous comments detailed - the introduction of the HI MCL does not appear to be an appropriate application of the HI concept.

• Because of the significant implementation challenges noted above with the HI MCL, DEP suggests that it would be better to use an established approach for regulating these four additional PFAS. For example, using a treatment technique, combined MCL, or individual MCLs would be more feasible for implementation. As noted above, DEP believes that the HI MCL concept, as well as a water system's ability to demonstrate compliance, is likely to be confusing to the public. DEP believes that setting a traditional MCLG and MCL, either individually or combined, for the four HI component PFAS (PFHxS, PFNA, PFBS, and HFPO-DA) instead of using the HI approach would improve clarity for primacy agencies, regulated water systems, and the public. The traditional MCLG and MCL framework is an established framework that can be more readily comprehended.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. Regarding risk communication, please see section 1.2 of the EPA response in this *Response to Comments* document. Regarding health effects required language for PN for a Hazard Index MCL, please see the section 9 of the EPA response in this *Response to Comments* document. The agency disagrees that the EPA "did not show whether it is more cost effective or more feasible to regulate these four PFAS with traditional MCLGs and MCLs instead of the Hazard Index, and it did not clearly articulate the costs and benefits associated with regulating these four PFAS in a more traditional manner." The EPA's cost analysis at proposal considered the costs associated with the individual MCLs for PFHxS, PFNA, and HFPO-DA because the proposed Hazard Index MCL would function as individual MCLs when these contaminants occur in isolation. While the rule structure has changed in the final NPDWR based on public comment received, the costing framework used at proposal is still fully applicable in the final rule: what was considered a Hazard Index MCL exceedance at proposal would be an individual MCL exceedance under the final rule should those contaminants occur in isolation. Further, the combination of a Hazard Index exceedance in the final rule (defined as two or more of PFHxS, PFNA, HFPO-DA, and PFBS) or an individual MCL exceedance for PFHxS, PFNA, or HFPO-DA is unchanged from a costing perspective to what the EPA proposed. Whether a system exceeds a Hazard Index MCL or individual MCL in the final rule, these costs are captured in the cost estimates the EPA considered and presented in Appendix N.3 of the EA (USEPA, 2024c) and discussed further in section 13.3 of the EPA response in this *Response to Comments* document.

While the EPA believes individual MCLs for these three PFAS will aid implementation, the EPA disagrees that solely regulating the additional PFAS using only individual MCLs would be better compared to the Hazard Index approach because the Hazard Index approach addresses dose additive health concerns from mixtures of PFHxS, PFNA, HFPO-DA and PFBS that is not addressed by individual MCLs alone. The EPA has assessed benefits associated with Hazard Index PFAS qualitatively in the HRRCA for the PFAS NPDWR. Specifically, as Hazard Index PFAS are reduced, the EPA anticipates additional public benefits from avoided cardiovascular, developmental, and immune effects. For further discussion of the quantitative and qualitative benefits associated with the PFAS NPDWR, see section 6.2 of the EA (USEPA, 2024d) and sections 13.4 through 13.8 of the EPA response in this *Response to Comments* document. For additional discussion on the HRRCA, please see section XII of the FRN, as well as section 14.7 of the EPA response in this *Response to Comments* document. The EPA discusses its rationale on the final NPDWR MCLs included in section V of the FRN, particularly V.B. and V.C. For high level implementation-related concerns, please see section 1.3 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046074)

5. Use of a Hazard Index approach complicates risk communication to the public.

Our members frequently have to address risk communication challenges regarding PFAS. The Environmental Council of the States (ECOS) has recognized these challenges for state agencies as well. In ECOS's White Paper "Processes & Considerations for Setting State PFAS Standards," the theme of needing improved risk communications regarding developing PFAS regulations appears throughout. ECOS, Feb. 2020, updated March 2023, at p. 8, 9. 36, 38, and 39, available at: https://www.ecos.org/documents/ecos-paperprocesses-and-considerations-for-setting-state-pfas-standards-2023-update/. To mitigate these challenges, the Coalition has long advocated for national standards, which allow for clearer risk communication than if there is a patchwork of state standards. It is difficult, for example, to explain to the public and other stakeholders why one state has MCLs for two PFAS compounds at certain levels, while another state regulates seven PFAS compounds at different levels. Uniform national standards allow for a more uniform understanding and clearer communication on these important issues. The use of a Hazard Index approach, however, frustrates the opportunity to provide clear communication to the public.

The Proposal demonstrates how unclear the HI approach is to communicate. EPA gives examples of how PFNA, HFPO-DA, PFHxS, and PFBS all can be below their respective HBWC, yet there is still an exceedance of the HI – which means there is an exceedance of the MCL. 88 Fed. Reg. at 18665 - 666. EPA adds to the confusion in its discussion of why only 4 compounds are included in the HI, and why it is not including PFOA and PFOS. The explanation that EPA gives as to why PFOA and PFOS are not part of the HI is that "the Agency believes doing so would not add meaningful health protection over setting an individual MCL." 88 Fed. Reg. at 18670. That statement is entirely inconsistent with the Agency's explanation of why it needs to use the HI approach. Further, this explanation is confusing and leaves the impression either an individual MCL or an HI may have more "meaningful health protection" than the other.

As recognized by ECOS and as experienced by our members, risk communication is vital with developing PFAS regulations. A national standard for drinking water should make risk communication easier, yet the HI approach makes it more difficult and confusing. This is yet another reason not to adopt an HI approach in drinking water standards.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. Please see section 1.2 of the EPA response in this *Response to Comments* document for additional discussion on PFAS risk communications. The EPA disagrees that the Hazard Index approach should not be adopted in drinking water standards as adopting a Hazard Index approach will protect against dose additivity from mixtures of these four PFAS. The EPA's final rule represents data-driven

drinking water standards that are based on the best available, peer-reviewed science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For discussion on feasibility considerations for the Hazard Index PFAS, please see section 5.2.1 of the EPA response in this *Response to Comments* document. For discussion on the decision to use the general Hazard Index approach, please see section 4.3.1 of the EPA response in this *Response to Comments* document, as well as the rationale described in the Hazard Index MCLG and the Mixtures Framework support documents. Information on the Hazard Index mixtures MCL is included in section V.B of the FRN, as well as section 5.2 of the EPA response in this *Response to Comments* document The EPA further provides rationale for not including the PFOA and PFOS in the Hazard Index in section V.B.2 of the FRN and sections 4.3 and 5.2.1 of the EPA response in this *Response to Comments* document.

Bowling Green Municipal Utilities (Doc. #1767, SBC-043930)

Hazard Index is an Inappropriate MCL: EPA's proposed use of a "hazard index" is not only difficult to communicate to the public, but also a misapplication of the concept scientifically. Moreover, EPA's benefit-cost analysis recognizes that the hazard index does not accrue any actual benefit.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. Please see section 1.2 of the EPA response in this *Response to Comments* document for additional discussion on PFAS risk communications. The commenter provides no explanation to support its statement that "this is a misapplication of the [hazard index] concept scientifically." Based on the agency's technical expertise, it was determined that the hazard index is the most cost-effective and least burdensome alternative for purposes of UMRA because this approach for mixtures achieves the objectives of the rule. For additional discussion about the hazard index, please see sections 4.3 and 5.2.1 of the EPA response in this *Response to Comments* document.

The EPA disagrees with the commenter regarding Hazard Index benefits. Contrary to the commenter's assertion, the EPA identified significant benefits associated with the Hazard Index and has assessed these benefits qualitatively in the EA for the PFAS NPDWR. Specifically, as PFHxS, PFNA, HFPO-DA and PFBS are reduced, the EPA anticipates additional public benefits from avoided cardiovascular, developmental, and immune effects. For further discussion of the quantitative and qualitative benefits associated with reduction of PFHxS, PFNA, HFPO-DA and PFBS that will result from the PFAS NPDWR, see section 6.2 of the EA (USEPA, 2024d) and

section 13 of the EPA response in this *Response to Comments* document. For additional discussion on the HRRCA, please see section XII of the FRN.

Corix Infrastructure Inc. (Doc. #1834, SBC-045369)

[With regards to the specific items EPA has requested comment on, Corix provides below:]

• With regards to whether the HI can be clearly implemented, Corix has concerns that the approach will be confusing for customers and other members of the public to understand and appreciate the complexities in the calculations. We request a standard approach to communicating and documenting compliance data.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. Please see the section 1.2 of the EPA response in this *Response to Comments* document for additional discussion on PFAS risk communications.

The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-045061)

Additionally, EPA's use of a hazard index adds another layer of confusion. If EPA includes a hazard index in the final version of the regulation, water utilities will be relying on EPA to develop a communication strategy to protect consumer confidence. Feasible standards with reasonable timelines will safeguard consumer confidence and protect our most vulnerable residents from additional burden.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. Please see section 1.2 of the EPA response in this *Response to Comments* document for additional discussion on PFAS risk communications.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042807)

PFHxS, HFPO_DA, PFNA, and PFBS

The proposed regulation includes a Hazard Index approach to address several PFAS compounds through a single measure: PFHxS, HFPO_DA, PFNA, and PFBS. To date, this approach has not been used in other drinking water regulations. The treatment of these compounds in the proposed regulation is problematic for several reasons:

1. Customer Communication – Water quality is a complex topic to begin with, and measures such as "parts per trillion" are sometimes difficult for customers to understand. However, units of measure can be explained with examples and other common-language descriptions. The complexity of the Hazard Index calculation does not lend itself to a simple explanation that customers will be able to understand.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. Please see section 1.2 of the EPA response in this *Response to Comments* document for additional discussion on PFAS risk communications. For additional discussion on the use of the Hazard Index in other programs, please see section 4 of the EPA response in this *Response to Comments* document. The general Hazard Index is a well-established methodology that has been used for several decades in at least one other regulatory context to account for dose additivity in mixtures assessments. The EPA routinely uses the Hazard Index approach to consider the risks from multiple contaminants of concern in the Remedial Investigations and Feasibility Studies for cleanup sites on the Superfund National Priorities List under CERCLA. Noncarcinogenic effects are summed to provide a Hazard Index that is compared to an acceptable index, generally 1. This approach assumes dose additivity in the absence of information on a specific mixture. These assessments of hazards from multiple chemical exposures are important factors to help inform the selection of remedies that are ultimately captured in the Superfund Records of Decision.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043671)

Water quality is a complex topic to begin with, and measures such as "parts per trillion" are difficult to understand; the complexity and change of the typical analysis into the Hazard Index calculation does not lend itself to a simple explanation.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. Please see section 1.2 of the EPA response in this *Response to Comments* document for additional discussion on PFAS risk communications.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044082)

Hazard Index

From a communication perspective, ASDWA recommends that EPA retain the Hazard Index instead of establishing four additional MCLs.

EPA asked for comment on the decision to use solely a Hazard Index for the four PFAS mixture rather than a combination of a Hazard Index and MCLs. While ASDWA's members could not reach a consensus on the overall use of the Hazard Index, regarding the implications for public communication, ASDWA recommends that EPA only use the Hazard Index and not implement individual MCLs for the PFAS mixture compounds. ASDWA's members agree with EPA's reasoning that including a Hazard Index and four additional MCLs would create confusion without any obvious benefit.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044072)

General Comments

ASDWA supports EPA's efforts to collectively address PFAS in a regulatory framework other than multiple individual maximum contaminant levels (MCLs).

Building upon previous comments, ASDWA generally agrees with EPA's decision to develop an NPDWR that addresses PFAS in groups rather than individual substances. Attempting to establish individual MCLs in the future for every PFAS that is shown to have detrimental health impacts would be time-consuming, cumbersome, and unrealistic for the long-term management of this class of chemicals. However, ASDWA's members could not reach a consensus on using EPA's proposed Hazard Index (HI) as the optimal regulatory framework.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044124)

Risk Communication

The implementation of the proposed HI approach adds confusion about how to interpret an exceedance of the HI-based MCL. As noted in the proposed rule, different water systems will likely have different concentrations of each of the four PFAS, depending on what potential contaminant sources are nearby, and not all PFAS may exceed their individual health-based

water concentrations (HBWC). EPA does give examples of situations in which the HI of 1.0 is exceeded due to detection and measurement of one of the four PFAS, specifically PFHxS, in the HI equation. [FN8:88 Fed. Reg. 18638, 18666 (Mar, 29, 2023)] However, as noted above, the target organ of concern for PFHxS (i.e., thyroid follicular epithelial hypertrophy/hyperplasia in parental male rats) is different than the target organs of effect for the other three PFAS. While the HI value would indicate an exceedance of the MCL and MCLG for PFHxS, because there is a single MCL for all four PFAS, it also implies an exceedance for PFNA, GenX, and PFBS with their associated potential health effects.

Other examples are given in which none of the HWBCs are, [FN9: Id. At 18665.] yet the HI is larger than 1.0. If the HI is larger than 1.0 due to lack of exceedance of the HBWC for each PFAS, each with a different critical effect, then it is difficult to determine what potential risk should be communicated to the public. The default communication would be to state that there is a risk for each of the critical effects, even though none of the PFAS exceeded its individual HBWC and a common MOA has not been demonstrated, which would be misleading and create inappropriate concern. It is also not clear how to communicate the potential dose additive risk in the absence of a common MOA. Risk communication is a crucial part of implementing a drinking water standard and if EPA chooses to move forward with this scientifically unjustified HI approach, then it should also provide guidance on how to appropriately communicate risk from exceedances of the MCL to the public.

Due to the different critical effects, different target organs of toxicity, likely different MOAs for the critical effects of each of the four different PFAS in the HI approach, and the difficulty in communicating risk associated with an HI-based MCL, individual MCLs for PFBS, PFHxS, GenX chemicals, and PFNA would be more appropriate. Having a separate MCL for each contaminant would ensure that the regulated community understands the compliance calculations for these chemicals, would allow for precise public notice to customers with specific health-effects information, and allow the proposed rule to fit within established compliance processes and state data systems.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. The agency agrees that risk communication is an important focus for water systems and primacy agencies, and the EPA believes that finalizing individual MCLGs and MCLs in addition to the Hazard Index framework may help support risk communication. With respect to the scenario of public notice of violations of individual MCLs and the Hazard Index MCL, the EPA agrees with the commenter and finds that issuing multiple for these violations may cause confusion as the adverse health effects and exposure concerns in this instance is not meaningfully different from either a Hazard Index or individual MCL perspective. To simplify implementation of PN in this scenario, the EPA is finalizing requirements in Appendix A to Subpart Q of Part 141 such that utilities who violate

the Hazard Index MCL and one or more individual MCLs because of the same compounds can issue one notification to satisfy the PN requirements for the multiple violations.

New York City Department of Environmental Protection (NYCDEP) (Doc. #1679, SBC-044205)

One concern about usage of the HI is that the constituent concentrations are essentially masked from direct reporting when compared to typical water industry MCLs for single analytes. As a new regulatory tool, the calculation of the HI will have to be explained to the public, as it may appear as though the water supplier is attempting to avoid reporting the HI constituent concentrations directly.

EPA Response: Please see the EPA response to comment Doc. #1632, SBC-044124 in section 5.3.1 in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044031)

13. EPA requests comment on its proposed decision to establish stand-alone MCLs for PFOA and PFOS in lieu of including them in the HI approach.

a. It is appropriate to establish MCLs for PFOA and PFOS, with a recommended MCL of

8.0 ppt, and a trigger level at ½ the MCL of 4.0 ppt (at the established PQL). There could be a lot of pushback from communities if EPA does not establish MCLs for PFOA/PFOS. An option could be to continue with an additive MCL approach. CWUC also prefers establishing MCLs for the four other compounds.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

Massachusetts Water Resources Authority (Doc. #1645, SBC-043285)

c. Hazard Index is Misplaced as a MCL

Maintaining public confidence in PWSs throughout the implementation of new regulations should be paramount. The unintended consequence of a lack of public confidence drives the public to less sustainable and less regulated sources of water, including bottled water. EPA's proposed use of a hazard index is extremely difficult to communicate to the public and is based on limited toxicology and occurrence data. MWRA recommends that EPA remove the hazard index MCL from this proposed rulemaking due to limited toxicological and occurrence data on

the four PFAS. More generally, MWRA asks EPA to reconsider the use of complicated and difficult to explain MCLs, such as a hazard index.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044176)

2. From a communication perspective, NCDEQ recommends EPA retain the use of the hazard index in lieu of establishing four additional MCLs.

EPA asked for comment on the decision to solely use a Hazard Index for the four PFAS mixture rather than a combination of both a Hazard Index and MCLs. NCDEQ recommends that EPA retain only the Hazard Index approach and not implement individual MCLs for the PFAS mixture compounds. NCDEQ agrees with EPA's reasoning that including both a Hazard Index and four additional MCLs would create confusion without any obvious benefit.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043707)

Comment Topics:

MCLs and Use of Hazard Index (HI)

Section VI

As proposed, the MCLs for PFOA and PFOS are 4 ppt with an MCLG of "non detect". Aurora Water urges EPA to consider an MCL of 10 ppt for PFOA and PFOS. With the current technologies for analyzing and treating drinking water, maintaining PFOA and PFOS levels below 4 ppt is not feasible. The prevalence of PFAS chemicals in the environment and the current available technology for treatment of PFAS in drinking water to non-detect levels would

be an astronomical effort. The cost of treatment to below 4 ppt would cost Aurora Water 190% more than what it would cost to treat to 10 ppt. Aurora believes that an MCL of 10 ppt would be adequately protective of public health based on the provided health studies. If EPA decides to use an MCL of 10 ppt now, it can be reviewed in subsequent rulemakings and lowered once treatment technologies are more advanced. Therefore, Aurora Water recommends the proposed 4 ppt MCL for PFOA and PFOS be increased to 10 ppt for each compound.

The hazard index (HI) is proposed as a calculation for a mixture of PFNA, PFHxS, PFBS, and GenX with an MCL of 1.0. Aurora Water is concerned about the use of an HI approach because it combines substances with different health impacts into a single index. EPA has previously noted, in their guidance "Identifying Pesticide Chemicals and Other Substances that Have Common Mechanisms of Toxicity," it would not use cumulative risk assessments for substances with largely different toxic effects or mechanisms of toxicity. We believe this statement applies to PFAS chemical compounds and EPA should apply the same reasoning to the PFAS mixture HI. Additionally, explaining an HI, which has three different critical health effects, to the public poses a scientific and communications challenge. Previously developed EPA guidance on cumulative risk for mixtures of chemicals does not support the idea of dose additivity for multiple compounds across different types of health effects. As a water utility, communicating a HI with multiple health effects to the public will be extremely difficult. Separating the hazard index chemicals and replacing with individual MCLs would simplify communication with the public. Therefore, Aurora Water argues for individual MCLs for each compound instead of a hazard index.

EPA Response: The EPA notes that the MCLG for PFOA and PFOS are not nondetect; rather, they are set at 0 (zero). Please see section 5.1.3 of the EPA response in this *Response to Comments* document for discussion around consideration of other PFOA and PFOS MCLs. After considering public comments, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. For additional discussion on cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document. Regarding the comment on cumulative risk assessments for pesticides, the cited guidance was specifically developed to support pesticide risk assessments under the Food Quality Protection Act (FQPA) of 1996. The FQPA stipulates, among other things, that when determining the safety of a pesticide chemical EPA shall base its assessment of the risk posed by the pesticide chemical on: aggregate (i.e., total dietary, residential, and other non-occupational) exposure to the pesticide and available information concerning the cumulative effects to human health that may result from dietary, residential, or other non-occupational exposure to other substances that have a *common mechanism of toxicity* (italics added for emphasis). A mixture is a "contaminant" for purposes of SDWA; please see the EPA response to comment Doc. #1727, SBC-053343 in section 5.2.1 in this *Response to Comments* document for additional discussion. The EPA's approach to develop the Hazard Index

MCLG is supported by the best available peer reviewed science, the EPA chemical mixtures guidance, expert review by the SAB, and is consistent with the SDWA statutory language for MCLG (see section 4.3.2 of the EPA response in this *Response to Comments* document). With respect to responses on the general Hazard Index approach for PFAS that elicit similar effects following exposure and dose additivity, please see section 4.3.2 of the EPA response in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043272)

• EPA requests comment on whether establishing a traditional MCLG and MCL for PFHxS, HFPO–DA, PFNA, and PFBS instead of, or in addition to, the HI approach would change public health protection, improve clarity of the rule, or change costs.

Response: From a simplicity standpoint, introducing the HI will be problematic. Customers may understand MCL and MCLG's better due to its long-standing history. It is unclear at this point, due to the lack of data (sampling in systems under 10,000), whether the HI approach will change public health protection, improve clarity of the rule, or change costs. However, costs are certain to be excessive in small systems regardless of the approach.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. For additional discussion on cost considerations when setting the MCL and alternative regulatory standards, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045747)

11. EPA should consider a single approach to regulating PFAS, either through individual MCLs or considering the effects of PFAS mixtures.

PWD recognizes the unique regulatory challenges posed by a family of greater than 9,000 different chemical compounds. It has long been a subject of debate in the scientific community as to whether PFAS should be regulated as a class, like disinfection by-products, or as individual species, each with their own MCL. These contaminants together can pose a greater health risk than they do individually and PWD appreciates the EPA's proposal to capture site-specific risks from PFAS mixtures. However, promulgating regulations that include both an approach to regulate individual contaminants as well as mixtures may create confusion across the water industry, primacy agencies, and the general public.

PWD understands that EPA classifies PFOA and PFOS as carcinogens and employs a different policy established by the Safe Drinking Water Act to regulate those chemicals as close as feasible to an MCLG of 0 ppt. Given their carcinogenicity classification and how the HI is

calculated, those PFAS cannot be included in the proposed HI calculation. Because the nuances of EPA's methodology can be difficult to explain to customers, PWD is requesting that EPA provide clearer messaging to help our customers understand the different regulatory approaches and stay informed of the potential health effects from exposure to these contaminants. PWD recommends that the HI concept be removed from this NPDWR to reduce the complexity of the rulemaking.

EPA Response: After a review of public comment, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044776)

WDEQ recommends that EPA consider issuing individual MCLs and MCLGs for GenX and PFNA until additional data and information is available to support the HI approach as currently proposed.

EPA Response: After considering public comments, the agency is promulgating individual MCLs for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document for additional discussion on these individual MCLs, including risk communication and feasibility concerns. For additional discussion on the EPA's feasibility analysis, please see sections 5.1.2 (for laboratory considerations), 5.1.3 (cost considerations and alternative MCLs), 5.1.4 (for treatment considerations) and 5.2.1 (for feasibility considerations for the Hazard Index PFAS) of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046073)

4. If the four additional PFAS are to be regulated at all, it should be done by setting individual MCLs.

Given the concerns, questions and uncertainties regarding the Hazard Index that are set forth above, the Coalition suggests that if EPA is going to regulate the four compounds covered in the Hazard Index, it should instead develop individual MCLs for these compounds. The Coalition is not expressing an opinion as to whether the information that EPA has is sufficient to use in developing drinking water standards, but we would review and comment on that information if and when EPA issues such a rulemaking, following the process set forth in the Safe Drinking Water Act.

EPA Response: Please see section 5.3.1 of the EPA response in this *Response to Comments* document and response to comment Doc. #1716, SBC-044776 in section 5.3.1 in this

Response to Comments document for discussion of setting individual MCLs for PFHxS, PFNA, and HFPO-DA.

Fairfax Water (Doc. #1789, SBC-045315)

5. EPA should issue initial MCLs for PFOA of 10 ppt and PFOS of 10 ppt. EPA should not utilize the Hazard Index approach for PFNA, PFHxS, PFBS, and HFPO-DA.

EPA Response: Please see section 5.1.3 of the EPA response in this *Response to Comments* document for discussion of alternative MCLs for PFOA and PFOS. Please see section 5.3.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1716, SBC-044776 in section 5.3.1 in this *Response to Comments* document for discussion of setting individual MCLs for PFHxS, PFNA, and HFPO-DA.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045832)

B. EPA's proposed MCL for PFBS, PFNA, PFHxS, and GenX expressed as a Hazard Index provides the required margin of safety but should include traditional individual levels to improve the clarity of the rule.

Commenters support the proposed Hazard Index (HI) approach as a feasible and protective level against dose additive impacts from PFBS, PFNA, PFHxS, and GenX. EPA's assumption "that a mixture of chemicals with similar apical effects should be assumed to also act in a dose additive manner unless data demonstrates otherwise" [FN27: 88 Fed. Reg. 18,664.] is consistent with the Agency's requirement to set (1) MCLGs allowing an adequate margin of safety and (2) MCLs as close as feasible to the health-based goals. [FN28: 42 U.S.C. §300g-1(b)(4).] Thus, we support this approach as a well-grounded action under the SDWA and necessary to protect communities exposed to multiple PFAS via drinking water.

Given the likelihood of co-occurrence of these substances, the well-grounded dose additivity assumption, and the feasibility of compliance, the HI MCL approach allows EPA to provide the required adequate margin of safety under the standard-development process of the SDWA. Thus, the Agency should not deviate from the proposed approach. However, to improve the clarity of the rule, EPA should consider establishing a traditional MCLG and MCL for each of these PFAS.

Establishing individual MCLs would not add any additional layer of public health protection because it functions the same as the HI MCL. As EPA rightfully noted, "a system cannot have MCL violations of an individually regulated PFAS without also exceeding the HI MCL." [FN29: 88 Fed. Reg. 18,671.] However, individual MCLs are clearer indicators to determine exceedances when only one of the PFAS is present in a drinking water system. Thus, we support the regulatory alternative considered by EPA where PFBS, PFNA, PFHxS, and GenX would expressly be subject to individual MCLs and the HI MCL for the mixture.

EPA Response: Please see section 5.3.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1716, SBC-044776 in section 5.3.1 in this *Response to Comments* document for discussion of setting individual MCLs for PFHxS, PFNA, and HFPO-DA.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045830)

For the reasons detailed below, Commenters support EPA's proposed NPDWRs as health-protective, feasible, and cost-justified standards. For clarity, however, we urge the Agency to establish traditional levels for PFBS, PFNA, PFHxS, and GenX in addition to the proposed Hazard Index (HI) MCL.

EPA Response: Please see section 5.3.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1716, SBC-044776 in section 5.3.1 in this *Response to Comments* document for discussion of setting individual MCLs for PFHxS, PFNA, and HFPO-DA.

Anonymous (Doc. #2799, SBC-047435)

This is a public comment on the proposed PFAS National Primary Drinking Water Regulation. The Docket ID is EPA-HQ-OW-2022-0114.

This regulation has been carefully developed and its justification is especially detailed and thorough. The overriding goal of protecting public health, saving lives and preventing costly and destructive illness is paramount.

Rather than review this regulation's extensive documentation and methods, I will offer some brief critical comments intended to make this regulation more effective. I write from the perspective of a social scientist living in the rapidly urbanizing desert Southwest, with over thirty years of experience researching and teaching environmental issues.

The environmental justice component of this regulation is a critical benefit which can only be realized if adequate public communication and resources are provided.

I am deeply concerned that the proposed unitless "Hazard Index" is confusing to the public. The use of "parts per trillion" is much clearer and more understandable to all parties. It also highlights the important fact that even small amounts of these contaminants can cause great harm.

Therefore, I recommend that all six PFAS contaminants each be given a specific Maximum Contaminant Level, expressed in parts per trillion.

Thus, the MCL for PFOA and PFOS should be 4.0 ppt. The MCL for PFHxS should be 9.0 ppt, and the MCL for PFNA should be 10 ppt. For PFBS the MCL should be 2000 ppt, and for HFPO-DA the MCL should be 10 ppt.

Again, this change would make these legally enforceable standards more understandable to the public, and therefore easier to enforce.

EPA Response: Please see section 5.3.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1716, SBC-044776 in section 5.3.1 in this *Response to Comments* document for discussion of setting individual MCLs for PFHxS, PFNA, and HFPO-DA.

Suffolk County Water Authority (SCWA) (Doc. #1589, SBC-043367)

Another possibility would be to set contaminant specific MCLGs for these four PFAS at a lower level due to the likely co-occurrence of the other PFAS, e.g., one quarter of the HBWC for each four subject PFAS. The MCLs for each could then be set as close as feasible to the respective MCLGs. In any event, the SCWA, like other responsible public water suppliers, typically plans to install treatment systems once half the MCL level has been detected for a particular contaminant when the MCLG for the contaminant is greater than zero. Here, it would be one half of the MCLG because the EPA is proposing to set the MCL at the MCLG. This is done for operational reasons so that the possibility of an MCL violation during periods of high demand can be greatly limited or eliminated altogether. It is SCWA's goal to treat all locations that have detections of PFAS to levels below the MCLG and to non-detectable levels when the MCLG is zero.

EPA Response: The agency notes that MCLGs are public health goals and are not enforceable standards. After a review of public comment, the agency is promulgating individual MCLs (i.e., the enforceable standards) for PFHxS, PFNA, and HFPO-DA in addition to the Hazard Index MCL for mixtures containing two or more of these PFAS and PFBS. Please see the section 5.3.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1716, SBC-044776 in section 5.3.1 in this *Response to Comments* document for discussion of setting individual MCLs for PFHxS, PFNA, and HFPO-DA. Section 5.3.1 also includes discussion about risk communication and feasibility concerns. With respect to implementation of the PFOA and PFOS MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

LSP Association (LSPA) (Doc. #1742, SBC-043597)

Slide 5: EPA is requesting comment on preliminary determinations to regulate PFHxS, PFNA, PFBS, HFPO-DA (commonly referred to as GenX Chemicals), and mixtures of these four PFAS.

● It is unclear to the LSPA why PFBS, a short chain, "second generation" PFAS that is commonplace in groundwater and exhibits much lower toxicity relative to the other three PFAS compounds, was included in this grouped Hazard Index Approach. We do not think there is

technical justification for including PFBS in the Hazard Index Approach; the LSPA urges USEPA to consider setting an individual MCL for PFBS.

EPA Response: Please see section 5.3.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1716, SBC-044776 in section 5.3.1 in this *Response to Comments* document for discussion of setting individual MCLs for PFHxS, PFNA, and HFPO-DA. The agency is deferring its individual regulatory determination for PFBS at this time. The HBWC for PFBS is different than PFHxS, PFNA, and HFPO-DA. However, PFBS (as well as PFHxS, HFPO-DA and PFNA) have dose additive health concerns and are known to co-occur as mixtures in drinking water. The EPA, therefore, is moving forward with regulating mixtures of two or more of PFHxS, HFPO-DA, PFNA and PFBS through a Hazard Index MCL. Please see section 3 for additional discussion on the EPA's regulatory determinations.

6 Occurrence

6.1 UCMR 3

Summary of Major Public Comments and EPA Responses

Some commenters supported the EPA's use of the best available public health information including data from the third Unregulated Contaminant Monitoring Rule (UCMR 3) and state occurrence data. A few commenters criticized the use of UCMR 3 data, stating that the data suffer from limitations. These commenters expressed concern over the high minimum reporting levels (MRLs), the exclusion of many small systems, and the lack of national monitoring of HFPO-DA. Some of these commenters assert that UCMR 3 does not represent best available occurrence data for this rule. The EPA disagrees with these commenters. While UCMR 3 does have higher reporting limits than those available through current analytical methods, the data still constitute the best available nationwide occurrence dataset to inform the occurrence and co-occurrence profile for the regulated PFAS for which monitoring was conducted. These data are also a critical component of the EPA's model to estimate national level occurrence for certain PFAS and ensure it is nationally representative as described in section VI.E. in the final rule preamble. The EPA also disagrees that the UCMR 3 excludes small water systems as it included a statistically selected, nationally representative sample of 800 small drinking water systems. Regarding commenter concerns for lack of UCMR monitoring data on HFPO-DA, the agency notes that the EPA also examined recent data collected by states who have made their data publicly available. These data included tens of thousands of samples from over ten thousand systems for each of the six PFAS chemicals included in the final rule, including approximately 36,000 HFPO-DA samples, and used lower reporting limits than the data from the UCMR 3. These additional state data came from 32 geographically diverse states. The EPA disagrees that this dataset is insufficient. A discussion of these data and public comments on this information is presented in section III.C and in section VI.B of the preamble. Please see sections 6.2 and 6.4 of the EPA response in this *Response to Comments* document for further discussion of the additional state data and section 6.5 of the EPA response in this *Response to Comments* document for how the state data were used to support the national occurrence model.

Individual Public Comments

<u>San Antonio Water System (SAWS) (Doc. #1570, SBC-042471)</u>

Preliminary examination of PFAS was conducted via UCMR3. However, the PFAS detections for UCMR3 do not warrant regulation. Only 1.4% of UCMR3 samples were above detection nationwide. The contaminants were placed back on the CCL for UCMR5 at the same time regulation was developed circumventing the established process.

EPA Response: The EPA disagrees that the agency has circumvented the established process for developing National Primary Drinking Water Regulations (NPDWRs). The EPA

implements a monitoring program for unregulated contaminants (i.e., UCMR) under the Safe Drinking Water Act (SDWA) 1445(a)(2) that requires the EPA to issue a list once every five years of priority unregulated contaminants to be monitored by public water systems (PWSs). However, there is no statutory requirement that a contaminant must be on this list or that it cannot be listed more than once prior to making a determination to regulate. The EPA may make a determination to regulate if the agency has sufficiently available information through other sources. Please see section 6.1 of the EPA response in this *Response to Comments* document, the UCMR 3 dataset is one of the many sources of occurrence data the agency considered for this regulation. The agency also considered occurrence data from 32 states, which provided the EPA tens of thousands of additional PFAS monitoring results to inform the agency's decision. See discussion in section VI.B of the FRN for this action for further discussion. Please see section 6.8 of the EPA response in this *Response to Comments* document regarding UCMR 5. Completion of the UCMR 5 data collection effort is not required prior to making a regulatory determination nor promulgation of the final rule. The UCMR 3 dataset, along with additional state data and robust analyses, demonstrate sufficient likelihood of occurrence of the PFAS being regulated to justify the EPA's determination. Please see section 3.1.2 of the EPA response in this *Response to Comments* document regarding the EPA's regulatory determination and evaluation of the occurrence criterion.

Santa Clarita Valley Water Agency (SCVWA) (Doc. #1578, SBC-042431)

Additional Perspective:

SCV Water's monitoring program for PFAS Chemicals has demonstrated the ubiquitous nature of these chemicals in the environment and we believe that relying on UCMR 3 data collected in 2013 and 2015 supplemented with other sources grossly underestimates the impact of PFAS Chemicals nationwide.

EPA Response: Please see section 6.1 of the EPA response in this *Response to Comments* document and section VI of the FRN for this action, where PFAS occurrence is discussed in detail. Also please see section 6.5 of the EPA response in this *Response to Comments* document regarding the model used by the EPA to generate national estimates of PFAS occurrence. The EPA believes it has generated robust estimates of PFAS occurrence that represent the best available science.

Greater North Dakota Chamber et al. (Doc. #1593, SBC-042801)

Lack of occurrence data at the proposed MCL level. The current UCMR 3 occurrence data for PFOA and PFOS seems to indicate levels at between 20 ppt and 40 ppt. EPA does not have a robust understanding of occurrence levels at the proposed MCL levels for PFOA and PFOS or the other four PFAS. This lack of occurrence data for a preliminary regulatory determination requires more thoughtful and thorough analysis.

EPA Response: Please see section 6.1 of the EPA response in this *Response to Comments* document and section VI of the FRN for this action, where PFAS occurrence is discussed in detail. As discussed in section 6.1 of the EPA response in this *Response to Comments* document, the UCMR 3 dataset is one of the many sources of occurrence data the agency considered for this regulation. The EPA also considered occurrence data from 32 states, which provided the agency tens of thousands of additional PFAS monitoring results to inform the EPA's decision. Also please see section 6.5 of the EPA response in this *Response to Comments* document and section VI.E of the preamble regarding how UCMR 3 data and state data were used to inform the national extrapolation of PFAS occurrence. The EPA believes it has generated robust estimates of PFAS occurrence that represent the best available science. The agency has previously made a final determination that there is sufficient information to regulate PFOA and PFOS, and as demonstrated through the best available information in section III of the final rule preamble, has determined that PFHxS, PFNA, HFPO-DA, and mixtures of those PFAS with PFBS meet the statutory criteria for regulation. Please see section 3.1.2 of the EPA response in this *Response to Comments* document regarding the EPA's regulatory determination and evaluation of the occurrence criterion.

Alameda County Water District (ACWD) (Doc. #1595, SBC-042346)

1. Economic Impact Analysis – EPA's cost assessment does not capture the full costs that will be borne by water agencies and ratepayers.

a. Occurrence model relies on UCMR 3 data and publicly available state data

The proposed PFAS NPDWR economic impact analysis utilizes an occurrence model which relies on data collected during UCMR 3, as the primary source of nationwide occurrence data, and includes publicly available data from state PFAS monitoring efforts.

UCMR 3 monitoring only included 5 of the 6 PFAS compounds included in the NPDWR since HFPO-DA was not included in UCMR 3 monitoring and is included in the NPDWR. Additionally, the monitoring method 537 used during UCMR 3 also had much higher reporting levels than the levels included in the NPDWR, with Minimum Reporting Levels (MRLs) of 40 ppt (PFOS), 20 ppt (PFOA), 30 ppt (PFHxS), 20 ppt (PFNA), 90 ppt (PFBS). Using the UCMR 3 data to develop the economic analysis may result in unrealistically low-cost estimates.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document regarding the Bayesian statistical model used to estimate national PFAS occurrence. Please see sections 6.1 and 3.1.2 of the EPA response in this *Response to Comments* document regarding available state data for HFPO-DA. The agency relied on additional occurrence data sources other than UCMR 3 when developing the Economic Analysis (EA). The agency has used the Bayesian statistical model described in Cadwallader et al. (2022) to support the EA for the proposed and final regulation by combining the available occurrence information from UCMR 3 and state datasets in a statistically robust and representative manner, utilizing those data to compute estimates of national occurrence for PFAS contaminants to levels below

UCMR 3 reporting limits, and providing estimates on the number of systems impacted by this final rule. These estimates directly informed the EA in USEPA (2024a). The EPA has generated robust estimates of PFAS occurrence that represent the best available science. For more information see the *Occurrence Technical Support Document* (USEPA, 2024b) as well as section VI of the Federal Register Notice (FRN).

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044302)

PFAS Occurrence, Health Risks and MCL Justification:

The only significant water utility PFAS occurrence data currently available is from UCMR 3 and any additionally required testing by states, which is limited. Unfortunately, in the case of PFOS and PFOA, the reporting levels used during UCMR 3 with method 537 were higher than the proposed MCL. This increases the risk of wide gaps in the understanding and knowledge of occurrence.

The EPA does not have a robust understanding of occurrence levels at the proposed MCL levels for PFOA and PFOS or the other four PFAS. This lack of occurrence data for a preliminary regulatory determination requires more thoughtful and thorough analysis.

EPA Response: Please see section 6.1 of the EPA response in this *Response to Comments* document. The agency disagrees with the commenter. The EPA has generated robust estimates of PFAS occurrence that represent the best available science. While UCMR 3 does have higher reporting limits than those available through current analytical methods, the more recent state drinking water data reflect lower reporting limits than those in UCMR 3 and provide occurrence data at the Maximum Contaminant Levels (MCLs) for all six regulated PFAS. These additional state data included over ten thousand systems from 32 states. Additionally, the agency has used the Bayesian statistical model described in Cadwallader et al. (2022) which combines the available occurrence information from UCMR 3 and state datasets in a statistically robust and representative manner, utilizing those data to compute estimates of national occurrence for PFAS contaminants to levels below UCMR 3 reporting limits, and providing estimates on the number of systems impacted by this final rule.

Austin Water (AW), Austin, TX (Doc. #1688, SBC-044452)

May 30, 2023

U.S. Environmental Protection Agency EPA Docket Center

Docket ID: EPA-HQ-OW-2022-0114

Mail Code 28221T

1200 Pennsylvania Avenue, NW Washington, DC 20460

Submitted via Federal eRulemaking Portal: https://www.regulations.gov

Re: Docket ID No. EPA-HQ-OW-2022-0114, Proposed National Primary Drinking Water Regulation (NPDWR) for Six Per- and Polyfluoroalkyl Substances (PFAS)

Dear U.S. Environmental Protection Agency (EPA),

Austin Water (AW) appreciates the opportunity to comment on the proposed NPDWR for six PFAS as published in the Federal Register on March 29, 2023. These comments note some observations and considerations we offer as a community water system and utility regarding the timing and approach for the proposed PFAS NPDWR.

AW provides water service to a population of over one million with over 250,000 metered connections, and wholesale service to 17 surrounding water systems that serve in total approximately 55,000 people. We strive to maintain excellent water quality for our customers, and our staff work diligently around the clock to provide quality services to our customers. Our top priority is protecting public health and meeting federal and state drinking water standards at all times. We have been closely monitoring information on the emerging research about PFAS and public health. We recognize that the presence of these substances is ubiquitous and has caused significant environmental impacts that must be addressed.

The Safe Drinking Water Act (SDWA) framework includes the implementation of nationwide monitoring through the Unregulated Contaminant Monitoring Rule (UCMR). The SDWA framework is designed to use UCMR data to track and research substance/contaminant occurrences and to use these occurrence data to inform decisions on the Regulatory Determinations that are made in the development of NPDWRs. While the Third UCMR (UCMR3) included six PFAS in the 2013-2015 monitoring timeframe (five of which are included in the proposed NPDWR), it did not include monitoring for hexafluoropropylene oxide dimer acid and its ammonium salt (collectively, GenX chemicals) which is also included in the proposed NPDWR.

EPA Response: Please see sections 6.1 and 3.1.2 of the EPA response in this *Response to Comments* document for the EPA's responses related to UCMR 3 data and regulatory determinations, respectively. As discussed in section 6.1 of the EPA response in this *Response to Comments* document, in addition to UCMR 3 data, the agency also considered occurrence data from 32 states, which provided the EPA tens of thousands of additional PFAS monitoring results to inform the agency's decision. These data included samples of HFPO-DA from multiple states, which the EPA used to inform this regulation. Please see section 3.1.2 of the EPA response in this *Response to Comments* document as well as section III.C of the FRN for more information about how EPA considered occurrence data for HPFO-DA.

<u>Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044749)</u>

3. Assessment of the Representativeness of the PWSs Sampled Under UCMR 3 Is Not Complete

EPA states that 4,920 PWSs were sampled for PFHxS, PFNA, and PFBS under UCMR 3, and specifically that a "statistically representative" population of small water systems serving 10,000

or fewer people was included; however, no explanation of the assumptions made or systems chosen is provided to support the determination that the UCMR 3 dataset is statistically representative of PWSs across the United States. With EPA proposing to issue NPDW regulations for six (6) PFAS prior to the completion of data collection and analysis under UCMR 5, it is critical that data being used to justify the proposed NPDW rule are in fact representative of the populations impacted by PFAS, the estimated number of affected PWSs, and the anticipated increased costs of operating affected PWSs. While EPA's website does not provide a numerical breakdown of how many PWSs are permitted within each category, the Center for Disease Control and Prevention (CDC) website states that there are over 155,000 PWSs in the United States, with 52,110 being Community PWSs and 18,239 being Nontransient non-community (NTNC) PWSs. UCMR 3 only required sampling from all PWSs serving more than 10,000 people and 800 representative PWSs serving 10,000 or fewer people. This suggests that the 4,920 PWSs sampled could represent less than 7% of the total assumed 70,349 combined Community and NTNC PWSs eligible for sampling under UCMR 3. Given the variables involved, it is uncertain whether this represents a statistically significant population size from which to draw conclusions. As the majority of PWSs in Wyoming are small systems serving rural communities with less than 10,000 people, an understanding of the representativeness of the data used to develop the rule is important to better assess the environmental and economic impacts to Wyoming.

Furthermore, an understanding of the distribution of PFAS in various media that may impact drinking water sources is not well developed, and those impacts are not evenly distributed throughout the United States. The WDEQ is concerned that the proposed rule relies primarily on data collected from eastern states; these data may not be representative of the PFAS sources and extent of potential PFAS contamination in rural western states.

WDEQ recommends that EPA provide details on how small PWSs were chosen for representation of all small PWSs across the United States under UCMR 3, whether the population size is statistically significant, and how this dataset accurately represents drinking water concentrations and distributions across the United States such that it provides a sound basis for proposing comprehensive NPDW regulation of PFAS.

EPA Response: A description of how small systems were representatively chosen for UCMR 3 monitoring is available in section 1. General Information of the Final UCMR 3 Rule: "Only a nationally representative sample of ''small'' community and non-transient non-community systems serving 10,000 or fewer people are required to monitor for the chemical analytes (see USEPA, 2001 for a description of the statistical approach for the nationally representative sample)." This statistical approach is outlined in *Statistical Design and Sample Selection for the Unregulated Contaminant Monitoring Regulation (1999)* (USEPA, 2001). The EPA refers the commenter to this resource for more details. Additionally, the EPA disagrees that the available data is not geographically representative of the nation because the agency presents its evaluation of available occurrence data from 32 states including many areas other than the

eastern part of the country, including Washington, California, Oregon, Idaho, North Dakota, and Colorado.

American Chemistry Council (ACC) (Doc. #1841, SBC-044839)

EPA Has Underestimated the Number of Systems That Will be Impacted by the Proposal

EPA's analysis of the systems expected to exceed the proposed MCLs relies on the data from the UCMR 3 national survey supplemented by more recent monitoring data from several states. In considering the state information, the Agency acknowledges that the USMR 3 data suffer from several limitations –

• The minimum reporting limits for PFOA, PFOS, PFHxS, and PFNA were above the proposed MCLs or HBWCs,

• Reported detections of PFNA and PFBS were too infrequent to provide a basis for analysis,

• Only a random sample of 800 systems serving 10,000 people or fewer were included in the survey, and

• HFPO-DA was not measured.

EPA Response: Please see section 6.1 of the EPA response in this *Response to Comments* document. Also please see section 6.5 of the EPA response in this *Response to Comments* document regarding potential underestimates in the number of impacted systems. The EPA disagrees that it has underestimated the number of impacted systems. The EPA also considered occurrence data from 32 states, which provided the EPA tens of thousands of additional PFAS monitoring results to inform the agency's decision. The agency used a Bayesian statistical model described in Cadwallader et al. (2022) for the proposed and final regulation by combining the available occurrence information from UCMR 3 and state datasets in a statistically robust and representative manner, utilizing those data to compute estimates of national occurrence for PFAS contaminants to levels below UCMR 3 reporting limits, and combining these results with findings from non-targeted monitoring data for the remaining PFAS to provide estimates on the number of systems impacted by this final rule. Additionally, the agency provides summary data tables in section VI of the FRN and in the *Occurrence Technical Support Document* (USEPA, 2024b), where the detection limits for most of the samples were at or below the PFAS MCLs finalized in this regulation. There were sufficient detections of PFNA and PFBS to inform development and finalization of this regulation. HFPO-DA data were also collected by numerous states.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045742)

The other three PFAS included in the preliminary regulatory determination (PFBS, PFNA, PFHxS) were collected during UCMR3 (2013-2015). However, at the time of the data collection and analysis, the minimum reporting levels (MRLs), or the lowest concentration that could be

reported, was much greater than it is currently. The HBWCs currently proposed for PFNA and PFHxS are less than the MRL from UCMR3, which makes the UCMR3 dataset questionable in assessing the occurrence of these compounds at the proposed HBWCs.

EPA Response: Please see section 6.1 of the EPA response in this *Response to Comments* document. Additionally, the UCMR 3 data remain relevant for their nationally representative selection and the insight they provide for occurrence at or above UCMR 3 minimum reporting levels (please see section 6.5 of the EPA response in this *Response to Comments* document), but they are not considered in isolation. As discussed in sections 6.1 and 6.2 of the EPA response in this *Response to Comments* document, in addition to UCMR 3 data, the EPA also considered occurrence data from 32 states, which provided the agency tens of thousands of additional PFAS monitoring results to inform the EPA's decision. Additionally, the agency provides summary data tables in section III.C and VI.B of the FRN and in the *Occurrence Technical Support Document* (USEPA, 2024b), where the reporting limits for most of the samples were at or below the PFAS MCLs finalized in this regulation. There were sufficient detections of PFNA, PFHxS, and PFBS to inform development and finalization of this regulation.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045740)

EPA should pursue a separate rulemaking determination from PFOA and PFOS for the constituents considered in the Hazard Index (HI) and should provide more data supporting its analyses:

7. EPA should remain consistent with the use of national occurrence data from the Unregulated Contaminant Monitoring Rule (UCMR) to determine if the contaminant occurs in public water systems at levels of public health concern.

The EPA's proposed rulemaking includes a preliminary regulatory determination for PFBS, PFNA, PFHxS, and HFPO-DA and its ammonia salt (trade name "GenX"). The notice also includes a proposed NPDWR and health-based Maximum Contaminant Level Goals (MCLGs) for a mixture of these chemicals. The use of a Hazard Index (HI) for the MCL and MCLG is proposed to account for the combined health risks from exposure to multiple PFAS in drinking water. The proposed HI compares measured exposure to PFBS, PFNA, PFHxS, and HFPO-DA to health-based reference values prior to combining them to see if they remain under the safe threshold value of 1 (unitless).

Regulatory determinations are made following the collection of nationwide data through the UCMR to determine whether regulation of a contaminant in drinking water presents a meaningful opportunity for public health risk reduction. Although data from 29 PFAS will soon be collected during the implementation of the Fifth Unregulated Contaminant Monitoring Rule (UCMR5), currently the Third Unregulated Contaminant Monitoring Rule (UCMR3) is the only national dataset to include PFAS. Of the six PFAS included in UCMR3, only PFOA and PFOS

resulted in a positive preliminary regulatory determination after considering the extent and degree of PFAS occurrence in public water systems.

National occurrence data generated from UCMR3 is insufficient to inform a National Primary Drinking Water Regulation for the proposed mixture of PFAS. It is unclear if EPA has sufficient national data to determine the extent of occurrence for HFPO-DA, PFNA, and PFHxS in drinking water at the proposed Health-Based Water Concentrations (HBWCs).

EPA Response: The EPA will not be pursuing a separate rulemaking for PFOA and PFOS and the Hazard Index PFAS as the agency currently has sufficient information to regulate the Hazard Index PFAS. Furthermore, the EPA has concluded it is most efficient and justified to regulate these six PFAS simultaneously. The agency has previously made a final determination that there is sufficient information to regulate PFOA and PFOS, and as demonstrated through the best available information in section III of the final rule preamble, has determined that PFHxS, PFNA, HFPO-DA, and mixtures of those PFAS with PFBS meet the statutory criteria for regulation. Please see section 6.8 of the EPA response in this *Response to Comments* document regarding UCMR 5 data. The EPA implements a monitoring program for unregulated contaminants (i.e., UCMR) under SDWA 1445(a)(2) that requires the EPA to issue a list once every five years of priority unregulated contaminants to be monitored by PWSs, however there is no statutory requirement that a contaminant must be on this list prior to making a determination to regulate. The EPA may make a determination to regulate if the agency has sufficiently available information through other sources. As discussed in section 6.1 of the EPA response in this *Response to Comments* document, in addition to UCMR 3 data, the agency also considered occurrence data from 32 states, which provided the agency tens of thousands of additional PFAS monitoring results to inform the EPA's decision. Please see the *Occurrence Technical Support Document* (USEPA, 2024b) for additional details. The UCMR 3 dataset, along with additional state data and robust analyses, demonstrate sufficient likelihood of occurrence of PFHxS, PFNA, and HFPO-DA. Please see sections 3.1.2 and 3.2.2 of the EPA response in this *Response to Comments* document regarding EPA's regulatory determination and evaluation of the occurrence criterion for these three PFAS and mixtures of these three PFAS and PFBS.

6.2 State Drinking Water Data

Summary of Major Public Comments and EPA Responses

Commenters generally supported the use of state datasets to inform the EPA's occurrence analyses. A few commenters discussed their own PFAS occurrence data, some of which were provided to the EPA, relative to the EPA's proposed regulatory levels and/or provided summaries of other monitoring efforts. Where possible, the EPA presents this information within its occurrence analysis – see the Other Data sections of USEPA (2024b). A few commenters recommended that the EPA expand the datasets used for the final rule to include additional and updated state sampling information. The EPA agrees with these suggestions to include additional and updated sampling information in order to evaluate PFAS occurrence in drinking water. Therefore, the agency has included updated information in its occurrence analyses as described

in section VI.B of the final rule preamble as well as the *Occurrence Technical Support Document* (USEPA, 2024b). The EPA notes that this information is consistent with the analyses contained in the proposal for this action and confirmatory of the EPA's original occurrence analyses.

A few commenters criticized the use of state datasets in occurrence analyses. These commenters claimed that the state datasets were insufficient for understanding PFAS contaminant occurrence and not dependable due to being collected under variable circumstances. These commenters expressed the need for enhanced quality control (QC) by the EPA to exclude data below reasonable reporting thresholds. The agency disagrees with commenters who contend that state datasets are insufficient. For both the rule proposal and this final action, the EPA took QC measures to ensure the EPA used the best available data for national extrapolation. For example, the EPA acknowledged in the proposal that states used various reporting thresholds when presenting their data, and for some states there were no clearly defined reporting limits. The EPA identified state reporting thresholds where possible and, when appropriate, incorporated individual state-specific thresholds when conducting data analyses. For other states, the EPA presented the data as provided by the state. Due to the reporting limitations of some of the available state data (e.g., reporting combined analyte results rather than individual analyte results), the EPA did not utilize all of these data in the subsequent occurrence analyses/co-occurrence analyses. Specific data analysis criteria (e.g., separation of non-targeted (i.e., monitoring not conducted specifically in areas of known or potential contamination) and targeted monitoring results were also applied. Additionally, the agency also verified that the vast majority of the data were collected using EPA Methods 533 and 537.1. Further, the EPA reviewed all available data thoroughly to ensure that only finished drinking water data were presented. A description of the scope and representativeness of the state data was provided in the proposal of this action in the PFAS Occurrence and Contaminant Background Support Document (USEPA, 2023a), as well as is available in updated *Occurrence Technical Support Document* for the final rule (USEPA, 2024b). These include describing the states the EPA found to have publicly available data, identifying the reporting thresholds where possible, and distinguishing whether monitoring was non-targeted or targeted (i.e., monitoring in areas of known or potential PFAS contamination). These QC measures ensured that the EPA utilized the best available data for each given analysis. Analyses aimed at extrapolation either utilized a robust statistical framework or were restricted to data from non-targeted monitoring to minimize bias.

State data that was collected to support the final rule included data from 32 states. Within this dataset, each PFAS chemical included in the final rule had tens of thousands of samples collected from over 10,000 PWS. Further, the vast majority of these state data utilized reporting limits on the order of single digit ng/L, lower than the minimum reporting levels in UCMR 3.

Individual Public Comments

San Antonio Water System (SAWS) (Doc. #1570, SBC-042473)

EPA put substantial weight in data collected at the discretion of the state's themselves under varying circumstances. The extrapolation of this limited data set is not a dependable or sufficient foundation for the broad and sweeping regulatory standards being imposed upon every state.

EPA Response: Please see section 6.2 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046037)

Water Quality

Aside from complying with UCMR3, which included monitoring for PFOA and PFOS, Newport News Waterworks (NNWW) began screening source waters and finished water for PFAS in 2019 in preparation for potential new MCLs. Data was needed to understand the sources, determine possible operational changes, and plan for treatment approaches in a highly variable coastal plain surface water system. Investigations confirmed multiple sources of PFAS in 4 of the 6 watersheds that supply water to the regional system. Years of data are beginning to yield basic trends and ranges for these contaminants, and the variability will be a challenge for operations, treatment, and compliance. An example from one of the storage reservoirs is provided below.

[Figure: see docket ID EPA-HQ-OW-2022-0114-1738]

With water quality variability within each of 4 watersheds (left graph is for Skiffes Creek Reservoir), the resulting variations at the WTP intakes will require extensive testing and modeling to ensure compliance with MCLs set at the analytical threshold.

The running annual average (RAA) for PFOA and PFOS in the finished water from both WTPs is depicted below and confirms that compliance at threshold-level MCLs will be difficult, even for diligent utilities, and will require substantial investment in PFAS-removing technologies (e.g., GAC).

[Figure: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: The EPA acknowledges the information on PFAS monitoring in the Newport News area submitted by the commenter. Please see section 5.1.2 of the EPA response in this *Response to Comments* document regarding the EPA's feasibility determination for the PFOA and PFOS MCLs.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046038)

Attachment 4

PFAS in Drinking Water – Compliance Outlook May 2023

WSSC Water's mission is to protect public health and safety by supplying safe, clean and reliable water to our 1.9 million customers. We are proud of our 105-year history of zero drinking water quality violations and remain committed to continuing this exceptional level of excellence.

[Figure: see docket ID EPA-HQ-OW-2022-0114-1738]

We draw the water we treat from two sources: the Patuxent and Potomac rivers. On the Patuxent River, we operate and maintain two reservoirs - Triadelphia and T. Howard Duckett. Our Patuxent Water Filtration Plant (WFP) draws water from the Duckett Reservoir and produces approximately 60 million gallons per day (MGD). Our Potomac WFP draws water straight from the Potomac River, producing between 100 and 120 MGD.

For several years, WSSC Water has been proactively testing for PFAS compounds in our drinking water, testing that went above and beyond federal and state requirements. In January of 2020 WSSC Water began monitoring for 18 PFAS compounds and expanded the monitoring in September of 2022 for 29 PFAS compounds that are included under the EPA's Fifth Unregulated Contaminant Monitoring Rule, also known as UCMR 5. The results of our testing are posted online (wsscwater.com/pfas).

[Table: see docket ID EPA-HQ-OW-2022-0114-1738]

[Figure: see docket ID EPA-HQ-OW-2022-0114-1738]

[Figure: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: The EPA acknowledges the results of PFAS testing provided by the Washington Suburban Sanitary Commission (WSSC) and their proactive efforts to understand and address PFAS contamination.

American Water Works Association (AWWA) (Doc. #1759, SBC-045578)

2. The agency's consideration of non-UCMR 3 data needs additional quality control to exclude system data that does not meet the necessary data quality for national representation, such as reported results that are below nationally reliable reporting limits, as recognized by EPA.

EPA Response: The agency disagrees that it should not consider all reported results as determined by individual state datasets and laboratories. While the EPA determines reporting levels based on nationally representative laboratory capabilities for the purposes of UCMR and for evaluation of feasibility as part of the establishment of regulatory standards under SDWA, individual laboratories and states may be capable of achieving lower levels and can set their own

reporting levels based on their own site-specific capabilities. Please see section 6.2 of the EPA response in this *Response to Comments* document regarding QC steps the agency took to ensure accurate and transparent representation of the available data.

American Water Works Association (AWWA) (Doc. #1759, SBC-045574)

Use of Non-UCMR 3 Data

EPA's occurrence analysis relies on data from both UCMR 3 and state monitoring programs. AWWA supports the consideration of the more recently collected data from state monitoring programs to improve understanding of occurrence, but there are several concerns about the agency's use of this data and the degree of quality control. These issues are discussed in more detail in the following paragraphs. As previously noted, the SDWA requires that EPA rely upon the best available public health information, including the occurrence database. [FN9: 42 U.S.C. § 300g-1(b)(1)(B)(ii)(II).] EPA must also provide sufficient information and explanation regarding the data selected and not selected as the basis of EPA's decision so that the public can meaningfully comment on the data selected as well as evaluate the data that EPA did not decide to rely upon.

It is unclear how data was screened for inclusion as part of the analysis. Several state monitoring datasets are documented to have reporting thresholds far below what is considered reliable for a national occurrence analysis; for example, reporting thresholds below 1 ppt are indicated for several states including New Jersey, Massachusetts, and California. In other cases, states did not indicate the applicable reporting thresholds. While the proposal acknowledges these data quality issues, the agency nonetheless elected to utilize this data without quality control. As AWWA noted in 2020, EPA should supplement monitoring data from UCMR 3 with high quality occurrence data (AWWA, 2020b). It is recommended that EPA re-evaluate the non-UCMR 3 data that is being leveraged and ensure that monitoring results that are neither achievable using the robust methods approved by EPA nor representative of high-accuracy data should not be considered as part of this analysis.

EPA Response: As discussed in section 6.2 of the EPA response in this *Response to Comments* document, the EPA took steps to assure that non-UCMR 3 data sources were the best available occurrence data of sufficient quality and accurately describe the steps taken to ensure data quality. Please see section 6.2 of the EPA response in this *Response to Comments* document as well as the *Occurrence Technical Support Document* (USEPA, 2024b) for more information. Additionally, the agency disagrees that it should not consider all reported results as determined by individual state datasets and laboratories after following the quality assurance (QA) steps documented. While the EPA determines reporting levels based on nationally representative laboratory capabilities for the purposes of UCMR and for evaluation of feasibility as part of the establishment of regulatory standards under SDWA, individual laboratories and states may be capable of achieving lower levels and can set their own reporting levels based on their own site-specific capabilities.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045767)

The use of PFAS data from multiple state monitoring programs is also problematic. There are differences in reporting thresholds, when reported, and the data itself has not been subjected to sufficient quality control measures.

EPA Response: Please see section 6.2 of the EPA response in this *Response to Comments* document.

Groundwater Resources Association of California (Doc. #1831, SBC-045348)

May 30, 2023

To:

Michael S. Regan, Administrator, U.S. Environmental Protection Agency

RE: GRA Comments on EPA's Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulations (Docket ID: EPA-HQ-OW-2022-0114)

TRANSMITTED ONLINE: https://www.regulations.gov/docket/EPA-HQ-OW-2022-0114/document

To whom it may concern

The Groundwater Resources Association of California (GRA [FN1: www.grac.org]) welcomes the opportunity to comment on the public review of the United States Environmental Protection Agency's (EPA) Proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulations (Docket ID: EPA-HQ-OW-2022-0114). GRA's vision is Sustainable Groundwater for All and our organization is dedicated to resource management that protects and improves groundwater supply and quality through education and technical leadership. GRA membership includes more than 1400 professionals located throughout California and the Western United States with technical, policy, and legal expertise on groundwater related matters.

The GRA acknowledges and commends the diligent and critical efforts made by the EPA and its technical experts in tackling one of the gravest challenges confronting our nation—the threat of PFAS contamination to our drinking water sources. Over the past couple of years, the EPA has demonstrated commitment and dedication to addressing this pressing issue. State agencies and local governments look to the EPA for regulatory leadership and guidance related to PFAS in our drinking water and the environment. EPA's proactive measures have set a worthy precedent on emerging contaminants, and we commend the EPA for taking the initial stride on this journey towards safeguarding our water resources. The path ahead entails collaboration and sustained efforts from all stakeholders to comprehensively tackle this multifaceted issue. The GRA firmly believes that by building upon the EPA's first steps, we can make significant strides in protecting the quality of our drinking water for generations to come.

Given GRA's groundwater focus, our comments on the proposed PFAS regulations are focused on the impacts these regulations will have on the availability, affordability, sustainability, and safety of drinking water sources derived from groundwater. Given the voluminous body of literature related to the referenced proposed regulations and the limited amount of time available for the public comment period (61 days), GRA is only providing comments on the primary regulatory document (Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation, Docket EPA- HQ-OW-2022-0114-0027). Based on our review of this document, GRA offers the following general comments and recommendations for consideration by the EPA as they finalize these regulations:

1. Request for Additional Clarity on Statewide PFAS Data: It is unclear from our reading of the report what statewide datasets were used to evaluate the occurrence, impacts, and costs of PFAS. The text states that data from 23 States was collected but the tables only show data from 10 States. We recommend that PFAS statistics from data collected across all 23 States be included. The Exhibit 2-4 in supporting document USEPA. 2023e (PFAS Occurrence and Contaminant Background Support Document. EPA-822-P-23-010) indicates that California data included testing for "Surface Water and Groundwater – Raw, Finished, and Unknown Water" and also states that "EPA reviewed the California PFAS data available online through April 2021. Finished water data were available from approximately 100 PWSs [Public Water Systems]. For analysis purposes, EPA only included results that were explicitly defined as being from treated water. Sampling in California is ongoing. California conducted sampling of 18 PFAS, including PFOS, PFOA, HFPO-DA, PFBS, PFHxS, and PFNA". The State Water Resources Control Board (SWRCB) of California and the United States Geologic Survey (USGS) have collected extensive PFAS data across the State as part of State Public Water Testing and Groundwater Ambient Monitoring and Assessment (GAMA) Priority Basin Project [FN2: https://www.waterboards.ca.gov/pfas/drinking_water.html; https://pubs.er.usgs.gov/publication/fs20213028]. This includes data from public supply and domestic water supply wells. As the State with the nation's largest population and highest Gross Domestic Product (GDP), PFAS occurrence, impacts, and costs in California would represent a significant proportion for the nation. Hence, we recommend that EPA reflects California data in the published regulatory documents and potentially expand the datasets to include the on-going state-wide testing and sampling programs, as outlined above.

EPA Response: The EPA acknowledges the information related to PFAS monitoring provided by the Groundwater Resources Association of California (GRA). As discussed in section 6.2 of the EPA response in this *Response to Comments* document, additional state data were collected after the rule proposal, where available. Depending on the intended purposes and describing the data accurately, some exhibits within proposed and final rule preambles and Occurrence Technical Support Document are limited to non-targeted monitoring results. In these instances, states with data produced through targeted monitoring efforts are not included. However, the EPA does present all state data collected through targeted monitoring efforts in the *Occurrence Technical Support Document* (USEPA, 2024b). Specific to California PFAS drinking water data, the EPA used all California data available through May 2023, taking QA

measures as described in the Technical Support Document to ensure it was representative of finished drinking water data only for drinking water rule analysis purposes.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045826)

The most recent sampling data, however, has been collected by the Wisconsin Department of Natural Resources (WDNR or the state agency). In March of 2022, the state agency launched a voluntary program for municipal water systems to sample for PFAS during the second trimester of 2022. [FN14: Wisconsin Department of Natural Resources, Voluntary Drinking Water PFAS Sampling Project for Municipal Systems, https://dnr.wisconsin.gov/topic/PFAS/PWSampling.] In October of 2022, the WDNR began the enforcement of its initial monitoring requirements pursuant to the state's drinking water program. [FN15: Wisconsin Department of Natural Resources, NR 809 Safe Drinking Water Standards Update, https://dnr.wisconsin.gov/topic/DrinkingWater/NR809.html (The WDNR relies on laboratory analysis that use EPA Method 537.1 to test for 18 PFAS, including the ones subject to this rulemaking).] To date, the state agency has collected samples under the state drinking water program from approximately 187 community water systems representing a public drinking water population of about 3 million.

EPA Response: The EPA acknowledges the commenters' referral to information on PFAS monitoring in Wisconsin. As described in the final rule preamble and *Occurrence Technical Support Document* (USEPA, 2024b), finished drinking water occurrence data from Wisconsin has been considered as part of the agency's final rulemaking.

Edward Cullen (Doc. #3075, SBC-047723)

EPA has summarized credible data demonstrating the health risks to people of exposure through drinking water to numerous forms of PFAS (i.e., PFOA, PFOS, PFHxS, HFPO-DA, PFNA, and PFBS; see March 29, 2023 FR). EPA has also presented data showing that specific forms of PFAS have been measured in public drinking water at multiple sites in the US, and measured concentrations indicate a threat to public health.

For example, non-targeted surveillance of public water systems conducted by states showed that PFOA concentrations were greater than or equal to 5.0 ppt in 33.2% of systems in New Hampshire, 33.7% of systems in New Jersey, 36.6% of systems in Massachusetts, and 49.0% of systems in South Carolina (Table 8 FR 88, p. 18674). For reference, EPA is proposing a Maximum Contaminant Level (MCL) of 4.0 ppt for PFOA. Broadly similar results were reported for PFOS.

Preliminary surveillance data from 16 states for PFHxS, HFPO-DA, PFNA, and PFBS showed that there are at least 214 water systems that exceed the Hazard Index (HI) limit of 1.0 proposed by EPA for these contaminants (FR 88, p. 18678).

EPA Response: The EPA agrees that sufficient information has been utilized to inform the EPA's final regulatory determinations for PFHxS, PFNA, HFPO-DA, and mixtures of these three PFAS and PFBS, as well as the final NPDWRs for PFOA, PFOS, PFHxS, PFNA, HFPO-DA, and mixtures of PFHxS, PFNA, HFPO-DA, and PFBS.

Clean Air Council, et al. (Doc. #1731, SBC-043867)

Comments

1. PFAS levels that exceed the proposed federal standards are prevalent in the Commonwealth of Pennsylvania, and Pennsylvania's compliance with the proposed federal standards is feasible.

a. PFAS are prevalent in Pennsylvania drinking water at levels above the proposed MCLs and HI.

In 2020–2021 the Pennsylvania Department of Environmental Protection ("PA-DEP") conducted an extensive survey to assess the presence of PFAS species in Public Water Systems ("PWSs"). The survey was conducted as part of the process of developing a Pennsylvania PFAS drinking water rule [FN2: Safe Drinking Water PFAS MCL Rule, 53 Pa.B. 333, 334–35 (January 14, 2023) (to be codified at 25 Pa. Code Ch. 109), available at https://www.pacodeandbulletin.gov/secure/pabulletin/data/vol53/53-2/53-2.pdf]. The survey was undertaken to generate statewide occurrence data, focusing on sampling of water entry points ("EPs") into water processing plants near identified sources of potential PFAS contamination, such as military bases, airports, or manufacturing facilities that may have used PFAS. Samples were collected from 412 entry points. 372 of those were targeted sites, and 40 were baseline sites in areas where PFAS contamination was deemed unlikely. Water testing was conducted for 18 PFAS species using the EPA–approved method 537.1.

Out of the more than 400 water systems sampled, approximately 250 did not show any detectable levels of the targeted 18 PFAS compounds [FN3: More details of the sampling plan are in the discussion of Pennsylvania's Safe Drinking Water PFAS MCL Rule. Id. at 334–36]. 102 samples exceed the EPA proposed 4 ppt limit for either PFOS or PFOA, and most of these samples exceed the limits for both. Some of the values recorded are quite high: For example, sample PWSID 477608- State of the Art (Centre County) had 62.1 ppt PFOS and 12.8 ppt PFOA. In sample 477075-Christman Lake Water System (Berks County), the water sampled contained 6.5 ppt and 59.6 ppt of PFOS and PFOA, respectively. Sample 477350-Saegertown Borough (Crawford County) recorded 187.1 ppt and 5.5 ppt of PFOS and PFOA, respectively. Samples with high levels of PFOA and PFOS were not localized in specific counties, but widespread throughout the Commonwealth [FN4: PA-DEP has made the the full sampling data available; see PA-DEP, Copy of BSDW_PFAS Sampling Project_All Results web edit.xlsx, https://files.dep.state.pa.us/Water/DrinkingWater/Perfluorinated%20Chemicals/SamplingResults/PFAS_Sampling_Final_Results_May_2021.pdf [hereinafter Full PA Sampling Data]].

PFOA and PFOS were the most prevalent PFAS species, found in approximately ¼ of the samples [FN5: Id. at 335, Table 1]. However, other PFAS species were found in a substantial fraction of entry points. For example, PFHxS was found in 13% of the samples, and PFBS in 16% [FN6: Id.]. These numbers are similar to data obtained in other states [FN7: See 88 Fed. Reg. 18648–49, Tables 1, 2]. Applying the EPA proposed methodology and associated values for determining the Hazard Index (HI) for PFHxS, HFPO–DA, PFNA and PFBS (Health Based Water Concentration of 9.0 ppt, 10.0 ppt, 10.0 ppt and 2000 ppt respectively, and a Hazard Index of 1 [FN8: See 88 Fed. Reg. 18665]) to the PA-DEP drinking water samples yields 13 samples with an HI > 1. All but one of these (Sample 410-15417-1 - Williamsport Mun Water Auth in Lycoming County) also contain PFOA and/or PFOS at values exceeding the proposed 4 ppt limit.

In the development of Pennsylvania's PFAS drinking water regulations, PA-DEP used the survey results as representative of all Public Water Systems ("PWS") in the Commonwealth [FN9: 53 Pa.B. 333]. Based on this assumption, the sampling data collected in the 2020–2021 survey by PA-DEP indicates that approximately 1⁄4 of the 3,785 entry points in the Commonwealth are contaminated with PFAS species at values that exceed the proposed PFAS NPWDR. The approximately 900 EPs with PFAS levels that were determined by EPA to be dangerous to public health, compared to the approximately 200 that exceed the PA-DEP MCLs, demonstrate that the proposed national standard would be more protective of public health in Pennsylvania [FN10: See Id.; Full PA Sampling Data, supra note 4].

EPA Response: The EPA acknowledges the commenter's referral to information on PFAS monitoring in Pennsylvania. The EPA notes occurrence information from the State of Pennsylvania is included within its occurrence analyses for the final rule as described in the final rule preamble and the *Occurrence Technical Support Document* (USEPA, 2024b).

Village of Woodbury (Doc. #1629, SBC-042958)

12. Additional PFAS compounds (i.e., PFHxS, PFNA, PFBS, HFPO-DA) do not have the same readily available occurrence data as far as we are aware.

EPA Response: The EPA disagrees that there is not sufficient occurrence data for PFHxS, PNFA, PFBS, and HFPO-DA to inform this regulation. The EPA evaluated tens of thousands of PFHxS, PFNA, PFBS, and HFPO-DA samples across more than 10,000 PWSs as a part of its rule occurrence analyses. Please see section 3.1.2 of the EPA response in this *Response to Comments* document regarding regulatory determinations and section 6.2 of the EPA response in this *Response to Comments* document regarding state datasets.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045825)

Certain municipal systems have been testing for PFAS since 2013 under the Third Unregulated Contaminant Monitoring Rule (UCMR-3). Due to concerning results from the UCMR-3 sampling, several water systems proactively monitored for PFAS concentrations in their drinking

water. [FN13: See Wisconsin Groundwater Coordinating Council Report to the Legislature 4 (2022), https://dnr.wisconsin.gov/sites/default/files/topic/Groundwater/GCCGWQuality/PFAS.pdf ("In the UCMR-3 sampling, PFAS were detected in municipal water systems in La Crosse, West Bend, and Rhinelander … The data from UCMR-3 served as an initial indicator of the fact that both groundwater and drinking water supplies in Wisconsin have been impacted by PFAS. Voluntary sampling by a few municipalities (from 2019 through the first quarter of 2022) has shown additional impacts … in Madison, Eau Claire, Wausau and Rib Mountain.").]

EPA Response: The EPA acknowledges the information provided by the commenter related to PFAS monitoring in Wisconsin groundwater systems. The agency considered data publicly available from the Wisconsin Department of Natural Resources prior to finalizing this regulation. Please see the *Occurrence Technical Support Document* (USEPA, 2024b) for more information.

6.3 PFAS Co-Occurrence

Summary of Major Public Comments and EPA Responses

Some commenters agreed with the agency's conclusion in the March 2023 proposal that the PFAS included in the regulation meaningfully co-occur. However, some other commenters stated that they believed the data used to assess PFAS co-occurrence were too limited to make substantive conclusions. The EPA disagrees that the data were too limited or that the co-occurrence analysis was inconclusive. Based on the non-targeted state monitoring data used in the co-occurrence analysis for the proposed rule preamble (from 11 states), findings of the pairwise and groupwise analyses established a strong likelihood that these chemicals meaningfully co-occur in drinking water. This was observed through odds ratios statistically significantly greater than 1 in the pairwise analysis as well as frequency at which multiple chemicals were detected in the groupwise analysis. Based on public comment, the agency has updated its co-occurrence analyses to include more recent non-targeted state data that became publicly available after the proposal analyses were finalized. See section VI.C. of the rule preamble. This ensures that findings are up to date. The more recent data, which now include non-targeted monitoring data from 18 states and are presented in section VI.C. of the final rule preamble, confirm the proposal analyses.

Individual Public Comments

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042979)

C. Occurrence of 4 Additional PFAS

In response to EPA's request for occurrence information, and having reviewed Section VII of the proposed NPDWR, EGLE DWEHD has reviewed three years of PFAS MCL compliance monitoring data collected under Michigan's SDWA. This data indicates that 11 public water

supplies (8 community water supplies and 3 non-transient noncommunity water supplies) would potentially exceed the proposed HI-based MCL alone.

EPA Response: The EPA acknowledges the information provided by the Michigan Department of Environment, Great Lakes, and Energy (EGLE) on the number of systems expected to exceed the Hazard Index MCL and the agency has considered publicly available data from Michigan EGLE prior to finalizing this regulation.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044417)

Page 18730. Section VII – Occurrence

Page 18730. EPA requests comment on the number of systems estimated to solely exceed the HI (but not the PFOA or PFOS MCLs) according to the approach outlined in USEPA (2023e).

• Based on an initial and limited review of Washington water systems, a very small percentage of systems exceed the HI but not the PFOA or PFOS MCLs. Most systems with high levels of the other PFAS also have PFOA or PFOS as the drivers.

EPA Response: The EPA acknowledges the information provided by the Washington State Department of Health (DOH) on the number of systems expected to exceed the Hazard Index MCL. These data provide confirmatory information that Hazard Index PFAS often co-occur with PFOA and PFOS.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045087)

Section III – Regulatory Determinations for Additional PFAS

1) What are the impacts on compliance from PFHxS/PFNA?

In Vermont, we have been receiving water quality data under EPA Method 537.1 since July of 2019, with at least two samples per Non-Transient Non-Community (NTNC) and Community water systems. We regulate PFOA, PFOS, PFHxS, PFHpA and PFNA as a combination of compounds at 20 ppt. In our data, when compared with the proposed MCLs of 4.0 ppt for PFOA and PFOS, we did not have any systems with elevated PFHxS or PFNA (alone or combined) to the point where our MCL of 20 was exceeded and the PFOA and/or PFOS results were at or below 4 ppt each. This means that if there were elevated results sufficient to have high PFHxS or PFNA, there were much higher levels of either PFOA or PFOS so that those respective MCLs would have also been exceeded. We do not see elevated PFHxS or PFNA by themselves without the presence of PFOA or PFOS.

Based on our water quality results, relying often on a single sample and confirmation sample collected within 10 days (and not the Running Annual Average (RAA)), we did not have systems that exceeded the Hazard Index of 1.0 based on the respective proposed four compounds that

would not have otherwise either exceeded the proposed PFOA or PFOS MCL respectively already.

EPA Response: The EPA acknowledges the information provided by the Vermont Agency of Natural Resources and Department of Health on the number of systems expected to exceed the Hazard Index MCL. These data provide confirmatory information that Hazard Index PFAS often co-occur with PFOA and PFOS. Additionally, the agency maintains that individual regulation of PFHxS, PFNA, and HFPO-DA and regulation of mixtures of these three PFAS and PFBS will provide necessary public health protection to those exposed to elevated levels of these four PFAS that are not exposed to levels exceeding the PFOA and PFOS MCLs.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-047688)

Given the extent of PFAS in the environment, the proposed HI represents less than 0.1% of PFAS. The EPA notice cites likely co-occurrence in drinking water as part of the justification for the public health protections of a Hazard Index. PWD is requesting that the EPA's analysis on the co-occurrence of PFBS, PFNA, PFHxS, and HFPO-DA be made publicly available as well.

EPA Response: The EPA's co-occurrence analysis and sources of the underlying data to support the analysis are publicly available in section VI.C of the final rule preamble and the *Occurrence Technical Support Document* (USEPA, 2024b).

American Water Works Association (AWWA) (Doc. #1759, SBC-045604)

The EPA's occurrence analysis fails to sufficiently document co-occurrence of this mixture of PFAS and AWWA's analysis of data from nearly 8,000 water systems does not demonstrate a pattern of co-occurrence.

EPA Response: The EPA disagrees. The data used in the EPA's co-occurrence analysis, including UCMR 3 and non-targeted state monitoring data, demonstrate co-occurrence of the six PFAS for which the EPA is finalizing regulation. PFAS co-occurrence has been documented in numerous peer reviewed publications (e.g., Guelfo and Adamson, 2018; Cadwallader et al., 2022; McMahon et al., 2022 (as cited in USEPA, 2024b)). Please see section 6.3 of the EPA response in this *Response to Comments* document.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045821)

Second, occurrence data developed under the SDWA and state-led monitoring programs provide sufficient indication that the occurrence of these PFAS in water systems is of great concern. Below, Commenters provide occurrence data from Wisconsin's community water systems to support EPA's findings that the occurrence and likely occurrence or co-occurrence of these substances presents a significant public health concern given their frequencies and levels.

EPA Response: The EPA agrees that the PFAS included in this rule are likely to co-occur.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045824)

B. Wisconsin's drinking water occurrence data further supports EPA's proposed regulation.

PFAS drinking water occurrence data from the State of Wisconsin supports EPA's finding that there is a substantial likelihood that the contaminants subject to this rulemaking occur or will occur in public water systems with a frequency and at levels of public health concern. Data thus far reveals that twenty-five community water systems across the state serving more than half a million people have detected levels of these PFAS at concerning frequencies and at levels higher than the proposed MCLs.

Wisconsin has 1,038 community water systems serving 69 percent of the state's population. [FN10: Wisconsin Department of Natural Resources, Wisconsin Public Water Systems 2021 Annual Drinking Water Report, Pub-DG-045 (2022) 6.] There are 610 municipal systems owned by cities, villages, towns, or sanitary districts that serve a population of approximately 4,026,471. [FN11: Id. at 6-7.] Most of these systems rely on groundwater, but a few of the largest systems obtain water from surface water. [FN12: Id. at 7-8.]

EPA Response: The EPA acknowledges the information provided by the commenter related to PFAS monitoring in Wisconsin and the agency has considered these data prior to finalizing the PFAS NPDWR.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042810)

In addition, there appears to be limited data available to determine the prevalence of co-exposure to these compounds. Further review of the extent to which these compounds are likely to present themselves as a mixture would be beneficial prior to establishing a brand-new compliance approach such as the Hazard Index.

EPA Response: The EPA disagrees with the commenter that there is limited data to determine co-occurrence and co-exposure. Please see section 6.3 of the EPA response in this *Response to Comments* document, FRN sections VI.C and VI.G, and section 9 of the *Occurrence Technical Support Document* (USEPA, 2024b).

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043670)

In addition, there appears to be limited data available to determine the prevalence of co-exposure to these compounds. Further review of the extent to which these compounds are likely to present themselves, as a mixture, would be beneficial prior to establishing a brand-new compliance approach such as the Hazard Index.

EPA Response: The EPA disagrees with the commenter that there is limited data to determine co-occurrence and co-exposure. Please see section 6.3 of the EPA response in this *Response to Comments* document, FRN sections VI.C and VI.G, and section 9 of the *Occurrence Technical Support Document* (USEPA, 2024b).

6.4 Occurrence Relative to the Hazard Index

Summary of Major Public Comments and EPA Responses

The EPA received comments on the analyses presented in the proposal of occurrence relative to the Hazard Index. Many commenters agreed that the Hazard Index PFAS co-occurred in mixtures at levels of health concern. Two of these comments came from states that conducted monitoring of Hazard Index PFAS post-UCMR 3 and stated that those occurrence data supported the EPA's findings. Several state agencies provided a summarized analysis of the number of systems expected to exceed the proposed Hazard Index of 1.0 in their state. The EPA notes that these estimates were based on the proposed Hazard Index , which included two significant figures. Since the EPA has determined to finalize the Hazard Index with one significant figure, these estimations are likely high. Nonetheless, these state data and the analyses provided by commenters provide illustrative confirmatory insight of the EPA's Hazard Index analyses (please see section V of the final rule preamble for additional discussion on the usage of significant figures).

One commenter suggested that a national dataset and model complete with all four Hazard Index PFAS are necessary to accurately estimate the number of systems that may exceed the Hazard Index. The EPA disagrees with the commenter; as described in section VI.F of the final rule preamble, state data and model outputs were combined to estimate exceedance of the Hazard Index on a national level. This allowed the EPA to incorporate findings across 18 state datasets for non-targeted monitoring for the Hazard Index PFAS that were not modeled directly. Several commenters stated that there was a limited amount of available data to determine the prevalence of co-exposure of the Hazard Index compounds, and that further review would be needed prior to establishing the Hazard Index. The EPA disagrees with these commenters and believes that sufficient data were available to reasonably assess the co-occurrence of Hazard Index PFAS. An analysis of co-occurrence of Hazard Index compounds using a substantial amount of data encompassing tens of thousands of samples across over 10,000 systems is provided in section VI.C of the final rule preamble and demonstrates that the four Hazard Index PFAS co-occur with each other as well as with PFOA and PFOS. One commenter suggested that more systems may exceed the Hazard Index than the PFOA and PFOS MCLs, since current treatment technologies have been optimized for PFOA and PFOS and not for other PFAS. The EPA's analysis of state datasets clearly contradicts this claim; using the best available data and scientifically robust analytical approaches, the EPA estimates more systems will exceed the PFOA and PFOS MCLs (4,000-6,500 systems) than the Hazard Index MCL (300-700 systems). Of the systems anticipated to exceed the Hazard Index MCL, 100-300 were anticipated to not also be exceeding the PFOA or PFOS MCLs. Including state data from targeted and non-targeted monitoring, 211

systems across 21 states observed results exceeding the final Hazard Index of 1. The use of a single significant figure for the Hazard Index MCL in this final rule will further increase the likelihood of more systems exceeding PFOA or PFOS MCLs than the Hazard Index MCL.

Individual Public Comments

3M Company (Doc. #1774, SBC-045654)

In addition to being procedurally improper, EPA's development of the HI-MCL is also substantively flawed. EPA's approach assumes co-occurrence of the four PFAS included in the hazard index, but EPA has not provided meaningful occurrence data showing substantial likelihood that those substances co-occur. Further, EPA's discussion of potential co-occurrence is replete with examples of EPA relying on data from sources that EPA claims supports its argument while ignoring sources that clearly undermine it. For example, the co-occurrence data presented at the system level for detection of any relevant PFAS shows wide variability among states (USEPA 2023h, p. 197), and states with the most systems tested show much lower frequency of co-occurrence detections.

EPA Response: The EPA disagrees with the commenter's claim that the EPA's occurrence analysis fails to sufficiently document co-occurrence of these PFAS in drinking water. The co-occurrence analysis demonstrates both that the Hazard Index PFAS co-occur with each other as well as with PFOA and/or PFOS. As stated in III.C.5 of the final preamble, regardless of the presence of PFOA and/or PFOS, 12.1 percent of systems included in state datasets that conducted non-targeted monitoring and monitored for at least 3 of the Hazard Index PFAS reported the presence of multiple Hazard Index PFAS. When limiting this to systems that reported the presence of PFOA or PFOS, over 46 percent of systems reported multiple Hazard Index PFAS (this can be observed in section VI.C.3.a of the preamble). Further, as shown in section VI.C.3.b of the preamble and 9.2.2 of the *Occurrence Technical Support Document* (USEPA, 2024b), pairwise odds ratios among Hazard Index PFAS (as well as PFOA and PFOS) are significantly higher than 1 at the system level and sample level, indicating a statistically significant association between every unique pair of PFAS regulated by this final rule.

The EPA also disagrees that the agency has ignored data from sources that undermine its claims. It is common and anticipated for chemical occurrence to vary across states. This is also the reason the EPA includes results separated by state. Of 18 states that were included in the non-targeted analysis of state data, 8 states saw both PFOA and/or PFOS and Hazard Index PFAS at detectable levels in over 20 percent of systems. Most of the states with data available included hundreds of systems. States that included over 500 systems were MI, OH, MA, IL, NY, NJ, ME, and VT. The percent of systems in these states that reported the presence of both PFOA/PFOS and Hazard Index PFAS were 4.3, 1.8, 49.9, 6.3, 38.5, 43.5, 11.9, and 5.7 percent, respectively. Please see section 6.3 of the EPA response in this *Response to Comments* document, section VI.C of the FRN, and the *Occurrence Technical Support Document* (USEPA, 2024b) for more information on PFAS co-occurrence.

American Water Works Association (AWWA) (Doc. #1759, SBC-045599)

Combined MCLG for PFHxS, PFNA, HFPO-DA, and PFBS

According to the proposal, EPA is proposing to establish a combined MCLG for four PFAS set at a hazard index of 1.0. In proposing this MCLG, EPA is making several key scientific determinations to support this decision:

1. PFNA, PFHxS, HFPO-DA, and PFBS are likely to co-occur in water in a way that is a "sufficiently similar mixture"

EPA Response: The EPA refers the commenter to section 4.3.2 of the EPA response in this *Response to Comments* document regarding the Hazard Index approach and notes that a "mixture" can be any combination of two or more of the Hazard Index PFAS. The EPA's evaluation of UCMR 3 data as well as data from state-led drinking water monitoring efforts shows that PFHxS, PFNA, and HFPO-DA each have a substantial likelihood to occur in finished drinking water and that these three PFAS and PFBS are also likely to co-occur in mixtures (USEPA, 2024b). Please see section 6.3 of the EPA response in this *Response to Comments* document, section VI of the FRN, and the *Occurrence Technical Support Document* (USEPA, 2024b) for more information on PFAS co-occurrence.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045101)

Section VII – Occurrence

Based on the data from 2019 to date in Vermont we would not have a system exceed the MCL based on the Hazard Index calculation that would not already exceed the MCL for either PFOA, PFOS or both. Note that we calculate compliance based on an initial sample and confirmation sample, not the running annual average, however, assuming the results remain consistent, the data available are a good indicator for how the draft rule would play out in the State.

EPA Response: The EPA acknowledges the commenter for providing information on systems estimated to solely exceed the Hazard Index MCL and the agency acknowledges commenter's assertion that there would be no Hazard Index exceedances if there were not also exceedances of PFOA, PFOS, or both. The EPA notes that this information further supports that there is co-occurrence of Hazard Index PFAS with PFOA/PFOS.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045220)

Occurrence

1. EPA requests comment on the number of systems estimated to solely exceed the HI (but not the PFOA or PFOS MCLs) according to the approach outlined in USEPA (2023e).

Until a national data set and model are complete with all four HI PFAS, it will be difficult to accurately estimate the number of systems impacted or exceed the HI. However, with the data presented by the EPA, it does appear that these PFAS co-occur in mixtures and are present in the finished drinking water at health impacting levels.

EPA Response: Please see section 6.4 of the EPA response in this *Response to Comments* document. Additionally, the agency agrees that the Hazard Index PFAS co-occur in mixtures at a level and frequency of public health concern.

6.5 National Occurrence Model

Summary of Major Public Comments and EPA Responses

A few commenters stated that they believed the model was an overly complicated approach to characterizing chemical occurrence and found it difficult to understand. Further, a few commenters stated that they believed the model was not transparent. The EPA disagrees; the occurrence approach used by the agency in this rulemaking is based on a widely utilized and accepted statistical approach which is used in a variety of professional fields. The EPA used this model to better inform the agency's understanding of probable PFAS occurrence. For more information about Bayesian statistics and the wide variety of potential applications, see, for example, Hoff (2009); van de Schoot et al. (2021); Aguilera et al. (2011); and Messner et al. (2001). While the model uses an advanced statistical method and requires some statistical background to fully understand, Bayesian hierarchical models have previously been employed to assess occurrence for drinking water contaminants, as was discussed in the March 2023 proposal preamble as well as Cadwallader et al. (2022). Cadwallader et al. (2022) describes the model structure while the annotated model code and inputs were provided directly as supporting information alongside the manuscript. This information was incorporated into the docket for this rule's proposal. Sufficient information to replicate the model run was provided. Thus, the agency disagrees with the assertion that the model was not transparent.

Regarding the model complexity, the core structure of this specific model is comparatively simple among Bayesian hierarchical models. The model uses a multivariate normal distribution of system-level means (of log transformed data) for the four modeled PFAS. It also includes a parameter for small systems to assess whether they appear to have systematically different (higher or lower) concentrations than large systems. As stated in Cadwallader et al. (2022), the model extrapolates to the nation by sampling from the multivariate normal distribution and accounting for whether the system being simulated was small. The multivariate normal distribution and the parameter to distinguish small systems from large systems are two simple but important pieces of the model structure.

Many commenters stated that the model relied on insufficient data and produced substantial underestimates of the number of systems that would fail to meet MCL requirements. The agency disagrees both that the approach taken would systematically underestimate PFAS occurrence and that the data were insufficient to inform the model. The Bayesian approach used here makes a

precedented assumption about drinking water chemical contaminant occurrence distributions (lognormality) and uses the available data to generate iterative estimates of distribution parameters that capture uncertainty through Markov Chain Monte Carlo (MCMC) simulation. Across these iterations, the density of the posterior distribution for model parameters is proportionate to the likelihood that a given value would have produced the observed data. The subsequent national extrapolations also reflect this uncertainty. In response to commenters' concerns regarding underestimation of occurrence, the EPA has presented extrapolated preliminary UCMR 5 results alongside the EPA's estimates from the proposed rule and the final rule. Please see Figure 1 in section 6.8 of the EPA response in this *Response to Comments* document. Estimates of impacted systems and entry points from American Water Works (AWWA) report (AWWA, 2023) are also included, given that they were mentioned by several commenters. The preliminary UCMR 5 results indicate that the EPA's occurrence estimates are reasonable.

For the results presented in the March 2023 proposal preamble, the model was fit using 171,017 analytical results across the 4,920 UCMR 3 systems. This was a nationally representative set of systems. 147,887 of the analytical results were collected as part of UCMR 3 while 23,130 were aggregated from 17 subsequently collected state datasets. The model was designed to utilize both results reported as observed concentrations (8,209 results) and results reported as less than a reporting limit (162,808 results). While the UCMR 3 used higher reporting limits than are currently available, both reported concentrations and values reported as below the minimum reporting level cumulatively make substantial contributions to informing the model's estimates of the PFAS occurrence distribution because of this statistically robust framework. Due to this efficient use of data, and the steps taken to maintain a nationally representative set of systems, the agency believes that the over 170,000 analytical results were sufficient to generate reasonable estimates of occurrence for the modeled contaminants.

Several commenters expressed concern with model bias resulting from the supplemental state data that was incorporated when fitting the model. The hierarchical structure of the model minimizes the bias impact of introducing additional state data for only some UCMR 3 systems (those with additional data available) because the data are explicitly linked to their parent systems rather than being pooled with all other data informing the model. The primary impact that these data have is on the model's estimate of specific system means for those systems that had additional data and informing the within-system variability parameters in the model. Refinement of a single system's mean estimate has a much smaller impact on the high-level distribution of system-level means and such shifts are proportionate to the added evidence derived from the supplemental data.

The addition of data from systems not included in the UCMR 3 would pose a much greater concern for bias, since not all states have publicly available data. States with additional data would become disproportionately represented in the fit of the high-level distribution, since each system acts as a data point in fitting the distribution. The resulting high-level distribution would shift to resemble the states with higher system representation in the source dataset more closely.

This would also be reflected in the subsequent national extrapolation. This same bias concern applies to national extrapolation approaches where some fraction of systems in a subset are identified as exceeding a given threshold and the national inventory of systems is multiplied by that fraction to generate a national estimate of systems that would exceed the threshold. If certain states have a disproportionate number of systems included in the subset compared to in the nation as a whole, the national estimate will be biased towards the tendencies of those states. In addition to this bias, the simple example approach discussed above would not naturally reflect uncertainty. Thus, for the purpose of national extrapolation, a nationally representative set of systems is more appropriate, even if data from other systems are available.

While the EPA believes the model design and data selected for the analysis presented in the March 2023 proposal remain appropriate given the data availability at the time, the EPA has also continued to collect newly available data from publicly available state datasets, as the agency committed to in the proposed rulemaking (USEPA, 2023b). The aggregated state dataset used to inform the model now includes over 65,000 samples from 28 states. The Bayesian hierarchical model has been refit using the updated dataset with the same methods and criteria for data selection that were used for the analysis presented in the March 2023 proposal. Estimates from the updated model run support the EPA's prior conclusions with respect to occurrence of the modeled PFAS.

Individual Public Comments

New Hampshire Water Works Association, Inc. (NHWWA) (Doc. #1576, SBC-042450)

EPA lacks sufficient water quality occurrence data to accurately assesses the extent and degree of the problem – knowledge that is required to form the basis for a national standard. Statistical derivations of incomplete data sets are not a reasonable or defensible approach.

EPA Response: The EPA disagrees that the agency lacks sufficient occurrence data to "accurately assess the extent and degree of the problem." The EPA has used the best available information and best available science to establish robust national occurrence estimates. Please see sections 6.5 and 6.2 of the EPA response in this *Response to Comments* document for further discussion of the available data and how they were used.

American Water Works Company Inc. (Doc. #1608, SBC-044000)

American Water is aligned with the comments provided by AWWA on the U.S. EPA's occurrence analysis suggesting that the U.S. EPA should apply a 2-tier approach to the occurrence analysis to better leverage UCMR 3 and appropriate non-UCMR data and also utilize any available UCMR 5 data in a revised analysis before the rule is finalized.

Additionally, American Water believes that relying on PFAS data from recent monitoring programs may significantly underestimate the number of surface water treatment plants that will require treatment if the data is not statistically adjusted to consider the effects of low flow

conditions in surface water supplies during drought periods. Our available surface water data in several locations shows a clear seasonal effect, which is consistent with PFAS concentrations increasing when surface source water flows decrease during drier seasons. While we do not have enough historical data to accurately project PFAS concentrations within our surface water supplies across the full range of expected flows, we can reasonably assume that this seasonal effect will be even more exaggerated during drought events. This indicates that a number of facilities that have had historical PFAS sampling concentrations below the proposed MCLs and/or PQLs, and thus excluded from the U.S. EPA occurrence analysis, may yield PFAS concentrations at or above the proposed MCLs during even brief drought conditions.

EPA Response: For the EPA's responses to other commenters, please see their respective comments in this *Response to Comments* document. Regarding seasonal variability, exceedance of the MCLs presented in the final rule is based upon running annual averages (RAAs). Systems monitoring quarterly will have samples from each season equally contributing to their RAA calculation. This provides systems with flexibility compared to if compliance was based on individual sample results. UCMR 3 and state data that were used to inform the national model came from all quarters of the year.

Prince William County Service Authority (Doc. #1609, SBC-042833)

PFAS Occurrence Data Projections

EPA's use of a statistically generated occurrence model underestimates the number of utilities that will be required to implement PFAS treatment. The Unregulated Contaminant Monitoring Rule 3 (UMCR3) dataset that served as the baseline for this statistical generation uses data from a time when minimum reporting limits for these PFAS compounds were two to twenty times higher than today. The supplemental data EPA used comes from only 18 states. Regrettably, none of this data is from Virginia. Of further concern, the supplemental data includes PFAS monitoring from drinking water analysis methods that are not EPA approved.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. After considering public comment, the EPA collected additional state data as part of the final rule updates. The supplemental state data used to inform the national occurrence model now comes from 28 states, including Virginia. For the proposed rule, this state data had come from 17 states. For steps the EPA took to transparently ensure QC of the state data, please see section 6.2 of the EPA response in this *Response to Comments* document. The vast majority of the data were collected using EPA approved methods.

Prince William County Service Authority (Doc. #1609, SBC-042843)

3. In the absence of current national PFAS occurrence data for drinking water, which EPA will obtain in the recently initiated UCMR5 effort, we believe EPA's statistical model significantly understates the number of water utilities impacted by the proposed rule. As a result, the cost to implement the PFAS rule will likely greatly exceed EPA's estimates.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043094)

Next, several of EPA's underlying analyses to support the rulemaking need improvement to be credible. The occurrence analysis lacks transparency on the levels of PFAS in communities nationally and criteria for data inclusion/exclusion is not clear. The approach to assessing national occurrence of PFAS is overly complicated.

EPA Response: Please see sections 6.5 and 6.2 of the EPA response in this *Response to Comments* document.

Orange County Water District (OCWD), California (Doc. #1634, SBC-043232)

To remedy the regulation's current occurrence estimate limitations, EPA should at least provide more transparent details of the Bayesian Model, including information on the model outputs with respect to the number and type of water systems impacted by the various regulatory options.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. Additionally, information about the Bayesian model is included in the docket for this rulemaking action.

Orange County Water District (OCWD), California (Doc. #1634, SBC-043230)

Estimated Cost

For several reasons, EPA has significantly underestimated the cost of the proposed regulation, including:

• An accurate estimate of nationwide occurrence of PFAS in drinking water underpins the entire regulation and is especially key to the cost estimates. Due to the current lack of reliable nationwide PFAS occurrence data in drinking water using detection limits relevant to the proposed maximum contaminant level goals (MCLGs), EPA has applied an opaque and overly complex Bayesian Hierarchical statistical model to estimate nationwide occurrence of PFAS. EPA's limited supporting information provided for the model, along with a single referenced scientific publication about the model, represents wholly inadequate technical documentation of such a foundational component of the regulation. The modeling effort requires many stated and unstated assumptions to utilize older, higher detection limit UCMR3 data with select recent state-level data collected from the same systems using lower detection limits. The wholesale exclusion of data from states like California, which have performed significant targeted PFAS drinking water monitoring is problematic and represents a lost opportunity for a more robust analysis. Similarly, the exclusion of non-UCMR3 sites from the state datasets analyzed represents an unnecessary and insufficiently justified limitation. Collectively, we believe these deficiencies

(and perhaps others) lead to a systematic underestimation of the number of systems impacted and thus an underestimate of the national costs of compliance. Furthermore, the occurrence and cost underestimates present inaccurate information to federal policymakers and elected officials assessing the scope of the problem and determining the amount of federal support available to affected systems.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document for a response related to the Bayesian model and the supporting information that was provided with it. Please see section 13.3 of the EPA response in this *Response to Comments* document for responses related to the EPA's cost estimates. For information about how the EPA establishes a Maximum Contaminant Level Goal (MCLG), please see section IV of the preamble for this action. The EPA disagrees that California data was excluded from the model; see Cadwallader et al. (2022) which describes that supplemental state data from California was included to inform the model fit for the rule proposal. For the final rule, California is the state with most samples included from supplemental state data.

Massachusetts Water Resources Authority (Doc. #1645, SBC-043282)

2. MWRA Comments

a. Occurrence Analysis is Not Transparent and Based on Limited Data

As proposed in the NPDWR, EPA uses an overly complex statistical approach to characterize national low-level PFAS occurrence. The occurrence analysis and how it is used in subsequent analyses has not been adequately explained in the materials provided by EPA.

EPA Response: The EPA disagrees that the statistical model is overly complex. Bayesian statistical models are commonly used in multiple professional fields, including being previously used to inform prior EPA regulations. For further discussion, please see section 6.5 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043708)

EPA is estimating that 5,000 water systems will be impacted by this proposed rule. The reality will likely be around 7,000 water systems that are impacted. One problem with EPA's estimates for how many systems are impacted and what the costs will be is that they have not completed their occurrence data assessment for PFAS chemicals. Since the UCMR 5 sampling program has not been completed it is clear EPA does not have a complete dataset for the PFAS levels across the country. Based on voluntary sampling for PFAS in public water systems in Colorado, it is estimated that there will be 60 water systems that will exceed the proposed MCLs for PFOA and PFOS.

EPA Response: Please see sections 6.5 and 6.8 of the EPA response in this *Response to Comments* document.

Massachusetts Coalition for Water Resources Stewardship (MCWRS) (Doc. #1691, SBC-044322)

2. EPA's estimate of impacted water systems falls at up to 6,300 with most being systems serving less than 10,000 people. This represents less than 10% of the 66,000 water systems subject to the proposed MCL rule. This appears to be extremely low given recent Massachusetts data based on a few years of PFAS monitoring. Massachusetts Department of Environmental Protection (MassDEP) reports that 29% of community and NTNC water systems will have to abandon sources, find new sources, connect with other systems or install treatment facilities to meet the proposed MCLs. This MassDEP figure likely underestimates the true number of water systems impacted in Massachusetts as it does not consider those systems that may see variable levels of PFOA and PFOS that could trigger an MCL violation in future testing rounds. Massachusetts is seeing PFAS in communities of all sizes and land use histories, from urban to rural areas, groundwater and surface water systems, towns with airports and military bases and those far removed from either. There is nothing unique about Massachusetts when it comes to PFAS in water supplies and no reason to believe that nationally only 9.5% of water systems will be impacted by the proposed MCL while Massachusetts will see nearly 30%.

EPA Response: The EPA disagrees that its PFAS occurrence estimates are extremely low. See section VI of the FRN and section 6.5 of the EPA response in this *Response to Comments* document for further discussion. Furthermore, Massachusetts was among the states with the most frequently reported the presence of PFOA and/or PFOS in non-targeted datasets (see section VI of the preamble). It is likely that MA is on the high end of the distribution for state-level occurrence frequencies. Further, available state data from MA were used to inform the national model fit for the proposed rule and additional data were collected to inform the final rule. It is among the states with the most available state data samples to inform the model.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044755)

7. EPA Should Revise the Potential Number of PWSs That May Be Required to Address PFAS Contamination

EPA states that "The resulting range of systems estimated to be impacted by the proposed regulation of an MCL concentration of 4.0 ppt for PFOA and PFOS and an HI of 1.0 for a mixture of PFHxS, HFPO DA, PFNA, and PFBS was 3,400-6,300 systems serving a total population of between 70 million and 94 million people. Among these systems, between 100 and 500 were estimated to be systems exceeding the HI for PFHxS, HFPO-DA, PFNA, and PFBS that had not already exceeded the proposed MCLs for PFOA and/or PFOS." However, in its evaluation of non-targeted data from 12 states, EPA describes that "when evaluating only a subset of the available state data representing non-targeted monitoring, that one or more PFHxS, HFPO-DA, PFNA, and PFBS were reported in approximately 13.9% of monitored systems; if these results were extrapolated to the nation, one or more of these four PFAS would be detectable in over 9,000 PWSs." Considering that HBWCs are relatively close to the minimum

reporting limit of EPA Methods 533 and 537.1 for three of the four PFAS, which would result in a HI greater than 1.0, it seems reasonable to assume that EPA's estimation of the number of facilities impacted maybe an underestimate.

WDEQ recommends that EPA reevaluate the number of PWSs that may be required to address PFAS impacts above the proposed MCL concentrations and proposed HI value. This information is necessary for states to better understand potential impacts from the proposed rule.

EPA Response: In regard to Wyoming Department of Environmental Quality's (WDEQ's) recommendation to reevaluate the number of PWSs that may be above the MCLs for this action, please see sections 6.5 and 6.6 of the EPA response in this *Response to Comments* document. Based on this additional work triggered by this and other comments, the EPA's final estimates of the total impacted PWSs has increased slightly from the proposal; however, the general range is similar. Anticipated Hazard Index MCL exceedances at systems not already exceeding an MCL for PFOA or PFOS decreased due to the use of a single significant figure in the final rule as opposed to two significant figures in the proposed rule (please see section 6.4 of the EPA response in this *Response to Comments* document). See discussion in sections VI.E and VI.F of the preamble for this rulemaking action. Furthermore, state datasets used a variety of reporting limits, which are based on reporting practices as well as individual laboratory capabilities. The broader minimum reporting level used for the UCMR program is tailored to be achievable by the majority of laboratories nationwide. For this reason, there is a wider range of values that may be reported that remain under the Health-Based Water Concentrations (HBWCs). Please see section VI.D of the preamble for a direct discussion of occurrence relative to the Hazard Index. Additionally, of the 13.9 percent described in the proposal preamble, which depicts detections at any reported concentrations and not just at or above the HBWCs, 11.1 percent were systems that had also observed PFOA and/or PFOS and 2.8 percent were systems that had not also observed PFOA and/or PFOS. The fraction of systems reporting the presence of a Hazard Index PFAS is not a suitable proxy for the fraction of systems that will exceed the Hazard Index MCL without also exceeding an MCL for PFOA or PFOS.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043576)

A Government Accountability Office (GAO) study of drinking water data collected from six states showed at least 18 percent of 5,300 water systems studied had PFOA and/or PFOS exceeding the proposed MCLs of 4 ppt alone. Levels of initial noncompliance may be even higher than anticipated due to sampling bias since the proposed limits are the lowest level many laboratories can reliably detect, and many systems have not already pursued such sensitive testing for all six chemicals listed.

EPA Response: The six states in the Government Accountability Office (GAO) study include Massachusetts, New Jersey, and New Hampshire. These states were captured in the EPA's analysis as having elevated frequencies of detection (see preamble VI.B). In the GAO report, Massachusetts, New Hampshire, and New Jersey had 37 percent, 35 percent, and 40

percent of systems, respectively, observe an occurrence at or above 4 ppt (combining for 852 of the 978 systems that observed PFOA and/or PFOS at or above 4 ppt). Illinois, Ohio, and Vermont reported such occurrences in 4 percent, 3 percent, and 6 percent of systems in the study, respectively. Note that these percentages include systems that observed concentrations at the MCL, while compliance is assessed by exceeding the MCL. Further, observed occurrences do not necessarily indicate that a system would exceed an MCL since exceedances are determined by RAAs. For the EPA's analyses, supplemental state data from each of these six states were used to inform the national model fit.

Florida Section American Water Works Association - Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044486)

The cost and timelines analysis should please consider the following:

• PFAS Nationwide Occurrence:

The Florida Water Sector believes EPA underestimated the amount of Public Water Systems (PWS) affected by the proposed rule. EPA used a "Bayesian hierarchical estimation model" fitted using PWS' Unregulated Contaminant Monitoring Rule, UCMR 3 data. However, the EPA UCMR 3 Minimum Reporting Level (please see https://www.epa.gov/dwucmr/third-unregulated-contaminant-monitoring-rule for PFOS (40 parts per trillion. ppt) and for PFOA (20 ppt) were an order of magnitude higher than the proposed maximum contaminant level (4 ppt). EPA should work with state primacy agencies to determine nationwide occurrence based on knowledge of current treatment methodologies' abilities to meet the proposed 4 ppt regulation and expected treatment changes to do so.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045221)

2. CT DPH agrees that EPA has demonstrated that the 6 proposed regulated "contaminants will occur and co-occur with a frequency and at levels of public health concern in PWSs." The EPA meets the second Statutory Criterion – Occurrence.

A preliminary analysis of the testing data that Connecticut public water systems voluntarily reported to the CT DPH is consistent with the national statistics in that the majority of MCL exceedances will be due to PFOA and/or PFOS concentrations. The limited drinking water results for Connecticut show that three of the four PFAS with proposed MCLs are often found as mixtures and co-occur in the sample with PFOA and PFOS.

The combined contamination occurrence model and state sampling evidence cited by EPA suggests a maximum of ~6,300 public water systems will be impacted by the proposed MCLs, or approximately one-tenth, of the ~66,000 public water systems impacted by these proposed MCLs. According to table 7, four states have measured PFOA and PFOS above the MCL at rates

higher than the maximum of the model. With UCMR3 data having relatively high reporting limits (20 or 40 ppt), the national data set is limited below the UCMR 3 reporting limit where "background" contamination of PFAS may impact PWS. It is possible that this model underrepresents the impact of PFAS on the finished drinking water, and this should be taken into account when calculating the costs of treatment.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. The upper end of the interval presented for the proposed rule does not constitute a maximum value. Rather, it is the upper end of a confidence interval. See subsection 10.3.2. of the *Occurrence Technical Support Document* (USEPA, 2024b) for further discussion. The majority of the supplemental state data from 28 states incorporated to inform the model utilized minimum reporting levels on the order of single digit ng/L. Regarding the EPA's regulatory determinations for PFHxS, PFNA, HFPO-DA, and mixtures of these three PFAS and PFBS, please see section 3.1.2 and 3.2.2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045579)

3. Non-UCMR 3 data should be leveraged more effectively. Specifically:

a. The agency should leverage existing methodologies used to by the UCMR program to incorporate data from systems beyond the scope of UCMR 3 as part of the Bayesian Model in a way that maintains the national representation of the data and provides additional confidence.

b. If the agency determines that there are insufficient resources within the agency to do this, the non-UCMR 3 data that is excluded from the Bayesian Model should be used to evaluate the Model outputs.

4. The non-UCMR 3 data that is included in the Bayesian Model and considered to be nationally representative should be evaluated and EPA should substantiate the basis for its inclusion.

5. The agency should consider a 2-tier approach that relies on best-available, system specific data on PFAS levels and TOC levels and relies on a probabilistic distribution approach to the remaining systems without known PFAS and TOC levels.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. Non-UCMR 3 data from systems that were not used to fit the national occurrence model were used and presented in several other analyses that were presented in the preamble as well as the *Occurrence Technical Support Document* (USEPA, 2024b). Please see section 6.2 of the EPA response in this *Response to Comments* document for discussions about state data and the QC efforts taken by the EPA. Because the total organic carbon (TOC) levels for all systems are not available, the EPA used TOC data provided by states in response to the fourth Six-Year Review to derive TOC probability distributions for influent into a PFAS treatment process; one distribution for ground water systems and another for surface water

systems. For further discussion about the use of TOC data, please see section 13.7 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045577)

Distinguishing Between PFAS Detections and Levels of Health Risk Concern

The SDWA only allows EPA to regulate a substance when "the contaminant is known to occur or there is a substantial likelihood that the contaminant will occur in public water systems with a frequency and at levels of public health concern." [FN13: 42 U.S.C. § 300g–1 (b)(1)(A)(ii).] The agency's discussion about the occurrence of PFAS in drinking water frequently discusses the likelihood of detections of PFAS. While this is useful, it would be more relevant, and therefore beneficial, for EPA to provide information about PFAS occurrence at levels closer to the relevant health risk levels, particularly the proposed MCLGs or MCLs. While occurrence at any level is useful to understand, it is misleading to the public and it is important that occurrence be contextualized with the relevant levels of health concern, given that that is the proper statutory focus under the SDWA. A detection of PFBS at 5 ppt, for example, represents a level that is less than 0.25% of the EPA's lifetime health advisory level (HAL). In comparison, a detection of PFHxS at 5 ppt represents a level that is 55% of the EPA's proposed health-based water concentration (HBWC). Put plainly, a detection of PFBS represents a much different level of risk than a detection of PFHxS. For this reason, EPA should ensure that the occurrence analysis provides context on PFAS occurrence that is more useful than detection.

Providing Transparency of Occurrence Analysis Outputs

While it has been previous practice of EPA to depict the conclusions of its occurrence analysis by presenting the number of water systems (in addition to the population) impacted by the proposed rule and the rule options. EPA failed to follow that practice here and did so without providing a proper explanation for this change in its analytical approach, as required by the APA. Instead, EPA provided a breakdown of the population impacted along with a more limited set of information about the small systems that are impacted.

AWWA previously inquired about additional information on Bayesian Model in Fall 2022 and received a series of statistical outputs that did not assist AWWA in an understanding the PFAS occurrence at systems. Following the rule's publication to the Federal Register AWWA discussed the absence of this data in the Docket with EPA staff during a conference call; in discussion with staff, EPA clarified that the data, in their entirety, was not available as part of the supporting information provided for this rulemaking [FN14: Conference call on March 28, 2023, between AWWA and EPA staff]. AWWA made a written request for this data following this conference call and has not received the completed information (Moody, 2023).

It is important that relevant occurrence information underpinning a rulemaking analysis be made available for public comment and included in the record as part of any final PFAS rule, and for all future proposals for national primary drinking water regulations, so that the public can

understand the overall impact of the rule on communities and to confirm that the benefits and costs attributed to the rule are accurate.

Summary of Recommendations for Improving Occurrence Analysis

In order to comply with the requirements of the SDWA and APA, AWWA makes the following recommendations to improve quality and transparency of the occurrence analysis:

1. The agency should provide clearer and more transparent information on the intended approach of the Bayesian Model, including information on the model outputs with respect to the number and type (e.g., system size, source) of water systems impacted by the various regulatory options.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. The EPA disagrees that the occurrence analysis did not include discussion of system counts (and the population associated with them) exceeding certain PFAS occurrence thresholds. Observed PFAS occurrence relative to thresholds of interest are presented in section VII of the proposal preamble and have been updated in VI.B and VI.D of the final rule preamble. The estimated number of systems and the associated population anticipated to be impacted were presented in section VII.F of the proposal preamble (VI.F of the final preamble) as well as the *Occurrence Technical Support Document* (USEPA, 2024b).

The EPA disagrees with the commenter that the data used to inform the model was not provided. The full dataset used to inform the model run that was utilized in the proposal preamble was provided as publicly available supplemental information and uploaded to the proposal docket. Additionally, the separated dataset consisting only of supplemental state data was also provided; please see section 6.5 of the EPA response in this *Response to Comments* document for further discussion. Summary statistics for high level model parameters were provided as well. Separate UCMR 3 data is also publicly available. With the model code also provided as supplemental information, all necessary information to run the model was provided. As discussed in section 6.5 of the EPA response in this *Response to Comments* document, the EPA is confident that its methods represent best available science. While the EPA notes that assembling and conducting QC of the state datasets and developing and running the model represent thousands of hours of work, the results generated by the model are reproducible with publicly available information, provided experts in environmental statistics are available to recreate the results and invest the necessary time resources.

Summary materials for the updated model run that supported the final rule may be found in the docket.

American Water Works Association (AWWA) (Doc. #1759, SBC-045572)

4. Analysis of Occurrence Data

The SDWA requires that EPA rely upon the best available public health information, including the occurrence database [FN8: 42 U.S.C. § 300g-1(b)(1)(B)(ii)(II)]. EPA must therefore ensure

that the data on which it relies meets this standard. Because "best" is necessarily comparative, EPA must also provide sufficient explanation regarding the data selected and not selected as the basis of EPA's decision so that the public can meaningfully comment on the data selected as well as evaluate the data that EPA did not decide to rely upon.

According to the proposal, EPA applied a statistical modeling approach to characterize occurrence data for PFAS using a combination of both national occurrence monitoring data from the UCMR 3 and more recently collected state data. According to the proposal, EPA applied a statistical modeling approach to characterize occurrence data for PFAS using a combination of both national occurrence monitoring data from the UCMR 3 and more recently collected state data. While EPA typically relies on nationally representative occurrence data from the UCMR program to drive decisions for NPDWRs, the agency previously noted an interest in using data collected by state monitoring programs given the UCMR 3 database's high reporting limits relative to the potential levels of health concern (EPA, 2021e). While EPA typically relies on nationally representative occurrence data from the UCMR program to drive decisions for NPDWRs, the agency previously noted an interest in using data collected by state monitoring programs given the UCMR 3 database's high reporting limits relative to the potential levels of health concern (EPA, 2021e). AWWA appreciates the agency's interest in advancing this rulemaking by leveraging more recently collected data using improved methods. A detailed understanding of contaminant occurrence in drinking water across the country is a key factor for developing not only regulatory determinations, but also drinking water standards. In review of this approach, several opportunities to improve the analysis were identified.

Application of the Bayesian Statistical Model

The engine of the occurrence analysis for the proposal is the Bayesian hierarchical statistical model (the Bayesian Model), that uses PFAS occurrence data from more recent monitoring programs to provide improved understanding of the UCMR 3 data below the reporting limits. Similarly, the occurrence analysis is the engine of the entire rulemaking, informing the EPA's understanding of the regulatory impacts of the rule. For this reason, it is imperative that the Bayesian Model be utilized appropriately and with statistical confidence.

While the Bayesian Model approach is sophisticated technically, it is an overly complex approach for characterizing national occurrence. While the Bayesian Model approach is sophisticated technically, it is an overly complex approach for characterizing national occurrence. Bayesian models can be useful in many applications but there are some key challenges that arise with the use of these models that make it non-optimal for regulatory applications. The key challenge is that the selection of priors and the posterior conditions is a very subjective decision that is subject to the discretion of the statistician that is crafting the model. As such, it is expected that the assumptions around these decisions are documented clearly and in detail. While EPA has provided a copy of the code used for the Bayesian Model, along with a recent publication about the model, there is a lack of a non-technical description of the agency's intended approach. The lack of a clear explanation of intent regarding the model's

code leaves stakeholders unable to confirm that the code is accurately developed, and therefore unable to meaningfully comment on this aspect of the proposal.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. The Bayesian statistical model represents best available science for assessing PFAS occurrence data on the national scale. Inherently, the programming and use of the model does require specialized statistical expertise. The EPA has attempted to explain the model in less technical terms, but a minimum statistical background may be necessary to fully understand the methods and decisions made in the model. The EPA also has described the results of the model output in plain language throughout the record for this rule, and those key summaries are interpretable by a nontechnical audience.

Additionally, as stated in Cadwallader et al. (2022), weakly informative priors were used for the model. A posterior distribution is the result of combining a prior with information derived from the data that informs the model. When there is a large amount of data to inform the model, information from the data informing the model quickly "washes out" the influence of the weak prior. Gelman et al. (2013), as cited in Cadwallader et al. (2022), describes the general preference for the usage of weak priors as well as difficulties associated with the use of noninformative priors. The decision to use a weak prior was not a key challenge in the model development given the extensive dataset available and the precedent for the use of lognormal distributions to describe chemical occurrence in drinking water. Further, usage of a weak prior relative to a noninformative prior improves computational efficiency of the model (as stated in Cadwallader et al., 2022).

American Water Works Association (AWWA) (Doc. #1759, SBC-045638)

Several of the EPA's analyses underlying the rulemaking need improvement to be credible. The occurrence analysis lacks transparency on the levels of PFAS in communities nationally and criteria for data inclusion/exclusion is not clear. It is also an overly complicated approach to assessing national occurrence data for PFAS, which are currently being collected as part of the UCMR 5 program.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. The EPA affirms that its analyses are credible and represent the use of best available science. The EPA further notes that all of the available occurrence information and data sources were provided as a part of the proposed rule and are also available in in sections III.C. and VI of the final rule preamble and the *Occurrence Technical Support Document* (USEPA, 2024b). The EPA also documented the QC steps that the agency took to ensure the data were accurately and transparently presented (please see section 6.2 of the EPA response in this *Response to Comments* document).

American Water Works Association (AWWA) (Doc. #1759, SBC-045575)

Additionally, EPA has noted that the Bayesian Model's incorporation of state monitoring data excludes all non-UCMR 3 data that was collected by water systems that did not participate in UCMR 3. While EPA reanalyzes this decision by highlighting that the UCMR 3 program was designed to collect data that is nationally representative, this approach fails to realize an opportunity to leverage the vast quantity of non-UCMR 3 data that is available. A project was conducted by Corona Environmental Consultants for AWWA that collected PFAS monitoring data from both UCMR 3 and state monitoring programs (Corona, 2021). This work successfully aggregated data from these programs from nearly 8,000 public water systems from across the country. Of these systems, 668 systems had participated in UCMR 3 and had more recent data available through state monitoring programs. Additionally, data was available for more than 3,100 water systems had participated in state monitoring programs but not UCMR 3. More effective inclusion of this data would expand the more recent data set for PFAS occurrence by a factor of nearly 5, which could improve our understanding of occurrence for smaller systems significantly.

It is reasonable that the EPA is interested in leveraging the non-UCMR 3 data in a way that is nationally representative, but there are two aspects of the proposed approach that require a more detailed review. First, it is not clear why EPA is willing to leverage an overly complicated Bayesian Model to assess occurrence but at the same time is unwilling to develop a statistical approach to incorporating the additional non-UCMR 3 data in a manner that is nationally representative. EPA has existing experience under the UCMR program selecting small water systems for participation in the UCMR program that will be nationally representative. It is not apparent that EPA considered or attempted to leverage the significantly sized dataset of non-UCMR 3 data more effectively, especially to improve the occurrence analysis for smaller systems. In order to fulfill its obligations under the SDWA, EPA must likewise use a statical approach to the smaller water systems in order to make better use of this dataset.

Additionally, it is likely that the non-UCMR3 data that EPA used for the Bayesian Model is biased and not nationally representative. Consequently the data EPA used is likely not the best available public health information to support the rulemaking. Bias is present in the data collected after UCMR 3 is correlated to states with elevated concerns about statewide PFAS contamination following UCMR 3 detection and improved understanding of likely sources of PFAS in the state. While EPA notes that non-UCMR 3 data collected by systems that did not participate in UCMR 3 should be excluded because it may not be nationally representative, the agency did not determine whether the systems that were included are nationally representative. Unless EPA addresses its inconsistent treatment of available data before issuing any final rule, it risks violating both the SDWA and the APA.

Finally, the occurrence analysis was improperly used to project a probabilistic distribution of PFAS levels across all water systems in violation of the SDWA and APA. This approach may be appropriate for systems where there is not available data as that actual data is the best available

data. However, in taking this approach EPA cannot ignore data for specific system PFAS levels. These systems, that have previously collected data, should be captured in the occurrence analysis based on their previously collected data. Similarly, EPA should reflect actual data when available in its EPA's occurrence analysis of PFAS and total organic carbon (TOC). Besides ensuring that the costs for these systems are accurately reflected, this will ensure that any unique relationships that may exist between TOC occurrence and PFAS occurrence will be captured.

The SDWA explicitly provides a mechanism for EPA to obtain nationally representative occurrence data for contaminants in drinking water by requiring EPA issue a new list of unregulated contaminants to be monitored in drinking water every five years [FN10: 42 U.S.C. § 300g-1(b)(1)(B)]. This list is known as the UCMR. The UCMR serves to better inform regulatory determinations, as contaminants are evaluated based on health effects and occurrence information, and EPA has historically relied on the UCMR process to collect occurrence data on contaminants to support a determination on whether to regulate contaminants. The UCMR serves to better inform regulatory determinations, as contaminants are evaluated based on health effects and occurrence information, and EPA has historically relied on the UCMR process to collect occurrence data on contaminants to support a determination on whether to regulate contaminants. There are times when more recent or robust data may be available outside of UCMR collection, [FN11: Fed. Reg. 68060, 68062 (November 14, 2022)] and in such cases, EPA can appropriately rely on a combination of UCMR and non-UCMR data when available, so long as in doing so it provides a reasoned explanation for its approach and ensures that it is relying on the best available data for national occurrence. EPA has not done so here and must revise its data and provide greater transparency into its data in order to fulfill its obligations under the SDWA.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document regarding model representativeness and data selection. The model was fit to a nationally representative set of systems and used to extrapolate across the country to generate national scale estimates. Incorporation of data from systems outside of this nationally representative set of systems would result in heavy bias of estimates towards states with additional data. The EPA disagrees that it ignored data from other systems. For analyses specific to state datasets, see the *Occurrence Technical Support Document* (USEPA, 2024b), section VI.B, and section VI.D of the final rule preamble. Regarding the dataset mentioned by the commenter, please see the EPA response to comment Doc. #1713, SBC-045902 in section 6.8 in this *Response to Comments* document. The set of nearly 8,000 systems mentioned by the commenter was developed without consideration for national representation. The set of systems included the 4,920 systems included in UCMR 3 with an additional 3,069 non-UCMR 3 systems with available data added. Of these additional systems, approximately 70 percent were from the New England region. This resulted in about 30 percent of the final set of systems being from New England. This is in comparison to the nationally representative UCMR 3 set of systems where New England's proportionate representation was closer to six percent. Thus, estimates generated by extrapolating from the set of 8,000 systems are likely heavily biased towards the New England region.

For discussion of UCMR 5, please see section 6.8 of the EPA response in this *Response to Comments* document. The EPA emphasizes that the agency must use best available science and information. Best *available* means what is currently available and not information that will be collected at some point in the future. The EPA has determined, as justified by the record for this rulemaking action, that there is sufficient information to regulate the six PFAS contained in this final regulation. Please see sections II.F and III of the FRN for further discussion.

American Water Works Association (AWWA) (Doc. #1759, SBC-046159)

4.0 Estimating National Occurrence

To estimate the costs of removing PFAS from drinking water nationally, national occurrence must be characterized. In parallel to this project, AWWA funded WITAF 057 to compile an occurrence database for PFAS in drinking water. In addition to data available for UCMR 3, WITAF 057 facilitated the collection of PFAS monitoring data from state databases and integrated these sources into a single data set. PWSs in this database included only active Community Water Systems (CWSs) and active Non-Transient Non- Community Water Systems (NTNCWSs). The inactive and transient non community water systems were eliminated from the dataset. Consecutive systems receiving all water from treated water wholesaler systems were not excluded from the database or from representation in the national cost estimation.

The WITAF 057 dataset consisted of 7,842 PWSs within these categories as compared to the 49,193 PWSs in the Safe Drinking Water Information System (SDWIS). To account for this incomplete occurrence data, the percent of systems impacted by a potential PFAS regulation within each system size category was multiplied by the active number of CWSs or NTNCWSs in EPA's SDWIS system at each size category to estimate the anticipated number of total water systems impacted in each size category. This methodology therefore assumed that existing occurrence data is representative of national occurrence. This assumption is considered conservative given a significant fraction of existing occurrence data came from UCMR 3, where the reporting limits of 20 parts per trillion (ppt) and 40 ppt for PFOA and PFOS, respectively, likely bias existing occurrence data to underrepresent true national occurrence that would be measured using the current reporting limits.

Monitoring data for PFAS compounds in the WITAF 057 database included more than 30 individual compounds but for this work was limited to the six PFAS covered by UCMR 3: PFOS, perfluoroheptanoic acid (PFHpA), PFHxS, PFNA, and PFBS. As compiled, the WITAF 057 database includes all monitoring results under UCMR 3 and various state monitoring programs, which may include multiple sample results for specific PFAS at a given PWS. Reported data were reviewed to ensure correct translation of reporting units; fields were included for PWS identification number, state, number of people served, source type, and system type. These data were analyzed to determine the maximum and average sample results for each PFAS at each PWS in the database.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. Also please see the EPA responses to comment Doc. #1759, SBC-045575 and Doc. #1713, SBC-045902 in sections 6.5 and 6.8, respectively, in this *Response to Comments* document regarding the substantial bias present in the dataset mentioned by the commenter.

Bowling Green Municipal Utilities (Doc. #1767, SBC-043927)

Occurrence Analysis is Not Transparent: An overly complex statistical approach is used to characterize national low level PFAS occurrence. The occurrence analysis and how it is used in subsequent analyses is not adequately explained. The Agency's commitment to a final rule publication in December 2023 (9 months in advance of the statutory deadline for promulgation), prevents EPA from considering Fifth Unregulated Contaminant Monitoring Rule (UCMR 5) monitoring data, that would dramatically improve the clarity and quality of the occurrence analysis.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document.

3M Company (Doc. #1774, SBC-045703)

9. Comments on Framework of a Bayesian Hierarchical Markov Chain Monte Carlo Occurrence Model (Appendix A, (U.S, 2023b))

(9A) EPA introduced bias in establishing PFOA/PFOS water concentrations

EPA states that small PWSs were selected using a population-weighted stratified random sampling design, in part because the data from these systems have lower detection limits. EPA states that non-detects are less informative than reported values. EPA states that if state data met certain specifications, then the data were comparable to UCMR 3 and could be used to inform the national occurrence model. Further, the state data were limited to those PWS already in the UCMR 3 data set.

The above approach by EPA is inconsistent with standard methods for selecting random samples for establishing an un-biased estimate of PFOA and PFOS water concentrations across the US. Limiting the state data to only those PWS selected by UCMR 3 imposes an artificial geographic restraint on the drinking water exposure distribution. EPA's logic results in only 17 states, which is likely unrepresentative of PFOS and PFOA water concentrations across the US. In fact, Table A-1 indicates that not only are few states selected, the number of systems included for each state are highly inconsistent. For example, only 1 PWS is available for the states of ME, GA, and ND; which effectively gives these states no influence on the final results, even though these states have many small communities representing a large number of populations and geographic factors.

Also, to generate an exposure distribution on a national level, a representative sample must be derived using metrics other than state population totals. The actual concentrations of PFOA or PFOS are a function of many factors, including distance from the PFAS source, topography, number of private drinking water wells in the area or state, climatology, distance to nearest large water and river systems, and other environmental factors. EPA's state data are clearly not representative of the PFAS exposure distribution on a national level. Therefore, any conclusions drawn based on these data do not represent the expected PWS concentrations across the US and cannot be used to support a MCL.

EPA does not explain what it means when it says that "… if the state data met certain specifications, EPA assumed that they were statistically comparable with the UCMR 3 data…" EPA must define what "certain specifications" means. For example, did EPA remove all PFOA or PFOS concentrations that were non-detects?

EPA uses a natural log of the PFAS concentrations. Many state-level data sets, especially those with a large number of non-detects, set the value to zero. Ln(0) is undefined. The results indicate that EPA removed all zero values from the data set because the use of a natural logarithm of zero does not exist. This approach arbitrarily deletes small values from the data set. According to best scientific practices, EPA should be using Ln(x+1) rather than the Ln(x) so as to not introduce bias into the analysis.

(9B) Conceptual Model Structure

EPA uses something called a "fixed factor shift" for small systems. This approach seems to increase the influence of small system data on the overall population mean. EPA does not explain why this adjustment is necessary (equation A-2). If the data are indeed representative of the US, no adjustment would be necessary. Equation A-2 seems to be an admission by EPA that the state data were not obtained using a pre-specified data collection plan containing DQOs, as required by EPA guidance documents. EPA must explain the degree to which equation A-2 influences the final answers.

EPA's use of small-system specific standard deviations is not clear, and it is not clear how EPA mathematically used these standard deviations. EPA states it uses within-system standard deviations pooled across size categories for PFHxS and PFHpA. Note, a within-system variance component for those systems with small sample sizes (and in particular when the small sample is composed predominately of non-detects) is unreliable at best. EPA must provide insight into the relative influence of this issue on the final results in order to assuage worries of veering from statistical best practices.

A Bayesian model is fully capable of estimating both within- and between- small system variances if the model is constructed correctly. There is no reason, outside of the model, to create covariance matrices or evaluate variance components independent of the full model. The beauty of a correctly constructed Bayesian Hierarchical Model is that the data inform the parameters and associated variance components at each level of the hierarchy. Therefore, EPA's approach as described in this section appears to be invalid.

As noted above, EPA did not include key geographic co-variates when building the Bayesian model (e.g., distance from the source, environmental metrics, climatology, etc.). These values should have been included in the model in an effort to correctly account for geographic variability among the water systems. Without these terms, or an attempt to build a model that explicitly accounts for geographic variance components, the outputs from the model are inaccurate and cannot be used to establish an exposure distribution for the US population.

EPA used "weakly informative prior distributions." EPA must provide the mathematical details of the prior distributions, and how the prior distributions were constructed. If indeed they are fully non-informative, EPA must provide the basis for using non-informative distributions. If the prior distributions do not account for natural geographic variability, then the prior distributions are incorrectly constructed and the resulting marginal predictive distributions are incorrectly constructed. Without this additional information, it is unclear whether EPA followed best available practices in the creation of its model.

EPA must provide the mathematical details of its calculations within the Bayesian model. EPA needs to provide mathematical equations showing the construction of the marginal mean distributions at each level of the hierarchy, the construction of marginal predictive distributions, the construction of the joint likelihood and prior distributions, etc. Without an explicit mathematical statement of the model, the model and its components cannot be fully evaluated.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document and review Cadwallader et al. (2022). Contrary to the commenter's claim, the small systems used to fit the model were not selected because they had data with lower reporting limits. As plainly stated in Cadwallader et al. (2022) and section VI.E of the final rule preamble, they were selected because they were included in the nationally representative set of small systems incorporated into UCMR 3 sampling. The EPA disagrees with the commenter's statement that limiting data to those samples collected from systems that participated in UCMR 3 "imposes an artificial geographic restraint on the drinking water exposure distribution." UCMR 3 systems constituted a nationally representative set of drinking water systems. A description of how small systems were representatively chosen for UCMR 3 monitoring is available in Section 1. General Information of the Final UCMR 3 Rule: "Only a nationally representative sample of ''small'' community and non-transient non-community systems serving 10,000 or fewer people are required to monitor for the chemical analytes (see USEPA, 2001 for a description of the statistical approach for the nationally representative sample)." This statistical approach is outlined in *Statistical Design and Sample Selection for the Unregulated Contaminant Monitoring Regulation (1999)* (USEPA, 2001). The EPA refers the commenter to this resource for more details.

The commenter has not provided any information or support for the statement that "EPA's state data are clearly not representative of the PFAS exposure distribution on a national level." For the model fitting process, the objective of data selection for supplemental state data was to maintain a nationally representative set of PWSs that originated with UCMR 3. Cadwallader et al. (2022) explains the decisions that went into data selection for the model. Therein, treatment of non-

detects is clearly stated (taken as cumulative distribution functions up to the point of the reporting limit). Further, the commenter's assumption that non-detects were converted to zero is inaccurate and the posed recommendation (Ln(x+1)) would equate to assuming that the true concentration of non-detects is, at minimum, 1,000 ng/L. The EPA considers this to be likely inaccurate.

The commenter's claim that additional parameters are required for the model to be valid is incorrect. The purpose of the model was to generate national-scale estimates and it does so using a nationally representative set of PWSs with data available. If the objective of the model was to predict PFAS concentrations at specific systems that hadn't collected data, additional parameters would likely be necessary. However, this is not (and was never) the intended purpose of the model.

Cadwallader et al. (2022) explain the fixed-factor shift used in the model and the model as a whole. UCMR 3 included a census of large systems but a representative sample of small systems. Large systems make up a smaller fraction of the national inventory of systems than they make up of systems in UCMR 3. Not distinguishing between large and small systems in the model would result in a national extrapolation biased towards large systems.

The within-system variabilities are high-level parameters. They are estimated by pooling data from all systems in the relevant category and the uncertainties around them are explored across model iterations. Please see Cadwallader et al. (2022).

The commenter's remarks regarding Bayesian models are inaccurate. For chemicals suspected of co-occurring, it is particularly relevant to incorporate covariance in the model. Not doing so would produce drastically inaccurate results when extrapolating occurrence across the nation. The model naturally found that the chemicals co-occur but was not coerced into doing so.

Geographic variability was inherent to the set of PWS that were included in the model fit, given that it was a nationally representative set of systems. Regional parameters were thus not necessary to generate national estimates.

Non-informative priors are not the same as weakly informative priors. Weakly informative priors are what were used. Model code was provided as supplemental information to Cadwallader et al. (2022) and incorporated by reference into the rule proposal record. This code includes the priors used in the model. The nature of the model, being hierarchical, incorporates variability across the nation. This is why the model includes a high-level distribution of system-level means. Also please see the EPA response to comment Doc. #1759, SBC-045572 in section 6.5 in this *Response to Comments* document.

Fairfax Water (Doc. #1789, SBC-045313)

3. In the absence of current national PFAS occurrence data for drinking water, which EPA will obtain in the recently initiated UCMR5 effort, we believe EPA's statistical model significantly

understates the number of water utilities impacted by the proposed rule. As a result, the cost to implement the PFAS rule could greatly exceed EPA's estimates.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document.

Fairfax Water (Doc. #1789, SBC-045298)

PFAS Occurrence Projections Underestimate the Cost to Implement

EPA's use of a statistically generated occurrence model underestimates the number of utilities that will be required to implement PFAS treatment. The Unregulated Contaminant Monitoring Rule 3 (UMCR3) dataset that served as the baseline for this statistical generation uses data from a time when minimum reporting limits for these PFAS compounds were two to twenty times higher than today. The supplemental data EPA used comes from only eighteen states. Regrettably, none of this data is from Virginia. Of further concern, the supplemental data includes PFAS monitoring from drinking water analysis methods that are not EPA approved.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. As part of the final rule updates, in response to this and other comments, the EPA updated the state data analyses to include available PFAS drinking water data from Virginia. The results of the updated analyses were confirmatory of the EPA's analyses to support the rule proposal. For steps the EPA took to transparently ensure QC of the state data, please see section 6.2 of the EPA response in this *Response to Comments* document. These steps included that the vast majority of the data were collected using EPA approved methods.

Earthjustice et al. (Doc. #1808, SBC-046131)

10. Are the state-level water quality data used to supplement the federal data when calibrating the Monte Carlo simulation models representative?

EPA relies primarily on federal water quality data to estimate point-of-entry concentrations of PFOA, PFOS, PFNA, HFPO-DA and its ammonium salt, PFHxS, and PFBS. EPA took an extra step and supplemented the federal data with state-level data from 11 states on point-of-entry concentrations. The state-level data are described as being useful because of the lower detection limits for identifying PFAS concentrations (pg. 4-20). At the same time, the EA would be strengthened with additional discussion regarding the representativeness of these state-level data. In particular, is there a potential selection bias to consider?

Additional qualitative discussion of this potential lack of representativeness may be sufficient. Or perhaps additional descriptive statistics can be provided to demonstrate the representativeness of the state-level data from these 11 states compared to the rest of the U.S.; perhaps by comparing PFAS concentrations across states with versus without state-level data based on the more widely available UCMR 3 federal data.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. For the proposed rule, supplemental state data for the model came from 17 states. For the final rule, supplemental state data comes from 28 states. The hierarchical nature of the model limits the bias impact. For the proposed rule, 11 states had non-targeted datasets. This has expanded to 18 non-targeted datasets. These results are presented separately from the model fit and findings.

Earthjustice et al. (Doc. #1808, SBC-046171)

[The analysis that follows shows that the $3.1 billion dollar difference in annualized cost can be explained by the following primary factors:]

2. Screening of occurrence datasets. Both EPA and AWWA relied on UCMR3 data collected by water utilities across the country. In addition, both approaches also used state data. EPA, as documented in Cadwallader et al., 2022, screened state data to only look at finished water samples and limited to UCMR3 water systems so occurrence samples would not be biased high due to non-PWS PFAS samples or PWS samples collected by water systems investigating known PFAS contamination sites (not necessarily used as drinking water sources). The inclusion of non-PWS samples resulted in higher median PFOA and PFOS data in the AWWA analysis and explains AWWA's 4,709 small systems required to comply vs EPA's 3,251 (Appendix B). The potential bias in the AWWA method indicates either the EPA approach is more appropriate, or the actual answer is somewhere between the two estimates. On the other hand, AWWA found a lower occurrence rate in large systems compared to EPA. This may be due to reliance on the UCMR3 data with higher detection limits for large system sampling. A model was described in Cadwallader et al., 2022 to fill in the non-detect median PFOA and PFOS levels. Developing a model may have been beyond the scope of the AWWA 2023 estimate, resulting in the difference in large systems exceeding the MCLs.

EPA Response: The EPA agrees with the commenter that the approach taken by the American Water Work Association (AWWA) introduces potential bias. The approach taken in the AWWA study referred to here was inherently different than the EPA's approach and utilized a simple extrapolation of a non-nationally representative set of PWSs. About 70 percent of the non-UCMR 3 PWSs included in the AWWA dataset were located in the New England region (please see the EPA response to comment Doc. #1713, SBC-045902 in section 6.8 in this *Response to Comments* document). The bias resulting from this sort of approach is also addressed in section 6.5 of the EPA response in this *Response to Comments* document.

Plymouth Village Water & Sewer District (Doc. #1827, SBC-044559)

[Please carefully consider the following points to help inform the pending rulemaking on this class of pervasive and persistent PFAS chemicals:]

• EPA lacks sufficient water quality occurrence data to accurately assess the extent and degree of the problem – knowledge that is required to form the basis for a national standard. Statistical

derivations of incomplete data sets are not a reasonable or defensible approach. In addition, EPA's proposed MCLs are vulnerable to excess false positive analytical results from factors such as Teflon-based materials commonly used in drinking water treatment systems.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. Regarding concerns related to background contamination and laboratory analysis, please see section 8.7 of the EPA response in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1841, SBC-044810)

[The Agency's proposal suffers from the following significant shortcomings –]

• EPA's estimate of the costs of its proposal relies on occurrence data for PFOA and PFOS that do not provide an appropriate baseline and is much lower than the costs predicted by an independent analysis,

[The Agency's proposal suffers from the following significant shortcomings –]

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. For the EPA's response to comments on the number of water systems expected to be triggered into treatment, including the Black & Veatch (B&V) report see section 13.3.3 in this *Response to Comments* document. The EPA notes that the analysis referenced by the commenter is produced under contract by AWWA, an organization that represents PWSs that will be regulated by this rule. Hence, while the EPA acknowledges that different analyses have been conducted, and the EPA has considered those analyses prior to finalizing this regulation, it is inaccurate to consider this analysis as "independent," but rather, it should be considered as a different approach by another engaged stakeholder with equities in the outcome of the EPA's decisions. Please see the EPA response to comment Doc. #1713, SBC-045902 in section 6.8 in this *Response to Comments* document for more information about the bias in the dataset utilized in the analysis referenced by the commenter. The EPA's model that generated occurrence estimates for PFOA and PFOS for the final rule was informed by over 55,000 samples of both chemicals. For PFOA this included over 8,600 reported concentrations while for PFOS it included over 7,400 reported concentrations across the nation.

American Chemistry Council (ACC) (Doc. #1841, SBC-044819)

[As outlined in these comments, the Agency's proposal suffers from a number of significant shortcomings, including the following –]

• EPA's estimate of the costs of its proposal relies on occurrence data for PFOA and PFOS that do not provide an appropriate baseline and is much lower than the costs predicted by an independent analysis,

• EPA does not have sufficient occurrence data for PFBS, HFPO-DA, and PFNA to serve as a basis for estimating costs of compliance with its proposed HI MCL,

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. The model that generated occurrence estimates for PFOA and PFOS for the final rule was informed by over 55,000 samples of both chemicals. For PFOA this included over 8,600 reported concentrations while for PFOS it included over 7,400 reported concentrations across the nation.

The EPA disagrees that it does not have sufficient occurrence data for PFBS, HFPO-DA, and PFNA. The EPA used occurrence data from 18 state datasets with non-targeted monitoring data to inform occurrence estimates for PFNA, HFPO-DA, and PFBS. More broadly, state data from 32 states informed the EPA's decisions in the final rule.

American Chemistry Council (ACC) (Doc. #1841, SBC-044840)

To account for these issues, EPA uses a model developed by Cadwallader et al. to estimate the national occurrence of three of the six substances included in the current proposal - PFOA, PFOS, and PFHxS. [FN164: Cadwallader A et al. A Bayesian hierarchical model for estimating national PFAS drinking water occurrence. AWWA Wat Sci 2022:e1284 (2022).] According to the Agency's description, state data on the occurrence and concentrations of the other three substances were then used to "superimpose PFNA, PFBS, and HFPO-DA concentrations onto the model output."

For their analysis, Cadwallader et al. modeled the data from 4,768 systems for which UCMR 3 data were available, supplemented by state data from 770 systems included in UCMR 3. It is likely that less than 10 percent of those modeled were systems serving less than 10,000 people. [FN165: EPA's accounting of the Safe Drinking Water Information System (SDWIS) as of January 2022 indicates a total of 4,482 CWSs serving 10,000 or more people. While the total number of systems appears to have changed somewhat between 2021 and the current proposal, that suggests that fewer than 300 systems serving under 10,000 people were included in the analysis conducted by Cadwallader et al.] As a result, the authors note that estimates for these smaller systems are "likely more uncertain." Based on this analysis, EPA concludes that 23.9 percent (22.1 to 25.9) of large systems (>10,000 people) would have an exceedance of one of the proposed MCLs while only 5.3 percent (3.4 to 7.6) of small systems (<10,000 people) would have an exceedance. [FN166: The numbers do not change significantly when considering just the MCLs for PFOA and PFOS.] Despite the cautions from Cadwallader et al., the proposal makes no effort to discuss the vast difference between the predicted impact on small vs large systems.

In contrast, the analysis by AWWA includes data from a larger number of systems (7,842) – nearly half of which serve less than 10,000 people. According to its analysis, AWWA estimates that 11 to 19 percent of small systems, and 7 to 16 percent of larger systems, will be impacted by the proposed MCLs for PFOA and PFOS. The analysis suggests that small systems are as likely, or perhaps more likely, to exceed the proposed MCLs for the two substances than large systems.

Since AWWA did not conduct an analysis for the four PFAS included in the proposed HI MCL, it is not possible to do a similar comparison for the potential impacts of that proposal. However,

a review of the available information provided by the Agency suggests a significant discrepancy in EPA's assessment. As part of its Economic Analysis, EPA provides estimates of the total number of systems impacted by the proposed option and the alternative Option 1a (PFOA and PFOS MCLs of 4 ppt only). A comparison of the two estimates indicates that EPA predicts that very few systems would be impacted by the HI MCL that would not also be impacted by the PFOA or PFOS MCLs (Table 4). According to this analysis, inclusion of the HI MCL would require fewer than 28 additional systems (<0.04 percent) to have an exceedance. This figure differs significantly from that provided in the Agency's analysis of occurrence data available in the Docket for this rulemaking. [FN167: USEPA. Per- and polyfluoroalkyl substances (PFAS) Occurrence and Contaminant Background Support Document. EPA 822-P-23-010. Office of Water (2023). (USEPA PFAS Occurrence Document).] This report estimates that between 700 and 1,300 systems would exceed the HI MCL, including between 200 and 400 systems not expected to exceed the proposed MCLs for PFOA and PFOS. [FN168: Ibid, at 206. In contrast, the text of the document indicates that the number is "approximately 100 to 500."]

Table 4. Comparison of Total Systems Impacted for Proposed Option (PFOA and PFOS MCLs = 4.0 ppt and HI of 1.0) and Option 1a (PFOA and PFOS MCLs = 4.0 ppt) [FN169: USEPA Economic Analysis, at 4-25 (Tables 4-18 and 4-19)].

[Table 4: See Docket ID EPA-HQ-OW-2022-0114-1841]

The reason for the 20+-fold difference in Agency estimates is not explained, or even acknowledged. Using this higher, and likely more accurate, estimate will have a substantial impact on the Agency's conclusions about the cost of the HI MCL proposal. The variability in the estimates of the number of additional systems that would be impacted by the proposed HI MCL, however, indicate a considerable amount of uncertainty about the Agency's analysis.

EPA Response: In contrast to the commenter's claim, the model discussed in Cadwallader et al. (2022) was fit to data from 4,920 systems. 16 percent (800) of these systems were small systems. The set of systems used for fitting was the full set of PWSs included in UCMR 3. This is clearly stated in Cadwallader et al. (2022). The added uncertainty surrounding small systems mentioned by the commenter is accounted for in the iterative nature of the Markov chain Monte Carlo model as it can be reflected as increased variability in parameter estimates (i.e., a wider spread in the posterior distribution). This uncertainty would be carried forward to subsequent analyses that maintain the iterative nature of the model. This uncertainty was also accounted for in the model design and justifies the use of parameters specific to small systems, such as the fixed factor shift and within-system variability.

The approach taken in the AWWA study referred to here was inherently different and utilized a simple extrapolation of a non-nationally representative set of PWSs. About 70 percent of the non-UCMR 3 PWSs included in the AWWA dataset were located in the New England region. The bias resulting from this sort of approach is addressed in section 6.5 of the EPA response in this *Response to Comments* document. The set of systems in the AWWA analysis is

inappropriate for national extrapolation. Please see the EPA response to comment Doc. #1713, SBC-045902 in section 6.8 in this *Response to Comments* document for further details.

The tables in section 4 referenced by the commenters show the number of water systems impacted by the proposed rule based on national occurrence model outputs for PFOA, PFOS, and PFHxS. At the time of proposal, the EPA estimated 528 water systems would exceed the Hazard Index based on PFHxS occurrence alone; these systems are not mutually exclusive with water systems exceeding the PFOA and or PFOS MCLs. As the EPA states in the FRN for proposal, the agency estimated between 100-500 were estimated to be systems exceeding the Hazard Index for PFHxS, HFPO-DA, PFNA, and PFBS that had not already exceeded the MCLs for PFOA and/or PFOS. This estimate by definition includes water systems that exceed the Hazard Index based on PFHxS occurrence alone, well as water systems that exceed the Hazard Index based on occurrence of the other compounds.

The commenter is incorrect in their assertion that the PFAS Occurrence Technical Support Document for the proposed rule (USEPA, 2023a) indicated between 200 and 400 systems were estimated to exceed the Hazard Index MCL without already exceeding an MCL for PFOS or PFOA. Exhibits 7-4 and 7-6 presented summaries of iterative results. Due to variability across iterations, these tables are not subtractive (e.g., the "Low" estimate for total systems impacted by any MCL in the rule cannot be subtracted by the "Low" estimate for systems impacted by either the PFOA or PFOS MCLs to determine the "Low" estimate for systems impacted by only the Hazard Index MCL). For this reason, the text explicitly, and correctly, describes this estimated range as 100-500 systems.

Orange County Water District (Doc. #3072-54, SBC-047387)

Good afternoon. My name is Jason Dadakis. I'm the executive director of Water Quality and Technical Resources with the Orange County Water District. We're a regional groundwater management agency located in southern California with a service area of 300 square miles and 2.5 million residents. Unfortunately, our groundwater basin, like many others around the country, has been profoundly impacted by PFAS. EPA's proposal will increase our number of impacted municipal wells from the current 58, due to state advisory exceedances, to over 100 impacted wells. This expansion requires several hundred million dollars more in treatment capital spending, above and beyond the several hundred million we've already committed, along with additional long-term operating costs. Based on our experience responding to PFAS impacts, we offer the following comments on EPA's proposed regulation. First, EPA has underestimated the cost of the proposed rule. Understanding nationwide PFAS occurrence is crucial to our robust cost-benefit analysis. EPA's statistical occurrence methodology is extremely complex, assumption heavy, and opaque. Furthermore, national cost models developed by AWWA as well as our own PFAS treatment project costs deviate significantly from EPA's projections. More accurate estimates of the Rule's costs are crucial for water systems and their rate payers as well as for policy makers weighing the appropriate level of federal support. Instead of rushing to finalize the proposed rule, we recommend EPA use the time it is afforded under the Safe

Drinking Water Act to review UCMR 5 PFAS data being collected right now to determine better national PFAS occurrence.

EPA Response: With regard to the EPA's national occurrence model, please see section 6.5 of the EPA response in this *Response to Comments* document. In regard to the EPA's cost analysis and how it compares to AWWA's analysis, the EPA disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document and the EPA responses to comment Doc. #1713, SBC-045902 and Doc. #1759, SBC-045575 in sections 6.8 and 6.5, respectively, in this *Response to Comments* document. In regard to waiting for UCMR 5 data, please see section 6.8 of the EPA response in this *Response to Comments* document and section VI.G of the preamble for this regulation.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-047687)

The Bayesian Model also excludes state monitoring data collected by public water systems that did not participate in UCMR3. This is because UCMR3 monitoring was designed to be nationally representative. However, the PFAS occurrence data that is available for systems beyond UCMR3 represents a significant expansion of water system data, especially for smaller systems that do not widely participate in this program.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045766)

Occurrence of PFAS in Drinking Water Supplies

There are major technical concerns regarding the Proposal that require EPA to take a fresh look at a rule that will impose enormous costs on non-profit public water systems like DC Water.

For example, EPA utilized a Bayesian statistical modeling approach to characterizing occurrence data for PFAS using a combination of both national occurrence monitoring data from the Third Unregulated Contaminant Monitoring Rule (UCMR3) and recently collected state data. EPA utilized the state data due to the high reporting limits in the UCMR3 database. This was done to develop a better understanding of PFAS occurrence in drinking water in U.S. public water systems – which is necessary for development of drinking water regulations.

The Bayesian Model is intended to provide improved understanding of PFAS occurrence at levels below the UCMR3 reporting limits. Bayesian models can be useful in many applications but there are some key challenges that arise with the use of these models that make it non optimal for regulatory applications. The key challenge is that the selection of prior and the posterior conditions is a very subjective decision and is at the discretion of the statistician that is crafting the model. While EPA provided a copy of the code used for the Bayesian Model, along with a recent publication about the model, there is a lack of a non-technical description of EPA's

intended approach. The lack of a clear intent of the model's code leaves stakeholders unable to confirm that the code is accurately developed.

EPA Response: Please see section 6.5 of the EPA response in this *Response to Comments* document. In regard to summarizing the model in non-technical terms, please see the EPA response to comment Doc. #1759, SBC-045572 in section 6.5 in this *Response to Comments* document.

6.6 Combining State Data with Model Outputs to Estimate National Exceedance of Either MCLs or Hazard Index

Summary of Major Public Comments and EPA Responses

One commenter stated that they believed it is difficult to determine whether the estimated number of systems exceeding the Hazard Index is a reasonable estimate until a complete national dataset is available. The EPA disagrees with this commenter. The agency believes that it has taken steps to produce reasonable estimates using a robust set of available data, and that the data and analyses are sufficient to inform the EPA's final regulatory decisions. Namely, this includes the use of non-targeted state datasets and multiple scenarios reflecting varying degrees of co-occurrence as described in section 10.3 of USEPA (2024b). Among other important uses for these data, the EPA considered them to inform the regulatory determination for the mixture of the Hazard Index PFAS and the EA. The EPA has used these data to clearly demonstrate that there is a substantial likelihood that combinations of the Hazard Index PFAS co-occur as mixtures in PWSs with a frequency and at levels of public health concern. See section III of the FRN for additional discussion. Additionally, these data support the EPA's EA, and considerations of costs and benefits consistent with SDWA's requirements. See section XII of the FRN for further discussion.

Individual Public Comments

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043204)

EPA requested comment on the number of systems estimated to solely exceed the HI but not the MCLs. Without a full dataset to calculate the running annual average and given the issues with the PQL and allowable error rate noted above, this determination is difficult to provide.

EPA Response: Please see section 6.6 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044033)

15. EPA requests comment on the number of systems estimated to solely exceed the HI (but not the PFOA or PFOS MCLs) according to the approach outlined in USEPA (2023e).

a. It is possible that more systems may exceed the HI then the MCLs, due to current treatment technologies that are focused on removing PFOA and PFOS. Particularly when considering PFHxS.

EPA Response: Please see sections 6.6 and 6.4 of the EPA response in this *Response to Comments* document. Additionally, regarding treatment technology's ability to remove Hazard Index PFAS, including PFHxS, please see section 10 of the EPA response in this *Response to Comments* document as well as the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* document (USEPA, 2024c), the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water* document (USEPA, 2024d), and the *Drinking Water Treatability Database*.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045027)

Occurrence

As discussed above, NJDEP established an MCL of 13ppt for PFNA in 2019, and MCLs of 14 ppt and 13ppt for PFOA and PFOS, respectively, in 2020. In the time that these standards have been in effect and implemented, 17 New Jersey water systems have exceeded the MCL for PFNA, 56 water systems have exceeded the MCL for PFOA, and 44 water systems have exceeded the MCL for PFOS. Several water systems have had exceedances of more than one PFAS.

EPA has requested comments on the number of systems estimated to solely exceed the HI but not the PFOA or PFOS MCLs. NJDEP does not have complete data sets for all 4 PFAS included in the HI. The available data is from water systems submitting additional PFAS under method 537 and 537.1 during routine compliance monitoring. Based on available data, zero systems will exceed PFBS based on 750 water systems submitting data, and 41 systems will exceed PFHxS based on 759 systems submitting data. The NJDEP does not currently have data available on GenX chemicals. Four systems will exceed the HI MCL based on PFNA alone. The four systems that will exceed for PFNA do not include those New Jersey systems that exceeded New Jersey's MCLs and are currently in the process of installing treatment. To date, New Jersey has had 17 water systems receive violations for exceeding the MCL for PFNA.

EPA Response: The EPA acknowledges the New Jersey Department of Environmental Protection (NJDEP) for providing information on systems estimated to solely exceed the Hazard Index MCL.

6.7 Additional Occurrence Data

Summary of Major Public Comments and EPA Responses

The EPA received several comments related to additional occurrence information. These include comments from a private citizen, water utilities, and non-governmental organizations. As noted in the Occurrence Technical Support Document, data sources reviewed by the agency for

information on PFAS occurrence in drinking water included UCMR 3, state drinking water monitoring programs, and the Department of Defense PFAS drinking water testing, as well as additional studies from the literature. Some of these data sources were mentioned by commenters and have already been considered by the EPA. For the final rule, based on these and other comments, the EPA continued to aggregate data from known, publicly available sources after the proposed rule was released. These additional data were incorporated into updated summaries and analyses, as appropriate, and were generally confirmatory of the EPA's conclusions in the proposed regulation.

Individual Public Comments

Linda Shosie (Doc. #1533, SBC-043959)

The information was hard to come by, but after multiple requests, in 2018 Tucson Water- the city agency responsible for providing drinking water to Tucson residents disclosed that there were also very high levels of PFOA, and PFOS in our water supply.

In one location, Tucson Water detected 13,000ppt of PFOS in the groundwater- 650,000 times higher than the current EPA's Health Advisory Levels (HAL) of 0.02 ppt. Since 1994, Tucson Water sent treated drinking water from the Tucson Airport Remediation Process (TARP) Water Treatment Facility, Superfund Site, to over 50,000 of their costumers containing up to 30 ppt of PFAS, more than, 1,000 times higher than EPAs HAL for either PFOA or PFOS. Tucson Water was forced to remove drinking water wells from service following the detection of these extremely high levels of PFOA and PFOS, but elevated levels of both chemicals remain in our drinking water. ADEQ has also detected unsafe levels of PFAS in several drinking water monitoring wells and private drinking water wells in Tucson.

EPA Response: Please see section 6.7 of the EPA response in this *Response to Comments* document. The EPA considered occurrence data from Arizona in its proposed and final rulemaking. See the *Occurrence Technical Support Document* (USEPA, 2024b) for more information. As described in this rule, systems exceeding the MCLs for the regulated PFAS will be required to take action to protect public health.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042878)

Because Massachusetts has a drinking water standard, we have sampling results for PFAS detected under Method 537 or 537.1. A local media outlet, WBUR, created a map (GRAPHIC 2) which provides a good graphical representation of detections in Massachusetts; this is useful for looking at the extent of PFAS in Community (COM), Non-Transient Non-Community (NTNC), and Transient Non-Community (TNC) PWS across the Commonwealth [FN14: https://www.wbur.org/news/2023/02/14/pfas-pfoa-massachusetts-drinking-water-clean-up]:

[Figure 2: See Docket ID EPA-HQ-OW-2022-0114-1601]

GRAPHIC 2: Map produced by WBUR of maximum PFAS level detected in each Massachusetts Community based on results from the Executive Office of Energy and Environmental Affairs data portal.

Data shows that 170 PWS have detected PFAS6 above the MMCL. MassDEP has looked at Massachusetts PWS sampling results and determined that 29% of our Community and Non-Transient Non-Community PWSs could be impacted by the draft EPA PFAS MCL. Some PWS in Massachusetts have already addressed PFAS to comply with the MMCL of 20 ppt for PFAS6; however, they will likely have to do even more to comply with EPA's proposed PFAS standard, which are lower than the MMCL. Those numbers are not reflected in MassDEP's chart of the potential universe of impacted PWS. MassDEP acknowledged to MWWA in a phone conversation [FN15: Jennifer Pederson, MWWA Executive Director, phone conversation on April 21, 2023 with Margaret Finn, PFAS Lead for MassDEP's Drinking Water Program] that it may have underestimated the number of systems impacted if it was to revisit those PWS already in compliance with the MMCL. Here is the data that MassDEP presented in a webinar on April 10, 2023 (GRAPHIC 3) [FN16: https://www.mass.gov/doc/presentation-on-epa-proposed-mcls-for-pws/download].

[Figure 3: See Docket ID EPA-HQ-OW-2022-0114-1601]

GRAPHIC 3: MassDEP presentation slide showing the approximate number of Community (COM) and Non-Transient, Non-Community (NTNC) Systems impacted by EPA's proposed MCLs.

Further, because MassDEP requires PWS to ensure that their laboratory uses a lower Method Detection Limit (MDL) of 2 ppt, MassDEP stated that 317 COM, NTNC and TNC PWS have detected PFOA and/or PFOS > 2 ppt but < 4 ppt at one or more of their finished water sources.

Staff from the Massachusetts office of Kleinfelder analyzed the data from the Massachusetts Executive Office of Energy and Environmental Affairs data portal and found that 45% of COM PWS in Massachusetts had detections above 4 ppt of PFOA/PFOS. [FN17: Presentation by Ben Powers, EIT, Kleinfelder, "PFAS Treatment in New England: A Regional Survey," April 2023, New England Water Works Association, Spring Conference.]

MassDEP was instructed by the Massachusetts legislature to conduct sampling of private wells for PFAS. The agency concentrated its efforts in towns that are predominantly served by private wells and offered a voluntary sampling program. Of the private wells tested, there were 311 private wells that had PFAS6 detections above 4 ppt.

EPA Response: Please see section 6.7 of the EPA response in this *Response to Comments* document. The EPA considered occurrence data from Massachusetts in its proposed and final rulemaking. See the *Occurrence Technical Support Document* for more information (USEPA, 2024b).

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043646)

i. McMahon et al (2022) analyzed 254 samples collected from five aquifer systems to evaluate PFAS occurrence in groundwater used as a source of drinking water in the eastern United States. McMahon et al (2022) detected 14 (of the 24 PFAS species they analyzed for) in groundwaters and reported 60% of public-supplies and 20% of domestic wells, respectively, contained at least one PFAS detection.

Da Silva et al (2022) monitored for the presence of 51 PFAS species in the Pensacola Bay System in Florida. Surface water was collected and analyzed from 45 different sites. PFOA and PFHxA were present in all samples; moreover, at least eight or more PFAS species were quantified at each site analyzed.

EPA Response: Please see section 6.7 of the EPA response in this *Response to Comments* document. The EPA discusses the work by McMahon et al. (2022) in the *Occurrence Technical Support Document* for the proposed and final rule (USEPA, 2023a; USEPA, 2024b). As described in this rule, PWS that exceed the MCLs for the regulated PFAS will be required to take action to protect public health.

Prince William County Service Authority (Doc. #1609, SBC-042839)

The Service Authority PFAS Data and Costs of Treatment

The Service Authority's PFAS data from UCMR3 yielded non-detections on PFOA and PFOS. Since 2018, the Service Authority has been proactively and voluntarily monitoring for PFAS at our entry points. We also participated in the Virginia Office of Drinking Water (ODW) PFAS monitoring and occurrence study in 2021. Our monitoring data for treated water from Fairfax Water's Griffith Plant located in Lorton Virginia, which is sourced by the Occoquan Reservoir, has found a range of 4.3 ppt to 5.8 ppt for PFOA and 4.1 ppt to 5.9 ppt for PFOS, with average PFOA and PFOS concentrations of 5.3 ppt and 4.9 ppt, respectively. Monitoring data for treated water from Fairfax Water's Corbalis Plant, sourced by the Potomac River, found a range of non-detect to 2.2 ppt for PFOA and non-detect to 1.9 ppt for PFOS, with average PFOA and PFOS concentrations of 1.4 ppt and 0.6 ppt, respectively.

EPA Response: Please see section 6.7 of the EPA response in this *Response to Comments* document. In response to this and other comments, the EPA considered state drinking water occurrence data from Virginia in its final rulemaking. Those data supported the EPA's conclusions in the proposed regulation. See the *Occurrence Technical Support Document* for more information (USEPA, 2024b).

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044346)

2. Page 18730, Column 2, Section VII—Occurrence

a. NHDES Comment - Please see the occurrence data below. The data are based on the most current water quality monitoring compliance sampling for PFAS that public water systems have completed to comply with NHDES's MLCs since October 2019. Please note that the summary provided below does not include PFAS results for over 100 sources of water that have either been deactivated or results from sources prior to having treatment installed to comply with NHDES' MCL. This means that the actual occurrence of PFAS in New Hampshire water systems was once much higher and contamination levels were also higher than reflected in the data below.

[Table: see docket ID EPA-HQ-OW-2022-0114-1690]

EPA Response: Please see section 6.7 of the EPA response in this *Response to Comments* document. In response to this and other comments, the EPA considered occurrence data from New Hampshire as part of its proposed and final rulemaking. Those data supported the EPA's conclusions in the proposed and final regulation. See the *Occurrence Technical Support Document* for more information (USEPA, 2024b).

PFAS Project Lab (Doc. #1786, SBC-044712)

Moreover, the mobility and persistence of PFAS released has resulted in widespread contamination of drinking water. In 2018, a joint USGS and EPA study measured 17 PFAS compounds in 25 paired samples of source and treated drinking water and found detectable levels of PFAS in 100 percent of samples (Boone et al. 2019). Furthermore, a 2020 analysis of public data sets of PFAS occurrence in drinking water in the U.S. revealed mixtures of PFAS are nearly ubiquitous in surface water, the predominate source of drinking water in the U.S., when testing with detection limits below 1 ng/L (Andrews & Naidenko 2020). It is estimated that over 200 million individuals receive drinking water with PFOA and PFOS levels at or above 1 ng/L (Andrews & Naidenko 2020), above EPA's proposed MCLGs for these compounds.

EPA Response: The EPA references the aforementioned study from Boone et al. (2019) in several sections of the *Occurrence Technical Support Document* (USEPA, 2024b) as an additional secondary drinking water study. With regard to the 2020 analysis mentioned in this comment, the EPA generally agrees that PFAS are ubiquitous in the environment. The agency's evaluation of finished drinking water data for the six PFAS included in this rule has found them at varying levels of detection with 4,100-6,700 PWSs serving a total population of 83-105 million people expected to exceed one or more of the final MCLs. As described in this rule, systems exceeding the MCLs for the regulated PFAS will be required to take action to protect public health.

Fairfax Water (Doc. #1789, SBC-045305)

Fairfax Water PFAS Treatment Evaluations and Cost Projections

Fairfax Water's PFAS data from UCMR3 yielded non-detections on PFOA and PFOS. Since 2021, Fairfax Water has been proactively and voluntarily monitoring for PFAS in our finished water on a quarterly basis and providing the results on our website. We also participated in the Virginia Office of Drinking Water (ODW) PFAS monitoring and occurrence study in 2021. Fairfax Water's monitoring data for treated water from its plant sourced by the Occoquan Reservoir has found a range of 3.7 ppt to 5.8 ppt for PFOA and 3.0 ppt to 5.1 ppt for PFOS, with average PFOA and PFOS concentrations of 5.1 ppt and 4.1 ppt, respectively. Monitoring data for treated water from our plant sourced by the Potomac River found a range of non-detect to 1.9 ppt for PFOA and non-detect to 2.6 ppt for PFOS, with average PFOA and PFOS concentrations of 0.6 ppt and 1.3 ppt, respectively.

EPA Response: Please see section 6.7 of the EPA response in this *Response to Comments* document. In response to this and other comments, the EPA considered state drinking water occurrence data from Virginia in its final rulemaking. Those data supported the EPA's conclusions in the proposed regulation. See the *Occurrence Technical Support Document* for more information (USEPA, 2024b).

New England Water Works Association (Doc. #1836, SBC-045379)

Because the New England states have been ahead of EPA in regulating PFAS, there is more complete occurrence data in the Northeast than would be available in the rest of the country. One of NEWWA's members, a consulting engineering company, performed a survey of New England utilities to determine costs associated with addressing PFAS. They presented their results at NEWWA's Spring Conference in April 2023. In their presentation, they highlighted the occurrence data for PFOA and PFOS on the following chart which was created with data obtained by the New England states and the EPA PFAS analytical tool. As you can see, nearly 30% of our community PWS will be affected if EPA finalizes its proposal as presented.

[Figure 1: see docket ID EPA-HQ-OQ-2022-0114-1836]

Figure 1: Community Water Systems in New England with detections over 4 parts per trillion, Kleinfelder 2023

EPA Response: Please see section 6.7 of the EPA response in this *Response to Comments* document. The EPA acknowledges the efforts of New England states and PWSs to proactively address PFAS drinking water contamination. In response to this and other comments, in its final rulemaking, the EPA considered state datasets from states in New England, including Maine, Massachusetts, New Hampshire, and Vermont. Those data supported the EPA's conclusions in the proposed regulation. See the *Occurrence Technical Support Document* for more information (USEPA, 2024b).

Midwest Environmental Advocates +more (Doc. #1846, SBC-045841)

Appendix A

1. City of Madison

Madison is located in the South Central Region of Wisconsin and its water utility serves approximately 235,000 non-transient people. All the system's drinking water comes from groundwater. There have been frequent detections of PFOS, PFOA, and PFHxS in this municipal water system since 2019. As a result of high detections, the water utility shut down one well.

Below is a more detailed account of the detections from this water system: [FN i: City of Madison, Water Utility: Perfluorinated Compounds, https://www.cityofmadison.com/water/water-quality/water-quality-testing/perfluorinated-compounds#:~:text=Madison%20Water%20Utility%20found%20a%20total%20PFAS%20concentration%20in%20Well,37%20ppt%20coming%20from%20PFBA; Wisconsin Department of Natural Resources, Drinking Water System Portal, https://dnr.wi.gov/dwsviewer/ ("WDNR Drinking Water System Portal").]

[Figure 1: see docket ID EPA-HQ-OW-2022-0114-1846]

PFHxS = 20 ppt PFOA 6.1 ppt PFOS = 5.9 ppt

[Figure 2: see docket ID EPA-HQ-OW-2022-0114-1846]

2. City of Eau Claire

Eau Claire is located in the West Central Region of Wisconsin and its water utility serves approximately a non-transient population of 66,060. All the system's drinking water comes from groundwater. There have been worrisome detections of PFOS, PFOA, and PFHxS in this water system. The highest PFAS concentration from this system's water wells are of PFOS at 60 ppt and PFHxS at 98 ppt, detected in July of 2021. As a result of high detections, the water system shut down four wells. Despite this action, levels of PFOS continue to be of concern as of April of 2023. Below is a more detailed account of the PFAS detections from this water system: [City of Eau Claire, PFAS Information: Test Results, https://www.eauclairewi.gov/government/our-divisions/utilities/pfas-information; WDNR Drinking Water System Portal.]

[Figure 3: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 4: see docket ID EPA-HQ-OW-2022-0114-1846]

3. City of La Crosse

La Crosse is located in the West Central Region of Wisconsin and its water utility serves a non-transient population of approximately 53,000. All the system's drinking water comes from groundwater. There have been detections of PFOS, PFOA, PFBS, and PFHxS in this municipal water system. A more detailed account of recent detections from this water system is below: [FN iii: WDNR Drinking Water System Portal.]

[Figure 5: see docket ID EPA-HQ-OW-2022-0114-1846]

4. City of Wausau

Wausau is located in the West Central Region of Wisconsin and its water utility serves a non-transient population of approximately 39,106. All the system's drinking water comes from groundwater. There have been high detections of PFOS and PFOA. Below is a more detailed account of the detections from this water system: [FN iv: Wausau, Water Works: PFAS Sample Results, https://www.ci.wausau.wi.us/Departments/WausauWaterWorks/PFAS/PFASSampleResults.aspx ; DNR Drinking Water Portal.]

[Figure 6: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 7: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 8: see docket ID EPA-HQ-OW-2022-0114-1846]

5. City of West Bend

West Bend is in the Southeast Region of Wisconsin and its water utility serves approximately 31,861 non-transient people. All the system's drinking water comes from groundwater. There have been high detections of PFOA and PFOS in this municipal water system. The highest PFAS concentration found in West Bend's water system is of PFOA at 200 ppt in July of 2020. The water utility shut down operations of a well in June of 2022 to lower the overall concentrations of PFAS in its system. Recent sampling results continues to show concerning levels of PFOA. Below is a more detailed account of the detections from this water system: [FN v: City of West Bend, Water Utility FAQs: Where are PFAS detected in the City of West Bend, https://www.ci.west-bend.wi.us/departments/water/waterfaqs.php; WDNR Drinking Water System Portal.]

[Figure 9: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 10: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 11: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 12: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 13: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 14: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 15: see docket ID EPA-HQ-OW-2022-0114-1846]

6. City of Marshfield

Marshfield is in the West Central Region of Wisconsin and its water utility serves approximately 18,708 non-transient people. All the system's drinking water comes from groundwater. There

have been high detections of PFOS, PFOA, and PFHxS in this municipal water system. PFBS has also been frequently detected. The highest PFAS concentrations found in Marshfield's drinking water wells are of PFOS at 101 ppt and PFHxS at 95.6 ppt in May of 2022. Below is a more detailed account of the detections from this water system: [FN vi: WDNR Drinking Water System Portal.]

[Figure 16: see docket ID EPA-HQ-OW-2022-0114-1846]

7. City of Hartford

Hartford is located in the Southeast Region of Wisconsin and its water utility serves a non-transient population of approximately 16,076. All the system's drinking water comes from groundwater. There have been concerning detections of PFOS and PFOA in this municipal water system. Below is a more detailed account of detections from this water system: [FN vii: WDNR Drinking Water System Portal.]

[Figure 17: see docket ID EPA-HQ-OW-2022-0114-1846]

8. Village of Weston

Weston is in the West Central Region of Wisconsin and its water utility serves a non-transient population of approximately 15,045. All the system's drinking water comes from groundwater. There have been detections of PFOS, PFOA, PFBS, and PFHxS in this municipal water system. The highest PFAS concentrations found in this water system are of PFOS at 47.4 ppt and PFHxS at 28.1 ppt in May of 2022. A more detailed account of recent detections from this water system is below: [FN viii: WDNR Drinking Water System Portal.]

[Figure 18: see docket ID EPA-HQ-OW-2022-0114-1846]

9. Village of Pewaukee

Pewaukee is located in the Southeast Region of Wisconsin and its water system serves a non-transient population of 8,166. All the system's drinking water comes from groundwater. This municipal water system has detected concerning levels of PFHxS, PFOA and PFOS. The highest concentration detected is of PFHxS at 43 ppt in April of 2023. Below is a more detailed account of detections from this water system: [FN ix: WDNR Drinking Water System Portal.]

[Figure 19: see docket ID EPA-HQ-OW-2022-0114-1846]

10. City of Rhinelander

Rhinelander is in the Northern Region of Wisconsin and its water system serves approximately a non-transient population of 7,783. All the system's drinking water comes from groundwater. In this water system, PFHxS has been found at levels of concern and represents the most worrisome detection thus far. As early as September of 2019, this substance was detected at 35.9 ppt. In October of 2019, PFHxS was detected at its highest level so far at 90.1 ppt. Further, PFOA has been consistently detected at levels higher than the proposed MCL. More recent sampling results

continue to detect concerning levels of PFHxS and PFOA. Below is a more detailed account of the PFAS detections from this water system: [City of Rhinelander, Water and Wastewater Utility: PFAS, ; WDNR Drinking Water System Portal.]

[Figure 20: see docket ID EPA-HQ-OW-2022-0114-1846]

PFHxS = 35.9 ppt

[Figure 21: see docket ID EPA-HQ-OW-2022-0114-1846]

PFHxS = 90.1 ppt

[Figure 22: see docket ID EPA-HQ-OW-2022-0114-1846]

PFHxS = 12.1 ppt

[Figure 23: see docket ID EPA-HQ-OW-2022-0114-1846]

PFOA = 4.5 ppt

[Figure 24: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 25: see docket ID EPA-HQ-OW-2022-0114-1846]

PFHxS = 9.4 ppt

[Figure 26: see docket ID EPA-HQ-OW-2022-0114-1846]

PFOA = 4.1 ppt

11. City of Prairie du Chien

Prairie du Chien is located in the South Central Region of Wisconsin and its water system serves a non-transient population of 6,005. All the system's drinking water comes from groundwater. This municipal water system has detected concerning levels of PFHxS and PFOS. Below is a more detailed account of detections from this water system: [FN xi: WDNR Drinking Water System Portal.]

[Figure 27: see docket ID EPA-HQ-OW-2022-0114-1846]

12. Town of Rib Mountain

Rib Mountain is a town adjacent to the City of Wausau with its own water system serving a non-transient population of 5,850. All the system's drinking water comes from groundwater. There have been detections of PFOS, PFOA, PFBS, and PFHxS. The highest levels found in this water system corresponds to PFOS at 85.6 ppt in November of 2021 and at 250 ppt in March of 2023, and to PFHxS at 75.5 ppt in December of 2021 and at 150 ppt in March of 2023. Below is a more detailed account of the detections from this water system: [FN xii: Town of Rib Mountain, PFAS Information,

https://www.ribmountainwi.gov/government/water___sewer_utility/pfas_information.php; WDNR Drinking Water System Portal.]

[Figure 28: see docket ID EPA-HQ-OW-2022-0114-1846]

PFOA = 8.09 ppt PFHxS = 63.6 ppt PFOS = 85.6 ppt

[Figure 29: see docket ID EPA-HQ-OW-2022-0114-1846]

PFOA = 4.9 ppt — PFOS = 6.56 ppt

[Figure 30: see docket ID EPA-HQ-OW-2022-0114-1846]

PFOA = 8.4 ppt PFBS = 16.5 ppt PFHxS = 75.5 ppt PFOS = 80.6 ppt

[Figure 31: see docket ID EPA-HQ-OW-2022-0114-1846]

PFHxS = 6.39 ppt PFOS = 7.13 ppt

[Figure 32: see docket ID EPA-HQ-OW-2022-0114-1846]

[Figure 33: see docket ID EPA-HQ-OW-2022-0114-1846]

PFBS = 27 ppt PFHxS = 150 ppt PFOA = 8.9 ppt PFOS = 250 ppt

13. Town of Sheboygan

Sheboygan is adjacent to the City of Sheboygan in the Southeast Region of Wisconsin and operates its own water utility serving a non-transient population of 4,596. All the system's drinking water comes from groundwater. This municipal water system has detected concerning levels of PFHxS. Below is a more detailed account of detections from this water system: [FN xiii: WDNR Drinking Water System Portal.]

[Figure 34: see docket ID EPA-HQ-OW-2022-0114-1846]

14. Village of Saukville

Saukville is located in the Southeast Region of Wisconsin and its water utility serves a non-transient population of approximately 4,424. All the system's drinking water comes from groundwater. There have been detections of PFOS, PFOA, PFBS, and PFHxS in this municipal water system. The highest PFAS concentrations found in this water system are of PFHxS at 34 ppt in June of 2022 and of PFOS at 33 ppt in September of 2022. Below is a more detailed account of detections from this water system: [FN xiv: WDNR Drinking Water System Portal.]

[Figure 35: see docket ID EPA-HQ-OW-2022-0114-1846]

15. Village of East Troy

East Troy is located in the Southeast Region of Wisconsin and its water utility serves a non-transient population of approximately 4,414. All the system's drinking water comes from groundwater. This municipal water system has detected PFOS, PFBS, and PFHxS. Below is a

more detailed account of detections from this water system: [FN xv: WDNR Drinking Water System Portal.]

[Figure 36: see docket ID EPA-HQ-OW-2022-0114-1846]

16. City of Prescott

Prescott is located in the West Central Region of Wisconsin and its water utility serves a non-transient population of approximately 4,258. All the system's drinking water comes from groundwater. This municipal water system has detected concerning levels of PFHxS. Below is a more detailed account of detections from this water system: [FN xvi: WDNR Drinking Water System Portal.]

[Figure 37: see docket ID EPA-HQ-OW-2022-0114-1846]

17. Village of Rothschild

Rothschild is located in the West Central Region of Wisconsin and its water utility serves a non-transient population of approximately 3,190. All the system's drinking water comes from groundwater. There have been frequent detections of PFOS, PFOA, PFBS, and PFHxS in this municipal water system. The most concerning detections relate to PFOS and PFOA. Below is a more detailed account of detections from this water system: [FN xvii: Village of Rothschild, Public Works, Utilities & Garbage: PFAS Information, https://www.rothschildwi.com/visitors/public_works_utilities___garbage/pfas_information.php.]

[Figure 38: see docket ID EPA-HQ-OW-2022-0114-1846]

PFOA = 7.42 ppt PFBS = 6.34 ppt PFHxS = 4.8 ppt PFOS = 12.2 ppt

[Figure 39: see docket ID EPA-HQ-OW-2022-0114-1846]

PFOA = 7.98 ppt PFBS = 6.39 ppt PFHxS = 3.42 ppt PFOS = 13.5 ppt

[Figure 40: see docket ID EPA-HQ-OW-2022-0114-1846]

PFOA = 6.73 ppt PFBS = 8.78 ppt PFHxS = 4.32 ppt PFOS = 11.9 ppt

[Figure 41: see docket ID EPA-HQ-OW-2022-0114-1846]

PFOA = 4.1 ppt — PFBS = 5.4 ppt — PFHxS = 4.2 ppt — PFOS = 9.9 ppt

18. City of Tomahawk

Tomahawk is located in the Northern Region of Wisconsin and its water system serves a non-transient population of 3,180. All the system's drinking water comes from groundwater. This municipal water system has detected concerning levels of PFOA. Below is a more detailed account of detections from this water system: [FN xxviii: WDNR Drinking Water System Portal.]

[Figure 42: see docket ID EPA-HQ-OW-2022-0114-1846]

19. Town of Brockway

Brockway is adjacent to the City of Black River Falls in the West Central Region of Wisconsin and operates its own water utility serving a non-transient population of 2,692. All the system's drinking water comes from groundwater. This municipal water system has recently detected concerning levels of PFOS. Below is a more detailed account of detections from this water system: [FN xix: WDNR Drinking Water System Portal.]

[Figure 43: see docket ID EPA-HQ-OW-2022-0114-1846]

20. City of Adams

Adams is located in the West Central Region of Wisconsin and its water utility serves a non-transient population of approximately 1,847. All the system's drinking water comes from groundwater. There have been frequent and high detections of PFOS and PFHxS in this municipal water system. The highest PFAS concentration found in this water system is of PFHxS at 43.3 ppt in May of 2022. Below is a more detailed account of detections from this water system: [FN xx: WDNR Drinking Water System Portal.]

[Figure 44: see docket ID EPA-HQ-OW-2022-0114-1846]

21. Village of Palmyra

Palmyra is located in the South Central Region of Wisconsin and its water utility serves a non-transient population of approximately 1,756. All the system's drinking water comes from groundwater. PFOS has been detected at high levels in water system. Below is a more detailed account of detections from this water system: [FN xxi: WDNR Drinking Water System Portal.]

[Figure 45: see docket ID EPA-HQ-OW-2022-0114-1846]

22. Village of Edgar

Edgar is located in the West Central Region of Wisconsin and its water utility serves a non-transient population of approximately 1,491. All the system's drinking water comes from groundwater. PFOA has been detected at high levels in this municipal water system. Below is a more detailed account of detections from this water system: [FN xxii: WDNR Drinking Water System Portal.]

[Figure 46: see docket ID EPA-HQ-OW-2022-0114-1846]

23. City of Mosinee

Mosinee is located in the West Central Region of Wisconsin and its east water system serves a non-transient population of 1,046. All the system's drinking water comes from groundwater. This municipal water system has detected concerning levels of PFOA and PFOS. The highest PFAS concentration detected is of PFOS at 29.4 ppt in May of 2022. Below is a more detailed account of detections from this water system: [FN xxiii: WDNR Drinking Water System Portal.]

[Figure 47: see docket ID EPA-HQ-OW-2022-0114-1846]

24. Village of Valders

Valders is located in the Northeast Region of Wisconsin and its water system serves a non-transient population of 967. All the system's drinking water comes from groundwater. This municipal water system has detected concerning levels of PFOA and PFOS. The highest PFAS concentration detected is of PFOS at 23 ppt in April of 2023. Below is a more detailed account of detections from this water system: [FN xxiv: WDNR Drinking Water System Portal.]

[Figure 48: see docket ID EPA-HQ-OW-2022-0114-1846]

25. Volk Field National Guard

The Air National Guard Volk Field is located in the West Central Region of Wisconsin near the Village of Camp Douglas. The military airport has its own water system serving a non-transient population of 400. PFHxS has been detected at high levels in this municipal water system. Below is a more detailed account of detections from this water system: [FN xxv: WDNR Drinking Water System Portal.]

[Figure 49: see docket ID EPA-HQ-OW-2022-0114-1846]

EPA Response: Please see section 6.7 of the EPA response in this *Response to Comments* document. In response to this and other comments, the EPA considered occurrence data from Wisconsin in its final rulemaking. Those data supported the EPA's conclusions in the proposed regulation. See the *Occurrence Technical Support Document* for more information (USEPA, 2024b).

6.8 UCMR 5

Summary of Major Public Comments and EPA Responses

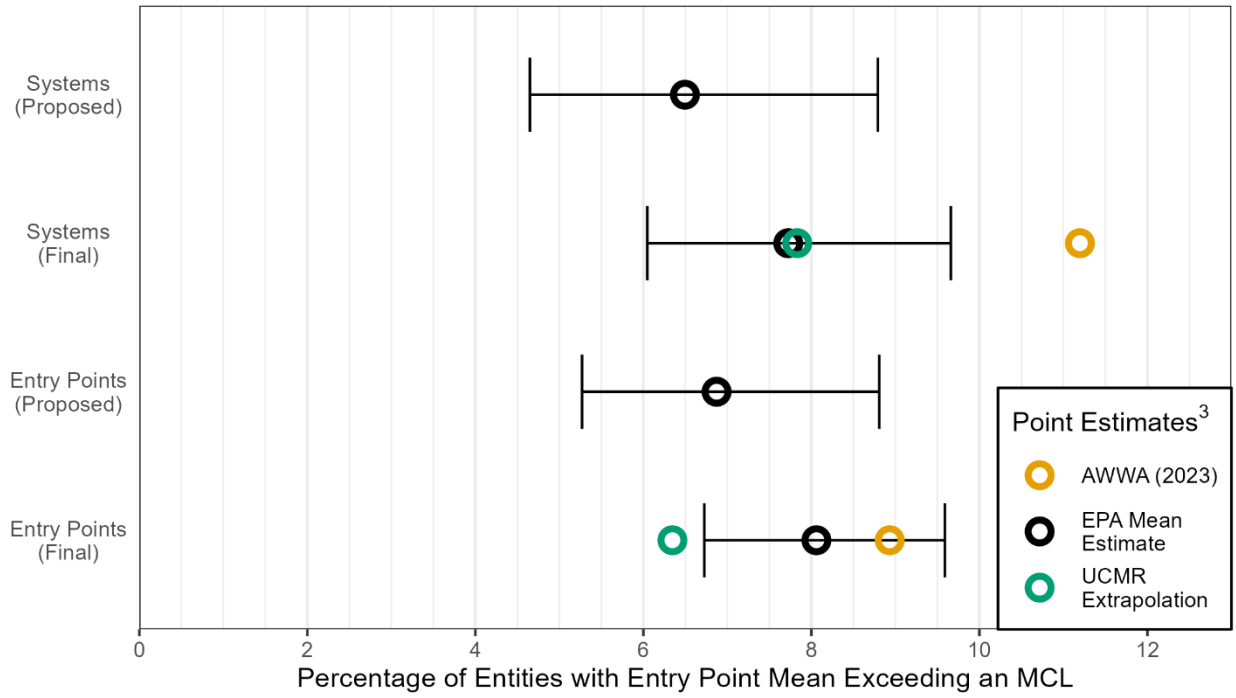
UCMR 5 occurrence data were not available to inform the proposal, but the agency discussed that additional nationwide monitoring data would be available for systems participating in the monitoring program. Some commenters called for the EPA to delay issuance of the final PFAS rule until the complete UCMR 5 occurrence dataset can be analyzed, and some commenters stated that rule promulgation should be delayed until at least a portion of the UCMR 5 data is obtained. The EPA disagrees with these commenters. The EPA is not required under the statute to wait for another round of UCMR data to be collected before proposing or finalizing a regulation; in this case, the completion of UCMR 5 data reporting is expected at the end of 2025, with the final dataset not being available until 2026. Rather, SDWA Section 1412(b)(1)(B)(ii)(II) expressly provides that the EPA must use the "best *available* public health information" in making a regulatory determination (emphasis added). The EPA has sufficiently robust occurrence information as documented in sections III.C. and VI of the final rule preamble and the Occurrence Technical Support Document to make regulatory determinations and promulgate a regulation for the six PFAS in this regulation. In addition to serving as a significant way for

helping many utilities reduce initial monitoring costs, the final full UCMR 5 dataset will also be valuable for informing future regulatory decisions for the 23 PFAS included in UCMR 5 that are not directly addressed by this proposed rulemaking. The agency believes that the best currently available occurrence data, including tens of thousands of samples per PFAS chemical in the final rule collected across 32 states, representing one of the most robust occurrence datasets ever used to inform development of a drinking water regulation of a previously unregulated contaminant, demonstrate sufficient occurrence or substantial likelihood of occurrence for the contaminants included in the final rule.

While the EPA is under no legal obligation to consider the preliminary, partial UCMR 5 dataset prior to rule promulgation, based on public comment and interest, the agency analyzed UCMR 5 data released as of February 2024 (USEPA, 2024e), though it did not serve as the basis for the agency's decision. See section VI.G of the FRN for the EPA's analysis of the UCMR 5 data, representing approximately three quarters of data and 24 percent of the anticipated final UCMR 5 dataset.

Figure 1 shows a comparison of national estimates derived from the preliminary UCMR 5 dataset with estimates developed independently of UCMR 5. The figure presents systems and entry points with entry point-level mean PFAS concentrations exceeding any of the PFAS MCLs. This includes estimates derived from the preliminary UCMR 5 dataset, national estimates from the EPA's proposed and final PFAS rule, and national estimates of impacted systems and entry points provided by AWWA, since the latter's estimates were referenced by several commenters. UCMR 5 data used for the extrapolation were limited to completed sample sets as well as entry points that included multiple complete sample sets. The entry point limitation was included to ensure that all results were based on a mean rather than a single sample result.

Figure 1: National Estimates[1] Compared to Preliminary UCMR 5 Results[2]



Notes:
[1]National estimates are shown with a mean estimate and an associated 90 percent confidence interval (error bars) and the values are as shown for the final rule in *Economic Analysis for the Final Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation* (USEPA, 2024a) and for the proposed rule in *Economic Analysis of the Proposed National Primary Drinking Water Regulation for Per- and Polyfluoroalkyl Substances* (USEPA, 2023c).
[2]The UCMR5 results include about 24 percent of the samples anticipated to be available in the completed dataset.
[3]The "UCMR Extrapolation" method weighs the results of currently available UCMR 5 data to account for the system size composition of the national inventory (e.g., large systems making up about 6.7 percent of systems in the national inventory and were adjusted accordingly). UCMR extrapolation also only uses complete sample sets and entry points with multiple complete sample sets. "AWWA (2023)" refers to the estimates provided in a study conducted by Black & Veatch on behalf of the American Water Works Association (AWWA, 2023).

Extrapolation of the preliminary UCMR 5 dataset indicates that 7.8 percent of systems and 6.3 percent of entry points would have an entry point-level mean exceeding a PFAS MCL. This is in comparison to estimates presented in USEPA (2023c) for the proposed rule which range from 4.6 to 8.8 percent of systems and 5.3 to 8.8 percent of entry points. For the final rule, occurrence estimates range from 6.0 to 9.7 percent of systems and 6.7 to 9.6 percent of entry points (USEPA, 2024a). The estimates derived from the UCMR 5 extrapolation indicate that the EPA occurrence estimate ranges are reasonable. The AWWA (2023) point estimates referenced by many comments are high compared to the UCMR 5 extrapolation (about 11.2 percent of systems and 8.9 percent of entry points). While the AWWA point estimate for entry points falls at the upper end of the EPA's estimated range, the AWWA point estimate for systems is beyond the upper end of the EPA's estimated range. The preliminary UCMR 5 dataset supports that the

EPA's occurrence analysis did not underestimate the number of systems that may have to take action such as treating drinking water to remove PFAS while the AWWA analysis likely significantly overestimated the number of systems that will have to take action. This overestimation would then result in inflated cost estimates. Since the UCMR 5 dataset is incomplete, extrapolated estimates may shift as additional data are collected.

Individual Public Comments

Water Environment Federation (WEF) (Doc. #1529, SBC-043304)

WEF asks that the following short-term and long-term impacts be taken into consideration with the proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation.

Short-term Impacts

Identify funding sources, not already accounted for, to support the water reclamation industry. Prioritize continued research and the proactive communication of these findings.

• Data: EPA is using the 3rd Unregulated Contaminant Monitoring Rule (UCMR 3) as the basis for the proposed NPDWR. If delayed to Summer 2024, EPA could analyze 2023 monitoring results from UCMR 5 to calibrate and confirm the results of the Bayesian Analysis. Also, as EPA recognizes, 'the minimum reporting levels (MRLs) were established based on the capacity of the analytical method, not based on a level established as "significant" or "harmful". In fact, the UCMR 3 MRLs are often a larger concentration than current "health reference levels" (to the extent that HRLs have been established).' [FN1: U.S. EPA The Third Unregulated Contaminant Monitoring Rule (UCMR 3): Data Summary, January 2017 https://www.epa.gov/sites/default/files/2017-02/documents/ucmr3-data-summary-january-2017.pdf.]

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Please see section 6.5 of the EPA response in this *Response to Comments* document regarding the EPA's national occurrence model. Regarding funding sources, please see section 2.4 of the EPA response in this *Response to Comments* document.

Greenville Utilities Commission (Doc. #1534, SBC-042637)

The Fifth Unregulated Contaminant Monitoring Rule (UCMR 5) will provide EPA with scientifically valid data on the national occurrence of 29 PFAS compounds in the nation's drinking water and at what levels. This data will ensure science-based decision-making and help prioritize protection of disadvantaged communities. Implementation of regulations before up-to-date information from UCMR 5 can be reported and analyzed does not follow sound scientific principles. The limited number of laboratories certified to analyze samples for UCMR 5 have caused ten-day turnaround times to become two month waits for data. Utilities will have to increase sampling to determine the effectiveness of potential treatment strategies which will further burden those laboratories.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Please see section 5.1.2 of the EPA response in this *Response to Comments* document regarding laboratory capacity.

U.S. Chamber of Commerce (Doc. #1537, SBC-042646)

Accordingly, we are planning to provide comments to EPA and will request that the agency withdraw the proposal and should await the results of the UCMR 5 process:

• Lack of occurrence data at the proposed MCL level. The current UCMR 3 occurrence data for PFOA and PFOS seems to indicate levels at between 20 ppt and 40 ppt. EPA does not have a robust understanding of occurrence levels at the proposed MCL levels for PFOA and PFOS or the other four PFAS. This lack of occurrence data for a preliminary regulatory determination requires more thoughtful and thorough analysis.

EPA Response: Please see sections 6.2, 6.5, and 6.8 of the EPA response in this *Response to Comments* document. The EPA disagrees that it does not have a robust understanding of occurrence levels for the PFAS which it is finalizing regulation for as demonstrated through the availability of tens of thousands samples from UCMR 3 and state monitoring data presented in the final rule preamble and *Occurrence Technical Support Document* (USEPA, 2024b). Regarding the EPA's regulatory determinations, please see section 3.1.2 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-042510)

The Department also recommends that EPA complete the nationwide PFAS occurrence study under UCMR 5 before finalizing the Hazard Index for the other four PFAS that EPA has proposed to regulate. EPA will have significantly more PFAS occurrence data upon the completion of UCMR 5. The process EPA is now taking to make a regulatory determination and to establish a MCL for these four PFAS, with limited state occurrence data, seems rushed. The agency will have significantly more data available to it in the next few years to do a much more thorough analysis.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Regarding the EPA's regulatory determinations, please see section 3.1.2 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-042527)

The Department recommends that EPA complete the nationwide PFAS occurrence study under UCMR 5 before finalizing the Hazard Index or an individual MCL for these four PFAS. EPA will have significantly more data on the occurrence of these four PFAS upon the completion of UCMR 5. The process EPA is now taking to make a regulatory determination and to establish a MCL for these four PFAS in this one action seems rushed. The agency will have significantly

more data available to it in the next few years to do a much more thorough analysis. Removing the Hazard Index will make the rule easier to implement, improve clarity, and reduce costs.

Section VII—Occurrence

EPA requests comment on the number of systems estimated to solely exceed the HI (but not the PFOA or PFOS MCLs) according to the approach outlined in USEPA (2023e). Completing the occurrence sampling under UCMR 5 would provide EPA the data to make a more informed decision on how to proceed with regulating PFAS. It would allow EPA to base its decision on unbiased, consistently collected, national information rather than relying on data from a subset of states that varies in terms of quantity and coverage, and that includes data from targeted or site-specific sampling efforts where it may be expected to have higher detection rates, or not be representative of levels found in all PWSs within a state.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Regarding the EPA's regulatory determinations, please see section 3.1.2 of the EPA response in this *Response to Comments* document.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042474)

Since UCMR5 sampling has not been completed there is not a nationwide data set available to establish regulations. As such, proposed regulatory standards are not supported by concrete data and are premature. After a nationwide dataset has been completed, a thorough and comprehensive assessment through peer review and committee evaluation should occur, providing a more reliable scientific approach to establishing PFAS regulations.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042472)

While more detections are expected with the lower UCMR5 detection limits, there is currently not a dataset that proves the need for these regulations. The first sampling event for UCMR5 was not even completed for most Public Water Systems (PWSs) when the proposed rule was posted on the docket. UCMR5 sampling should be completed and evaluated prior to this rule being finalized.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Security Water District, Security Water and Sanitation Districts/Enterprises (Doc. #1587, SBC-042784)

Back in 2016, there was a 6-week turn-around time to obtain PFAS sampling results. With the EPA Lifetime Health Advisory being issued on May 19, 2016, The Security Water District was

able to shut down all of its wells by September, 2016 — a remarkable accomplishment. During this time, however, we were making million-dollar decisions before we even had sample results back. There are many pitfalls that can result from making decisions based on incomplete information, and we fear that is what EPA is doing by promulgating this rule now. We feel that a better approach would be to wait at least until the July, 2023 UCMR-5 data is released, so that these important decisions are made based on the best information available. We feel that the best tactic would be to wait for the October, 2023 data, which would include 2 quarters of data, but would also include 3,500+ water systems. We feel that the latter alternative would dramatically improve the clarity and quality of the occurrence analysis.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. For the final rule, the EPA has analyzed UCMR 5 data released as of February 2024. See section VI.G of the FRN. This includes approximately three quarters of data though it did not serve as the basis for the agency's decision.

Water & Health Advisory Council (Doc. #1590, SBC-042788)

The U.S. EPA has not justified the need for such extremely costly drinking water regulations for PFAS. Current U.S. population PFAS exposure levels are 70 to 90% lower than they were 25 years ago (see Figure 1 below) (CDC, 2019). The U.S. EPA's evaluations of risk include the assumption that drinking water is a minor contributor of exposures to PFAS relative to other pathways (default relative source contribution (RSC) of 20%), yet the agency is placing a great and costly burden on drinking water providers. In fact, the national drinking water occurrence database for PFOA and PFOS and other PFAS is very weak, and the data quality of the sources that have been assembled is not uniform. It does not provide a reliable basis for drinking water distributions and exposures, and economic impact analyses. The U.S. EPA should await the reports from the Unregulated Contaminant Monitoring Rule 5 (UCMR5) survey that is underway before making a regulatory decision. The first-round data will be available in less than a year. This occurrence data will likely show that communities nation-wide will have varying levels of PFAS in their drinking water; not all should be treated with the same level of urgency. The higher drinking water concentrations of PFOA and PFOS are mostly in groundwater supplies impacted by manufacturing and users' sites. In communities where high levels of PFAS exist, water utilities have and should continue to address drinking water exposures with urgency. However, communities with extremely low detections of PFAS that may also be facing well established public health risks from other sources such as elevated levels of other regulated chemicals, failing infrastructure, and reduced access to water supplies, should be able to utilize their resources to address those high priority concerns.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. The EPA disagrees that this NPDWR is not justified. As described in sections II and III of this final rule, the EPA made determinations in accordance with the SDWA to regulate the 6 PFAS included in this rule. Briefly, in 2021, the EPA made a determination to regulate two PFAS—PFOA and PFOS—in drinking water under SDWA. The agency has

determined that PFHxS, PFNA, and HFPO-DA may have individual adverse health effects, and any mixture of these three PFAS and PFBS may also have dose-additive adverse effects on the health of persons; that there is a substantial likelihood that PFHxS, PFNA, and HFPO-DA occur individually with a frequency and at levels of public health concern and that mixtures of these three PFAS and PFBS occur and co-occur in PWSs with a frequency and at levels of public health concern; and that, in the sole judgment of the Administrator, individual regulation of PFHxS, PFNA, and HFPO-DA, and regulation of mixtures of these three PFAS and PFBS, presents a meaningful opportunity for health risk reduction for persons served by PWSs. Please see section 3.1 of the EPA response in this *Response to Comments* document for more information. Additionally, the EPA disagrees that the drinking water occurrence information used to inform this rule is "very weak." The agency used the best available data, consisting of tens of thousands of samples, and scientifically robust analytical approaches to inform its analyses. Further, the EPA disagrees that occurrence data suggests that PFOA and PFOS concentrations are higher in groundwater systems as supported by the available data the EPA used in its analyses, and the commenter did not cite any underlying data or rationale for this argument. Rather, based on available data, concentrations are observed to vary between different source water types and geographic locations, thus a national-level regulation is justified to protect those served by PWSs with levels of PFAS exceeding the EPA's MCLs.

Alameda County Water District (ACWD) (Doc. #1595, SBC-042347)

National occurrence data is currently being collected under UCMR 5 which uses EPA methods 533 and 537.1, with MRLs of 4 ppt (PFOS), 4 ppt (PFOA), 3 ppt (PFHxS), 4 ppt (PFNA), 3 ppt (PFBS), and 5 ppt (HFPO-DA). The lower detection levels possible using the newer method will result in a higher, and more representative, number of occurrences among water systems, providing a more refined basis for EPA to identify the needs for treatment and develop a more accurate cost assessment. EPA should base the Economic Impact Analysis on UCMR 5 monitoring results, to provide a more accurate representation of occurrences.

ACWD is in California, which conducted statewide PFAS monitoring for select water systems that were identified as being in proximity to potential sources of PFAS contamination. ACWD was not in the vicinity of potential PFAS sources and was not identified for monitoring by the state; additionally, ACWD had no PFAS detections during the UCMR 3 monitoring. ACWD believes in being proactive in the protection of public health and conducted PFAS monitoring on a voluntary basis at our groundwater sources. Our monitoring detected PFOS and PFOA concentrations at levels above the MCLs being proposed as part of the PFAS NPDWR, but below the UCMR 3 MRLs. Though ACWD's data was provided to the state, the monitoring we conducted was not required by the state. EPA should consider that there are most certainly other water systems which had no detections during UCMR 3 monitoring, and were not identified during statewide PFAS monitoring efforts, but do have PFAS concentrations above the proposed MCLs, and those agencies will not appear for the purposes of occurrence data and the economic analysis. EPA should base the Economic Impact Analysis on UCMR 5 monitoring results, which would better represent occurrence data by identifying systems in situations similar to our own.

EPA Response: Please see sections 6.8 and 6.2 of the EPA response in this *Response to Comments* document as well as section VI of the final rule preamble. The EPA collected and assessed state data from 32 states to support the final rulemaking that included reporting limits lower than the minimum reporting levels used for UCMR 3. These data support the EPA's estimates of national occurrence for the six PFAS, as well as the regulatory determinations for PFHxS, PFNA, HFPO-DA, and PFBS and mixtures of these four PFAS. Please see section 3.1.2 and 3.2.2 of the EPA response in this *Response to Comments* document regarding the EPA's regulatory determination and evaluation of the occurrence criterion for PFHxS, PFNA, HFPO-DA, and PFBS and mixtures of these four PFAS.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042809)

3. Data Limitations – These four PFAS compounds have not been fully studied, and we believe setting a regulatory standard at this time is premature. EPA should consider delaying the establishment of regulatory standards for these PFAS compounds until full review of the results from the Unregulated Contaminant Monitoring Rule (UCMR 5) monitoring, which began this year.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. The EPA disagrees that it is premature to regulate PFHxS, PFNA, PFBS, and HFPO-DA and the agency has concluded that all four have been sufficiently studied to regulate, consistent with the requirements of the Safe Drinking Water Act. Regarding the EPA's regulatory determinations, please see section 3.1.2 of the EPA response in this *Response to Comments* document.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042813)

The addition of regulatory standards for other PFAS compounds, in addition to PFOA and PFOS, should be revisited upon completion of UCMR 5.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042877)

Occurrence:

Testing under the Unregulated Contaminant Monitoring Rule (UCMR) program is and has always been an important step in the EPA rulemaking process. The occurrence data collected through this monitoring is used to support decisions to regulate particular contaminants in the interest of public health. The UCMR5 program just commenced at the beginning of this year (2023); therefore, EPA cannot possibly have a full sense of occurrence for the suite of PFAS compounds in drinking water. EPA's regulatory determination for perfluorohexane sulfonic acid (PFHxS), hexafluoropropylene oxide dimer acid (HFPO-DA) and its ammonium salt (also

known as a GenX chemicals), perfluorononanoic acid (PFNA), and perfluorobutane sulfonic acid (PFBS) are based on a very limited data set and could only be enhanced by waiting for the results of UCMR5 to provide a more robust data set for determining occurrence across the nation. EPA should delay promulgation of this rule until it has an opportunity to vet at least one full year of data obtained through UCMR5.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Regarding the EPA's regulatory determinations, please see section 3.1.2 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043631)

5. The full impact of the proposed PFAS Rule remains uncertain as data collection for 29 PFAS species under UCMR5 is still ongoing. UCMR5 data collection is scheduled to be completed in December 2025. Therefore, imposing a rule now on six (6) PFAS species is unreasonable and premature. Under the current proposed regulation, systems could be required to install treatment technologies by 2026 and then subsequently be subjected to additional PFAS regulations.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. For additional discussion on the compliance timeline, please see section 12.1 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043635)

A. UCMR3 data were used in the development of the USEPA economic analysis. Only six (6) PFAS species (PFOS, PFOA, PFNA, PFNxS, PFHpA and PFBS) were considered under UCMR3—five (5) of which are proposed for regulation under the PFAS rule (PFOS, PFOA, PFNA, PFNxS, and PFBS). UCMR5, however, will consider 29 species of PFAS (for data collected between January 1, 2023, and December 31, 2025); UCMR5 also includes consideration of GenX (HFPO-DA) which was not monitored in UCMR3 but is regulated in the proposed PFAS Rule. Moreover, UCMR5 PFAS have notably lower reporting limits as compared to UCMR3. A higher number of species being considered, in tandem with lower reporting levels, could increase the likelihood that more Public Water Systems (PWSs) will be impacted by the proposed rule. It is recommended that UMCR5 data be incorporated into the national occurrence model as well as USEPA's cost analysis as soon as its available, as this would help clarify the most appropriate regulatory framework and associated costs.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Regarding the EPA's national occurrence model, please see section 6.5 of the EPA response in this *Response to Comments* document. Regarding UCMR 3 data, please see section 6.1 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043642)

3) Utility Impacts

1. The USEPA model substantially underestimates the practical impact of compliance cost to individual utilities and the industry as a whole (which is supported by ratepaying consumers).

A. It is likely that the analysis undercounts the utilities nationwide that will have to add treatment to comply with the proposed PFAS Rule, which will be clearer after UCMR5 data are fully compiled.

i. It is possible that even UCMR5's monitoring may not be sufficiently indicative of industry-wide compliance, particularly with regards to small systems (i.e. specifically those serving fewer 3,300) as 800 will be randomly selected, subject to availability of appropriations and sufficient laboratory capacity. If EPA does not receive the appropriations needed each year, then a reduced number of small systems will perform monitoring.

ii. The Minimum Reporting Levels (MRLs) of PFAS species considered under UCMR3 (specifically those that are in the proposed PFAS Rule) range from 20 ng/L for PFOA to 90 ng/L for PFBS. The UCMR5 MRLs for the same species range from 3-4 ng/L (and 5 ng/L for GenX which is included in UCMR5, but not a part of UCMR3) illustrating a notable improvement in MRLs and also highlighting the potential that lower concentrations of these species could have been missed during the UCMR3 assessment—resulting in a likely underestimation of PFAS occurrence and utility impact. It is recommended that USEPA allow utilities time to complete UCMR5, for a clearer, and more refined understanding of national PFAS occurrence, ahead of the proposed rule.

Table 5: UCMR3 and UCMR5 PFAS Species MRL's, adapted from Crone et al (2019).

[Table 5: See Docket ID EPA-HQ-OW-2022-0114-1602]

The UCMR 3 MRLs were established based on the capability of the analytical methods (at the time), not based on a level established as "significant" or "harmful."

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document regarding UCMR 5, see section 6.5 of the EPA response in this *Response to Comments* document regarding the national PFAS occurrence model, and section 6.1 of the EPA response in this *Response to Comments* document regarding the usage of UCMR 3 data.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043645)

4) Treatability

1. If utilities are required to develop and implement systems to comply with the proposed Rule in the next three years, those systems may not be properly sized or function as intended if additional PFAS compounds are added to the regulation in the future.

A. UCMR3 captures occurrence data from 2013-2015 and only reflects six PFAS species, while UCMR5 will capture data from Jan 2023-Dec 2025 for 29 species of PFAS (inclusive of the six monitored during UCMR3), offering a better foundational understanding of occurrence to inform future regulation. Therefore, imposing a rule now on six (6) PFAS species is unreasonable and premature. Under the current proposed regulation, systems could be required to install treatment technologies by 2026 and then subsequently be subjected to additional PFAS regulations. It is recommended that USEPA give utilities time to complete UCMR5 for a better understanding of the occurrence prior to imposing the proposed PFAS rule.

B. According to the Crone et al (2019) analysis of the UCMR3 data, 4% of water systems reported at least one detectable PFAS compound. This percentage is likely to increase once UCMR5 data for all 29 species is completed by December 2025. This is likely true with regards to both surface and groundwater systems:

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document regarding UCMR 5 and section 6.1 of the EPA response in this *Response to Comments* document regarding UCMR 3 data.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043653)

7. Under the Safe Drinking Water Act, the USEPA has until September 2024 to finalize the new drinking water standards, 9 more months after the current plan (by the end of 2023). It is recommended that more time be given to PWSs to provide UCMR5 data to the national occurrence model and allow the model to estimate national occurrence for additional PFAS and help to evaluate national temporal trends in PFAS exposure (Cadwallader et al 2022).

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043071)

Inclusion of Data from Fifth Unregulated Contaminant Monitoring Rule

This year, drinking water monitoring for PFAS under the UCMR 5 began. UCMR 5 is expected to be the most comprehensive occurrence dataset for PFAS collected to-date. In accordance with UCMR 5, more than 10,300 systems will monitor for 29 PFAS using EPA Methods 533 and using single-digit minimum reporting limits. While a complete dataset will not be compiled until 2026, more than 3,400 water systems are actively collecting monitoring data this year. By the end of summer this year, all these systems will have collected at least one sample and EPA will have received these results. Previous research has shown that preliminary data collected from UCMR monitoring provides accurate insights about occurrence when compared to the complete dataset.

UCMR 5 data collected during the first half of 2023 would represent a significant increase in the available data that is nationally representative. Specifically, this dataset will provide information

on nearly 70% of the number of water systems that are typically represented by a UCMR program. While this data would not be a full UCMR sampling program, it would significantly expand the universe of nationally representative data at reporting levels that are presently appropriate. Given that the goal of the UCMR 5 program is to inform EPA on the occurrence of PFAS, EPA can ill afford to ignore this data, which would be of a much higher quality and value than existing data.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043059)

4. EPA's statistical approach to estimate occurrence of PFAS in drinking water is overly complicated and EPA would be ill-advised to finalize the rule without considering incoming data from more than 3,500 water systems currently collecting samples under the UCMR 5.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document regarding UCMR 5 and section 6.5 of the EPA response in this *Response to Comments* document regarding the national PFAS occurrence model.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043106)

The Unregulated Contaminant Monitoring Rule 5 program is currently collecting additional data, at more utilities and at lower concentrations than UCMR3 on the occurrence of PFAS in drinking water. The first data sets should soon be available to the Agency. "Occurrence data are collected through UCMR to support the Administrator's determination of whether to regulate particular contaminants in the interest of protecting public health." However, this PFAS regulatory rule was proposed a few months before UCMR5 data are available. The UCMR process was designed specifically to collect occurrence data for EPA to use to assess the percent of the population potentially exposed and exposure levels as a basis for making regulatory decisions. Given that EPA could still meet its requirements through Congress to regulate PFAS by a certain deadline, EPA should consider how the first two quarters of UCMR5 data could be used to guide the development of these regulations.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Based on this and other comments, the EPA has presented results from approximately three quarters of UCMR 5 monitoring, and the agency notes that those results are consistent with the EPA's occurrence estimates.

Water One – Water District No. 1 of Johnson County, Kansas (Doc. #1627, SBC-042324)

Regulatory Process

The proposed PFAS regulation appears to completely bypass the EPA's established Unregulated Contaminant Monitoring Rule (UCMR) regulatory process and it is premature in the process particularly since it is superseding the collection and analysis of the UCMR 5 data.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. The EPA disagrees that the agency has circumvented the established process for developing NPDWRs. The EPA implements a monitoring program for unregulated contaminants (i.e., UCMR) under SDWA 1445(a)(2) that requires the EPA to issue a list once every five years of priority unregulated contaminants to be monitored by PWSs, however there is no statutory requirement that a contaminant must be on this list prior to making a determination to regulate or that the agency must wait for this information if the agency has sufficiently available information through other sources. The UCMR 3 dataset, additional state data (please see section 6.2 of the EPA response in this *Response to Comments* document), and the EPA's robust analyses demonstrate sufficient likelihood of occurrence of the PFAS being regulated.

Orange County Water District (OCWD), California (Doc. #1634, SBC-043233)

Additionally, under the SDWA, EPA has until September 2024 to finalize these regulations, so the agency should strongly consider using at least some of this time to incorporate additional high-quality nationwide data from the ongoing UCMR5 monitoring that began in 2023, instead of rushing to implement a regulation based on an inadequate estimate of national occurrence.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043279)

• EPA requests comment on the underlying assumptions that, under UCMR 5, individual water systems would be able to request the full release of data from the labs for use in determining their compliance monitoring frequency and that PWSs may be able to use these lab analyses to demonstrate a ''below trigger level'' concentration using the UCMR 5 analyses by following up with the lab for a more detailed results report.

Response: Water systems should be allowed to use their UCMR 5 monitoring data to determine compliance monitoring frequency and demonstrate a "below trigger level" concentration. EPA should establish a standard that labs release two reports, the standard report, and a separate report with qualified data.

EPA Response: The EPA agrees with the commenter that, provided the data were collected using EPA method 533 or 537.1, water systems can utilize previously collected data, such as from UCMR 5, to satisfy the rule's initial monitoring requirements and determination of

compliance monitoring frequency. Please see section 8.3 of the EPA response in this *Response to Comments* document.

Massachusetts Water Resources Authority (Doc. #1645, SBC-043283)

EPA is also in the process of implementing the UCMR5. There are 29 PFAS included in UCMR5; sample collection for these 29 PFAS at thousands of PWSs began at the beginning of this calendar year and will continue through 2025. EPA's commitment to a final NPDWR publication in December 2023 (nine months in advance of the statutory deadline for promulgation), prevents EPA from considering any data collected as part of UCMR5. EPA's positive regulatory determinations for PFHxS, PFNA, HFPO-DA or GenX, and PFBS rely on very limited relevant occurrence data. Under the SDWA, EPA has a responsibility to demonstrate that positive regulatory determinations are for contaminants that occur or are likely to occur at levels of public health concern in drinking water and that there is a meaningful opportunity for health risk reduction through a drinking water standard. Waiting for the complete set of UCMR5 data to be available seems prudent given the potential financial and resource implications of this proposed regulation.

Using the UCMR5 PFAS data would dramatically improve the clarity and quality of EPA's occurrence analysis. MWRA recommends that EPA at least review UCMR5 data collected through June 2023 if EPA is intent on making a final NPDWR publication this December. Waiting until the complete UCMR5 data set is available for review and analysis in 2025, before finalizing a PFAS NPDWR would provide an even broader understanding of the occurrence of PFAS throughout the country.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Please see sections 3.1.2 and 3.2.2 of the EPA response in this *Response to Comments* document regarding the EPA's regulatory determination and evaluation of the occurrence criterion for PFHxS, PFNA, HFPO-DA, and PFBS and mixtures of these four PFAS.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043305)

The Unregulated Contaminant Monitoring Rule 5 program is collecting additional data, at more utilities and at lower concentrations than UCMR3. The first data sets should be uploaded soon. "Occurrence data are collected through UCMR to support the Administrator's determination of whether to regulate particular contaminants in the interest of protecting public health." However, this PFAS regulatory rule was proposed a few months before UCMR5 data are available. The UCMR process was designed specifically to collect occurrence data for EPA to use to assess the percent of the population potentially exposed and exposure levels as a basis for making regulatory decisions. Given that EPA could still meet its requirements through Congress to regulate PFAS by a certain deadline, EPA should consider how the first two quarters of UCMR5 data could be used to guide the development of these regulations.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

GFL Environmental (Doc. #1648, SBC-043219)

Other Important Factors to be Considered

EPA is using the third Unregulated Contaminant Monitoring Rule (UCMR 3) as the basis for the proposed NPDWR. If the proposed NPDWR implementation were delayed to the summer of 2024, EPA could analyze 2023 monitoring results from UCMR 5 to validate the impact of extrapolations assumed based on UMCR 3 data, which were collected using unvalidated testing methodology at significantly higher detection limits as compared to the UMCR 5 protocols.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that it used UCMR 3 as the only basis for the proposed NPDWR (see section 6.1 of the EPA response in this *Response to Comments* document). While the agency did use UCMR 3 results to inform the proposed rule and as the framework basis for the EPA's national occurrence model, the EPA also collected and analyzed an extremely robust dataset of state monitoring information consisting of tens of thousands of samples (please see section 6.2 of the EPA response in this *Response to Comments* document). Additionally, the EPA disagrees that UCMR 3 was collected using unvalidated testing methodology. PFAS data for UCMR 3 were collected using EPA Method 537, ver. 1.1, which was validated by the EPA, Office of Research and Development, National Exposure Research Laboratory. Method validation included both in-house performance data collection and a second laboratory demonstration using a minimum of two additional laboratories.

Inland Empire Utilities Agency (IEUA), California (Doc. #1666, SBC-043389)

The following are IEUA's comments on EPA's proposed rule.

Comment 1 – Cost Analysis – EPA's cost-benefit analysis should be updated to account for the cost to public water system and wastewater and water recycling utilities to upgrade treatment systems to comply with anticipated exceedances of one or more MCL.

In accordance with the Safe Drinking Water Act (SDWA) requirements, EPA has determined that the quantified and non-quantifiable benefits of the proposed PFAS NPDWR justify the costs. Costs are taken into consideration when establishing an enforceable Maximum Contaminant Level (MCL) as close as feasible to the Maximum Contaminant Level Goals (MCLG). In developing the financial impact EPA relied on multiple data sources including the Third Unregulated Contaminant Monitoring Rule (UCMR3) to estimate the PFAS occurrence and potential impact to public water systems. Since the analytical methods used by these data sources may have a minimum reporting level higher than the proposed MCL, we believe that more public water systems are anticipated to exceed one or more MCL and therefore, we recommend EPA to update the occurrence model and the cost-benefit analysis after the completion of the Fifth

Unregulated Contaminant Monitoring Rule (UCMR 5) in 2025. UCMR 5 will provide additional data that is a more accurate indication of current PFAS values at the proposed reporting levels which is critically needed to improve EPA's understanding of the frequency that PFAS are found in the nation's drinking water systems and at what levels. This data will ensure science-based decision-making and help to quantify the costs more accurately.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. The agency would like to clarify that, for the proposed and final rule, the EPA assessed the costs to all entities subject to the rule, including PWSs that exceed the MCLs. For more information on the EPA's response to comments on the agency's cost estimates, see section 13.3 in this *Response to Comments* document. For the EPA's response to comments on the Administrator's determination that the benefits of the rule justify the costs, see section 13.8 in this *Response to Comments* document. For the EPA's response to comments on feasibility of the MCLs, see section 5 in this *Response to Comments* document.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043669)

May 30, 2023

Michael S. Regan, Administrator

U.S. Environmental Protection Agency

1200 Pennsylvania Avenue, NW

Mail Code: 4607M

Washington, DC 20460

RE: Per- and polyfluoroalkyl substances (PFAS): Perfluorooctanoic acid (PFOA) and Perfluorooctanesulfonic acid (PFOS) National Primary Drinking Water Regulation Rulemaking, Docket No. (Docket ID: EPA-HQ-OW-2022-0114)

Dear Administrator Regan,

We appreciate the opportunity to comment on the Environmental Protection Agency's proposed rule, PFAS National Primary Drinking Water Regulation Rulemaking – EPA-HQ-OW2022-0114. The City of Allentown supports and considers itself a partner in EPA's efforts to ensure safe drinking water for all citizens, all communities. The City of Allentown (City) is the third largest city in Pennsylvania and is the economic driver to the Lehigh Valley, the 68th-most populous metropolitan area in the United States. The City's water system serves approximately 200,000 people in the region. The City has reviewed the proposed rule and offers the following comments also contributed by the operator of the City's system, Lehigh County Authority (LCA) for your consideration.

PFHxS, HFPO_DA, PFNA, and PFBS: The proposed regulation includes a Hazard Index (Index) approach to address several PFAS compounds through a single measure: PFHxS, HFPO_DA, PFNA, and PFBS. To date, this approach has not been used in other drinking water regulations. The treatment of these compounds in the proposed regulation is problematic for several reasons:

1. Data Limitations – These four PFAS compounds have not been fully studied, and we believe setting a regulatory standard at this time is premature. We ask that the EPA consider delaying the establishment of regulatory standards for these PFAS compounds until full review of the results from the Unregulated Contaminant Monitoring Rule (UCMR 5) monitoring, which began this year.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Regarding the EPA's regulatory determinations, please see section 3.1.2 of the EPA response in this *Response to Comments* document.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043673)

The addition of regulatory standards for other PFAS compounds, should be revisited upon completion of UCMR 5.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Regarding the EPA's regulatory determinations, please see section 3.1.2 of the EPA response in this *Response to Comments* document.

Austin Water (AW), Austin, TX (Doc. #1688, SBC-044453)

The analytical methods used to detect PFAS have become much more sensitive since the UCMR3 monitoring occurred and these enhanced methods are required by EPA for the sample analysis for 29 PFAS in the current Fifth UCMR (UCMR5). The UCMR5 is ongoing through 2025 and includes monitoring for all six PFAS listed in the proposed NPDWR, including GenX chemicals. AW had no detection of PFAS during our monitoring for UCMR3, and we are prepared to meet the monitoring requirements of UCMR5. Since UCMR5 will collect a considerable amount of additional data using analytical methods with increased sensitivity, the data from UCMR5 should be considered in the proposal for a final PFAS NPDWR. Using the UCMR5 sample result data would greatly improve the clarity and quality of the occurrence analysis and better inform any subsequent action on regulatory requirements for drinking water.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document regarding UCMR 5 and section 6.1 of the EPA response in this *Response to Comments* document regarding UCMR 3.

Massachusetts Coalition for Water Resources Stewardship (MCWRS) (Doc. #1691, SBC-044319)

MCWRS urges EPA to reconsider this approach, gather critical additional data, wait for the results of the upcoming UCMR 5 to be obtained and analyzed and delay any action on a final MCL until all of the needed information has been reviewed and many questions answered.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Massachusetts Coalition for Water Resources Stewardship (MCWRS) (Doc. #1691, SBC-044330)

7. Alternative Approach-While MCWRS does not agree with the proposed MCLs, an alternative implementation plan is offered regardless of what the final MCLs may be. That plan would include:

f. Delay implementation until UCMR5 (already underway) is completed and the nationwide data analyzed. This would allow EPA to gain a better understanding of PFAS occurrence and levels in drinking water and is frankly the purpose of the UCMR program. Putting the MCLs in play prior to UCMR5 being completed defeats the purpose of having a UCMR program.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. The EPA is under no legal obligation to delay the final rule until UCMR 5 is completed, as the UCMR 5 is not the basis for the rule and the agency currently has sufficiently robust occurrence information. In terms of implementation, the UCMR 5 data collection effort will be complete before the initial monitoring requirement deadline. Thus, the UCMR 5 data will support implementation without the need to delay because they will be available to satisfy initial monitoring requirements on the current timeline. For additional information on the final rule's initial monitoring requirements and the use of UCMR 5 data to support fulfillment of those requirements, please see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045902)

4. The PFOA and PFOS MCLs are based on inadequate data

SDWA requires that data be collected by "best available methods (if the reliability of the method and the nature of the decision justifies use of the data)." [FN99: 42 U.S.C. [sec] 300g-1(b)(3)(A)(ii).] As discussed previously, UCMR data has always been and is still considered the most reliable data. As measurement methods have improved over time, the reliable quantitation limit, or minimum reporting levels for PFOA and PFOS have changed. In UCMR 3, the minimum reporting levels for PFOA and PFOS were 40 ppt and 20 ppt, respectively. In UCMR 5, the minimum reporting level for both PFOA and PFOS is 4 ppt, thus making the UCMR 5 data

far more relevant for the regulatory action EPA is considering. In addition to having greater relevance, because PFOA and PFOS are able to be detected at much lower levels, the UCMR 5 data also represents the best available methods.

Considering the potentially economically significant costs of the proposed rulemaking, EPA must use the best available methods as these provide the most reliable and relevant data. When UCMR 5 sample collection and analysis is complete, EPA will have data from all public water systems serving more than 3,300 [FN100: Note that transient noncommunity water systems (TNCWSs) (i.e., non-community water systems that do not regularly serve at least 25 of the same people over 6 months per year) are not required to monitor under UCMR 5.86 Fed. Reg. 73131, 73132 (December 27, 2021)]. The UCMR 3 data, due to the higher quantitation levels, is simply not sufficiently reliable. Nationwide UCMR 5 sampling will be complete in 2025 and these data will be the most reliable data to use to determine whether there is a substantial likelihood that these PFAS will occur frequently and at concentrations where they are likely to exceed their respective health risk levels. As proposed, EPA estimates that the number of impacted systems will be between 3,400 and 6,300 [FN101: 88 Fed. Reg. at 18680]. In fact, the number of impacted entities is almost double what EPA estimates [FN102: See PFAS National Cost Model Report, Black & Veatch Holding Company, prepared for the American Water Works Association, Appendix A (March 7, 2023): https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=2023-03-14-102450-257].

EPA Response: The EPA strongly disagrees with the commenter that the PFOA and PFOS MCLs are based on inadequate data. In regard to the EPA using the best available science and information, please see sections 6.8, 6.2, and 6.5 of the EPA response in this *Response to Comments* document. The EPA also disagrees with many of the assumptions in AWWA's B&V report and the report's overall conclusions about the estimated national costs. Please see section 13.3.3 of the EPA response in this *Response to Comments* document for more details.

The EPA's occurrence estimates represent best available science. Please see sections 6.5 and 6.8 of the EPA response in this *Response to Comments* document, as well as the EPA response to comment Doc. #1759, SBC-045575 in section 6.5 in this *Response to Comments* document. The Black & Veatch report relies on a non-nationally representative set of systems to extrapolate to the nation. The set of systems included the 4,920 UCMR 3 systems but added an additional 3,069 systems from select states. New England accounted for about 70 percent of these additional systems (1,142 were in New Hampshire, 605 were in Vermont, 298 were in Massachusetts, and 73 in Rhode Island). An example of the impact of this approach is that New Hampshire went from representing less than 0.5 percent of systems in the nationally representative set of systems in UCMR 3 to representing over 14.6 percent of systems included in the Black & Veatch extrapolation. Similarly, Vermont went from representing about 0.24 percent of UCMR 3 systems to representing about 7.7 percent of the systems in the final set of systems used for extrapolation. This indicates substantial bias in results that overrepresents the New England region. Thus, the agency asserts the results of this analysis would not be nearly as

representative as the analysis conducted by the EPA and presented in the proposed and final rule preamble. Additionally, the EPA disagrees that the UCMR 3 data are not "sufficiently reliable" and were not collected using best available methods (see section 6.1 of the EPA response in this *Response to Comments* document).

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045936)

COMMENT 3 — A FINAL MCL WOULD BE ARBITRARY AND CAPRICIOUS UNLESS AND UNTIL THE PFAS PREVALENCE, AND THEREFORE THE MCL'S COSTS AND BENEFITS, ARE INFORMED BY DATA FROM UCMR 5.

On December 27, 2021, the EPA published UCMR 5, which requires sampling for 30 compounds between 2023 and 2025. UCMR data is intended "to support EPA's future regulatory determinations and, as appropriate, assist in the development of national primary drinking water regulations." [FN16: EPA, UCMR 5 Fact Sheet, available at https://www.epa.gov/system/files/documents/2022-02/ucmr5-factsheet.pdf.] Specifically, UCMR 5 is intended to "provide new data that is critically needed to improve EPA's understanding of the frequency that 29 PFAS (and lithium) are found in the nation's drinking water systems" to assist the EPA with making science-based decisions. [FN17: EPA, Revisions to the Unregulated Contaminant Monitoring Rule (UCMR 5) for Public Water Systems and Announcement of Public Meetings, 86 Fed. Reg. 73131, 73132 (Dec. 27, 2021) (Codified at 40 CFR Part 141).] The 29 PFAS in UCMR5 include PFOA, PFOS, and the four PFAS compounds in the proposed Hazard Index.

EPA states that UCMR 5 is intended to assist in making science-based drinking water regulations relating to the PFAS included in the Hazard Index. UCMR 5 was published in December 2021, and just began implementation this year, so most of the data has yet to be collected. EPA admits that the data from the UCMR 5 is not available for analysis of the proposed MCL at this time, but instead will be utilized for the "implementation of monitoring requirements under the proposed rule." [FN18: Proposed Rule, 88 Fed. Reg. at 18644.]

UCMR 5 is the first that requires monitoring for HFPO-DA or GenX. The other five PFAS were covered by UCMR 3 between 2013 and 2015, but they were only reportable at concentrations that were generally an order of magnitude higher than those in UCMR 5 or the proposed MCL. The proposed rule is therefore leapfrogging ahead of the very tool that is designed to inform EPA's assessment of contaminants' prevalence, and therefore the costs and benefits of promulgating an MCL.

To avoid acting arbitrarily, EPA should consider the monitoring data it receives from now through 2025, and provide the public an updated estimate of costs and benefits, before proceeding to a final MCL.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. The EPA disagrees that the agency has "leapfrogged" the established

process for developing NPDWRs or is acting arbitrarily. The EPA implements a monitoring program for unregulated contaminants (i.e., UCMR) under SDWA 1445(a)(2) that requires the EPA to issue a list once every five years of priority unregulated contaminants to be monitored by PWSs, however there is no statutory requirement that a contaminant must be on this list, if the agency has sufficiently available information through other sources. Additionally, completion of the UCMR 5 data collection effort is not required prior to making a regulatory determination nor promulgation of the final rule. The UCMR 3 dataset, along with additional state data and robust analyses, demonstrate sufficient likelihood of occurrence of the PFAS being regulated.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044767)

1. EPA Should Complete Collection and Analysis of UCMR 5 PFAS Data Prior to Finalizing the PFAS NPDW Rule

Developing a proposal to regulate PFAS under the SDWA prior to completion of ongoing UCMR 5 sampling efforts is inconsistent with EPA's integrated approach to PFAS (as stated in the Strategic Roadmap) to invest in research to increase understanding of PFAS exposures. UCMR 5 requires analysis for twenty-nine (29) PFAS compounds with a Minimum Reporting Limit (MRL) of 4.0 ppt, while UCMR 3 PFAS data represents concentrations of only six (6) PFAS with MRLs of 10 ppt to 90 ppt, from fewer PWSs overall. While EPA acknowledges that UCMR 5 data will not be available to inform this proposal, UCMR 5 data will be available to inform the implementation of monitoring requirements under the proposed PFAS NPDW rule. Additionally, more recent data collected by states and used by EPA to supplement UCMR 3 data shows that the continued occurrence of five of the six PFAS proposed for regulation "occur at lower concentrations and significantly greater frequencies than were measured under UCMR 3." However, the use of state-collected data is often not representative of PFAS impacts on PWSs due to those data being collected as a result of previously known PFAS impacts; thus, that data should not be used to model or predict the occurrence of anticipated concentrations nationwide. Developing and promulgating enforceable regulations prior to completing UCMR 5 misses an opportunity to expand our understanding of PFAS impacts on PWSs and subsequent human health exposures nationwide and to inform regulation development with higher quality data.

EPA Response: Please see sections 6.8 and 6.5 of the EPA response in this *Response to Comments* document. Additionally, the EPA disagrees with the commenter that the state data should not be used to evaluate occurrence. The EPA has presented the data that was collected under non-targeted frameworks and the data collected under targeted efforts (i.e., where it is collected in areas of known or suspected PFAS contamination) and utilized it appropriately based on this and other factors. See sections III and VI of the FRN and the *Occurrence Technical Support Document* (USEPA, 2024b) for extensive discussion of the data the EPA considered for this regulation.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044771)

While WDEQ does not have comments in response to EPA's request for specific conditions that should be mandated for systems to be eligible for exemptions under SDWA § 1416(b)(2)(C), WDEQ does strongly recommend that UCMR 5 data collection and analysis be completed prior to finalization of the proposed PFAS NPDW rule, specifically to apply a more comprehensive understanding of PFAS occurrence and concentrations in PWSs to better inform financial and infrastructural implications for affected PWSs in Wyoming.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Monte Vista Water District (MVWD) (Doc. #1718, SBC-043528)

Cost Analysis

EPA's financial impact used multiple data sources, including the Third Unregulated Contaminant Monitoring Rule (UCMR3), to estimate the PFAS occurrence and potential impact to public water systems. The analytical methods used by these data sources may have a minimum reporting level higher than the proposed MCL, and therefore public water systems may exceed one or more MCL's. MVWD recommends EPA update the occurrence model and the cost-benefit analysis after the completion of the Fifth Unregulated Contaminant Monitoring Rule (UCMR5) in 2025. UCMR5 will provide additional data that is a more accurate indication of current PFAS values at the proposed reporting levels which is critically needed to improve EPA's understanding of the frequency that PFAS are found in drinking water systems and at what levels. This data will ensure science-based decision-making and help to quantify the costs more accurately.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document in regard to UCMR 5 and section 6.5 of the EPA response in this *Response to Comments* document in regard to the national occurrence model. In regard to the EPA's cost estimates, please see section 13.3 of the EPA response in this *Response to Comments* document.

Monte Vista Water District (MVWD) (Doc. #1718, SBC-043534)

Cost Analysis

EPA's financial impact used multiple data sources, including the Third Unregulated Contaminant Monitoring Rule (UCMR3), to estimate the PFAS occurrence and potential impact to public water systems. The analytical methods used by these data sources may have a minimum reporting level higher than the proposed MCL, and therefore public water systems may exceed one or more MCL's. MVWD recommends EPA update the occurrence model and the cost-benefit analysis after the completion of the Fifth Unregulated Contaminant Monitoring Rule (UCMR5) in 2025. UCMR5 will provide additional data that is a more accurate indication of

current PFAS values at the proposed reporting levels which is critically needed to improve EPA's understanding of the frequency that PFAS are found in drinking water systems and at what levels. This data will ensure science-based decision-making and help to quantify the costs more accurately.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document in regard to UCMR 5 and section 6.5 of the EPA response in this *Response to Comments* document in regard to the national occurrence model. In regard to the EPA's cost estimates, please see section 13.3 of the EPA response in this *Response to Comments* document.

U.S Conference of Mayors, National League of Cities and National Association of Counties (Doc. #1733, SBC-043899)

3. Additional Scientific Data and Cost-Benefit Analysis

The Agency anticipates releasing updated data in its upcoming Fifth Unregulated Contaminant Monitoring Rule (UCMR 5), expected within the next nine months. According to EPA's website, "the monitoring provides EPA and other interested parties with nationally representative data on the occurrence of contaminants in drinking water, the number of people potentially being exposed, and an estimate of the levels of that exposure. These data can support future regulatory determinations and other actions to protect public health." Notably, this current dataset includes monitoring for 29 different PFAS chemicals, including for all six PFAS chemicals being considered under this proposal.

The information obtained from this monitoring dataset would be of great value to support the Agency as it develops its regulatory framework for proposing new drinking water standards for PFAS. This updated data will provide a deeper insight into the monitoring and testing capacities of public water systems and laboratories across the nation, as well as better inform the cost-benefit analysis. Setting the MCL levels at the detect level when more data has yet to be released denies the Agency the ability to adjust these levels in the future, making permanent strict compliance actions for which the costs may not be justified. Therefore, we urge the Agency to either propose a higher MCL standard such as 10 ppt for PFOS and PFOA, or consider waiting to finalize any MCL levels until at least this new dataset becomes available for EPA to utilize.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. For the EPA's response related to the PFOA and PFOS MCLs and determination of feasibility, please see section V.A of the FRN, specifically V.A.2 regarding alternative MCLs.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045999)

Complete occurrence data from UCMR 5 will help EPA complete this cost analysis that the agency says currently is "unlikely to be substantially" underestimated. AMWA reiterates its

earlier comment that EPA should reconsider finalizing the regulatory determination of the HI PFAS as it collects and analyzes UCMR 5 data.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document regarding UCMR 5 data. Regarding the EPA's regulatory determinations, please see sections 3.1.2 and 3.2.2 of the EPA response in this *Response to Comments* document.

City of Thornton, Colorado (Doc. #1748, SBC-044784)

Without UCMR5 data, EPA is woefully uninformed about national PFAS occurrence and significantly underestimating costs there.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. The EPA disagrees that the agency is uninformed about national PFAS occurrence, as the agency's analyses have produced scientifically robust estimates of national occurrence.

American Water Works Association (AWWA) (Doc. #1759, SBC-045576)

Inclusion of Data from Fifth Unregulated Contaminant Monitoring Rule

This year, drinking water monitoring for PFAS under the Fifth Unregulated Contaminant Monitoring Rule (UCMR 5) began. UCMR 5 is expected to be the most comprehensive occurrence dataset for PFAS collected to-date. Indeed Congress took the additional step of explicitly instructed EPA to include these substances in UCMR 5 as part of the National Defense Authorization Act for Fiscal Year 2020 (Congress, 2019). In accordance with UCMR 5, more than 10,300 systems will monitor for 29 PFAS using EPA Methods 533 and 537.1 using single-digit minimum reporting limits. While a complete dataset will not be compiled until 2026, more than 3,500 water systems are actively collecting monitoring data this year. By the end of summer this year, EPA will have at least one sample result from these 3,500 water systems. Previous research has shown that preliminary data collected from UCMR monitoring provides accurate insights about occurrence when compared to the complete dataset (Eaton et al, 2018).

UCMR 5 data collected during the first half of 2023 would represent a significant increase in the available data that is nationally representative. Specifically, this dataset will provide information on nearly 70% of the number of water systems that are typically represented by a UCMR program. While this data would not be a full UCMR sampling program, it would significantly expand the universe of nationally representative data at method reporting levels deemed appropriate in the proposed rule. As the goal of the UCMR 5 program is to inform EPA on the occurrence of PFAS, EPA can ill afford to ignore these data, which would be of a much higher quality and value than its current Bayesian Model approach.

The UCMR program is designed to collect national occurrence data on contaminants not currently subject to NPDWRs, and EPA "require[ed] collection of data under UCMR 5 to inform EPA regulatory determinations and risk-management decisions" (EPA, 2021c). Given that

Congress explicitly instructed EPA to include PFAS chemical in UCMR 5, Congress clearly intended for the national occurrence date resulting from UCMR 5 to inform EPA's regulatory determinations about these substances. This strongly suggests that EPA should wait to take final regulatory action on these substances until all UCMR 5 data has been collected so that that its decisions can be fully informed with the best available information. This is particularly true given that the SDWA's an-backsliding provisions will require continued regulation of these substances once EPA has issued a final NPDWR: EPA must make the most informed decision possible at this stage to fulfill its statutory obligations and prevent unnecessary and unjustified regulations. [FN12: See 42 U.S.C. § 300g-1(b)(9) ("Any revision of a national primary drinking water regulation shall be promulgated in accordance with this section, except that each revision shall maintain, or provide for greater, protection of the health of persons.").]

But even if EPA does not wait until all UCMR-5 data has been collected, it must at the very least incorporate and prioritize data already provided to the agency under UCMR-5 in making regulatory decisions under this proposal. Given that much of the UCMR 5 data has already been collected, EPA cannot meet the SDWA's directive to rely on the best available public health information without taking into account this most current and comprehensive set of data.

EPA Response: Please see section 3.1.2 of the EPA response in this *Response to Comments* document in regard to the EPA's regulatory determinations, section 6.8 of the EPA response in this *Response to Comments* document in regard to UCMR 5, and section 6.5 of the EPA response in this *Response to Comments* document in regard to the national occurrence model.

American Water Works Association (AWWA) (Doc. #1759, SBC-045563)

3. EPA's statistical approach to estimating occurrence of PFAS in drinking water is overly complicated and EPA would be ill-advised to move forward with a final rule without considering incoming data from more than 3,500 water systems currently collecting samples under the Fifth UCMR 5 (EPA, 2021c).

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document in regard to UCMR 5 data and section 6.5 of the EPA response in this *Response to Comments* document in regard to the EPA's modeling approach for estimating national PFAS occurrence.

American Water Works Association (AWWA) (Doc. #1759, SBC-045580)

6. EPA should not finalize the occurrence analysis without considering the availability of high-quality, nationally representative data from the UCMR 5 program to either improve the existing occurrence analysis or replace the analysis.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Connecticut Section of the AWWA (CTAWWA) and Connecticut Water Works Association (CWWA) (Doc. #1763, SBC-044235)

Timeline for Finalizing the PFAS Rule

We recommend that findings from the fifth Unregulated Contaminant Monitoring Rule (UCMR5) monitoring period, specifically on the 29 PFAS compounds, be reviewed and incorporated into the PFAS Rule to ensure that it adequately limits risk. Nationwide monitoring results will provide greater insight into the occurrence of PFAS and guide the rule-making effort. We note that the EPA has committed to publishing the Final Rule in December 2023, which is nine months prior to the statutory deadline. This additional time could be utilized to analyze UCMR5 results.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043861)

EPN recommends that in the final rule, EPA commit to reviewing the results of UCMR5 as soon as data are available to identify any co-occurring PFAS.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Additionally, see VI.C. and VI.G. of the final rule preamble for the updated PFAS co-occurrence analysis.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045269)

The importance of this issue recently came to our attention, when multiple water systems across the nation began reporting data quality issues with the methods for the first quarter of UCMR 5 monitoring (since January 2023), particularly with EPA Method 533 (for 25 PFAS). CA-NV AWWA urges EPA to complete the two-year UCMR 5 monitoring period, engage with stakeholders to develop a comprehensive assessment of the findings, and then use the results to inform and develop practical PFAS drinking water regulations. The benefits of this approach include a better understanding of laboratory capacity for trace level analyses, time to resolve technical issues with the analytical methods (including sample contamination and false-positives), more robust and consistent data to use for PQL development, and a realistic understanding of the analytical costs. Overall, EPA will have better and more reliable information by waiting. The collection of reputable data is a critical factor that must be completed prior to the development of the technical and economic impacts analyses.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045277)

EPA should adhere to the established SDWA regulatory process, and should adjust timeframes in the rulemaking and in the final regulation.

7. This rulemaking should be informed by additional occurrence data from UCMR 5 and State monitoring.

In this rulemaking, EPA has relied on data from UCMR 3 that provides an incomplete basis for the preliminary determination to set the MCLs proposed in this rulemaking. This shortcoming is especially true for small systems [FN9: In its Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation Appendices (EPA Document No. EPA-822-P-23-002, hereafter "Proposed PFAS Rule Economic Analysis"), the text notes, "Because UCMR 3 included only a sample of small systems, there is greater uncertainty in the occurrence estimates for small systems compared to large systems."], and for the four PFAS chemicals other than PFOA and PFOS, i.e., PFHxS, PFNA, PFBS, and HFPO-DA (GenX). Occurrence of these four PFAS is not sufficiently understood, and EPA needs to consider updated data available from states and to be collected under UCMR 5. In the Economic Analysis [FN10: Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation Appendices. USEPA, Office of Water, EPA-822-P-23-002. March 2023] a footnote states, "PFBS and PFNA were not included in the model because 19 reported values across the country from the primary dataset (UCMR 3) were insufficient for fitting the national model...." [FN11: Proposed PFAS Rule Economic Analysis, p. A-2]. Moreover, knowledge gaps about occurrence and the co-occurrence of chemicals included in the Hazard Index require additional data and new analysis for the Index to be valid.

EPA Response: The EPA has followed the SDWA regulatory process. Please see section 6.2 of the EPA response in this *Response to Comments* document in regard to the use of state data in addition to UCMR 3 data. Please see section 6.5 of the EPA response in this *Response to Comments* document regarding the national occurrence model and handling of small systems. Please see section 6.6 of the EPA response in this *Response to Comments* document regarding the combination of state data with national occurrence model output. See also section 10.3 of the PFAS *Occurrence Technical Support Document* (USEPA, 2024b). Please see section 6.3 of the EPA response in this *Response to Comments* document and preamble sections VI.C and VI.G regarding PFAS co-occurrence. Regarding costs associated with exceedances of the Hazard Index MCL, please see section 13.3.2 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that there is incomplete occurrence data or that it does not represent all sizes of water systems. The EPA collected PFAS data from 32 states, in addition to the UCMR 3 dataset, to inform the final rule. See VI. of the preamble for state data analysis, assessment of occurrence relative to the Hazard Index, and the assessment of PFAS co-occurrence. The *Occurrence Technical Support Document* presents additional analysis (USEPA, 2024b).

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045283)

11. Focus limited funding on the elimination of continued environmental loading.

Since the voluntary phase-out of PFOA and PFOS, the levels found in human blood serum have substantially declined, indicating that a preventative approach is effective [FN12: Hurley, S. et al. 2017. Time trends in per- and polyfluoroalkyl substances (PFASs) in California women: Declining serum levels, 2011-2015. Env. Sci. Tech 52(1)]. EPA estimates that human exposure primarily comes from food and air and estimates about 20% of PFAS exposure from drinking water. Advanced drinking water treatment comes at a significant economic, financial, and environmental cost (in terms of CO2 emissions and carbon use), which ultimately is paid for by the consumers, regardless of the water system size or demographic. Prior to requiring public water systems to employ advanced treatment to eliminate a continual supply of PFAS entering watersheds, EPA should fully understand the occurrence of PFAS in drinking water. The current UCMR 5 efforts will help inform that objective.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

San Diego County Water Authority, CA (Doc. #1779, SBC-045287)

EPA is also seeking comment on regulating the four PFAS as a mixture using a Hazard Index approach. The Hazard Index (HI) is a calculation used to evaluate potential health risks from chemical mixtures and would be the first use of this approach by EPA in setting drinking water standards. The HI assumes dose addition and co-occurrence among the chemicals. The Water Authority recommends that the Hazard Index based on these four chemicals be established after monitoring data is available under the Fifth Unregulated Contaminant Monitoring Rule (UCMR 5). The timing would align considering that EPA expects to finalize the rule at the end of 2023, after which water systems would have three years to comply. UCMR 5 data collection will occur from January 2023 through December 2025, and will provide significantly more data to be considered in establishing the HI. Additional data would also be available from states such as California that have required monitoring that was not considered by EPA in the proposed Rulemaking. For example, monitoring for Gen X was not part of UCMR 3 but is part of UCMR 5. Additionally, PFNA has been voluntarily phased out of production and use and may be less likely to cooccur. The availability of this additional data will allow for refinement of the Hazard Index approach to regulating the PFAS as a mixture.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. State data from California, as well as 31 other states. were considered in the proposed rulemaking. These data are discussed in sections III.C. and VI.B. of the final rule preamble as well as the PFAS *Occurrence Technical Support Document* (USEPA, 2024b).

Safe Drinking Water Branch, Hawaii Department of Hawaii (Doc. #1801, SBC-043752)

The UCMR5 and the PFAS Rule

Normally, EPA conducts UCMR study to collect enough data first. After careful analysis of the test result, EPA then proposes the new regulation. However, this time the proposal of the PFAS rule and UCMR5 happen at the same time. It demonstrates that EPA made a rush decision without solid scientific evidence. It is very dangerous for EPA to establish such non-scientific precedent. It will impact the trust between EPA and the whole water industry.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Additionally, the EPA disagrees that the agency has made a "rush decision without solid scientific evidence." The EPA implements a monitoring program for unregulated contaminants (i.e., UCMR) under SDWA 1445(a)(2) that requires the EPA to issue a list once every five years of priority unregulated contaminants to be monitored by PWSs, however there is no statutory requirement that a contaminant must be on this list. The agency may make a regulatory determination if the agency has sufficiently available information through other sources. Additionally, completion of the UCMR 5 data collection effort is not required prior to making a regulatory determination nor promulgation of the final rule. The UCMR 3 dataset, along with additional state data and robust analyses, demonstrate sufficient likelihood of occurrence of the PFAS being regulated.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045480)

a. EPA has underestimated the impact of the rule on small water systems. Advocacy is concerned that EPA has underestimated the impact of the proposed rule on small water systems. More specifically, the agency underestimates the number of systems that will be required to comply. EPA's proposed MCLs are set at the lowest concentration that PFOA and PFOS can be reliably quantified in a laboratory (i.e., 4.0 ppt). As a result, many systems will be subject to the proposed requirements. Advocacy is concerned that EPA's estimates for the number of impacted public water systems is not based on the best available data. EPA decided not to wait for the fifth Unregulated Contaminant Monitoring Rule (UCMR 5) occurrence data to inform its analysis for the number of water systems that will be subject to the proposed rule. The collection of this data started this year and is expected to continue into 2025. Under UCMR 5, EPA published the method reporting limit (MRL) [FN8: The method reporting level (MRL) is the level at which the test can report a quantifiable value with high confidence] of 4.0 ppt each for PFOA and PFOS, same as the proposed MCLs. Instead, for the proposal, EPA used UCMR 3 and state data with levels above the proposed monitoring or compliance levels in this proposal. Because it represents a lower limit than UCMR 3, the results of UCMR 5 data will provide a more accurate accounting of water systems likely to be subject to EPA's regulations, an outcome not currently acknowledged or accounted for in EPA's analysis.

EPA Response: Please see sections 6.2 and 6.8 of the EPA response in this *Response to Comments* document. Also please see section 6.5 of the EPA response in this *Response to*

Comments document regarding how the national PFAS occurrence model incorporated both state data and UCMR 3 data. While the EPA clearly states in the proposed and final rule preamble that the UCMR 3 MRLs are higher than the proposed and final PFAS MCLs, the EPA disagrees that the analyses would systematically underestimate the impact of the final rule on small systems. State occurrence data that were used primarily had reporting limits on the order of single digits ng/L, often lower than the EPA's UCMR 5 MRLs. Since the EPA has considered these data, which are representative of all size water systems, and also used it in combination with UCMR 3 to model national occurrence estimates for small and large systems, the agency has concluded that it has reasonably estimated impacts to small systems.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045768)

Monitoring for PFAS under the Fifth Unregulated Contaminant Monitoring Rule (UCMR5) began this year. UCMR5 will be the most comprehensive occurrence dataset for PFAS collected to date. While a complete dataset will not be compiled until 2026, more than 3,400 water systems are actively collecting monitoring data this year. By the end of summer this year, all these systems will have collected at least one sample and EPA will have received these results. While this may not be a complete data set, it will significantly improve the understanding of PFAS occurrence in U.S. public water systems. We request that EPA delay issuance of the final PFAS standards until UCMR5 data can be used to better determine national PFAS occurrence and a more accurate assessment of the number of impacted systems, costs and benefits of the proposed rule can be completed.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045774)

Monitoring for PFAS under UCMR5 began this year. UCMR5 will be the most comprehensive occurrence dataset for PFAS collected to date. EPA should delay issuance of the final PFAS standards until UCMR5 data can be used to better determine national PFAS occurrence and a more accurate assessment of the number of impacted systems, costs and benefits of the proposed rule can be completed.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Pennsylvania Municipal Authorities Association (Doc. #1832, SBC-045788)

[PMAA's specific comments on the Proposal are as follows:]

12. PMAA believes that the results from the Fifth Unregulated Contaminant Monitoring Rule ("UCMR 5") will provide EPA with a more scientifically valid and robust database on the occurrence of PFAS chemicals in the nation's drinking water. This data will ensure that a

prospective PFAS final regulation will be based upon the best available science, and EPA should defer moving forward with the Proposal until such data is available, evaluated and subject to public review and comment. In fact, EPA recommends that data from UCMR 5 be used for initial monitoring requirements once the Proposal is finalized. (See, EPA PowerPoint from March 29, 2023 webinar on Proposed PFAS National Primary Drinking Water Regulation, slide 19).

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Columbia Water (Doc. #1833, SBC-045795)

Due to the continued uncertainty of the effects on public health caused by PFAS chemicals, and EPA's apparently significant underestimation of the costs of making the capital and operational/maintenance investments necessary to treat water to the proposed standards, we believe EPA must withdraw the proposed MCL's for PFAS chemicals and make use of information to be gathered in the coming UCMR5 rule to inform additional future research into the prevalence and health effects of the PFAS chemicals.

Sincerely,

Clint Shealy, PE, Assistant City Manager for Columbia Water City of Columbia, South Carolina

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. The EPA disagrees that there is uncertainty about the risks to public health caused from the six regulated PFAS: see section III and IV of the preamble for this action and sections 3.1.1, 3.2.1, and 4 of the EPA response in this *Response to Comments* document. The EPA also disagrees it has significantly underestimated the costs to treat water to the regulatory standards (see section 13.3 of the EPA response in this *Response to Comments* document),

Massachusetts Water Resources Authority (Doc. #3072-49, SBC-047381)

EPA also seems to have jumped out ahead of the logical regulatory process by making this proposal now while water systems are expending substantial effort and cost to collect the UCMR 5 PFAS data with appropriate detection levels. That data should have been in place before the rule was proposed to substantially refine its impact.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

Greenville Utilities Commission (Doc. #3072-53, SBC-047385)

Okay, thank you. Good afternoon. My name is Anthony Whitehead. I'm the water quality manager for Greenville Utilities Commission. The proposed MCLs for PFAS compounds will be extremely difficult and expensive for many water providers to meet. PFAS compounds are

ubiquitous, not just near known spill or contamination sites through these compounds being used in many products encountered in our lives each day, including food wrappers, cookware, personal care products, clothing, and cosmetics. Drinking water is the only one of several routes of exposure to PFAS compounds and the drinking water industry should not be disproportionately targeted by regulatory action to reduce PFAS exposure. UCMR 5 will provide EPA with scientifically valid data on the national occurrence of 29 PFAS compounds in the nation's drinking water and at what levels. This data will ensure science-based decision making and help prioritize protection of disadvantaged communities. Implementation of regulation before up-to-date information from UCMR 5 can be reported and analyzed does not follow sound scientific principles. The limited number of laboratories certified to analyze samples for UCMR 5 have caused 10-day turnaround times to become two month waits for data. Utilities will have to increase sampling to determine the effectiveness of potential treatment strategies which will further burden those laboratories.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. Regarding laboratory capacity, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-047702)

Section 8.2: Cost of HI PFAS

Complete occurrence data from UCMR 5 will help EPA complete this cost analysis that the agency says currently is “unlikely to be substantially” underestimated. EPA should reconsider finalizing the regulatory determination of the HI PFAS as it collects and analyzes UCMR 5 data.

In Table 41 (88FR 18703) EPA states there are insufficient UCMR 3 data for PFBS and PFNA and that there are no UCMR 3 data for GenX available. If EPA does not have the data to support whether utilities will be out of compliance with the HI, how can it assume that these potential exceedances do not need to be part of the cost estimate? Cleveland Water disagrees with EPA that not including this information in the national cost estimates is insignificant.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document. The EPA notes that while UCMR 3 data for PFBS and PFNA were not included within the EPA’s national occurrence model as referenced by the commenter, nor was HFPO-DA included within the UCMR 3, as a part of its overall occurrence analysis the agency did evaluate and present UCMR 3 data on PFBS, PFNA, and PFHxS, and also evaluated a robust dataset of more recent state monitoring data for all of the PFAS which it is regulating, including HFPO-DA. Those data summaries and results are presented in the *Occurrence Technical Support Document* (USEPA, 2024b) and section VI of the preamble. Therefore, the EPA has sufficient data available for all PFAS which it is regulating and has included this information within its cost estimates. After considering recommendations from public commenters to further analyze the costs of the Hazard Index and the data available to support a quantitative analysis of the costs of the Hazard Index, the EPA decided to conduct a sensitivity analysis of the costs of the Hazard

Index at the national level. The results of the sensitivity analysis supported the EPA's assumption in the proposal that quantified national costs are marginally underestimated as a result of this lack of sufficient nationally representative occurrence data. For more information on the EPA's cost analysis, see section 13.3.2 of the EPA response in this *Response to Comments* document.

Loudoun Water (Doc. #1717, SBC-043522)

The Unregulated Contaminant Monitoring Rule is the critical path to provide EPA with nationally representative data on the occurrence of PFAS in drinking water, as well as the number of people potentially being exposed, and an estimate of the levels of that exposure. Loudoun Water believes that the collection of water system data in the fifth UCMR (UCMR 5) is likely to show that many more systems will be affected by the regulation than EPA has estimated.

EPA Response: Please see section 6.8 of the EPA response in this *Response to Comments* document.

7 Analytical Methods

7.1 Validated EPA Methods

Summary of Major Public Comments and EPA Responses

Several commenters note analytical differences between EPA Methods 533 and 537.1, such as differences in the quality control (QC) acceptance levels between the methods, sample preservation and holding times, as well as variability in sample and spike duplicates. In some instances, these commenters request specific modification to the methods, revisions to the EPA laboratory certification manual, or for the agency to develop guidance that laboratories and state accreditation/ certification bodies could use. These commenters note that while both methods are valid under the final rule, variability between the two may lead to differences in sampling results and may impact a water system's compliance status. The EPA agrees that Methods 533 and 537.1 have some differences that allow for analysis of varying chain lengths and molecular structures of PFAS. Method 533 generally captures "short chain" PFAS (i.e., those with carbon chain lengths of 4 to 12) and fluorotelomer sulfonic acids. Method 537.1 includes some overlap with Method 533's analyte list while including some longer-chain PFAS. However, the agency notes that all six PFAS finalized for regulation can be analyzed by either Method 533 or 537.1 and neither method has inherent QC issues that lead to significant variation in sampling results when followed. This is because the ability of the methods to meet QC is determined during method development, through both single and multi-laboratory validation. All laboratories, internal and external, are required to demonstrate that all QC criteria listed in Section 9.0 of the methods can be met. This ability to meet QC criteria also has been corroborated by laboratories participating in the fifth Unregulated Contaminant Monitoring Rule (UCMR 5) Laboratory Approval Program (LAP), where there was overwhelming success in meeting method QC acceptance criteria. While there are differences between the methods and how they measure their respective target analytes, both EPA Methods 533 and 537.1 utilize the same technologies (solid phase extraction (SPE) with liquid chromatography/mass spectrometry) and perform comparably as evidenced by the similar QC acceptance criteria and performance data provided in each method. The methods are clear and outline specific instructions regarding requirements that are needed for compliance monitoring measurements.

Some public commenters suggested that the EPA allow alternate analytical procedures or modifications to the two published EPA methods for meeting the monitoring requirements in the final rule. The EPA continues to specify the use of Methods 533 and 537.1 because consistent, reliable compliance data are necessary for implementation of the regulation at the Maximum Contaminant Level (MCL). However, the EPA recognizes that improvements in analytical technology and methodology occur. The EPA's Drinking Water Alternate Test Procedure (ATP) Program provides a mechanism for submission and review of alternative methods to measure a contaminant for nationwide use under 40 CFR 141.27. A method developer may apply for the EPA review of a method modification or a new method through the ATP Program. In the meantime, the agency has concluded that Methods 533 and 537.1 are reliable for use in

compliance monitoring with respect to accuracy and recovery (lack of bias) and precision (good reproducibility) at the MCL levels. With respect to improvements in analytical technology, the EPA further notes that the agency is required to review National Primary Drinking Water Regulations (NPDWRs) every six years and determine which, if any, are appropriate for revision (i.e., the Six-Year Review Process). The purpose of the review is to evaluate current information for regulated contaminants and to determine if there is any new information on health effects, analytical methods, occurrence and exposure, implementation, and/or other factors that provides a health or technical basis to support a regulatory revision that will improve or strengthen public health protection. This process allows the agency to consider these and other information as appropriate in deciding whether existing NPDWRs should be identified as candidates for revision as required by the Safe Drinking Water Act (SDWA).

Some commenters sought clarity on which methods are approved for use in compliance monitoring for the final PFAS NPDWR. Some of these commenters requested that only Method 533 be approved for monitoring under the final NPDWR, noting that it may be more suitable should additional PFAS analytes within its scope be targeted for regulation at the future date. Others requested that they be permitted to use Method 537, version 1.1. The EPA disagrees and reaffirms that Methods 537.1, version 2.0 and Method 533 are both applicable and suitable for use in compliance monitoring in the final rule. The EPA notes that the EPA Method 1633 is not a drinking water method and, as such, may have different time and resource requirements than the EPA Method 533 or Method 537.1, ver. 2.0. The EPA notes that HFPO-DA is one of the PFAS regulated under the final NPDWR and only Method 537.1, version 1.0 and version 2.0, and Method 533 support the collection of data for HFPO-DA. The agency notes that the primary difference between Method 537.1, version 1.0 and Method 537.1, version 2.0 is the field reagent blank (FRB) preparation: version 2.0 exposes the FRB to the preservative (Trizma) at the time of field sample collection. Version 1.0 combines the lab reagent water and the preservative together in the FRB prior to field sampling. Version 2.0 was created to more-closely mimic the FRB process used in Method 533. Additionally, Version 2.0 explicitly states that the SPE cartridge sorbents may not be modified with monomers other than styrene divinylbenzene (SDVB).

Several commenters requested that all laboratories be required to identify their quantitation limits (i.e., the smallest detectable concentration of an analyte greater than the detection limit where the accuracy (precision and bias) achieves the objectives of the intended purpose) and/or method detection limits (MDLs; i.e., the minimum result which can be reliably discriminated from a blank). Specifically, some commenters note if labs have to demonstrate they can get below the practical quantitation level (PQL), the EPA should establish reporting or detection limits demonstrating they can get to these levels. While the agency does not require laboratories to demonstrate that they can get below the PQLs, the EPA is finalizing rule trigger levels below the PQL to support the monitoring provisions discussed in section VIII of this preamble. The EPA disagrees with these commenters that such reporting is needed to support compliance monitoring for the rule and that such reporting would be a cost burden on laboratories. All labs are required per the approved methods to demonstrate whether laboratory reagent blank (LRB) QC samples have background concentrations of less than one-third the minimum reporting level (MRL; i.e.,

the minimum concentration that can be reported as a quantitated value for a method analyte in a sample following analysis). Therefore, for a laboratory to be compliant with the methods, they must be able to detect, not necessarily quantify, analytes at or above 1/3 the MRL.

After review of public comment, the EPA is establishing two approved methods to support the monitoring requirement of this NPDWR. These two liquid chromatography/tandem mass spectrometry (LC/MS/MS) analytical methods were developed by the EPA and validated to quantitatively monitor drinking water for targeted PFAS: the EPA Method 533: *Determination of Per- and Polyfluoroalkyl Substances in Drinking Water by Isotope Dilution Anion Exchange Solid Phase Extraction and Liquid Chromatography/Tandem Mass Spectrometry* (USEPA, 2019) and EPA Method 537.1, Version 2.0: *Determination of Selected Per- and Polyfluorinated Alkyl Substances in Drinking Water by Solid Phase Extraction and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)* (USEPA, 2020). All six PFAS compounds regulated by the NPDWR can be measured by both the EPA Methods 533 and 537.1, ver. 2.0 and both methods are acceptable for meeting the monitoring requirements of this regulation. These methods are incorporated by reference in the final rule (see 40 CFR § 141.901(a)) and are publicly available in the EPA's Docket ID No. EPA-HQ-OW-2022-0114. For additional discussion on analytical methods, please see section VII of the final rule NPDWR preamble. For additional discussion on the PQLs for the PFAS regulated under this final NDPWR, please see section 7.2 of the EPA response in this *Response to Comments* document. For discussion on feasibility of the MCLs with respect to laboratory capacity, capability, or other analytic challenges to reliably measure samples for the final NPDWR, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding commenter concerns about laboratory testing and potential contamination issues, please see section 8.7 of the EPA response in this *Response to Comments* document.

Individual Public Comments

Mike Pettit (Doc. #1542, SBC-043347)

Overall Critique of Method 1633

EPA Method 1633 is a method for the determination of per- and polyfluoroalkyl substances (PFAS) in drinking water using solid-phase extraction and liquid chromatography/tandem mass spectrometry (LC/MS/MS). While this method has been widely used for PFAS analysis, there are some critiques that can be made:

• Limitations in the number of PFAS analyzed: The method focuses on the analysis of only 14 PFAS compounds, which may not be enough to capture the full range of PFAS contaminants that may be present in the environment.

• Sample matrix effects: The method can be subject to matrix effects, which means that the presence of other compounds in the water sample can interfere with the analysis and affect the accuracy of the results

• Reliance on internal standards: The method relies on the use of internal standards to correct for matrix effects and other sources of variability, but the use of internal standards can introduce its own sources of variability and uncertainty

• Lack of standardized quality control criteria: While the method provides guidelines for quality control and quality assurance, there is no standardized set of criteria for assessing the quality of the results obtained using this method.

• Limited sensitivity: The method has a relatively high detection limit for some PFAS compounds, which means that it may not be sensitive enough to detect low levels of these contaminants in water samples.

Overall Critique of Method 533

Method 533 also has several glaring flaws:

• Limited detection range: EPA Method 533 has a lower limit of detection (LOD) of 0.05 ng/L for some PFAS compounds, which is lower than the LOD of previous methods. However, this LOD may still not be low enough to detect some of the newer, lower concentration PFAS compounds that are of concern.

• Limited sample volume: EPA Method 533 only allows for a maximum sample volume of 1 liter, which may not be sufficient to detect low-level PFAS contamination in larger water systems. This can be a particular issue for detection of PFAS in source waters that may be subject to contamination, as many water sources are larger than 1 liter

• Sample collection issues: Sample collection for PFAS analysis can be complicated by the unique properties of these compounds. PFAS compounds can adsorb to containers and tubing, which can lead to false negative results. Additionally, PFAS compounds can be found in a wide range of matrices, and the presence of other organic compounds or high levels of minerals in water can interfere with the analysis

• Limited scope of analysis: EPA Method 533 only covers a limited number of PFAS compounds, primarily those that have been detected in drinking water in the US. As new PFAS compounds are discovered, EPA Method 533 may need to be updated to ensure that all relevant compounds are being monitored.

EPA Response: With respect to clarification on which analytical methods are approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document. The EPA notes that the EPA Method 1633 is not a drinking water method and, as such, may have different time and resource requirements than the EPA Method 533 or Method 537.1, ver. 2.0. Regarding commenter concerns about laboratory testing and potential contamination issues, please see section 8.7 of the EPA response in this *Response to Comments* document. The EPA also disagrees that EPA Method 533 has "glaring flaws" toward implementing the monitoring requirements of the final NDPWR; neither methods 533 nor 537.1 ver. 2.0 have inherent QC issues when explicitly followed. This is

because the ability of the methods to meet QC is determined during method development, through both single and multi-laboratory validation. All laboratories, internal and external, are required to demonstrate that all QC criteria listed in Section 9.0 of the methods can be met. This ability to meet QC criteria also has been corroborated by laboratories participating in the UCMR 5 LAP, where there was overwhelming success in meeting method QC acceptance criteria. Furthermore, EPA Method 533 does not require the calculation of a limit of detection (LOD), does not allow for samples greater than 250 mL, and is not applicable for the analysis of source waters.

Missouri Department of Natural Resources (Doc. #1563, SBC-042522)

Additionally, EPA Method 533 allows for quality assurance/quality control (QA/QC) samples to be ±50% at or near the MRL and not ±30% for all analytes as indicated in the preamble. From EPA Method 533 Section 9.2.3.2 Evaluate Analyte Recovery "Results for analytes fortified at concentrations near or at the MRL (within a factor of two times the MRL concentration) must be within 50–150% of the true value. Results for analytes fortified at all other concentrations must be within 70–130% of the true value. If the LFB [Laboratory Fortified Blank] results do not meet these criteria, then all data for the problem analytes must be considered invalid for all samples in the Extraction Batch." This difference in acceptance level identifies one of the key issues associated with proposing to set a MCL at the same value as the practical quantitation limit (PQL) or MRL. This issue is not one that can be solved by simply lowering the PQL/MRL to 2 ppt. Based on UCMR 5 lab approvals, it is already known that more than 25 percent of laboratories nationwide will not be able to meet a PQL lower than 4 ppt with a 95% confidence interval (CI). In addition to causing more issues with laboratory capacity nationwide, the number of samples that would be rejected under the method, and therefore requiring resampling, would increase even with a ±50% Method QA/QC acceptance level.

EPA Response: With respect to the analytic requirements of the EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document. The EPA also disagrees with the commenter claims' that "25% [of labs] cannot" meet the PQL; as discussed in the final rule preamble, the PQL reflects a minimum quantitation level that "with 95 percent confidence, can be achieved by capable analysts at 75 percent *or more* of the laboratories using a specified analytical method" (emphasis added). Greater than 75 percent of labs requesting participation in UCMR 5 were able to meet the PQLs / MRLs, and the EPA anticipates the number of labs available for compliance monitoring to grow. With respect to concerns on the feasibility of the PQLs, including discussion on how the PQLs were established for the NPDWR, please see section 7.2 of the EPA response in this *Response to Comments* document.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042733)

Analytical Methodology:

There must be leeway in the rule to utilize any current or future EPA approved analytical methods. We believe there will be advancements in analytical technology and the rule should be flexible enough to incorporate future approved methods for PFAS analysis.

EPA Response: With respect to alternate analytical procedures or modifications to the two EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

COMM Water Department (Doc. #1577, SBC-042441)

There must be leeway in the rule to utilize any current or future EPA approved analytical methods. In Massachusetts, our regulations are so prescriptive that PWSs have not been able to utilize Method 533 because it had not yet been approved by EPA at the time our regulations were drafted. We believe there will be advancements in analytical technology and the rule should be flexible enough to incorporate future approved methods for PFAS analysis.

EPA Response: With respect to alternate analytical procedures or modifications to the two EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Association of State and Territorial Solid Waste Management Officials (ASTSWMO) (Doc. #1583, SBC-042404)

[Overall, as movement is made toward better regulation and oversight of these contaminants, ASTSWMO's membership recognizes a corresponding need for research, communication, and improved understanding within the following areas:]

• finalization of PFAS-specific analytical methods to facilitate analysis of PFAS in surface water, groundwater, and other media;

EPA Response: With respect to the EPA's discussion on the validated analytical methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document. The development of new analytical methods in non-drinking water matrices is not in scope of the current NPDWR; please see section 15.1 of the EPA response in this *Response to Comments* document.

New York Section American Water Works Association (NYSAWWA) (Doc. #1591, SBC-042369)

We note that many labs in New York State are currently reporting at +/- 1.8 ppt for PFOA/PFOS. In order to ensure all water suppliers are measuring and reporting contaminants in the same way, we recommend that EPA methods establish standard Reporting Limits (RLs) for all labs.

EPA Response: With respect to commenter concerns on the identification of laboratory quantitation limits and/or MDLs, please see section 7.1 of the EPA response in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042884)

Analytical Methodology:

There must be leeway in the rule to utilize any current or future EPA approved analytical methods. In Massachusetts, our regulations are so prescriptive that PWSs have not been able to utilize Method 533 because it had not yet been approved by EPA at the time our regulations were drafted. We believe there will be advancements in analytical technology and the rule should be flexible enough to incorporate future approved methods for PFAS analysis.

EPA Response: With respect to alternate analytical procedures or modifications to the two EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Marlene Ladderbush (Doc. #1612, SBC-042917)

There must be leeway in the rule to utilize any current or future EPA approved analytical methods. In Massachusetts, our regulations are so prescriptive that PWSs have not been able to utilize Method 533 because it had not yet been approved by EPA at the time our regulations were drafted. We believe there will be advancements in analytical technology and the rule should be flexible enough to incorporate future approved methods for PFAS analysis.

EPA Response: With respect to alternate analytical procedures or modifications to the two EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Town of Lincoln Water Department (Doc. #1613, SBC-043029)

There must be leeway in the rule to utilize any current or future EPA approved analytical methods. In Massachusetts, our regulations are so prescriptive that PWSs have not been able to utilize Method 533 because it had not yet been approved by EPA at the time our regulations were drafted. We believe there will be advancements in analytical technology and the rule should be flexible enough to incorporate future approved methods for PFAS analysis.

EPA Response: With respect to alternate analytical procedures or modifications to the two EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043111)

2. Differences in the Analytical Methods (including sample preservation and holding times)

EPA indicated that either EPA Method 533 or EPA Method 537.1, Version 2 would be "acceptable for meeting the monitoring requirements of this regulation." With the exception that Method 537.1 relies on post extraction internal standard calibration while Method 533 uses an extracted internal standard or isotope dilution calibration, both methods are comparable. However, there are many trivial differences between the two methods. In a 1987 Report to Congress, the Agency stated:

An evaluation of the monitoring programs established under the authority of major environmental laws, demonstrates that the analytical methods are sometimes unnecessarily different, as they relate to similar sample matrices, target analytes, and data quality objectives.

The unnecessarily different requirements between the wo methods make it difficult for laboratories to comply, especially since both methods state "Changes may not be made to sample preservation, the quality control (QC) requirements, or the extraction procedure."

Table 4 below summarizes some of the unnecessary differences found. The text which follows discusses these changes in more detail.

Table 4. Unnecessarily Different Changes between Methods 537.1 and 533

[Table 4: See Docket ID EPA-HQ-OW-2022-0114-1625]

The detailed comments below provide the EMC's thoughts on some of these unnecessary differences found. Ideally, the EMC would request EPA modify both methods as stated below. However, the EMC recognizes that process could be difficult in the expected time frame for this rule so alternatives could include 1) revising the certification manual or 2) coming up with other guidance that laboratories and state accreditation/certification bodies could use.

1. MDL. If EPA requires laboratories to report to the trigger level, , the EMC encourages EPA to require laboratories to establish MDLs that are below the trigger levels.

2. Sample Size. The EMC encourages EPA to allow flexibility in sample size to allow laboratories to go up to full volume of the 250 mL bottle for both methods with the prescribed 500 mg of sorbent.

3. SPE Sorbent, reagents and elution order. EPA apparently fixed the SPE step so they could reduce the level of validation required. The SVDB polymer defined in 537.1 does not perform as well as WAX does for the smaller PFAS (< 6 C). If method 537.1 were not defined by the SPE media, but rather was defined by the mode of calibration, then 537.1 could be used for smaller PFAS analytes. Accordingly, 533 was developed using the WAX sorbent which works well for small chain PFAS because it bases the binding on the pKA of the carboxylic and sulfonic moieties on the PFAS compounds. Thus, chain length doesn't matter. WAX binds C4-C18 with no problems.

4. Applying correction for low or irreproducible recovery because you are not using the best media for the analyte should not be the option. The EMC encourages EPA to allow flexibility in the selection of the SPE cartridge, reagents and elution step to allow improvements in this technology. The EMC further recommends EPA consider by-passing the SPE step completely and allow for direct injection without SPE or hydrophilic-interaction chromatography (HILIC) as an alternative separation technique.

5. Extract volume, solvent and storage. The EMC recommends the 80:20 ratio be used as this improves peak shape and to allow multiple injections from the same vial if sealed as stated in Method 533 or to allow self-sealing vials.

6. Second Source Quality Control Check. The EMC recommends the second source standard specified in 9.3.10 be required for Method 533 as well, especially for the six regulated analytes.

7. Sample Collection, Preservation and Holding Time.

a) The EMC supports the EPA statement that no changes to sample preservation should be allowed. However, the unnecessary differences in sample preservative, sample temperature, and holding time between the two methods makes it impossible for one bottle to be used for both methods and the current requirements present other challenges. The EMC recommends the ammonium acetate preservative as stated in Method 533.

b) The language in 537.1 could imply samples must be at 10 C the moment they are collected, which is impossible. The language in 533 is more appropriate.

c) Method 533 also allows for a 28-Day holding time (as shown in Table 15) and that should be allowed in 537.1 as well. A peer-reviewed article in the October 2019 issue of Environmental Science and Technology indicates that freezing is the preferred option for storage of samples and that samples stored in this manner are stable for at least 180 days. EMC request the Agency to consider this peer-reviewed science in revising the sample preservation and holding time requirements.

7. Scan Rate. EPA defined the minimum amount of data points across a peak allowed as 10 scans per second. Many modern Mass Spectrometers (MS) can collect the same quality of data at much faster scanning speeds so it is likely a modern (<5 yrs) MS can collect >20 data points with a 4-5 second peak width and so laboratories can easily run a 8-10 min method with same data quality compared to EPA's method done on older mass specs for EPA 533 and 537.1 validation that need >20 min.

8. Sample pH and peak asymmetry. The EMC supports the pH 6-8 range in Method 533. Verification of the narrow pH range in Method 537.1 does not improve the extraction efficiency and is harder to check in the laboratory. For 6 - 8 you can use wide range paper, for 6.5 - 7.5 you need narrow range paper. If the same elution and final solvent in Method 533, was allowed the peak asymmetry check would not be needed as the extra water would improve peak shape. Notice, however, that Method 537.1 indicates you cannot add extra water to improve peak symmetry.

9. Quality Control. The EMC also supports the EPA statement that no changes to the QC requirements are allowed but believes that changes to the extraction procedure should be allowed since the extraction procedures in Methods 537.1 and 533 are very different, and further advances in this technology are likely.

a. The requirement for an Initial Demonstration of Capability (IDC) and on-going QC should be sufficient to ensure reliable data are obtained with any modifications to the SPE extraction. However, assuring data in the modified procedure are equivalent or better than the data acquired using the existing extraction, equivalent or better would mean recovery of spikes in the IDC closer to 100%, with % RSD of < 10%. The EMC suggests the recovery limits for precision to be 10% and accuracy to be 90-110% instead of the required 20% and 70-130%.

b. The EMC also suggests adding a Certified Reference Material or single-blind Performance Evaluation sample to have an independent check as part of the IDC.

EMC believes either method is sufficiently accurate for regulating the six PFAS analytes in drinking water. However, the EMC would request EPA to either revise the methods as described above to be more consistent or to 1) alternatively revise the drinking water certification manual, or 2) develop other similar guidance that can be use by laboratories and state certification bodies to include the recommendations. Specifically, the EMC recommends EPA:

a) Revise Method 537.1 to use the same sample volume and bottles, the ammonium acetate preservative, the same temperature preservation, storage, holding time, and the pH 6-8 requirement to be consistent with 533.

b) Modify Method 533 to require a second source verification standard particularly for the regulated analytes as they are available.

c) Since the other unnecessarily different requirements in the table above are not listed in the items that cannot be changed, EMC believes laboratories can implement these requirements effectively. However, EMC is concerned that laboratory assessors working in state accreditation/certification programs might be less flexible. Accordingly, EMC recommends section 1.3 of both methods be modified to state:

The laboratory may select SPE media, LC columns, LC conditions, and MS conditions different from those used to develop the method. At a minimum, the internal standards specified in the method must be used, if available. The laboratory may select the aqueous sample volume within the range of 100–250 mL that meets their objectives. Changes may not be made to sample preservation, holding time, or quality control (QC) requirements. The chromatographic separation should minimize the number of compounds eluting within a retention window to obtain a minimum of 10, and preferably 15 - 20 scans across each peak. Instrumental sensitivity (or signal- to- noise) will decrease if too many compounds are permitted to elute within a MRM transition window.

Method modifications should be considered only to improve method performance, including increased productivity. In all cases where method modifications are proposed, the analyst must

perform the procedures outlined in the Initial Demonstration of Capability (IDC, Sect. 9.1), verify that all QC acceptance criteria in this method (Sect. 9.2) are met, and verify method performance in a representative sample matrix (Sect. 9.3.2).

EPA Response: The agency disagrees with the commenter that there are significant analytic differences between the two methods (533 and 537.1, ver. 2.0) that would make it difficult for laboratories to comply with the final NPDWR as neither method has inherent QC issues when explicitly followed and both can meet the monitoring requirements of the final rule. With respect to analytic differences between the EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document. Regarding method modifications not expressly permitted within the methods, such as the flexibility to select SPE cartridges different than those prescribed in the methods, the EPA notes that the procedures and requirements listed in the methods are based on empirical evidence collected during method development and performance data collection. Changes to those procedures and requirements may lead to unintended consequences leading to poorer data quality. As discussed in section 7.1 of the EPA response in this *Response to Comments* document, the agency notes that all six PFAS finalized for regulation can be analyzed by either Method 533 or 537.1. Modified methods may be submitted to the agency as ATPs and considered for approval, per the discussion in section 7.1 of the EPA response in this *Response to Comments* document.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043116)

Revision 2.0 of Method 537.1

Finally, the EMC notes that a March 2020 revision 2.0 of Method 537.1 has been published by EPA. The only change appears to be related to the field reagent blank. The proposed rule cites the November 2018 version 1.0. EMC seeks clarity on which method EPA plans to approve.

EPA Response: With respect to the EPA's discussion on the validated analytical methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043108)

1. Detection and Reporting Limits

EMC supports the MCLs proposed by EPA but has concerns over some of the other terms used in the proposed regulation and in EPA Methods 533 and 537.1. The table below summarizes a variety of terms used in the proposed rule, the methods, and from other sources.

Table 1. Maximum Contaminant Levels, Detection Limits, Lowest Concentration Minimum Reporting Limits, Minimum Reporting Limits, Practical Quantitation Limits, and Trigger Levels

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1625]

Method 537.1 uses an obsolete definition for Detection Limit. In 2017, as part of a Clean Water Act Method Update Rule, the Agency changed this definition to reflect the latest science. Because the MDL is widely recognized as the lowest concentration that indicates detection, and because the proposed rule may require reporting values below the MRL, EMC recommends the MDL be included in both methods, but updated to the current definition.

EPA Response: With respect to commenter concerns on the identification of laboratory quantitation limits and/or MDLs, please see section 7.1 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044890)

• DEP supports inclusion of EPA Method 537 version 1.1 as an approved method for PFAS analysis. While DEP recognizes that EPA Method 537 version 1.1 does not include HFPO-DA (GenX) as an analyte, which would be a regulated PFAS compound under this proposed rulemaking, it is a valid, EPA-approved method for the other PFAS that EPA is proposing to regulate.

• In [sec] 141.01(a)(2)(ii), Method 537.1, version 1.0 from November 2018, is referenced as EPA document ID EPA/600/R-18/352. DEP notes that version 2.0 from March 2020, EPA document ID EPA/600/R-20/006 is not referenced in the proposed rulemaking. DEP has not been accrediting laboratories for version 2.0 because it contains more than just editorial changes from version 1.0. DEP requests clarification as to whether version 2.0 is an acceptable EPA-approved method for analysis of the regulated PFAS in the proposed rulemaking.

EPA Response: With respect to clarification on which analytical methods are approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Town of Tewksbury, Massachusetts (Doc. #1637, SBC-043247)

There must be leeway in the rule to utilize any current or future EPA approved analytical methods. In Massachusetts, our regulations are so prescriptive that PWSs have not been able to utilize Method 533 because it had not yet been approved by EPA at the time our regulations were drafted. We believe there will be advancements in analytical technology and the rule should be flexible enough to incorporate future approved methods for PFAS analysis.

EPA Response: With respect to alternate analytical procedures or modifications to the two EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043319)

2. Differences in the Analytical Methods (including sample preservation and holding times)

EPA indicated that either EPA Method 533 or EPA Method 537.1, Version 2 would be "acceptable for meeting the monitoring requirements of this regulation." With the exception that Method 537.1 relies on post extraction internal standard calibration while Method 533 uses an extracted internal standard or isotope dilution calibration, both methods are comparable. However, there are many trivial differences between the two methods. In a 1987 Report to Congress, the Agency stated:

An evaluation of the monitoring programs established under the authority of major environmental laws, demonstrates that the analytical methods are sometimes unnecessarily different, as they relate to similar sample matrices, target analytes, and data quality objectives.

The unnecessarily different requirements between the wo methods make it difficult for laboratories to comply, especially since both methods state "Changes may not be made to sample preservation, the quality control (QC) requirements, or the extraction procedure."

Table 4 below summarizes some of the unnecessary differences found. The text which follows discusses these changes in more detail.

Table 4. Unnecessarily Different Changes between Methods 537.1 and 533

[Table 4: See Docket ID: EPA-HQ-OW-2022-0114-1646]

The detailed comments below provide the EMC's thoughts on some of these unnecessary differences found. Ideally, the EMC would request EPA modify both methods as stated below. However, the EMC recognizes that process could be difficult in the expected time frame for this rule so alternatives could include 1) revising the certification manual or 2) coming up with other guidance that laboratories and state accreditation/certification bodies could use.

1. MDL. If EPA requires laboratories to report to the trigger level, , the EMC encourages EPA to require laboratories to establish MDLs that are below the trigger levels.

2. Sample Size. The EMC encourages EPA to allow flexibility in sample size to allow laboratories to go up to full volume of the 250 mL bottle for both methods with the prescribed 500 mg of sorbent.

3. SPE Sorbent, reagents and elution order. EPA apparently fixed the SPE step so they could reduce the level of validation required. The SVDB polymer defined in 537.1 does not perform as well as WAX does for the smaller PFAS (< 6 C). If method 537.1 were not defined by the SPE media, but rather was defined by the mode of calibration, then 537.1 could be used for smaller PFAS analytes. Accordingly, 533 was developed using the WAX sorbent which works well for small chain PFAS because it bases the binding on the pKA of the carboxylic and sulfonic moieties on the PFAS compounds. Thus, chain length doesn't matter. WAX binds C4-C18 with no problems.

4. Applying correction for low or irreproducible recovery because you are not using the best media for the analyte should not be the option. The EMC encourages EPA to allow flexibility in the selection of the SPE cartridge, reagents and elution step to allow improvements in this

technology. The EMC further recommends EPA consider by-passing the SPE step completely and allow for direct injection without SPE or hydrophilic-interaction chromatography (HILIC) as an alternative separation technique.

5. Extract volume, solvent and storage. The EMC recommends the 80:20 ratio be used as this improves peak shape and to allow multiple injections from the same vial if sealed as stated in Method 533 or to allow self-sealing vials.

6. Second Source Quality Control Check. The EMC recommends the second source standard specified in 9.3.10 be required for Method 533 as well, especially for the six regulated analytes.

7. Sample Collection, Preservation and Holding Time.

a) The EMC supports the EPA statement that no changes to sample preservation should be allowed. However, the unnecessary differences in sample preservative, sample temperature, and holding time between the two methods makes it impossible for one bottle to be used for both methods and the current requirements present other challenges. The EMC recommends the ammonium acetate preservative as stated in Method 533.

b) The language in 537.1 could imply samples must be at 10 C the moment they are collected, which is impossible. The language in 533 is more appropriate.

c) Method 533 also allows for a 28-Day holding time (as shown in Table 15) and that should be allowed in 537.1 as well. A peer-reviewed article in the October 2019 issue of Environmental Science and Technology indicates that freezing is the preferred option for storage of samples and that samples stored in this manner are stable for at least 180 days. EMC request the Agency to consider this peer-reviewed science in revising the sample preservation and holding time requirements.

7. Scan Rate. EPA defined the minimum amount of data points across a peak allowed as 10 scans per second. Many modern Mass Spectrometers (MS) can collect the same quality of data at much faster scanning speeds so it is likely a modern (<5 yrs) MS can collect >20 data points with a 4-5 second peak width and so laboratories can easily run a 8-10 min method with same data quality compared to EPA's method done on older mass specs for EPA 533 and 537.1 validation that need >20 min.

8. Sample pH and peak asymmetry. The EMC supports the pH 6-8 range in Method 533. Verification of the narrow pH range in Method 537.1 does not improve the extraction efficiency and is harder to check in the laboratory. For 6 - 8 you can use wide range paper, for 6.5 - 7.5 you need narrow range paper. If the same elution and final solvent in Method 533, was allowed the peak asymmetry check would not be needed as the extra water would improve peak shape. Notice, however, that Method 537.1 indicates you cannot add extra water to improve peak symmetry.

9. Quality Control. The EMC also supports the EPA statement that no changes to the QC requirements are allowed but believes that changes to the extraction procedure should be allowed

since the extraction procedures in Methods 537.1 and 533 are very different, and further advances in this technology are likely.

a. The requirement for an Initial Demonstration of Capability (IDC) and on-going QC should be sufficient to ensure reliable data are obtained with any modifications to the SPE extraction. However, assuring data in the modified procedure are equivalent or better than the data acquired using the existing extraction, equivalent or better would mean recovery of spikes in the IDC closer to 100%, with % RSD of < 10%. The EMC suggests the recovery limits for precision to be 10% and accuracy to be 90-110% instead of the required 20% and 70130%.

b. The EMC also suggests adding a Certified Reference Material or single-blind Performance Evaluation sample to have an independent check as part of the IDC.

EMC believes either method is sufficiently accurate for regulating the six PFAS analytes in drinking water. However, the EMC would request EPA to either revise the methods as described above to be more consistent or to 1) alternatively revise the drinking water certification manual, or 2) develop other similar guidance that can be use by laboratories and state certification bodies to include the recommendations. Specifically, the EMC recommends EPA:

a) Revise Method 537.1 to use the same sample volume and bottles, the ammonium acetate preservative, the same temperature preservation, storage, holding time, and the pH 6-8 requirement to be consistent with 533.

b) Modify Method 533 to require a second source verification standard particularly for the regulated analytes as they are available.

c) Since the other unnecessarily different requirements in the table above are not listed in the items that cannot be changed, EMC believes laboratories can implement these requirements effectively. However, EMC is concerned that laboratory assessors working in state accreditation/certification programs might be less flexible. Accordingly, EMC recommends section 1.3 of both methods be modified to state:

The laboratory may select SPE media, LC columns, LC conditions, and MS conditions different from those used to develop the method. At a minimum, the internal standards specified in the method must be used, if available. The laboratory may select the aqueous sample volume within the range of 100–250 mL that meets their objectives. Changes may not be made to sample preservation, holding time, or quality control (QC) requirements. The chromatographic separation should minimize the number of compounds eluting within a retention window to obtain a minimum of 10, and preferably 15 - 20 scans across each peak. Instrumental sensitivity (or signal-to- noise) will decrease if too many compounds are permitted to elute within a MRM transition window.

Method modifications should be considered only to improve method performance, including increased productivity. In all cases where method modifications are proposed, the analyst must perform the procedures outlined in the Initial Demonstration of Capability (IDC, Sect. 9.1),

verify that all QC acceptance criteria in this method (Sect. 9.2) are met, and verify method performance in a representative sample matrix (Sect. 9.3.2).

EPA Response: The agency disagrees with the commenter that there are significant analytic differences between the two methods (533 and 537.1, ver. 2.0) that would make it difficult for laboratories to comply with the final NPDWR as neither method has inherent QC issues when explicitly followed and both can meet the monitoring requirements of the final rule. With respect to analytic differences between the EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document. Regarding method modifications not expressly permitted within the methods, such as the flexibility to select SPE cartridges different than those prescribed in the methods, the EPA notes that the procedures and requirements listed in the methods are based on empirical evidence collected during method development and performance data collection. Changes to those procedures and requirements may lead to unintended consequences leading to poorer data quality. As discussed in section 7.1 of the EPA response in this *Response to Comments* document, the agency notes that all six PFAS finalized for regulation can be analyzed by either Method 533 or 537.1. Modified methods may be submitted to the agency as ATPs and considered for approval, per the discussion in section 7.1 of the EPA response in this *Response to Comments* document.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043310)

1. Detection and Reporting Limits

EMC supports the MCLs proposed by EPA but has concerns over some of the other terms used in the proposed regulation and in EPA Methods 533 and 537.1. The table below summarizes a variety of terms used in the proposed rule, the methods, and from other sources.

Table 1. Maximum Contaminant Levels, Detection Limits, Lowest Concentration Minimum Reporting Limits, Minimum Reporting Limits, Practical Quantitation Limits, and Trigger Levels

[Table 1: See Docket ID: EPA-HQ-OW-2022-0114-1646]

Method 537.1 uses an obsolete definition for Detection Limit. In 2017, as part of a Clean Water Act Method Update Rule, the Agency changed this definition to reflect the latest science. Because the MDL is widely recognized as the lowest concentration that indicates detection, and because the proposed rule may require reporting values below the MRL, EMC recommends the MDL be included in both methods, but updated to the current definition.

EPA Response: With respect to commenter concerns on the identification of laboratory quantitation limits and/or MDLs, please see section 7.1 of the EPA response in this *Response to Comments* document. The detection limit calculation present in Method 537.1 is an optional determination. Other regulatory bodies may choose to employ other detection limit calculations, such as the MDL calculation from 40 CFR part 136, Appendix B at their discretion as a more stringent approach.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043299)

[Detailed recommendations are appended to this letter, but a few are emphasized below:]

• It is advisable to decrease the field blank testing requirement to one of the following, in priority order of preferred change:

• Updates are required to Method 533 to harmonize the sample volume and sorbent weight with that permitted in Method 1633 and enable use for regulatory compliance. Also, this method needs to be modified to permit self-sealing autosampler vials.

EPA Response: Please see the EPA response to comment Doc. #1646, SBC-043323 in section 8.7 in this *Response to Comments* document. The EPA notes that the commenter provides three options with respect to not requiring an FRB at each sampling site, however, the options provided are not viable toward maintaining the integrity of results since FRBs are a method QC requirement. This requirement is necessary to ensure that any detections are part of the field sample and not introduced during the sampling process. The suggestions made would not account for contamination at the time of sampling or contamination due to the conditions of the sampling site. FRBs are only required if target analytes are present in the field sample at or above the method MRL. Additionally, all holding times in the methods are based on storage stability study results conducted during method development. Further, the EPA notes that the EPA Method 1633 is not a drinking water method and, as such, may have different time and resource requirements than the EPA Method 533 or Method 537.1, ver. 2.0. The EPA further notes that neither method 533 nor 537.1 ver. 2.0 have inherent QC issues when explicitly followed. This is because the ability of the methods to meet QC is determined during method development, through both single and multi-laboratory validation. All laboratories, internal and external, are required to demonstrate that all QC criteria listed in Section 9.0 of the methods can be met. This ability to meet QC criteria also has been corroborated by laboratories participating in the UCMR 5 LAP, where there was overwhelming success in meeting method QC acceptance criteria. With respect to alternate analytical procedures or modifications to the two EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043324)

Revision 2.0 of Method 537.1

Finally, the EMC notes that a March 2020 revision 2.0 of Method 537.1 has been published by EPA. The only change appears to be related to the field reagent blank. The proposed rule cites the November 2018 version 1.0. EMC seeks clarity on which method EPA plans to approve.

EPA Response: With respect to clarification on which analytical methods are approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044908)

It is also worth mentioning that EPA method 533 and 537.1 allow for variability in sample and spike duplicates [FN5: https://cfpub.epa.gov/si/si_public_record_Report.cfm?dirEntryId=343042&Lab=NERL]. For samples measured below twice the MRL, i.e., below 8.0 ppt, the accepted relative percent difference (RPD) is 50% or less. To illustrate, suppose a sample is analyzed and found to have a concentration of 5.0 ppt. If the same sample is then reanalyzed and found to have a concentration of 3.0 ppt, the RPD calculation would be 50%, indicating that the laboratory's results are within the acceptable range. If a water sample can yield measurements of between 5.0 ppt and 3.0 ppt, the difference is roughly equal to one drop of PFAS in 10 Olympic sized swimming pools [FN6: https://dnr.mo.gov/monitoring/understanding-data], it demonstrates the variation allowed in results, and can significantly impact a water system's compliance status. This distinction is crucial because it can determine whether a water system would need to implement costly treatment techniques (5.0 ppt) or if it falls below the Maximum Contaminant Level (MCL) with a reasonable margin of safety (3.0 ppt), requiring no immediate action. There are significant cost differences for these results, but both would be valid under the proposed rule. Water utilities need to base costly treatment decisions on reliable data so that we do not ask customers to pay for expensive capital improvements that may not make an appreciable improvement in water quality.

EPA Response: With respect to analytic differences between the EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document. With respect to implementation concerns around variability around sample results, the agency notes the following: First, the agency notes that quantitative sampling results do not have an estimate of standard error and therefore are generally not reported. Second, the EPA does not expect laboratories to conduct intensive statistical analyses of their analytical results so there is no calculated error associated with their reported measurements. In effect, quantitated measurement values stand as a single reported result. Lastly, any laboratory that provides drinking water analyses on PFAS in support of the NPDWR are held to the same standard for reporting results per the analytical method. The EPA further notes that compliance with the MCL is determined by running annual averages where individual sample results will not cause a system to be out of compliance (unless that result is 4x above the MCL in which they are in violation immediately). For commenter concerns regarding PQLs, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

American Council of Independent Laboratories (ACIL) (Doc. #1692, SBC-044742)

5. Revision 2.0 of Method 537.1

ACIL notes that a March 2020 revision 2.0 of Method 537.1 has been published by EPA. The proposed rule cites the November 2018 version 1.0. ACIL seeks clarity on which method EPA plans to approve.

EPA Response: With respect to clarification on which analytical methods are approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

American Council of Independent Laboratories (ACIL) (Doc. #1692, SBC-044738)

Choice of Method: 533 or 537.1

There are two 500 series methods available for the 6 PFAS that are the focus of the initial MCLs. While both method 537.1 and method 533 can report these 6 PFAS at a similar level of sensitivity, there are significant differences in the two methods.

1) EPA 533 is an isotope dilution method for 25 PFAS that includes all targets in consideration for the MCL, and short chain PFAS such as PFBA and PFPeA, and additional ether PFAS such as NFDHA, PFEESA, PFMPA and PFMBA not covered by EPA 537.1.

2) The use of the weak anion exchange column for preparation, and isotope dilution and recovery correction for quantification makes EPA 533 a preferable method conforming broadly to current PFAS best practice. The use of isotope dilution and recovery correction also improves method performance close to the method reporting limits. In ongoing use, our labs have documented fewer quality control issues with the use of 533 compared with 537.1. The analytical approaches in EPA 533 broadly mirror those in EPA 1633 draft for aqueous sample analysis indicating that the scope of EPA 533 can be expanded if needed.

3) The EPA is increasing its scrutiny to more PFAS, for example, the CERCLA notice EPA–HQ–OLEM–2022–0922; FRL–906401–OLEM] RIN 2050–AH25 posted to 40 CFR part 302 specifically addresses PFBA as needing measurement in solid waste. In addition, the toxicity profile of PFBA is mentioned several times in the MCL document. The preparation technique used in EPA 537.1 is not suitable for PFBA and PFPeA. We believe the use of 533 for drinking water will more than likely suit future alignment of PFAS targets across multiple regulatory needs better than 537.1 will. Given more targets are under consideration for addition to the PFAS MCL, potentially under the hazard index, 533 is a more suitable method. The EPA has also announced intentions to add PFAS targets to 533 at a future date.

For these reasons, the ACIL recommends that the EPA specify a preference for method 533 over 537.1. While costs of additional isotopically labeled standards is a consideration, the improvement in data quality, robustness, and alignment with EPA 1633 draft practices more than compensate.

EPA Response: With respect to clarification on which analytical methods are approved for meeting the monitoring requirements in the final NPDWR as well as discussion on analytic

differences between the EPA methods, please see section 7.1 of the EPA response in this *Response to Comments* document. The EPA notes that perfluorobutanoic acid (PFBA) and perfluoropentanoic acid (PFPeA) are not regulated as part of the final NPDWR and any potential analytic requirements for these PFAS are out of scope for this rulemaking.

Susan Gorman-Chang (Doc. #1705, SBC-045083)

3. Add to the regulations a phrase that states as testing technologies become more sensitive and reliable, the MCLs will be ratcheted down in response, and testing technologies will be reviewed annually by the EPA to identify the most sensitive and reliable methods and promulgate their use. This gives these EPA regulations the flexibility to evolve as our technology evolves. This is especially important for PFAS and PFOS as the EPA has found that NO level is safe for human consumption.

EPA Response: The agency disagrees that the language suggested by the commenter is necessary for the final NPDWR. Please see section 7.1 of the EPA response in this *Response to Comments* document for considerations on how the agency considers improvements in analytic performance when revising NPDWRs. Specifically, the agency is required to review NPDWRs every six years and determine which, if any, are appropriate for revision (i.e., the Six-Year Review Process). The purpose of the review is to evaluate current information for regulated contaminants and to determine if there is any new information on health effects, analytical methods, occurrence and exposure, implementation, and/or other factors that provides a health or technical basis to support a regulatory revision that will improve or strengthen public health protection. This process allows the agency to consider these and other information as appropriate in deciding whether existing NPDWRs should be identified as candidates for revision as required by SDWA.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045956)

It is also worth mentioning that EPA methods 533 and 537.1 allow for variability in sample and spike duplicates [FN5: EPA. (2020, June 6). Method 537.1.] and could have significant consequences for water systems' compliance. For samples measured below twice the MRL (i.e., below 8.0 ppt), the accepted relative percent difference (RPD) is 50% or less. To illustrate, suppose a sample is analyzed and found to have a concentration of 5.0 ppt. If the same sample is then reanalyzed and found to have a concentration of 3.0 ppt, the RPD calculation would be 50%, indicating that the laboratory's results are within the acceptable range. If a water sample can yield measurements of 5.0 ppt and 3.0 ppt, the difference between one drop of PFAS in 10 Olympic-sized swimming pools [FN6: Missouri Department of Natural Resources. (2023). Understanding data. https://dnr.mo.gov/monitoring/understanding-data], it demonstrates the variation allowed in results that can significantly impact a water system's compliance status. This distinction is crucial because it can determine whether a water system would need to implement costly treatment techniques (5.0 ppt) or require no immediate action as it falls below the MCL with a reasonable margin of safety (3.0 ppt).

EPA Response: Please see the EPA response to comment Doc. #1672, SBC-044908 in section 7.1 in this *Response to Comments* document**.**

Arizona Water Company (Doc. #1758, SBC-044539)

PFAS Contamination and Sampling

Certain contaminants have field sampling kits available for use in confirming laboratory results. Company operators use these kits to quickly check levels of contaminants in the field when continuous monitoring is not available. Company engineers recommend the EPA work with scientists and engineers to develop a field sampling kit for operator and management use.

EPA Response: With respect to the analytic requirements of the EPA methods, please see section 7.1 of the EPA response in this *Response to Comments* document. After finalization of the PFAS NPDWR, the EPA intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. In addition to the analytical method sampling requirements, the EPA has developed guidance on PFAS analytical test methods and the recommended procedures for appropriate sample collection in the field. The EPA has not approved nor is aware of any PFAS "field sampling kits … to quickly check levels of contamination in the field."

American Water Works Association (AWWA) (Doc. #1759, SBC-045626)

As a matter of policy, EPA should not set a precedent for the use of analytical results that are not reliably achievable for all water systems as this would create an equity issue. Moreover, the current minimum reporting levels for EPA Methods 533 and 537.1 are appropriate based on ongoing experience with PFAS analytical results.

EPA Response: With respect to the analytic requirements of the EPA methods, please see section 7.1 of the EPA response in this *Response to Comments* document. The agency is clarifying for the commenter that the EPA is not "setting a precedent for use of analytical results that are not readily achievable for all water systems." With respect to concerns on the feasibility of the PQLs, including discussion on how the PQLs were established for the NPDWR, please see section 7.2 of the EPA response in this *Response to Comments* document as well as 5.1.2 for additional discussion on implementing MCLs at the PQLs.

Millie Garcia-Serrano (Doc. #1803, SBC-044292)

[Overall, as movement is made toward better regulation and oversight of these contaminants, ASTSWMO's membership recognizes a corresponding need for research, communication, and improved understanding within the following areas:]

• finalization of PFAS-specific analytical methods to facilitate analysis of PFAS in surface water, groundwater, and other media;

EPA Response: With respect to the EPA's discussion on the validated analytical methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document. The development of new analytical methods in non-drinking water matrices is not in scope of the current NPDWR; please see section 15.1 of the EPA response in this *Response to Comments* document.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045466)

[Actions that EPA should consider to enable more laboratory capacity are:]

2. Create a forum from the scientific and laboratory communities as well as other impacted stakeholders to review and fast-track/streamline analytical methods and processes while maintaining quality.

EPA Response: With respect to alternate analytical procedures or modifications to the two EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-045385)

Analytical Methodology:

There must be leeway in the rule to utilize any current or future EPA-approved analytical methods. We believe there will be advancements in analytical technology and the rule should be flexible enough to incorporate future approved methods for PFAS analysis.

EPA Response: With respect to alternate analytical procedures or modifications to the two EPA methods approved for meeting the monitoring requirements in the final NPDWR, please see section 7.1 of the EPA response in this *Response to Comments* document.

Halff Associated Inc. (Doc. #3072-43, SBC-046366)

Good afternoon, everyone, and thank you for the opportunity to speak today. My name is Oscar Martinez. I'm with Halff Associates, Inc. I am an environmental contractor and I know we're speaking about the Clean Water and Drinking Water Act, but I also wanted to speak upon the test method, Method 1633 in particular. You know, it's for other matrices, for blood, solid waste, and the groundwater and surface water. I know that the EPA is working hard to do a multi-laboratory evaluation of the test procedure and I hope that this will propagate and that they will accept that test method. In addition to that, in order for that test method, in order for us to have clean water, we must also clean up the environment and that test method would greatly support the cleanup efforts that are currently working their way through CERCLA and RCRA as PFOS has both been, are now the public comment period for both CERCLA and RCRA also. So, I think we definitely need to make sure that those standards are in place. I know the public comment period

is coming up for the both of those also but without those cleanup standards we cannot have clean drinking water, and I'll see my time to somebody else. Thank you.

EPA Response: The EPA notes that the EPA Method 1633 is not a drinking water method and is therefore not validated for use under this final NPDWR. Additionally, cleanup actions are not in scope of this current rulemaking; for additional discussion, please see section 15.1 of the EPA response in this *Response to Comments* document.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043866)

EPA's HI MCL of one is also implementable and feasible because EPA Methods 537.1 and 533 have quantitation levels (ranging from 3 to 5 ppt) below the health-based reference levels for these four PFAS chemicals. These low quantitation levels allow public water systems (PWS) to take early action to modify treatment if monitoring data indicate concentrations of the four PFAS are approaching the health-based reference levels

EPA Response: The EPA agrees that the final MCLs are implementable and feasible in part for reasons cited by the commenter that there are two validated methods available to support the rule: with respect to the analytic requirements of the EPA methods, please see section 7.1 of the EPA response in this *Response to Comments* document. With respect to PQLs, including discussion on how the PQLs were established for the NPDWR, please see section 7.2 as well as 5.1.2 of the EPA response in this *Response to Comments* document for additional discussion on implementing MCLs at the PQLs.

Village of Woodbury (Doc. #1629, SBC-042955)

9. In order to ensure all water suppliers are measuring and reporting contaminants in the same way, we recommend that EPA methods establish standard Reporting Limits (RLs) for all labs.

EPA Response: With respect to commenter concerns on the identification of laboratory quantitation limits and/or MDLs, please see section 7.1 of the EPA response in this *Response to Comments* document.

7.2 Practical Quantitation Levels (PQLs) for Regulated PFAS

Summary of Major Public Comments and EPA Responses

As discussed in the final NPDWR preamble, PQLs reflect the level of contaminants that laboratories nationwide can reliably quantify within specific limits of precision and accuracy during routine laboratory operating conditions and are based on a multi-laboratory assessment of analytical capacity. For purposes of a NPDWR, establishing PQLs are an important consideration for feasibility of MCLs in that they ensure water systems nationwide can monitor and dependably comply with such MCLs and deliver drinking water that does not exceed the maximum permissible level.

A few commenters critiqued how the proposed PQLs were established for the rule. Some of these commenters provided feedback on the feasibility of the proposed PQL and suggested that it may be too low, resulting in recurring QC failures that will necessitate repeat sample analysis, increased cost, and reduced laboratory capacity. Other commenters suggest that lower PQLs can be attainable by larger labs with advanced analytical instruments. After review of public comment, the agency disagrees that PQLs should be established at either a higher or lower level than that proposed. Based on the multi-laboratory data acquired for the UCMR 5 rule, the UCMR 5 MRLs reflect "a minimum quantitation level that, with 95 percent confidence, can be achieved by capable lab analysts at 75 percent or more of the laboratories using a specified analytical method" (USEPA, 2022). The EPA calculated the UCMR 5 MRLs using quantitation-limit data from multiple laboratories participating in a MRL setting study. The calculations account for differences in the capability of laboratories across the country. Laboratories approved to analyze UCMR samples must demonstrate that they can consistently make precise measurements at or below the established MRLs. After reviewing data from laboratories that participated in the MRL setting study under UCMR 5 and in consideration of public comment, the EPA finds that the following MRLs set in UCMR 5 are the most appropriate PQLs for the PFAS regulated by the final NDPWR (see also CFR Table 1 to § 141.903 (f)(1)(iv) of Subpart Z in the CFR that lists the PQLs for the PFAS regulated under this action). The EPA anticipates that over time, as technology advances and as laboratories gain experience with the PFAS Methods, laboratories will generally improve their capability to measure at lower levels.

Table 1: PQLs for Regulated PFAS

Contaminant	PQL (ng/L)
PFOA	4.0
PFOS	4.0
HFPO-DA	5.0
PFHxS	3.0
PFNA	4.0
PFBS	3.0

The final NPDWR does not require laboratories to demonstrate that they can get below the PQLs in order to comply with the rule. However, the final NPDWR discusses how utilities may be able to use sample results below the PQL to determine analyte presence or absence in managing their treatment operations. Additionally, the EPA is finalizing rule trigger levels below the PQL to support the monitoring provisions of the final NPDWR. While results below the PQL may not have the same precision as a sampling result at or above the PQL, they are useful for operational purposes such as understanding that PFOA and PFOS may be present, which can inform treatment decisions and monitoring frequency. For additional discussion on PQLs, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section V of the final rule NPDWR preamble and section 5.1.2 of the EPA response in this

Response to Comments document. For additional discussion on monitoring provisions of the rule more broadly, please see section VIII of the final rule NPDWR preamble, section 8 of the EPA response in this *Response to Comments* document, and section 8.8 in this *Response to Comments* document for trigger levels, specifically.

Many commenters requested that the EPA provide clarification on how laboratories and public water systems (PWSs) should report levels below the PQLs for monitoring frequency purposes. All results at or above the trigger level (which are below the PQLs for the PFAS regulated under this NPDWR) are to be reported as numeric values and used for determining monitoring frequency. The EPA intends to provide guidance materials on this to support successful implementation of the final rule.

Individual Public Comments

Missouri Department of Natural Resources (Doc. #1563, SBC-052827)

In addition, the Department is also concerned that the proficiency testing (PT) used to approve laboratories for UCMR 5 sampling was not sufficient to confirm a viable MRL. It is not clear from information that EPA has made publicly available to date, whether any of the 8 PT studies conducted included true values "at or near" the proposed MCL. In coordination with laboratories that EPA has approved for UCMR 5 analysis, we are aware that at least six of the eight PT studies had an average concentration of 55 ppt true value. Since EPA approves laboratories based on two PT tests, it is not clear how many approved laboratories have demonstrated proficiency "at or near" the proposed MRL and MCL of 4.0 ppt. Without the opportunity to review all of the proficiency testing data, it is difficult for interested parties to adequately comment on whether or not the MRL established was based on sufficient supporting evidence that laboratories could meet low-level true values around the MCL. The Department recommends that EPA make the PT study results from UCMR5 available, so interested parties can confirm that the use of a two significant digit MCL is appropriate and that there will be sufficient laboratory capacity to meet the demand with 75% of laboratories and a 95% confidence interval.

EPA Response: With respect to concerns on the feasibility of the PQLs, including discussion on how the PQLs were established for the NPDWR, please see section 7.2 of the EPA response in this *Response to Comments* document. While proficiency testing (PT) data for the UCMR 5 LAP are not made public due to the use of PT being used as laboratory audit tools throughout the UCMR 5 monitoring cycle, PT samples are not the tool for which laboratory MRLs were confirmed, but only a blind study to demonstrate overall lab efficiency. Laboratories must submit a Method application for each method they requested UCMR approval for through the LAP, containing an extensive Initial Demonstration of Capability (IDC), outlined in Section 9.1 of each PFAS Method, along with all raw data files that support the IDC. Each application IDC contains an MRL Confirmation, based on Method criteria, to verify that each lab participating in UCMR 5 meets the MRLs listed in the UCMR 5 Rule and the UCMR 5

Laboratory Approval Manual (LAM). These files are reviewed by EPA scientists to ensure all MRLs are met. As part of the UCMR 5 LAP application process, laboratories are required to confirm they can achieve the UCMR 5 MRLs for each analyte according to the procedure in 40 CFR 141.40(a)(5)(iii) and outlined in Sections 5.3.1 through 5.3.4 and Section 6.3.5, Table 4 of the UCMR 5 LAM. For additional discussion on implementing MCLs at the PQL, laboratory and analytic considerations when setting the MCL, or use of sample results below the PQLs to help operators manage their treatment operations, please see section V of the final rule NPDWR and section 5.1.2 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-052825)

EPA requests comment on the merits and drawbacks of the target- specific HI or RPF approach.

The Department agrees the general HI approach "provides the most health protective endpoint for multiple PFAS in a mixture to ensure there would be no known or anticipated adverse effects on the health of persons." However, as noted in the federal register notice, most PFAS have a given health effect that is "poorly characterized or not studied at all." Additionally, "PFAS lack human epidemiological or experimental animal hazard and dose-response information across a broad(er) effect range thus limiting derivation of target-organ specific values." When setting a maximum contaminant level (MCL), there are more considerations than just the most health protective endpoint. EPA must also take into account the ability for water system customers to pay for the installation of treatment and the ongoing operation and maintenance costs associated with that treatment. Relying on a hazard index of "potential" unrelated additive health effects could cause an unnecessary increased cost of treatment that could cause a significant burden to small water systems who may struggle with maintaining technical, managerial, or financial capacity. Under the Safe Drinking Water Act (SDWA), the EPA must review its standards for drinking water every six years, and adhere to an anti-backsliding provision that requires each revision to drinking water standards to be at least as protective as the former regulation. Due to anti-backsliding provisions, it is prudent to set limits with known and quantifiable characterized health effects and allow the process of six-year reviews to strengthen limits, if and when, known and quantifiable health effects are shown to require a revision.

An additional drawback to the HI approach is that trigger levels under the approach are not quantifiable. EPA Method 533 allows for quality assurance/quality control (QA/QC) samples to be ±50% at or near the MRL and not ±30% for all analytes as indicated in the preamble. From EPA Method 533 Section 9.2.3.2 Evaluate Analyte Recovery "Results for analytes fortified at concentrations near or at the MRL [minimum reporting level also known as PQL] (within a factor of two times the MRL concentration) must be within 50–150% of the true value. Results for analytes fortified at all other concentrations must be within 70–130% of the true value. If the LFB [Laboratory Fortified Blank] results do not meet these criteria, then all data for the problem analytes must be considered invalid for all samples in the Extraction Batch." This difference in acceptance level identifies one of the key issues associated with proposing to set a MCL at the same value as the practical quantitation limit (PQL) or MRL. This issue is not one that can be

solved by simply lowering the PQL/MRL to 2 ppt. Based on UCMR 5 lab approvals, it is already known that more than 25 percent of laboratories nationwide will not be able to meet a PQL lower than 4 ppt with a 95% confidence interval (CI). In addition to causing more issues with laboratory capacity nationwide, the number of samples that would be rejected under the method, and therefore requiring resampling, would increase even with a ±50% Method QA/QC acceptance level. Likewise, EPA's conclusion that PWS would be notified of "J Qualified" results, which are results below the PQL/MRL, is not correct. The Laboratory Certification Manual does not currently require the reporting of data below the MRL. Therefore, "J Qualified" data would not always be available for use in MCL calculation determinations, and these compliance determinations would need to follow the SOC standard monitoring framework utilizing monitoring results that are quantifiable. For this reason, the Department recommends that EPA remove the hazard index at this time and proceed with the PFAS rule mirroring the SOC standard monitoring framework where a detection above the PQL triggers increased quarterly monitoring in lieu of a hazard index.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory considerations) and section 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. The EPA disagrees that the PQLs are not set at a reasonable quantitation level. The basis of this determination is included in section 7.2 of the EPA response in this *Response to Comments* document and includes discussion on how the PQLs were established. Please also see the EPA response to comment Doc. #1672, SBC-044908 in section 7.1 in this *Response to Comments* document for discussion on variability around sampling results. The EPA also disagrees with the commenter claims that "25% [of labs] cannot" meet the PQL; as discussed in the final rule preamble, the PQL reflects a minimum quantitation level that "with 95 percent confidence, can be achieved by capable analysts at 75 percent *or more* of the laboratories using a specified analytical method" (emphasis added). Greater than 75 percent of labs requesting participation in UCMR 5 were able to meet the PQLs/MRLs, and the EPA anticipates the number of labs available for compliance monitoring to grow.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-052948)

• DEP notes that in the example calculation on page 18665 of the preamble, which the text identifies as using the proposed PQLs as the measured values for each of the component PFAS, the numerical values entered for each PFAS are whole numbers with only one significant figure. In other words, the values used in the example calculation are 5 ppt for GenX, 3 ppt for PFBS, 4 ppt for PFNA, and 3 ppt for PFHxS. The calculated result of 1.2 for the HI is incorrect in this example, because with only one significant figure in the values used in the calculation, the result should also only have one significant figure and be 1 (not 1.0). However, as noted above, the PQLs as defined in the proposed rulemaking each contain two significant figures. This inconsistency is confusing and further supports DEP's comments that MRLs need to be clearly identified for each regulated PFAS, including the number of significant figures.

EPA Response: For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. The EPA is clarifying in the final NPDWR that the Hazard Index and individual PFAS for PFHxS, PFNA, and HFPO-DA Maximum Contaminant Level Goals (MCLGs) and MCLs are expressed to one significant figure (for additional discussion, please see section 4.3.4 of the EPA response in this *Response to Comments* document) whereas the PFOA and PFOS MCLGs and MCLs are expressed to two significant figures (for additional discussion, please see section 5.1.7 of the EPA response in this *Response to Comments* document). With respect to rounding and compliance calculations, please see section VIII.B.3 of the final rule preamble, as well as the EPA response to comment Doc. #1726, SBC-045150 in section 5.2.1 in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-052950)

• With regard to the HI calculation, DEP notes that if each component PFAS is detected at a level equal to its PQL, the HI MCLG will be exceeded. Since the MCLG and the MCL are both set at 1.0, this means that the MCL would also be exceeded. This is confirmed by the example calculation on page 18665 of the preamble to the proposed rule, which shows that the resulting HI, when each of the four component PFAS are detected at their respective PQLs, would be 1.2. DEP believes that this low level for the HI MCL may present a significant implementation challenge. DEP recognizes that if compliance with the HI MCL is determined based on an RAA of quarterly HI calculated results, this may partially alleviate this concern, since one individual quarterly result over the HI MCL would not be an immediate violation. However, as noted above, it is not clear or consistently stated in the regulatory language how compliance is to be determined.

EPA Response: For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. The EPA clarifies for the commenter that the final NPDWR expresses the Hazard Index MCLG and MCL to one significant figure. Therefore, if each component PFAS is found at levels equal to its PQL, then the Hazard Index MCL will not be exceeded (assuming the results are the same after four quarterly samples). This is because the concentrations of each of the four PFAS at their PQLs would equal a Hazard Index of 1.2015 (unrounded), which would not be in violation of the MCL as this result would be rounded to a Hazard Index value of 1. Additionally, as the commenter notes, compliance is based on running annual averages to allow for additional operational flexibility and slightly elevated fluctuations. The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis with respect to the Hazard Index MCL, please see section 5.2 of the EPA response in this *Response to Comments* document. For additional discussion on how compliance and violations are assessed in the final rule, please see section VIII (Monitoring and Compliance Requirements) of the final rule preamble, Subpart Z § 141.905

(Violations) of the Code of Federal Regulations (CFR), and section 8.2 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-052951)

• As previously noted, setting an MCL at a level such that a detection at the PQL would cause an MCL exceedance is not feasible. As noted above, detection of each of the HI PFAS at its respective PQL would cause an exceedance of the HI MCL according to the proposed regulation. This would not allow a water system to demonstrate compliance with the HI MCL unless one or more components are either not detected or detected below the PQL. However, as already noted, detections below the PQL should not be used for compliance determinations or other regulatory purposes and should be treated the same as non-detections. This would complicate a water system's ability to demonstrate compliance, and it also would complicate the public's understanding of this MCL. MCLs should be set at levels that allow for demonstration of continued compliance by allowing a buffer between the MCL and levels that are considered to be accurate and precise detections. The HI MCL should be set at a level that is higher than the MCLG of 1.0.

EPA Response: Please see the EPA response to comment Doc. #1626, SBC-052950 in section 7.2 of this *Response to Comments* document.

Mike Pettit (Doc. #1542, SBC-043349)

Testing Limitations

It is also important to consider the feasibility of the proposed lab analyses, specifically the requirement to monitor PFAS contaminants at a level as low as 4 parts per trillion (ppt). While this level may be attainable by larger labs with advanced analytical instruments, it may not be feasible for smaller labs with limited resources and capabilities. These labs may require significant investments in technology and training, which may not be feasible for many communities that rely on them for testing and analysis. Moreover, setting such a low threshold may also lead to false positives, as the sensitivity of testing instruments may not be sufficient to distinguish between trace amounts of PFAS contamination and background levels of naturally occurring organic compounds. This could result in unnecessary costs and resources being expended on remediation efforts that are not actually addressing a significant health risk. It is vital to note that testing at 4 ppt levels for PFAS compounds presents several challenges, particularly in terms of contamination and testing limits. PFAS compounds are ubiquitous, and there are numerous sources of contamination, including laboratory equipment, sample containers, and the environment. Therefore, it is crucial to maintain strict protocols to minimize contamination and ensure accurate test results. At such low levels, the analytical instrumentation used in the testing process can be pushed to its limit, and the probability of false positives or negatives increases. Additionally, some PFAS compounds have similar molecular structures, making it difficult to differentiate between them. As a result, the accuracy and reliability of test

results can be impacted, leading to potential errors in data interpretation and subsequent decision-making. Another significant challenge with testing for PFAS at such low levels is the limitations of the instrumentation used for analysis. Many instruments are simply not capable of reliably detecting PFAS at the parts-per-trillion (ppt) level without introducing significant levels of error into the analysis. For example, liquid chromatography-mass spectrometry (LC-MS), which is commonly used to analyze PFAS, can be highly sensitive but may also be subject to interference from matrix components, resulting in false positive or negative results. In addition, matrix effects can lead to variability in the measurements obtained, making it difficult to achieve reliable and consistent results. Furthermore, even if an instrument is capable of detecting PFAS at the ppt level, there is still a risk of contamination. Trace amounts of PFAS can be present in laboratory equipment, reagents, and even the environment, leading to false positives and making it difficult to distinguish between true detection and contamination. It is therefore vital for the EPA to consider the practicality and feasibility of the proposed lab analyses requirements, and to work with smaller labs to ensure that they have the necessary resources and support to meet these standards, or to develop alternative strategies that are both effective and feasible. This would require a collaborative effort from all stakeholders, including regulatory agencies, industry groups, and local communities, to ensure that the health and safety of all Americans are protected, while also promoting sustainable economic growth and development.

EPA Response: The EPA disagrees that the PQLs are not set at a reasonable quantitation level. For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory considerations) and section 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document. Regarding commenter concerns about laboratory testing and potential contamination issues, please see section 8.7 of the EPA response in this *Response to Comments* document. The EPA further notes that neither methods 533 nor 537.1 ver. 2.0 have inherent QC issues when explicitly followed (please see section 7.1 of the EPA response in this *Response to Comments* document for additional discussion).

New York Section American Water Works Association (NYSAWWA) (Doc. #1591, SBC-042370)

5. Messaging to consumers becomes complicated if a water supply has records of results that are below the PQL when labs provide results to their own internal limits and not the EPA's value of 4 ppt. When issuing Consumer Confidence Reports (CCRs), a supplier may be accused of lacking transparency should the results be stated as zero or "below detection" when the results are less than 4 ppt, despite having publicly recoverable records of reported values?

6. We are concerned that with the MCL set at the PQL, it suggests that USEPA will revise the MCL as soon as lab methods improve and a lower PQL is attainable. Thus, those systems that

are observing current trigger level concentrations could expect to be in violation of a lower MCL in the near future, making long range planning difficult.

EPA Response: With respect to commenter concerns on Consumer Confidence Reports (CCRs) and communicating results to consumers, for the purposes of reporting results in CCRs, "detected" is defined in § 141.151(d) to be at or above the levels prescribed in § 141.902(a)(5). The EPA agrees that reporting results in CCRs above the trigger level, or one-half of the MCL as defined in the final rule, promotes transparency for consumers. Consistent with the EPA response in section 7.2, results below the PQL can be useful in identifying that PFAS contaminants are likely present and can therefore help consumers make informed decisions related to their drinking water and can take additional actions, if appropriate. For additional discussion on CCR reporting requirements, see section 9.1in this *Response to Comments* document. For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. For additional discussion on how the EPA considers evolving science and revising NPDWRs, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

New York Section American Water Works Association (NYSAWWA) (Doc. #1591, SBC-042367)

Jennifer McLain, Director

Office of Ground Water and Drinking Water

US Environmental Protection Agency

1200 Pennsylvania Avenue, NW

Mail Code: 4601M

Washington, DC 20460

Re: Docket ID# EPA-HQ-OW-2022-0114-0027

Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

Comment Submittal

Dear Director McLain,

The New York Section American Water Works Association (NYSAWWA) represents drinking water utilities across New York State, providing safe, reliable, and affordable water to over 15 million residents. Our core principle is the protection of public health, and we take pride in New York State's leadership role in advancing these initiatives. Our diverse membership consists of leading experts in drinking water treatment, engineers responsible for designing and constructing our systems, academics at the forefront of innovative research, and pioneers driving the

development of emerging technologies. Together, we ensure that New York's water supply remains of the highest possible quality now and in the future. On behalf of NYSAWWA membership, I am writing to provide our comments and concerns regarding the recently proposed regulations by the United States Environmental Protection Agency (USEPA) regarding per- and polyfluoroalkyl substances (PFAS). As responsible water suppliers committed to providing safe and reliable drinking water to our communities, we appreciate the opportunity to contribute to the rulemaking process and share our perspectives on this critical issue.

We have carefully reviewed the proposed regulations and offer the following comments and recommendations:

1. We note that UCMR 5 data is only required to report down to the PQL of 4 ppt (for PFOS/PFOA specifically). Thus, for water that is at or below the proposed MCL and/or PQL, the data generated provides no actionable information relative to the extent of PFOS/PFOA. The UCMR effort appears in conflict with the sentiment expressed by EPA in the quotation below.

"This suggests the overwhelming majority of laboratories with the necessary instrumentation to support PFAS monitoring have the capability to provide screening measurement results above the proposed trigger level of 1/3 of the MCL (i.e., 1.3 ppt for PFOS or PFOA). Hence, a utility may use the lower-level measurements as a warning that they may be nearing the PFOA and PFOS MCLs of 4.0 ppt prior to exceeding them and can make informed treatment decisions about managing their systems (e.g., replacing GAC)."

We believe this is a key limitation to the development of the proposed rule. Bad (or limited) data does not produce good regulation.

2. We are concerned that establishing an MCL at the PQL could encourage poor practices. It becomes advantageous for water supplies to utilize labs who report only at the PQL (as is ongoing for UCMR 5 in accordance with USEPA direction). By doing so, water supplies who may have concentrations hovering below the PQL, but in detectable range by some labs could avoid reporting levels of PFOS/PFOA by simply reporting that results are below detection limits because they are utilizing a lab that can only report to the PQL.

EPA Response: The EPA disagrees that the PQLs are not set at a reasonable quantitation level. For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. The agency disagrees that the UCMR efforts conflict with the final NPDWR. This is because utilities may be able to use data from UCMR 5 sampling to satisfy initial monitoring requirements in the final NPDWR. With respect to commenter concerns that establishing an MCL at the PQL would "encourage poor practices," the agency also disagrees. The basis of this decision is discussed in greater detail in the EPA's response in section 8.8 on rule trigger levels and in section XIII of the final rule preamble, where water systems must demonstrate they are below the final rule trigger levels to be eligible for reduced triennial monitoring (i.e., utilities who only go to labs who can go as low as the MCL will not be eligible for reduced monitoring).

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042982)

5. EGLE DWEHD encourages EPA to consider including PQLs of 2.0 ng/l, consistent with Michigan's SDWA, considering these have been successfully employed since 2020.

6. Laboratory performance evaluation tolerances (70-130%) are concerning given the PQL = MCL for PFOS and PFOA. It seems there is no margin for error at this level. At the MCL for PFOS (4 ppt), the reported value could range from 2.8 to 5.2 ppt and be within QC tolerances but result in the sample being in or out of compliance, respectively.

EPA Response: For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. With respect to implementation concerns around variability around sample results, please see the EPA response to comment Doc. #1672, SBC-044908 in section 7.1 in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043650)

3. Linking MCLs to PQLs: The MCLs for PFOA and PFOS are established at their respective practical quantitation limits (PQLs) usings Methods 533 and 537.1. However, improved laboratory performance and/or the development of more sensitive methods could lower the PQLs, which could conceivably open the door for lowering the MCLs, potentially resulting in thousands of treatment systems inappropriately designed/sized.

4. PQLs are not referenced in USEPA Methods 533 and 537.1. Instead, the EPA refers to the "Lowest Concentration Minimum Reporting Level (LCMRL)," which represents the lowest true concentration for which recovery is predicted to fall between 50% and 150%, at a confidence level of 99%. In USEPA Method 533, the LCMRL is 3.4 ng/L for PFOA and 4.4 ng/L for PFOS; while in Method 537.1, LCMRL is 0.82 ng/L for PFOA and 2.7 ng/L for PFOS (Table 7). It is unclear if/how these LCMRLs lead to PQLs 4.0 ng/L for PFOA and 4.0 ng/L for PFOS which inform the proposed MCLs. It is recommended that this relationship be explained more clearly.

Table 7: Lowest Concentration Minimum Reporting Level (LCMRL) Between USEPA Methods

[Table 7: See Docket ID EPA-HQ-OW-2022-0114-1602]

EPA Response: For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. For additional discussion on how the EPA considers evolving science and revising NPDWRs, please see section 5.1.6 of the EPA response in this *Response to Comments* document.

Minnesota Department of Health (MDH) (Doc. #1610, SBC-042853)

Reevaluate the PQLs to determine if they can be lowered, especially for PFOS and PFOA, based on current laboratory RLs and standards used for calibration.

EPA Response: For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043109)

In Table 19, EPA used the term PQL as a regulatory term which is confusing to laboratories as most laboratories use the PQL as a Reporting Limit equal to the low calibration point, which in Method 533 is 2 ng/L. The methods use the MRL term instead of PQL. However, no MRLs are published in the methods. The methods do publish LCMRLs, but these values do not otherwise appear to be used in the methods.

EMC believes the MRL is the lowest concentration at which quantitative data can be reported and recommends the Agency use a different term in Table 19, such as Compliance Level, Consumer Confidence Reporting Level, or Detection Limit for Consumer Confidence Reporting. This way, a Public Water System (PWS) would not have to unnecessarily create concerns for their consumers, unless the MCL or HI was exceeded.

(Note: If Gen X, PFNS, and PFHxS are all not detected, PFBS could be as high as 600 ng/L and the HI would be below 1.0.)

EMC requests the Agency consider using consistent terminology for both the final rule and the methods and specifically requests the following:

• Include Method Detection Limit requirements in 533 and update the MDL section of 537.1.

• Publish MRLs in Methods 537.1 and 533.

• Replace PQL with Compliance Level, Consumer Confidence Reporting Level, or Detection Limit for Consumer Confidence Reporting in the final rule, or some other term that is not PQL.

EPA Response: For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. With respect to commenter concerns on the identification of laboratory quantitation limits and/or MDLs, please see section 7.1 of the EPA response in this *Response to Comments* document. The multi-laboratory Lowest Concentration Minimum Reporting Limit (LCMRL) calculation, used to generate the UCMR 5 MRLs, is a statistical calculation to determine an MRL value where the 75th percentile of laboratories can meet the 50-150 percent accuracy threshold. This is described in detail in Appendix A of USEPA (2010): An MRL is set after a statistical determination that 75 percent or more of laboratories will be able to meet that level with a 95 percent confidence interval (CI). The UCMR 5 MRLs

are not intended to represent the lowest achievable measurement level an individual laboratory may achieve. These MRLs are derived using the quantitation level results from multiple laboratories participating in an analytical study and account for differences in the capability of laboratories across the country. Note that EPA Methods 533 and 537.1, rev. 2.0 only require the confirmation of an MRL, whose concentration is determined based on the intended use of the method.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044881)

Practical Quantitation Levels (PQLs) / Reporting Levels

• DEP recommends that EPA fully evaluate whether PQLs should be set any lower than 4.0 parts per trillion (ppt) for any of the PFAS included in the proposed rule. PQL is defined in 40 CFR [sec] 141.2 as "the minimum concentration of an analyte (substance) that can be measured with a high degree of confidence that the analyte is present at or above that concentration." This definition makes the PQL essentially equivalent to a repo1iing level. As part of our state rulemaking process, DEP conducted a survey of laboratories accredited in Pennsylvania for PFAS analysis. While many laboratories indicate that they may be able to detect and report PFAS compounds to approximately 2 ppt, the potential incidence of quality assurance (QA)/ quality control (QC) failures increase as repo1iing limits decrease. EPA states as much in the preamble to the proposed rulemaking, on page 18680: "Establishing a quantitation level that is too low may result in recurring QC failures that will necessitate repeating sample analyses, increase costs, and potentially reduce laboratory capacity." DEP has experience with this situation. During implementation of the DEP Bureau of Safe Drinking Water's PFAS Sampling Plan used to generate occurrence data and inform our state PFAS MCL rulemaking process, we utilized the services of two different laboratories. The lab with lower reporting levels, at approximately 2 ppt, experienced significantly more QC failures, and each location with an affected sample needed to be resampled and reanalyzed. The other lab used approximately 4 ppt as a reporting limit and had no QC failures. It is imperative to consistently define across all laboratories what is and is not a detectable level; using a PQL less than 4.0 ppt may not be feasible. EPA should investigate the incidence of QC failures at lower reporting levels before considering lowering the PQLs.

• DEP requests clarification on what levels are to be reported when a PFAS is detected below its respective PQL. DEP also suggests that an MRL should be clearly identified for each regulated PFAS and that MRL should be defined in [sec] 141.2. In [sec] 141.XX(a)(9), the proposed rule states that "a reportiable detection means at or above one-third of the levels described in the table outlined in ..." As noted earlier, DEP has identified inconsistencies and inaccuracies in the cross references and citations but believes that this table is referring to the PQLs. This seems to indicate that any detection over one-third of a PQL, or 1.3 ppt for PFOA or PFOS, would be reported as such. However, with the PQL set at 4.0 ppt for PFOA and PFOS, detections below that level would not be considered accurate or precise and would be counted as zero in the RAA calculation. It is critical for EPA to clarify what levels are to be repo1ied.

• Building on the previous comment, DEP believes that the definition of PQL suggests that detections below the PQL - or MRL if that term is defined and utilized - should be reported as not detected or zero since a detection below that level is not expected to be an accurate representation of the actual concentration. Results reportied at or above one-third the PQL and up to the PQL would be qualified data and would not be legally defensible as a true detection. Detections below the PQL should be reported as not detected or zero.

• DEP also believes it is confusing to say a reportable detection is "at or above one-third of the levels described in the table" instead of clearly listing the actual numbers for reporting. As noted earlier, the table referenced by [sec] 141.01(b)(2)(i) appears to be intended to list reportiing limits, but that table is missing from the proposed rulemaking. DEP cannot comment on information that is missing from the proposed rulemaking. Again, DEP believes this is an importiant component to include in the rulemaking to clarify reporting limits.

• Reporting levels for calculating MCL compliance and determining monitoring frequencies must be consistently applied and clearly defined. It is not implementable or appropriate to have different reporting levels for use in different parts of the proposed regulation.

MCLs and Trigger Levels for PFOA and PFOS

• DEP is concerned that the proposed MCLs may not be feasible and may result in significant implementation challenges. More specifically, DEP recommends that the MCLs for PFOA and PFOS should not be set at levels equal to the PQL. As noted above, PQL is defined in 40 CFR [sec] 141.2 as "the minimum concentration of an analyte (substance) that can be measured with a high degree of confidence that the analyte is present at or above that concentration." EPA-approved methods, Method 533 and Method 537.1, allow+/- 30% recovery for QC samples. In addition, the proposed regulation requires+/- 30% recovery for performance evaluation (PE) samples. By setting the MCLs equal to the PQL, if QC is biased high by up to 30%, which is acceptable, a low level detection in a sample that is just over the PQL/MCL may also be biased high. With a PQL of 4.0 ppt for PFOA and PFOS and a+/- 30 % QC allowance, any detection up to 5.2 ppt is within the acceptable analytical margin of error (30% of 4.0 is 1.2, and 4.0 +1.2 = 5.2). Therefore, with the PQLs set at 4.0 ppt, the lowest the MCLs should be set at is 6 ppt. By setting the MCLs for PFOA and PFOS at a level equal to the PQL, some water systems may exceed the MCL with low-level detections that are within the margin of analytical error. This is not a feasible level for implementation, and it presents significant implementation challenges.

EPA Response: For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. Further, the agency agrees that results below the PQL should not be used for compliance calculations (for discussion on how compliance and violations are assessed, please see section 8.2 of the EPA response in this *Response to Comments* document). The agency disagrees that “reporting levels for calculating MCL compliance and determining monitoring frequencies must be consistently applied and clearly defined.” The specific reporting levels for calculating MCL compliance and determination of monitoring

frequency is defined in the regulatory text of the final NPDWR; please see CFR 141.903 and 141.904 of the final NPDWR for regulated PFAS for compliance requirements and reporting and recordkeeping requirements, respectively. Furthermore, while results below the PQL, such as trigger levels, may not have the same precision as a sampling result at or above the PQL, they are useful for operational purposes such as understanding that PFOA and PFOS may be present, which can inform treatment decisions and monitoring frequency. For additional discussion on implementing MCLs at the PQL or use of sample results below the PQLs to help operators manage their treatment operations, please see section V of the final rule NPDWR preamble and section 5.1.2 of the EPA response in this *Response to Comments* document). With respect to implementation concerns around variability around sample results, please see the EPA response to Doc. #1672, SBC-044908 in section 7.1 of this *Response to Comments* document. The EPA provided more specificity on trigger levels in CFR § 141.902(a)(5).

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043311)

In Table 19, EPA used the term PQL which is confusing to laboratories as most laboratories set the PQL as their MRL equal to the low calibration point, which in Method 533 is 2 ng/L. The methods use the MRL term instead of PQL. However, no MRLs are published in the methods. The methods do publish LCMRLs, but these values do not otherwise appear to be used in the methods. EMC believes the MRL is the lowest concentration at which quantitative data can be reported and recommends the Agency use a different term in Table 19, such as Compliance Level, Consumer Confidence Reporting Level, or Detection Limit for Consumer Confidence Reporting. This way, a PWS would not have to unnecessarily create concerns for their consumers, unless the MCL or HI was exceeded.

(Note: If Gen X, PFNS, and PFHxS are all not detected, PFBS could be as high as 600 ng/L and the HI would be below 1.0.)

EMC requests the Agency consider using consistent terminology for both the final rule and the methods and specifically requests the following:

• Include Method Detection Limit requirements in 533 and update the MDL section of 537.1.

• Publish MRLs in Methods 537.1 and 533.

• Replace PQL with Compliance Level, Consumer Confidence Reporting Level, or Detection Limit for Consumer Confidence Reporting in the final rule, or some other term that is not PQL.

EPA Response: Please see the EPA response to comment Doc. #1625, SBC-043109 in section 7.2 in this *Response to Comments* document.

NCASI (Doc. #1651, SBC-043225)

2.0 Laboratory limitations for Proposed Regulatory Limits and Action Levels

It is not clear that drinking water providers are able to manage a process to the levels of a Practical Quantitation Level (PQL), as EPA has assumed in their evaluation. Due to variability in samples, sampling technique, laboratories, etc., managing a drinking water treatment process for a variety of water treatment facilities (e.g., ranging from small private to large municipal) to the quantification level may be operationally infeasible. Drinking water providers manage risk by not only restricting concentrations to that of the MCLs, but also rely on action levels well below the MCLs, to provide some level of additional operational certainty. Setting MCLs at the PQL does not allow operators to do this.

The proposed rulemaking indicates trigger levels at 1/3 the MCLs, which equates to 1.3 ppt for PFOA/PFOS and a 0.3 HI for other listed PFAS. This means that action levels are not able to be reliably quantified. EPA recognizes the challenges of finding laboratories that can provide accurate quantitation below 4 ppt: "EPA anticipates there would not be sufficient laboratory capacity if the quantitation level were set at a level below 4.0 ppt. The rigorous laboratory certification and quality assurance/quality control (QA/QC) procedures could limit the number of laboratories that can achieve lower quantitation levels and many water systems would not be able to secure the services of laboratories that are capable of consistently providing precise and accurate quantitation of concentrations of PFOA and PFOS at levels lower than 4.0 ppt." (pg. 18667).

EPA Response: The EPA disagrees that the PQLs are not set at a reasonable quantitation level. With respect to these concerns on the feasibility of the PQLs, including discussion on how the PQLs were established for the NPDWR, please see section 7.2 of the EPA response in this *Response to Comments* document. For additional discussion on implementing MCLs at the PQL or use of sample results below the PQLs to help operators manage their treatment operations, please see section V of the final rule NPDWR and section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043711)

PQLs

The current proposal sets the practical quantitation limit (PQL) at 4.0 ppt. PQLs are the lowest concentration of analyte that can reliably be measured within specified precision and accuracy during routine laboratory conditions. Aurora Water agrees with a PQL of 4 ppt and believes their in-house instrument should be able to reliably achieve this level. Aurora strongly disagrees with the consideration of using the proposed trigger level value instead of zero for any samples below the PQL when calculating the running annual average to determine compliance. Any data below the PQL is not considered reliable and would be extremely unfair to water systems if they must report anything below what is considered accurate for compliance calculations. However, EPA will use sample results below the PQL to determine water system monitoring schedules. The monitoring trigger level is set at 1.33 ppt, which is far below what has been determined to be

reliable measurement levels. Since any measurement below 4 ppt has been determined to be unreliable, Aurora Water argues that systems should not be required to report anything below that level or be held to any levels below that PQL. To resolve this PQL level issue Aurora Water is proposing an MCL of 10 ppt and a trigger level of 4 ppt.

EPA Response: For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. Further, the agency agrees that results below the PQL should not be used for compliance calculations (for discussion on how compliance and violations are assessed, please see section 8.2 of the EPA response in this *Response to Comments* document). For additional discussion on implementing MCLs at the PQL or use of sample results below the PQLs to help operators manage their treatment operations, please see section V of the final rule NPDWR preamble and section 5.1.2 of the EPA response in this *Response to Comments* document.

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045943)

COMMENT 7 — NEITHER METHOD 533 OR METHOD 537.1 COULD ADEQUATELY OR RELIABLY MEASURE THE PROPOSED MCLS, PQLS, OR TRIGGER LEVELS.

EPA has not properly applied the meaning of the information provided in Method 533, 537.1 or UCMR5 to set the trigger level, Practical Quantitation Level ("PQL"), and MCL. Typically, the trigger level is less than the PQL, which is less than the MCL.

The trigger level, or the point where regulated entities industries need to take action, is generally set at or above the minimum reporting level ("MRL"), which is the lowest highly accurate reporting value that 75% of laboratories can satisfy. Typically EPA has set the trigger level at the MRL with the exception of lead. [FN26: HDR, One Water: Exploring Interconnectivity – Safe Drinking Water Act Wall Chart (17th Edition 2022) (https://www.hdrinc.com/sites/default/files/2022-05/hdr-sdwa-wall-chart-2022.pdf)] This makes sense because regulatory requirements should be based on a sound scientific determination that the sample is accurate and that the analyte is present.

The PQL is the minimum concentration at which an analyte can be measured with a high degree of confidence that the analyte is present or above the given concentration. The PQL is determined by performing a linear regression of the proficiency data or multiplying the Minimum Detection Level ("MDL") by between 5 and 10. [FN27: Analytical Feasibility Support Document for the Six-Year Review of Existing National Primary Drinking Water Regulations (Reassessment of Feasibility for Chemical Contaminants). EPA-815-R-03-003; EPA Office of Ground Water and Drinking Water: Washington, DC; 20003; https://www.epa.gov/sites/default/files/2014-12/documents/815b09003.pdf] The PQL is higher than the Minimum Detection Level (and thus the MRL) to account for variability and uncertainty that can occur near the Minimum Detection Level. In other words, the PQL is higher because it ensures that the measurements are reliable.

The MCL is informed by the PQL and is generally suggested to be 20% greater than the PQL. At the minimum, the PQL and MCL can be the same.

The method the EPA used to determine the PQL is improper and setting the PQL at the MRL will lead to imprecise results.

In creating this rule, EPA did not properly set the PQLs. Instead of setting the PQL at 5-10x the MDL for each compound, the EPA took the MRL from UCMR 5 and converted that to the PQL. This action is improper because it ignores the precision component of the data collection and does not indicate that the samples are repeatable. Furthermore, EPA has not pointed to an instance where it used the MRL as the PQL previously, nor has it explained how this action is permissible.

The EPA only addresses concerns with the PQLs by asserting that instrumentation is sufficient to measure these low proposed PQLs. Although the measurements could be accurate at this level, they are not precise or reliable. Because the MRL is not a level for which the results are repeatable, the proposed PQL is arbitrary and unsupported by the EPA's own documentation.

If the proper PQL calculation methods are used, neither Method 533 and Method 537.1 support the proposed PQLs.

The information available to the public on Method 533 does not support the claim that this method could determine if the concentrations of PFOA, PFOS, PFNA, PFBS, PFHxS, and HFPO-DA would meet the standards proposed by this rule. Specifically, Method 533 does not include an MDL or proficiency data which could be used to calculate the PQL. Therefore, there is insufficient information to determine if the proposed PQL is proper given the parameters of Method 533.

Method 537.1 includes MDLs for the 6 PFAS regulated under this proposed rule. Given the general rule of multiplying the MDL by between 5 to 10 to calculate the PQL, only the PQL for PFOA is within EPA's approved range as shown by the table below. For this reason, the proposed PQLs for PFOS, PFNA, PFBS, PFHxS, and HFPO-DA are arbitrary because they are calculated contrary to EPA's established methods. The proposed MCL for PFOS is also improper because it is also below EPA's approved range for PQLs.

[Table 2: See Docket ID EPA-HQ-OW-2022-0114-1714]

EPA Response: The EPA disagrees that the PQLs are not set at a reasonable quantitation level and further disagrees that they are "not precise or reliable" and that the PQLs were calculated "contrary to EPA's established methods." The reason for this is that the EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory

considerations) and 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

Washington County Department of Public Health and Environment (Doc. #1739, SBC-043568)

[To address the issues described here, EPA should make one of the following changes to the proposed NPDWR for PFAS:]

• Reevaluate the PQLs to determine if they can be lowered, especially for PFOS and PFOA, based on current laboratory RLs and standards used for calibration.

EPA Response: For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document.

Wisconsin Department of Health Services (Doc. #1823, SBC-044280)

Candidate reference doses considered in development of the proposed PFOA and PFOS maximum contaminant levels (MCLs) include health-based developmental outcomes, the Health-Based Water Concentrations (HBWCs) for PFNA and PFBS are based on developmental effects, and HFPO-DA and PFHxS are associated with similar toxicological endpoints as well. Because of this, exposures on timescales shorter than chronic exposure durations matter. Given that technical limitations already informed the selection of the practical quantitation limits (PQLs), exceedances of the PFOA and PFOS MCLs will be well above established health-based thresholds.

EPA Response: Compared to MCLs, "health-based thresholds," (i.e., MCLGs) do not account for analytic feasibility and can therefore be set at a level below these thresholds. The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 (for laboratory considerations) and section 5.1.4 (for treatment considerations) of the EPA response in this *Response to Comments* document.

American Council of Independent Laboratories (ACIL) (Doc. #1692, SBC-044737)

2. Terminology Used in Proposed Regulation

ACIL members have concerns over some of the terms used in the proposed regulation and in EPA Methods 533 and 537.1.

Method 537.1 uses an obsolete definition for Detection Limit. In 2017, as part of a Clean Water Act Method Update Rule, the Agency changed its previous definition to reflect the latest science.

Because the MDL is widely recognized as the lowest concentration that indicates detection, and because the proposed rule would require reporting values below the MRL, ACIL recommends the MDL be included in both methods, but updated to the current definition.

The Agency should employ the definition of Method Detection Limit found in 40 CFR Part 136, Appendix B (i.e., "The minimum measured concentration of a substance that can be reported with 99% confidence that the measured concentration is distinguishable from method blank results.").

In Table 19 and in Section VI, EPA used the term practical quantitation limit or PQL as the ''lowest concentration of an analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory operating conditions'' (USEPA, 1985). This is a subjective limit. The ACIL would prefer the limits to be stated in terms of objective, documented limits such as the Lowest Concentration Minimum Reporting Limit (LCMRL).

EPA Response: For discussion on PQLs for the PFAS regulated by the final NPDWR, including discussion on how the PQLs were established, please see section 7.2 of the EPA response in this *Response to Comments* document. With respect to commenter concerns on the identification of laboratory quantitation limits and/or MDLs, please see section 7.1 of the EPA response in this *Response to Comments* document.

8 Monitoring and Compliance Requirements

8.1 General Monitoring Requirements

Individual Public Comments

Groundwater Resources Association of California (Doc. #1831, SBC-045349)

[Based on our review of this document, GRA offers the following general comments and recommendations for consideration by the EPA as they finalize these regulations:]

2. Equity, Affordability, and Resource Constraints Considerations for Community and Small Water Systems: California has approximately 2900 Community Water Systems [FN3: Community Water System (CWS): a public water system that serves at least 15 service connections used by yearlong residents or regularly serves at least 25 yearlong residents of the area served by the system. (California Health & Saf. Code, § 116275, subd. (i).)] (CWS), 1300 Small Community Water Systems [FN4: Small Community Water System: a CWS that has no more than 3,300 service connections or a yearlong population of no more than 10,000 persons. (California Health & Saf. Code, § 116275, subd. (z).)] (SCWS), and over 300,000 known domestic wells [FN5: 5https://www.ppic.org/blog/consolidating-small-water-systems-is-a-springboard-to-water-justice/ https://www.waterboards.ca.gov/drinking_water/certlic/drinkingwater/documents/needs/2023needsassessment.pdf]. More than half of the CWS/SCWS have fewer than 100 connections [FN2: https://www.waterboards.ca.gov/pfas/drinking_water.html; https://pubs.er.usgs.gov/publication/fs20213028]. CWS/SWS providers suffer from limited staffing, are run by volunteer boards, and their rates do not cover long-term improvements [FN2: https://www.waterboards.ca.gov/pfas/drinking_water.html; https://pubs.er.usgs.gov/publication/fs20213028]. As such, it will be challenging for these water systems and agencies to comply with the proposed annual sampling requirements without significant external funding and resources. These CWS/SCWS may also have limited access to analytical laboratories that meet the standards established in the regulations, which may impact their ability to demonstrate compliance with the proposed regulations.

EPA Response: Regarding the compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document. In addition, compliance monitoring frequency is based upon previous sampling results. Based on available occurrence information (see sections III.C and VI of the final rule preamble), the agency anticipates that many water systems will not be required to conduct monitoring more often than once every three years as they will not demonstrate levels of PFAS at or above rule trigger levels (see section 8.8 of the EPA response in this *Response to Comments* document for more information about those levels). For those that do have levels of regulated PFAS at or above the rule trigger levels, sampling must occur more frequently to ensure adequate public health protection and an understanding of current levels of regulated PFAS. For discussion of laboratory availability and

capability, please see section 5.1.2 of the EPA response in this *Response to Comments* document. The EPA intends to make resources available to support rule implementation. Additionally, as noted in section II.E of the preamble to the final rule, funding under the Infrastructure Investment and Jobs Act (IIJA), often referred to as the Bipartisan Infrastructure Law (BIL), will assist many disadvantaged communities, small systems, and others with the costs of addressing emerging contaminants, like PFAS, when it might otherwise be cost-challenging. Additionally, to support BIL implementation, the EPA is offering water technical assistance (WaterTA) to help communities identify water challenges and solutions, build capacity, and develop application materials to access water infrastructure funding (USEPA, 2023).

El Paso Water (Doc. #1757, SBC-044530)

We must oppose requirements for more stringent testing that is not reliable and produces no additional benefits for the consumer.

EPA Response: The EPA disagrees with the commenter that monitoring for regulated PFAS is not reliable and produces no additional benefits for the consumer. Please see sections 8.1.1. and 8.1.2 of the EPA response in this *Response to Comments* document regarding initial monitoring requirements and compliance monitoring requirements, respectively. These monitoring requirements ensure that public water systems (PWSs) are complying with the regulated PFAS Maximum Contaminant Level (MCLs) and that consumers of PWS are aware of the levels of regulated PFAS in their water systems.

Skippy McMuffins (Doc. #2110, SBC-046217)

We live in Alabama and want PFAS tested, reported, and removed. The water testing lab in Montgomery was closed. This is environmental racism. Do better ADPH.

EPA Response: The PFAS National Primary Drinking Water Regulations (NPDWR) will require all community water systems (CWSs) and non-transient, non-community water systems (NTNCWSs) to conduct monitoring of regulated PFAS to ensure compliance with the final MCLs. Please see sections 8.1.1 and 8.1.2 of the EPA response in this *Response to Comments* document regarding the final rule initial monitoring and compliance monitoring requirements, respectively. If the compliance monitoring results exceeds the final MCLs, water system will be required to take action to address regulated PFAS and reduce concentrations to at or below the MCLs. The final rule will also require reporting under the Consumer Confidence Report (CCR) rule to inform customers of levels of regulated PFAS (see section 9.1 of the EPA response in this *Response to Comments* document). The State of Alabama current sampling efforts are outside of the scope of this regulation.

8.1.1 Initial Monitoring Requirements

Summary of Major Public Comments and EPA Responses

The majority of comments the EPA received on the proposed initial monitoring requirements related to the number of initial samples systems would be required to collect and the intervals between required samples. Most commenters were generally supportive of the EPA's proposed initial monitoring requirements, including the flexibilities to use previously-acquired monitoring data to satisfy some or all the initial monitoring requirements and, for those groundwater systems serving 10,000 or fewer that do not have this data, that they be required to only collect two samples at each entry point to the distribution system (EPTDS) to satisfy initial monitoring requirements. For a discussion of comments and final rule requirements specific to the use of previously-acquired monitoring data to satisfy the initial monitoring requirements see section VIII.C of the preamble and section 8.3 below.

While most commenters were supportive of the number of initial monitoring samples the EPA proposed, a few commenters indicated they thought the EPA should not allow the flexibility for groundwater systems serving 10,000 or fewer to collect only two samples. Instead, they suggested that the EPA require quarterly samples to be collected by all systems to meet initial monitoring requirements, suggesting that this would be fully consistent with the Standardized Monitoring Framework (SMF) framework for other synthetic organic contaminant (SOCs). A couple of these commenters suggested that there are no data demonstrating that smaller systems are less likely to have elevated levels of PFAS than large systems or that groundwater systems are less likely to have elevated levels of PFAS than surface water systems. Additionally, other commenters generally suggested that two samples may not generate enough data to accurately capture the level of PFAS in drinking water and any potential seasonal variability. Related to potential seasonal changes in measured PFAS concentrations, some commenters from state agencies indicated that they have not observed seasonal variations in concentrations of PFAS measured by groundwater systems, whereas other commenters suggested the opposite and that they have seen changes seasonally based on their state's monitoring data.

The EPA disagrees with commenters that suggest two samples for small groundwater systems would not accurately capture the baseline level of regulated PFAS in drinking water. The EPA determined the initial monitoring requirements based on both source water type and system size considerations. First, from a national-level perspective, the EPA's model for estimating national PFAS drinking water occurrence (see section VI.E of the preamble) indicates that, regardless of source water type, small systems generally have lower mean PFAS concentrations and lower within-system variability than large systems. Further accounting for source water type, as compared to all groundwater systems, all surface water systems potentially have a larger number of sources of contamination and greater hydrology variability so more monitoring data is necessary to ensure an appropriately protective monitoring schedule. Both the differences in the occurrence estimations for large and small sized systems as well as the general source water characteristics of groundwater systems were collectively considered as part of establishing the proposed initial monitoring requirements for small groundwater systems. Consequently, the

agency expects that these small groundwater systems will be less likely to experience variations throughout a year and, where there may be seasonal variations, requiring the samples to be collected in different parts of a year will provide sufficient information to determine the appropriate compliance monitoring schedule. Given the different experiences cited by commenters, any seasonal variation is likely based on the specific geographic location and other localized factors. If there are regional factors that suggest more frequent sampling is warranted by particular PWSs, the rule provides that primacy agencies may increase the required monitoring frequency, where necessary, to detect variations within the system (e.g., fluctuations in concentrations due to seasonal use or changes in water source).

In response to comments about the alignment of the fifth Unregulated Contaminant Monitoring Rule (UCMR 5) sampling with initial monitoring requirements, some commenters indicated that requiring larger groundwater systems to collect four samples would translate into these systems needing to collect two additional samples beyond those collected for the UCMR 5 monitoring effort. The EPA acknowledges that while the initial monitoring requirements of this rule generally align with the UCMR 5 sampling requirements, groundwater systems serving greater than 10,000 would need to collect two additional samples within the three years following rule promulgation to supplement UCMR 5 results. As described previously, the model for estimating national PFAS drinking water occurrence indicates that larger systems have greater within-system variability than smaller systems, therefore it is appropriate that these larger groundwater systems collect four initial monitoring samples; this is consistent with initial monitoring requirements for groundwater systems under existing SOC NPDWRs.

In addition, a few commenters recommended that the number of required samples for initial monitoring be based on the results of the first two samples, with subsequent monitoring only required if regulated PFAS are detected in those earlier samples. The EPA recognizes there is some logic to this approach; however, there would be challenges implementing it. Specifically, it could be challenging for primacy agencies to track and implement the proposed approach, particularly for groundwater systems serving 10,000 or fewer which would require the additional samples to occur in quarters not represented by the first two samples. Furthermore, tracking this varying monitoring would result in additional administrative burden and oversight challenges for primacy agencies, rather than having a consistently defined schedule for monitoring requirements as is used for other SOCs.

The EPA also received several comments from state agencies about the required intervals associated with initial quarterly and semiannual sample collection. In its proposal, the EPA specified that samples be collected at least 90 days apart, whether the samples were required of a system monitoring on a quarterly basis or a system monitoring semi-annually. A small number of commenters noted that they believed that semiannual samples should be separated by more than 90 days to better capture seasonal variations (e.g., seasonal changes in the percent contributions of water blended from different sources, other fluctuations in concentrations). One commenter suggested semiannual samples should be collected at least 180 days apart, which would also be in better alignment with the required schedule for UCMR 5 semiannual sampling. The EPA

agrees with these comments. In the final rule, the EPA is requiring that the samples be collected 5 to 7 months apart for semiannual initial monitoring (see Table 2 to Paragraph (a)(4)(i)(B) of the regulations governing the UCMR program in 40 CFR Section 141.40).

With respect to the sample collection timing requirements for quarterly initial monitoring (for all surface water systems and groundwater systems serving greater than 10,000), a few commenters indicated that they were opposed to the proposed requirement for samples to be spaced at least 90 days apart. These commenters indicated that such a requirement was unnecessarily prescriptive and would make sample collection logistically challenging for PWSs. These commenters suggested the EPA change the required spacing in a way that still satisfies the EPA's intent to not have samples collected only a few days apart, but in different quarters, so that quarterly samples are more representative of fluctuations in concentrations over time. The EPA agrees with these comments and sees the value of systems being able to use four existing samples collected in separate quarters but also allowing flexibility that they are not all spaced at least 90 days apart. In the final rule, the EPA is modifying the required spacing of quarterly initial monitoring samples to be 2 to 4 months apart if samples are collected in a 12-month period. For systems that need to supplement previously-acquired data to satisfy all the initial monitoring requirements, the final rule requires that they must also be 2 to 4 months apart from the months of available pre-existing data. This will also better parallel the language outlining the required spacing of quarterly samples collected for the UCMR 5 monitoring effort.

Some commenters asked the EPA to clarify which systems would be subject to the initial monitoring requirements for surface water systems and which systems would be subject to the requirements for groundwater systems, in some cases presenting examples of specific scenarios. One example is when a system relies on surface water at some EPTDS and groundwater at other EPTDS. The EPA has modified the language of the final rule in Section 141.902(b)(1)(ii) to clarify that initial monitoring requirements are to be determined based on the type(s) of water serving as the source for a given EPTDS; thus, one system may have different initial monitoring requirements that apply to their different EPTDS. In response to questions, the EPA is clarifying in Section 141.902(b)(1)(iv) that, if an EPTDS uses water blended from multiple sources (some groundwater and some surface water), or if it uses different types of sources throughout the year, the system must follow the monitoring frequency for a surface water system (since water from surface water sources is used at least in part, for at least a portion of the year). This approach is more protective of public health because, as described earlier, generally surface water systems have more variable hydrology and potentially more sources of contamination so more monitoring data are necessary to ensure an appropriately protective monitoring schedule.

Some commenters asked for clarification about whether PWSs supplying groundwater under the direct influence of surface water (GWUDI) would qualify for semiannual initial monitoring at those EPTDSs. As noted in 141.902(b)(1)(iii), GWUDI systems follow the requirements for surface water systems. GWUDI systems may be as susceptible to contamination as surface water systems; thus, these systems must use the sampling requirements for surface water during the initial sampling phase to establish baseline levels of regulated PFAS.

In the proposal, the EPA requested public comment on the proposed initial monitoring timeframe, particularly for NTNCWS or all systems serving 3,300 or fewer. Many commenters expressed support for the EPA requiring initial monitoring as soon as possible with a few commenters explicitly supporting the EPA's proposed initial monitoring timeframe (noting it allows sufficient time for water systems to comply with the initial monitoring requirements). However, other commenters suggested that water systems would not be able to utilize the full three years following rule promulgation to perform initial monitoring and take actions to ensure compliance with the MCLs if monitoring results showed elevated levels of PFAS. While the agency agrees that it may be difficult to conduct initial monitoring and take necessary remedial actions (e.g., treatment installation) within three years, the EPA finds that it is practicable for all systems to complete their initial monitoring within three years. This is particularly the case since the large majority of systems serving greater than 3,300 will have sufficient monitoring data from UCMR 5 and many other systems will have at least some data to satisfy the rule's initial monitoring requirements. Moreover, the EPA is exercising its authority under Safe Drinking Water Act (SDWA) § 1412(b)(10) to implement a nationwide two-year capital improvement extension to comply with MCL. Consequently, water systems will have up to the full three years following rule promulgation to plan and conduct monitoring and still have two additional years to complete any actions needed to comply with the MCLs.

Several commenters suggested that the EPA consider a staggered initial monitoring timeframe by system size, such as those used in other previous NPDWRs, where, for example, larger sized systems conduct monitoring first followed by smaller systems. In the examples provided by commenters, this staggered monitoring could also allow systems to achieve compliance on a staggered schedule. A few commenters suggested that this is necessary to address potential laboratory capacity issues and to allow smaller systems additional time to plan and obtain resources to conduct the monitoring. The EPA disagrees that staggering the monitoring requirements to allow different compliance dates is necessary. SDWA 1412(b)(10) specifies that all systems must demonstrate compliance three years following rule promulgation except where a state or the EPA may grant an extension of up to two additional years to comply with MCL(s) if the EPA or the state (for an individual system) needs additional time for capital improvements. Therefore, the intent of the statute is to allow extensions to complete the capital improvements necessary to comply with the MCL. The EPA considers the three years sufficient for completing the rule's initial monitoring requirement. In response to some questions raised, the EPA added the date by which initial monitoring must be reported to the EPA (and other compliance dates) to 40 CFR § 141.900(b)(2). The EPA's allowance of previously-collected monitoring data will also significantly reduce the potential for laboratory capacity challenges. As noted above, the EPA has revised the required intervals between samples collected for initial monitoring under this rule to closely parallel the intervals required for UCMR 5, to promote the useability of existing data.

The EPA is not prescribing any staggering of monitoring (e.g., based on system size) but encourages primacy agencies to work with the systems they oversee to ensure their initial monitoring occurs and adjust schedules (within the three years following rule promulgation) as appropriate. Related to laboratory capacity considerations, see section 5.1.2; in addition to the

allowance of previously-collected data to satisfy initial monitoring requirements, as described in the rule proposal, the EPA anticipates that laboratories will be able to adjust to demand and that the demand will be distributed across the three-year implementation period.

Several commenters requested that the EPA clarify whether only samples collected under UCMR 5 would be allowed to fulfill initial monitoring requirements, or if data under other monitoring efforts, such as state monitoring, would also be acceptable. As provided in the proposal and final rule, a state may accept results from all appropriate monitoring efforts, as determined by the state, including, but not limited to, UCMR 5 and other state-led efforts. For a discussion of comments related to how existing monitoring data can be used to satisfy initial monitoring requirements, see section 8.3 below.

Individual Public Comments

Wisconsin Department of Natural Resources (Doc. #1828, SBC-044805)

Monitoring Requirements

WDNR supports ASDWA's comment regarding changing the 90-day monitoring reference to quarterly monitoring. The 90-day monitoring is problematic for Wisconsin's implementation process, which is evidenced by experience implementing the Stage 2 Disinfectants and Disinfection Byproducts Rule.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document for a discussion of initial monitoring requirements, including revisions made in the final rule to the interval required between samples. Regarding discussion of compliance monitoring requirements, including the required intervals between sample collection, please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Wagner Engineering (Doc. #3072-9, SBC-047361)

Once the rule is finalized later this year, what will EPA's message be to water utilities that either are not participating in UCMR 5, or are not scheduled to take samples until 2024 or 2025? If these systems wait until they've completed UCMR 5 testing, they will not have time to implement any required treatment before the rule effective date in late 2026.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document for a discussion of initial monitoring requirements and timing. See also section 12.1 of the EPA response in this *Response to Comments* document for a discussion of the nationwide 2-year extension for MCL compliance granted by the EPA to allow time for capital improvements, which would allow systems that sample in 2024 or 2025 additional time to implement treatment before the MCLs become effective, if needed.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045222)

Monitoring & Compliance

1. EPA is also proposing and taking comment on a modification to the Standard Monitoring Framework for Synthetic Organic Compounds in that groundwater systems serving 10,000 or fewer are initially required to only monitor twice for regulated PFAS within a 12-month period, each sample at least 90 days apart.

CT DPH agrees with reducing the sampling burden on these small systems and recommends that each sample be collected at least 180 days apart. Semiannual samples represent seasonal fluctuations in use and groundwater conditions that provide better representative samples of extremes in conditions as opposed to samples collected 90 days apart.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Ross Renick (Doc. #1553, SBC-042562)

Additionally, the sampling frequency proposed in the webinar during the initial monitoring period should be standardized, not based on the number of source users. Two samples in a 12-month period I do not believe will be sufficient in protecting the public from PFAS. Also, allowing a 3-year period to collect those samples does not seem feasible to be able to collect samples and then implement the proper technology to filter PFAS. If a public source waits until the final year of the 3-year window and samples twice towards the end of that calendar year, they will unlikely be able to implement the proper technology by the time the rule is in effect. If the timeline of enforceable MCLs is not advanced, I would urge you to require standardized sampling every year for all public water sources. This relates to environmental justice concerns as smaller populations would not be afforded the same protections with less infrequent sampling. I recognize that there is funding available through the EPA's Emerging Contaminants in Small or Disadvantage Communities Grant Program, which I believe should be utilized for additional sampling in smaller communities.

In closing, I thank you for the opportunity to comment on this proposed regulation. I would urge the EPA to take a precautionary approach to mitigating PFAS in our water supplies. This is still a new and emerging contaminant with limited available data. I believe it would be wise to have more stringent regulations early on in this process until either more data is available, or sources of PFAS can be contained and cleaned up.

Thank you,

Ross Renick

EPA Response: Please see section 8.1.1of the EPA response in this *Response to Comments* document. After the initial monitoring period, sampling frequency is determined by prior sampling results. Please see section 8.1.2 of the EPA response in this *Response to Comments* document regarding compliance monitoring requirements. Additionally, please see section 12.1 of the EPA response in this *Response to Comments* document for a discussion of the nationwide 2-year extension for MCL compliance granted by the EPA to allow time for capital improvements based on initial monitoring results.

American Water Works Association (AWWA) (Doc. #1759, SBC-045611)

[Examples of these systems may include:]

• Water systems scheduled for UCMR 5 monitoring in 2025: The proposal provides a 3-year timeline for water systems to comply with both the initial monitoring requirements and compliance with the MCL. Initial monitoring for the rule will need to begin immediately following promulgation of the rule to ensure that there is adequate time to take necessary action if PFAS levels exceed one or more of the MCLs. Given that the EPA's target date for a final rule is December 2023, all water systems without pre-existing data sufficient to meet these requirements will need to be monitored during 2024. This precludes the use of samples from 2025 under UCMR 5 program, as these results would give these systems less than a year to comply with the three-window for compliance, if treatment was needed.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document for further discussion of initial monitoring requirements and section 8.3 of the EPA response in this *Response to Comments* document for discussion of the use of pre-existing data. Please see section 12.1 of the EPA response in this *Response to Comments* document for a discussion of the nationwide 2-year extension for MCL compliance granted by the EPA to allow time for capital improvements, which would allow systems that sample in 2025 additional time to implement treatment before the MCLs become effective, if needed.

Missouri Department of Natural Resources (Doc. #1563, SBC-042535)

EPA seeks comment on the Agency's proposed initial monitoring timeframe, particularly for NTNCWS or all systems serving 3,300 or fewer.

The Department recommends EPA look at a staggered initial monitoring timeframe such as used with the implementation of the Stage 2 Disinfecting Byproduct Rule. EPA established schedules (1-4) in that rule based on population, with Schedule 1 systems being larger and the first to start compliance monitoring. Large systems will have better Technical, Managerial and Financial (TMF) capabilities to provide treatment. They also serve larger populations and coincide with locations that typically have PFAS contamination issues based on UCMR3 data.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Oregon Health Authority (OHA) (Doc. #1582, SBC-042761)

Section IX – Monitoring and Compliance Requirements

• EPA requests comment on the proposed monitoring flexibility for groundwater systems serving 10,000 or fewer to only collect two samples at each entry point to the distribution system (EPTDS) to satisfy initial monitoring requirements.

OHA supports the proposed monitoring flexibility for groundwater systems serving 10,000 or fewer to only collect two samples at each EPTDS to satisfy initial monitoring requirements. This would allow groundwater systems that conducted UCMR5 monitoring or have previously acquired data to potentially use their results to comply with the initial monitoring requirements in the rule and reduce the burden on these water systems.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042983)

7. EGLE DWEHD requests simplification of proposed rule language and proposes that EPA re-word 141.XX (Mon Req)(b)(i) to include GUDI and strike (b)(iii). We also suggest the following amended language for (i): "All surface water systems, all GUDI systems, and groundwater systems serving greater than 10,000 must take four consecutive quarterly samples …"

EPA Response: The EPA disagrees with this recommendation because moving the requirements for GWUDI systems from 40 CFR § 141.902(b)(iii) to § 141.902(b)(i) would entail rearranging where requirements are specified, but not any substantive difference to the requirements. The EPA is therefore retaining § 141.902(b)(iii). Further, referencing requirements for "systems" rather than all CWS and NTNCWS could be misconstrued as creating

requirements for transient non-community water systems (TNCWSs), which are not subject to this rule, and thus the EPA retained the reference to specific system types. Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044009)

Rule Implementation

Initial Monitoring

American Water supports the proposed initial monitoring scheme where surface water systems and groundwater systems serving over 10,000 people collect four (4) quarterly samples but groundwater systems serving 10,000 people or fewer would only be required to collect two (2) samples 90 days apart. This approach appropriately reduces the burden on the smaller groundwater systems.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043046)

Compliance Deadlines

DEQ suggests EPA allow flexibility in the compliance deadlines to ensure feasibility, allowing staggered compliance deadlines depending on the system size.

Large and medium-sized water systems will have previously collected data from UCMR 5, while many small systems will be taking their first PFAS samples when the final PFAS NPDWR is implemented. If these small systems exceed the MCL, the three-year compliance timeline will be challenging to meet.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044034)

16. EPA requests comment on the proposed monitoring flexibility for groundwater systems serving 10,000 or fewer to only collect two samples at each EPTDS to satisfy initial monitoring requirements.

a. Groundwater systems are the most likely to be contaminated with PFAS compounds.

EPA Response: The EPA disagrees that groundwater systems are the most likely to be contaminated with PFAS, based on the agency's model for estimating national occurrence which suggests otherwise (see section 8.1.1 of the EPA response in this *Response to Comments* document.). The commenter provided no supporting information or data for this claim.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043085)

Additionally, the timeline for the initial monitoring period of 3 years is appropriate. It is important to note, however, that this timeline is in concert with the compliance deadline for meeting or exceeding the MCLs. As such, water systems will not be able to wait until the third year of the compliance window to perform initial monitoring requirements because this would not leave time to comply with the MCLs, if elevated levels of PFAS are found.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044887)

In [sec] 141.XX, Table 1 to paragraph (b)(l)(iv) notes a population delineation for initial monitoring requirements of 10,000, but Table 2 to paragraph (b)(2)(iv) notes a population delineation of 3,300 for reduced monitoring level. DEP notes that this difference is confusing, and that it is further evidence that the population delineations are arbitrary, as noted in the previous comment.

EPA Response: The EPA clarifies that the first table the commenter referenced related to initial monitoring requirements and the second related to compliance monitoring requirements. The EPA disagrees that including requirements specific to systems of different sizes is arbitrary, and this approach has been used in other NPDWRs, including the monitoring requirements for other SOCs. Additionally, please see section 8.1.1 of the EPA response in this *Response to Comments* document, particularly the reference to data from the EPA's national occurrence model for PFAS in drinking water which indicates that larger systems have greater within-system variability. The EPA revised the compliance monitoring requirements, as discussed in section 8.1.2 of the EPA response in this *Response to Comments* document, to remove consideration of system size in light of the public comments received, which removes the potential for any similar confusion as raised by the commenter.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044885)

• For initial monitoring, EPA proposes allowing groundwater systems serving 10,000 or fewer customers to only collect two samples at each EP instead of four consecutive quarterly samples. DEP recommends requiring all water systems to conduct monitoring for four consecutive quarters for initial monitoring. Allowing a reduction from four quarterly samples to only two samples is appropriate for regulated synthetic organic chemicals (SOCs) because monitoring would be required during the quarters in which those chemicals are most likely used and would affect water system sources. However, for PFAS chemicals, there may be seasonal variations, which would not be captured by allowing a system to reduce monitoring to only two samples.

• DEP requests clarification on which systems will be considered "groundwater systems" for the proposed monitoring flexibility allowing groundwater systems serving 10,000 or fewer

customers to only monitor twice for initial monitoring. If a system has their own groundwater sources, but also purchases finished water from a surface water system, will the purchasing system still be considered a groundwater system for the purposes of initial monitoring under this proposed rule?

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document. Initial monitoring frequency is based on the population served and on the source water type associated with each of the PWS's EPTDSs, regardless of whether the PWS is a "parent" system or "purchasing" system.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044098)

ASDWA recommends that the rule specify the date(s) by which initial monitoring must be completed.

The date specified in 141.XX(b)(1)(vi) only applies to monitoring that is needed to supplement previously acquired data to meet the initial monitoring requirements.

ASDWA recommends that EPA provide additional clarification to define the types of ground water systems for which the less frequent (1 sample every six months) initial sampling requirements apply.

The final rule should clarify and explain its reasoning on whether springs and ground water systems under the direct influence of surface water (GWUDI) can qualify for less frequent initial monitoring. The rule should also provide examples of ground water systems that would not be eligible for less frequent monitoring, such as water systems that mostly purchase surface water to provide drinking water to their customers but also have their own ground water wells.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document. Less frequent (twice in 12 months) initial monitoring requirements apply only to PWSs serving 10,000 or fewer and any EPTDS within those PWSs that rely exclusively on groundwater.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044089)

To address these laboratory capacity concerns, ASDWA recommends that EPA include language within the final rule requiring initial monitoring to be staggered based on system size. Systems serving less than 3300 people should monitor last, as the majority of these systems will not have conducted UCMR 5 monitoring and will likely need the most time to budget for costs and meet monitoring requirements.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044133)

To alleviate the initial laboratory capacity issues and reduce public water system sampling costs, TCEQ supports:

• Allowing groundwater systems serving 10,000 or fewer people to monitor twice for regulated PFAS within a 12-month period instead of four samples within this period.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044374)

• EPA seeks comment on the Agency's proposed initial monitoring timeframe, particularly for NTNCWS or all systems serving 3,300 or fewer (pg. 18681 Federal Register Volume 88, Number 60).

O It is the commenters' opinion that the proposed initial monitoring timeframes, in which water systems must complete the initial monitoring requirements within three years following rule promulgation, are appropriate and allow sufficient time for water systems to comply with the initial monitoring requirements. The commenters agree that the reduced monitoring requirements for NTNCWS and systems serving fewer than 3,300 persons offer significant burden reductions and sufficient time for rule compliance.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document. The EPA notes that there are no reduced monitoring requirements or different initial monitoring timing requirements for NTNCWSs or systems serving fewer than 3,300 persons.

Aidan Cecchetti (Doc. #1640, SBC-044367)

• EPA requests comment on the proposed monitoring flexibility for groundwater systems serving 10,000 or fewer to only collect two samples at each EPTDS to satisfy initial monitoring requirements (pg. 18682 Federal Register Volume 88, Number 60).

O It is the commenters' opinion that the proposed monitoring flexibility for groundwater systems serving 10,000 or fewer is appropriate and consistent with other NPDWRs. The commenters do not foresee any challenges regarding implementation of this type of monitoring flexibility.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043273)

• EPA requests comment on the proposed monitoring flexibility for groundwater systems serving 10,000 or fewer to only collect two samples at each EPTDS to satisfy initial monitoring requirements.

Response: Monitoring flexibility is essential for small systems

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044178)

F. Laboratory Readiness

1. NCDEQ recommends EPA consider staggering the initial monitoring requirements based on system size to help address potential laboratory capacity issues.

EPA should evaluate whether laboratory capacity required to support the PFAS NPDWR will be impacted, especially as water systems continue to test under UCMR 5 in 2024 and 2025. The factors that should be considered are the time it takes to get a laboratory certified for PFAS methods; the number of laboratories that are currently capable of analyzing for PFAS and being able to manage the volume of samples; the method requirements for temperature and time frames for laboratories to store and analyze the samples; shipping delays; and the competing demands for laboratories to analyze PFAS in other environmental media, while at the same time meeting other new and existing drinking water regulatory needs.

NCDEQ's current observation indicates that the number of laboratories capable of analyzing for PFAS in time to meet the new rule compliance demands is limited. The volume and number of samples that water systems will need to be analyzed based on expected occurrence and sampling frequency could exceed laboratory capacity for all laboratories and each laboratory individually. There may also be an impact on laboratory capacity due to limited suppliers for PFAS standard reagents. Analytical method requirements for temperature and timeframes to store and analyze PFAS samples may also require laboratories to significantly increase their refrigeration storage. Additionally, laboratories have competing demands to analyze PFAS in other environmental media and, at the same time, meet other new and existing drinking water regulatory needs. For example, the Lead and Copper Rule Revisions (LCRR) and the future Improvements will likely create additional demands on laboratories, particularly if a significant number of systems will need to re-start initial monitoring based on revised compliance sampling locations. These revisions would significantly increase the number of lead and copper compliance samples. We recognize that these demands could transform the way laboratories provide analytical services in the future, including adjusting their business operations to enable quicker and flexible services to meet increase in demand.

If EPA's evaluation concludes that capacity of laboratory at regional or national level is an issue, NCDEQ recommends that EPA consider providing additional time for more laboratories to get certified and prepare to analyze PFAS samples. EPA could include language within the final rule that would require initial monitoring to be staggered based on system size. Systems serving less than 3,300 people should monitor first, as the majority of these systems will not have conducted UCMR 5 monitoring.

EPA Response: Regarding staggering initial monitoring deadlines, please see section 8.1.1 of the EPA response in this *Response to Comments* document. Regarding the comments about laboratory availability and capabilities, see section 5.1.2 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044184)

5. NCDEQ recommends that the rule specify the date(s) by which initial monitoring must be completed.

The date specified in 141.XX(b)(1)(vi) only applies to monitoring that is needed to supplement previously acquired data to meet the initial monitoring requirements.

6. NCDEQ recommends that EPA provide additional clarification to define the types of ground water systems for which the less frequent (1 sample every six months) initial sampling requirements apply.

The rule should clarify and explain its reasoning on whether springs and ground water systems under the direct influence of surface water (GWUDI) can qualify for less frequent initial monitoring. The rule should also provide examples of ground water systems that would not be eligible for less frequent monitoring, such as water systems that mostly purchase surface water to provide drinking water to their customers but that also have their own ground water wells.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043200)

The Department would support allowing monitoring flexibility of two samples at each entry point to the distribution systems (EPTDS) with data collected previously for groundwater systems serving less than 10,000 to satisfy initial monitoring requirements. This would be consistent with previous rules.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044418)

Page 18730. Section IX – Monitoring and Compliance Requirements.

EPA requests comment on the proposed monitoring flexibility for groundwater systems serving 10,000 or fewer to only collect two samples at each EPTDS to satisfy initial monitoring requirements.

• In Washington State, there are more detections in groundwater than in surface water. Detections are generally consistent over time with little seasonal variability.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044425)

EPA seeks comment on the Agency's proposed initial monitoring timeframe, particularly for NTNCWS or all systems serving 3,300 or fewer.

• The initial monitoring of 2 samples in 90 days is acceptable.

• DOH has time and cost concerns over the impact from increased quarterly monitoring for detected results below the PQL, and the challenge in computing HI for PWS that have detections of other PFAS with MCLs.

EPA Response: Please see section 8.1.1. of the EPA response in this *Response to Comments* document for a discussion of initial monitoring requirements. Please see section 8.8 of the EPA response in this *Response to Comments* document for a discussion of the trigger levels established under this rule and use of values below the practical quantitation levels (PQLs) for the determination of monitoring frequency. Please see section 8.1.2 of the EPA response in this *Response to Comments* document for a discussion of compliance monitoring requirements. Section 8.1.2 contains a discussion of the annual monitoring tier added for PFAS in the final rule, akin to a tier available for other SOCs, which may help address the commenter's concern about time and costs required for systems that have detections of PFAS above trigger levels. Regarding calculating the Hazard Index, the EPA has explained the process in the final rule and intends to disseminate implementation materials about calculating the Hazard Index as part of a larger set of materials to aid with implementation of the rule.

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044347)

3. Page 18730, Column 2, Section IX—Monitoring and Compliance Requirements

a. Page 18730, Column 2, Bullet 7 - EPA requests comment on the proposed monitoring flexibility for groundwater systems serving 10,000 or fewer to only collect two samples at each EPTDS to satisfy initial monitoring requirements.

NHDES Comment - NH would be a proponent of allowing monitoring flexibility for systems to only collect two samples at each EPTDS to satisfy initial monitoring requirements. However, we recommend that this flexibility be based on sample results rather than system source type or population served. For example, any system would be eligible to only collect two samples during the initial monitoring period if those two sample results were below the proposed rule trigger level. [Rule Reference: 141.XX (b)(1) (i) and (ii) – Page 18751, Column 3]

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045029)

NJDEP does not support EPA's modification to the Standard Monitoring Framework (SMF) for SOCs that would allow groundwater systems serving less than 10,000 customers to take two samples at each entry point to the distribution system (EPTDS) within a 12-month period, 90 days apart. Sampling twice in one year may not generate enough data to accurately capture the level of PFAS in drinking water being served by a system to the public. Public water systems with multiple wells may use some of these wells seasonally and depending on the sampling schedule, wells with elevated levels of PFAS may be offline during the sampling event. Second, as stated above, NJDEP has observed cases where water systems receive non-detect results initially, only to later exceed the MCL. Having the samples collected in close proximity on a temporal basis will potentially not fully capture potential violations. NJDEP recommends that EPA consider requiring all community and non-transient non community water systems to conduct initial quarterly monitoring. Of the 95 water systems in New Jersey that have received PFAS MCL violations for PFNA, PFOA, and PFOS, all have utilized groundwater sources at the treatment plants that exceeded the MCLs.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document. Also, regarding the portion of the comment suggesting samples collected in close proximity temporally may not necessarily capture the range of possible concentrations of regulated PFAS in water, see section 8.1.2 of the EPA response in this *Response to Comments* document for discussion of ongoing compliance sampling requirements.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045102)

Section IX -Monitoring and Compliance Requirements

1) Proposed monitoring flexibility of GW <10,000 to only collect two Entry Point to Distribution System (EPTDS) samples to satisfy initial monitoring requirements.

While 10,000 is often a clear "line" to draw to separate systems, the data in Vermont do not support this distinction as having systems above that population or with a surface water source as having more vulnerability to PFAS contamination. There should be an initial framework by

which the system needs to collect 1 or 2 samples which then drives the future sampling, with options for quarterly, annual, and triennial sampling.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document regarding initial monitoring requirements. Please see section 8.1.2 of the EPA response in this *Response to Comments* document regarding compliance monitoring frequencies, including the annual monitoring tier added in the final rule in response to public comments.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045230)

9. EPA seeks comment on the proposed initial monitoring timeframe, particularly for Non-Transient Non-Community public water systems or all systems serving 3,300 or fewer.

CT DPH has been encouraging all PWSs to test their water for PFAS since 2018, and have required all new source, including those for transient non-community public water systems, to test for PFAS prior to their activation. CT DPH agrees with EPA that community and non-transient non-community PWSs should test their systems. With UCMR5 and state monitoring programs, previously collected data should reduce the burden of testing for many systems.

Federal funds should be made available to assist initial sampling for the remaining small and very small community and non-transient non-community systems as those systems typically have fewer resources. CT DPH also recommends that EPA stagger the initial monitoring requirements based on system size.

EPA Response: Please see section 8.1.1. of the EPA response in this *Response to Comments* document for a discussion of initial monitoring requirements. For discussion of the use of existing data to satisfy initial monitoring requirements, please see section 8.3 of the EPA response in this *Response to Comments* document. As noted in section II.E of the preamble to the final rule, funding under the IIJA, often referred to as the BIL, will assist many disadvantaged communities, small systems, and others with the costs of addressing emerging contaminants, like PFAS, when it might otherwise be cost-challenging. Additionally, to support BIL implementation, the EPA is offering WaterTA to help communities identify water challenges and solutions, build capacity, and develop application materials to access water infrastructure funding (USEPA, 2023).

American Water Works Association (AWWA) (Doc. #1759, SBC-045621)

9. Monitoring Requirements

The agency is providing a compliance timeline of three years for water systems subject to the rule to perform initial monitoring requirements for PFAS at each entry point to the distribution system. The initial monitoring requirements may be waived for some systems that are either participant in UCMR 5 or have participated in eligible state monitoring programs since January 2019. Initial monitoring will determine if systems are eligible for a reduced monitoring

frequency under the proposed framework and if the system will need to install treatment (or take non-treatment action) to reduce PFAS to levels below the MCL.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document. The EPA agrees with the majority of this statement, except for the portion suggesting that initial monitoring requirements of this NPDWR are being "waived" for systems with existing data. Instead, water systems may use existing data to satisfy the initial monitoring requirements of this NPDWR. The state can then use these data, provided within three years of rule promulgation, to determine the monitoring schedule required at the start of the compliance monitoring period. Regarding the use of previously collected data to satisfy initial monitoring requirements, please see section 8.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045624)

Additionally, the timeline for the initial monitoring period of three years is appropriate. It is important to note, however, that this timeline is in concert with the compliance deadline for meeting the MCLs. As such, water systems will not be able to wait until the third year of the compliance window to perform initial monitoring requirements because this would not leave time to comply with the MCLs, if elevated levels of PFAS are found.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document. Please see section 12.1 of the EPA response in this *Response to Comments* document for a discussion of the nationwide two-year extension for MCL compliance granted by the EPA to allow time for capital improvements, which would allow systems additional time to implement treatment before the MCLs become effective, if needed.

New Mexico Environment Department (NMED) (Doc. #1766, SBC-044254)

Compliance

NMED recommends that EPA allow flexibility in the compliance deadlines to ensure feasibility, similar to the flexibility offered as a part of the final arsenic regulation that allowed staggered compliance deadlines depending on system size.

NMED appreciates and is supportive of EPA's efforts to regulate these forever chemicals and wants to work with EPA to achieve enhanced protection of public health through implementation of the more stringent regulations. However, if EPA doesn't address concerns being raised by state agencies and other organizations, the ability to successfully implement the regulations will be limited.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document. Please see section 12.1 of the EPA response in this *Response to Comments* document for a discussion of the nationwide two-year extension for MCL compliance granted by

the EPA to allow time for capital improvements, which would allow systems additional time to implement treatment before the MCLs become effective, if needed.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043869)

EPN strongly recommends that the final regulation require all PWS to conduct an initial round of monitoring unless explicitly waived in writing by the state.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document. Water systems subject to this rule will need to conduct initial monitoring unless demonstrated to and approved by the state that they have previously-collected data to satisfy the NPDWR's initial monitoring requirements. Please see section 8.3 of the EPA response in this *Response to Comments* document for a discussion of the use of pre-existing data. For the portion of the comment referencing "all PWS," the EPA notes that CWSs and NTNCWSs are subject to this NPDWR. TNCWSs are not required to conduct monitoring under this NPDWR. For an explanation of the rationale for this decision, please see section 1.4 of the EPA response in this *Response to Comments* document.

Metropolitan Water District of Southern California (Doc. #1777, SBC-045435)

Furthermore, while the proposed rule allows systems to use previously collected monitoring data to satisfy the initial monitoring requirements, it is unclear what happens if agencies do not use previously collected monitoring data to satisfy the initial requirements, but their prior data shows they would be out of compliance. Monitoring and compliance of PFAS constituents significantly impact water agencies' day-to-day operations and financial standing. It is important to coordinate a stakeholder-driven assessment of use and application of a mixture-based screening tool prior to implementation of a Hazard Index-based MCL and MCLG. Metropolitan recommends that EPA carefully consider all the factors and provide clarification of these issues before requiring water agencies to collect monitoring data and trigger a compliance schedule.

EPA Response: The EPA has followed the regulatory development process as outlined under SDWA and considered all factors and comments in determining the final NPDWRs, including the monitoring requirements. For the final rule, no systems will be found to be out of compliance with the MCLs as a result of their initial monitoring results, whether those are determined through new sampling or through use of previously-collected data; rather, these data will be used to determine the ongoing compliance monitoring frequency. The EPA notes that while the agency is allowing use of previously-collected data as a monitoring flexibility in the final rule, water systems are not required to use, nor are states required to allow the use of, previously-collected data to satisfy the final rule initial monitoring requirements. Also, as a condition of using previously collected data to satisfy the initial monitoring requirements, the laboratory used by the water system must be capable of producing results at or below the MCLs. Please see section 8.1.1 of the EPA response in this *Response to Comments* document for more on initial monitoring requirements and section 8.1.2 of the EPA response in this *Response to*

Comments document for compliance monitoring requirements. Additionally, the EPA is planning to disseminate educational materials about calculating the Hazard Index as part of a larger set of materials to aid with implementation of the rule, with the goal of reducing challenges systems might have associated with computing the Hazard Index. For more on the Hazard Index MCL, please see section 5.2 of the EPA response in this *Response to Comments* document.

Citizens Energy Group (Doc. #1838, SBC-044868)

EPA seeks comment on the Agency's proposed initial monitoring timeframe, particularly for NTNCWS or all systems serving 3,300 or fewer.

Citizens believes that small systems (those serving fewer than 3,300 service connections) should be directed to collect the analytical data needed to support decision making. As offered in prior comments, if the data available to a small system provides sufficient information to support compliance with the proposed rule before the compliance date, there should not be obligations to sample just for the sake of collecting additional data. Each small system should collect sufficient data needed to ensure compliance and the delivery of water that meets the requirements of the Safe Drinking Water Act for their customers.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document. The EPA clarifies that following initial monitoring, the frequency of monitoring will be determined by previous sampling results. For discussion of the compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Paul Eldredge (Doc. #2770, SBC-047325)

We urge EPA to proceed carefully so as to ensure personnel are appropriately educated with the adoption of new well-developed standards in an efficient manner that minimizes costly mistakes such as the acquisition of unnecessary or insufficient equipment or usage of improper procedures. We want to ensure updates in standards not only strengthen public health protections and environmental safety but are enforced appropriately. We advise that new rules harmonize with other related requirements and allow for a thorough plan for phased implementation.

EPA Response: Regarding phased implementation, please see section 8.1.1 of the EPA response in this *Response to Comments* document. Regarding training, the EPA is developing guidance and training materials to aid states and systems in rule implementation. The EPA agrees that these new standards do strengthen public health protections, have been designed with an awareness of other related requirements, and will be enforced in a similar fashion as it is conducted under other NPDWRs. For a discussion of the modifications to the SMF for SOCs that the EPA made for PFAS, see section 8.1.2 summary.

Robert Hollander (Doc. #1516, SBC-042710)

2. 88 FR 18668, 1st column

If EPA sufficiently advertises and/or highlights the ability of water utilities to use data obtained from UCMR 5 monitoring to satisfy initial monitoring requirements, this will likely reduce demand for laboratory services prior to the compliance effective date.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document on initial monitoring and section 8.3 of the EPA response in this *Response to Comments* document on the use of existing data to satisfy initial monitoring requirements.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042984)

8. Regarding flexibility during initial monitoring for groundwater supplies serving a population less than 10,000, EGLE DWEHD generally does not have issue with EPA's proposed approach.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Little Hocking Water Association (Doc. #1835, SBC-045518)

Further, the proposed rule's monitoring requirements are not protective of health because the known difference between water systems that draw from surface water versus groundwater is not taken into account. Because levels of contamination in surface water vary much more than groundwater, systems that draw from surface water (or from groundwater influenced by surface water) should be subject to more stringent testing requirements. For systems whose source water contains widely varying levels of contamination, infrequent testing would miss times when concentrations are high. This is not protective of public health.

EPA Response: The EPA agrees that levels of some contaminants in surface water can vary more than levels in ground water, but this is not true for PFAS in all cases, as noted in some comments received in response to the proposed rule. Nevertheless, the EPA agrees with the commenter and is requiring surface water systems (and large groundwater systems) to conduct quarterly monitoring initially, which is a more stringent requirement than applies to groundwater systems serving 10,000 or fewer people that are required to collect two samples. Please see section 8.1.1 of the EPA response in this *Response to Comments* document for discussion of initial monitoring requirements. Following initial monitoring, monitoring frequency is based on previous sampling results not source water type, so if a sampling location demonstrates elevated levels of regulated PFAS, regardless of source water type, more frequent monitoring will be required. Please see section 8.1.2 of the EPA response in this *Response to Comments* document for discussion of compliance monitoring requirements.

Citizens Energy Group (Doc. #1838, SBC-044860)

Section IX – Monitoring and Compliance Requirements

EPA requests comment on the proposed monitoring flexibility for groundwater systems serving 10,000 or fewer to only collect two samples at each EPTDS to satisfy initial monitoring requirements.

Citizens supports EPA's proposal that imposes less stringent initial monitoring obligations on medium and small/very small systems. Offering flexibilities to these systems is appropriate given the limited resources (both personnel and budgets) that these systems typically have available.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-045383)

Certified labs have been challenged with analyzing the number of samples that PWS send them. PWS can wait upwards of 3 weeks for sample results and then the primacy agencies must perform quality assurance evaluations, which can take several more weeks. Samples are expensive ($250-$350 per sample), with field blanks being run in the majority of cases, thereby doubling the costs. Follow-up confirmatory samples will be needed to validate initial results. NEWWA recommends that monitoring should be phased in by system size to reduce the resource burden on the labs and primacy agencies who must review and verify the quality of the data.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document. For discussion of compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document. States determine confirmation sampling requirements for compliance sample purposes, although a system may voluntarily collect additional samples to provide it with more information. Regarding laboratory considerations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

8.1.2 Compliance Monitoring Requirements

Summary of Major Public Comments and EPA Responses

Regarding the requirements for compliance monitoring, the comments the EPA received related primarily to the frequency with which sampling would occur under different circumstances, whether each EPTDS would be allowed to be on a different compliance monitoring schedule, and the trigger levels that would support decisions about reduced triennial monitoring. Regarding the latter point, commenters also addressed laboratory capabilities to measure levels below PQLs. Trigger levels, including the use of values below the PQLs, are addressed in section 8.8 of the EPA response in this *Response to Comments* document. Laboratory availability and

capability are also addressed in section 5.1.2 of the EPA response in this *Response to Comments* document.

The EPA proposed to allow systems eligible for reduced monitoring, and serving 3,300 or fewer, to collect one compliance monitoring sample triennially and to allow eligible larger systems to collect two samples during a three-year compliance period. The EPA specifically requested comment on whether all water systems, regardless of system size, should be allowed to collect and analyze one sample per three-year compliance period if the system does not measure any regulated PFAS in their system at or above the rule trigger level. Several commenters stated that they did not agree with a different number of triennial samples eligible systems must collect being based on the size of the population a system serves. These commenters suggested that one sample collected every three years is sufficient for systems of any size on reduced monitoring. The EPA agrees with these commenters that systems eligible for triennial monitoring should be allowed to collect one sample every three years, regardless of system size, especially considering other changes to the compliance monitoring framework, as described below.

Several commenters recommended that an annual sampling frequency tier be added to the required monitoring framework for various reasons including the mobility and persistence of PFAS in the environment, to ensure that systems that have previously demonstrated elevated levels of regulated PFAS are not allowed to move directly from quarterly to triennial monitoring, and based on their concerns that some laboratories may not be able to produce results at or below the rule trigger levels (resulting in some systems remaining on quarterly monitoring indefinitely even if they can consistently demonstrate they are below the MCLs). A few commenters supported offering three possible monitoring frequencies: quarterly, annually, and triennially, whereas many other commenters recommended against allowing triennial sampling at all and recommended that sampling be required no less than annually, to best protect public health. Those commenters supportive of allowing both annual and triennial monitoring, depending on prior sample results, suggested that annual monitoring should be an option for systems with regulated PFAS concentrations that are reliably and consistently below the MCLs. This modification would parallel the three tiers of monitoring allowed for other organic chemicals under the SMF.

A few commenters recommended that PFAS compliance sampling requirements mirror requirements for other SOCs under the SMF. The EPA agrees and has developed the PFAS NPDWR monitoring requirements generally based on the structure of the SMF for SOCs, which the agency anticipates will aid in successful understanding and implementation of the monitoring requirements. For example, the EPA agrees that an annual monitoring frequency should be available for PFAS, like other SOCs, and notes that the trigger levels for PFAS are analogous to the "detection limits" that determine a system's monitoring frequency for some other SOCs. But, as subsequently explained, the EPA does not agree with making the monitoring requirements for PFAS fully consistent with requirements for other SOCs. For example, PFAS are extremely persistent in the environment, and, as discussed in section 8.5 of this comment response document, the EPA has decided that no waivers for PFAS monitoring will be allowable. In

addition, the SMF for SOCs requires systems monitoring triennially to collect either one sample every three years or two samples every three years depending on the size of the population they serve, and, as noted above, the final PFAS rule will require systems monitoring triennially to collect only one sample regardless of their size.

The EPA does not agree with the comments suggesting that no systems should be allowed to sample triennially and that the longest sampling interval at any location should be one year. Based on the EPA's national occurrence estimates, most water systems subject to the rule's requirements will not have results for regulated PFAS that exceed the MCLs, and many will not identify PFAS at or above the triggers levels, thus allowing for reduced monitoring. These systems, after demonstrating results below the trigger level and therefore no or very little presence of regulated PFAS during the initial monitoring period or through ongoing compliance monitoring, should be able to reduce their monitoring burden and conduct triennial sampling, while still sufficiently maintaining public health protection. If a system monitoring triennially did have a sample result with elevated levels of a regulated PFAS (at or above the trigger level), it would be required to immediately initiate quarterly monitoring which would provide the primacy agency and water system with frequent sampling information to ensure compliance with the MCL and public health protection, as well as enable them to know whether treatment or other actions may be necessary to address regulated PFAS in that system's water. Additionally, the rule specifically provides that primacy agencies may increase the required monitoring frequency for compliance sampling for a variety of reasons, including to detect variations within specific systems (e.g., fluctuations in concentrations due to seasonal use patterns or changes in water sources). For any system that has regulated PFAS concentrations at or above the trigger level, but reliably and consistently below the applicable MCL, the EPA is introducing in the final rule an annual monitoring frequency within the compliance monitoring framework, consistent with the SMF for SOCs. A demonstration of reliably and consistently below the MCL would include consideration of at least four quarterly samples below the MCL. Annual samples would be collected during the quarter with the highest concentration measured during the prior round of quarterly sampling. The EPA expects this modification in the final rule to reduce the number of systems that are required to be on quarterly monitoring for extended periods of time, compared to the EPA's proposal, while still providing prompt information about PFAS levels in the water system to enable treatment or other actions should the regulated PFAS levels exceed the MCLs.

In adopting a three-tiered monitoring framework, the EPA is modifying the required sampling frequency from triennial to annual for systems determined by states to be reliably and consistently below the MCL and changing the threshold for this determination from the trigger level to the MCL. To further reduce monitoring, any system that transitions into annual sampling will be required to collect three years of annual samples each of which show concentrations of regulated PFAS below trigger levels (i.e., not an average of the three annual sample results) before then being eligible for triennial monitoring. If eligible for triennial monitoring, the sample collected triennially would need to be collected in the same quarter during which prior annual monitoring results were highest.

This additional, annual tier is intended to create a gradual step-down schedule for affected PWSs to confirm levels of regulated PFAS are remaining consistently low or decreasing. The modifications to the requirements for a reliable and consistent determination and the creation of the new annual sampling tier in the final rule make the requirements for regulated PFAS more consistent with the NPDWR requirements for SOCs. They also represent flexibilities that address concerns about laboratory capability. The EPA believes this three-tier approach, including the eligibility criteria for each outlined above, provides the best approach to protect public health and moderate the total cost of sampling borne by a system.

A few commenters were not supportive of the EPA's initial proposal to compare the running annual average (RAA) to trigger levels to determine eligibility for a "reliably and consistently below the MCL" determination that would allow the PWS to sample at the entry point triennially, after collecting at least four consecutive quarters of quarterly samples. In light of the public comments about the proposed threshold for a reliable and consistent determination and the incorporation of an annual monitoring frequency, the EPA removed the requirement to compare the RAA to the trigger levels to be eligible for such a determination. Instead, the EPA is specifying that a state must consider at least four consecutive quarters of data to make a reliable and consistent determination, with all four quarters required to demonstrate individual results below the MCLs (i.e., not the RAA result of the four quarters). States may establish additional criteria for making these determinations. In addition, the determination makes a system eligible for annual monitoring, not triennial monitoring, justifying the increased flexibility with respect to making this determination accorded to states in the final rule.

The EPA also received some comments about the practice by systems that have installed treatment for PFAS to regularly sample finished water to ensure the efficacy of their treatment media (e.g., filters), above and beyond what they would do for compliance monitoring. A few commenters suggested systems that have installed treatment would conduct this additional sampling voluntarily, typically for process control purposes. A few state agency commenters suggested that any system that is treating its water for PFAS should be required to sample more frequently than triennially (e.g., annually) no matter the levels of previous PFAS detections, since the effectiveness of treatment media may decline over time, if not replaced. The EPA disagrees with the commenters recommending a greater sampling frequency for systems that treat their water for PFAS and does not see a compelling reason to depart from the three-tier compliance monitoring program for a system that has installed treatment. In the final rule, the EPA is adding an annual tier of sampling for any system with concentrations reliably and consistently below the MCL but not consistently below the trigger level. The EPA believes this tier will likely apply to most systems treating their water for regulated PFAS, at least for the first three years of treatment, as the EPA estimates as part of its rule costs that systems needing to install treatment will adopt a treatment target of 80 percent of the MCLs. The majority of systems with elevated levels of regulated PFAS contamination are likely to sample quarterly, at least initially (unless they have treatment for PFAS in place prior to the collection of initial monitoring samples). In practice, the result is that most systems with PFAS contamination will likely not be eligible for triennial sampling unless their PFAS treatment is consistently optimized

and maintained. However, the rule provides that primacy agencies may increase the required monitoring frequency, where necessary to detect variations within the system, and this approach could be applied to those systems that have installed treatment. In addition, the EPA notes that, when systems are treating for other regulated chemicals pursuant to NPDWRs, no distinctions are made between the monitoring frequency required of a system that is treating for a chemical and a system that has not installed treatment. Thus, using the same monitoring frequency for systems regardless of whether they are treating their water for PFAS is consistent with existing NPDWRs.

The EPA requested comment on the proposed allowance for a water system to potentially have each EPTDS on a different compliance monitoring schedule based on specific EPTDS sampling results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three-year compliance period), or if compliance monitoring frequency should be consistent across all of a system's sampling points. A few commenters recommended that all EPTDS used by a system monitor at the same frequency, or that doing so be optional, to reduce the complexity of monitoring requirements or the potential for mistakes to be made with respect to sampling windows. However, the overwhelming majority of those who commented on this topic indicated they supported allowing different sampling frequencies for different EPTDS. The EPA agrees that it would be beneficial to allow different sampling frequencies for different EPTDS because it would allow utilities to realize cost savings if only the EPTDS with elevated levels of PFAS are required to sample most frequently. In addition, the EPA notes it allows systems to use different sampling frequencies for different EPTDS for compliance with other NPDWRs.

To determine compliance monitoring frequency only, the EPA proposed a rule trigger level of one-third the MCLs (1.3 ng/L for PFOA and PFOS and 0.33 for Hazard Index PFAS (PFHxS, PFNA, HFPO-DA, and PFBS)) and invited comments on alternatives. If results for an EPTDS are below the trigger level, systems would be eligible for reduced triennial monitoring. Some commenters raised concerns about potential laboratory analytical and capacity issues associated with endeavoring to measure PFAS concentrations at levels below the PQLs and the rule trigger levels, which are discussed in detail in section 8.8, as well as section 5.1.2, of the EPA response in this *Response to Comments* document; see also section 7.2 of the EPA response in this *Response to Comments* document for further discussion of the PQLs. Some suggested that laboratories cannot achieve levels below the PQLs, which would result in water systems not being eligible for reduced monitoring based on not demonstrating results below trigger levels. The EPA recognizes that some laboratories may not be able to produce results at these lower levels with the same degree of accuracy and precision as results at or above the PQLs, and notes that there is not a requirement that they do so for these purposes of determining monitoring frequency.

Data below the PQL will be critical to ensuring that systems are monitoring at the correct frequency and whether a contaminant is present within a certain range. Moreover, while results near the trigger level may be less definitive than results at or above the PQL, such results are

appropriate for establishing monitoring frequency, as well as for reporting as part of the annual CCR. CCR reporting is based on detected contaminants and for the purposes of the PFAS NPDWR, 141.151(d) defines "detections" as results at or above the rule trigger levels (see section IX of the preamble for more information on CCR requirements.

Under the final rule, for monitoring frequency determination purposes, unlike the determination of compliance with the MCLs, systems are required to use all sample results, including those below the PQLs. The latter are not quantified with the same precision and accuracy as is associated with the compliance calculation determination, as discussed in subsection VIII.B of the preamble and section 8.2 of the EPA response in this *Response to Comments* document. Additionally, the determination of monitoring frequency is not based on an RAA result (for systems monitoring quarterly), but each individual sampling result. As an illustration of the approach, if a water system has quarterly sampling results at an EPTDS from initial monitoring for PFOA that are 2.0, 1.5, 5.0, and 1.5 ng/L, there are two results (i.e., 2.0 and 5.0 ng/L) at or above the EPA's final trigger level for PFOA (i.e., 2.0 ng/L). Thus, the water system would not be eligible for triennial monitoring at this EPTDS for all regulated PFAS when compliance monitoring begins. Providing a different example, if a water system that is currently required to conduct quarterly compliance monitoring has quarterly sampling results at an EPTDS for PFOA that are 2.0, 3.5, 2.5, and 1.5 ng/L, all results are below the MCL for PFOA (i.e., 4.0 ng/L), however three results are above the PFOA trigger level. In this case, because four quarters of data have been collected and assuming all other regulated PFAS sampling results are below their MCLs as well, the water system could be deemed reliability and consistently below the MCL by the primacy agency and be eligible to monitor annually at this EPTDS. For all frequencies of ongoing compliance monitoring, including quarterly, annual and triennial, this determination is to be done the same way where all sample results are used, even those below the PQLs.

Several other issues related to monitoring flexibilities were raised in public comments. One commenter asked, if a PWS has a result from an EPTDS for a single regulated PFAS at a concentration above the trigger level, but other regulated PFAS are below trigger levels, must the system initiate quarterly sampling for all regulated PFAS at the EPTDS or are they only required to initiate quarterly sampling for the specific PFAS observed at or above the trigger level. As described in the rule proposal, if any regulated PFAS is detected, which, for the purposes of the PFAS NPDWR the EPA considers results at or above a trigger level as "detections," the system must monitor quarterly at that sampling point for all regulated PFAS. This is appropriate as the same analytical methods are used for the analysis of all regulated PFAS (no extra analyses need to be performed to measure the other PFAS) and the regulated PFAS have been shown to significantly co-occur.

In addition, commenters questioned whether quarterly sampling would be triggered when a result is equal to but does not exceed the trigger level for systems monitoring triennially. One commenter pointed out that the language proposed for inclusion in § 141.905(b)(2) stated that systems monitoring triennially whose sample result is at or exceeds the trigger level must begin quarterly sampling, whereas § 141.902(b)(2)(ii) stated the trigger level must be exceeded before quarterly monitoring is required. The EPA is clarifying this point in the final rule to reflect the

EPA's intent that quarterly sampling would be triggered when a result is at or above the trigger level as prescribed in § 141.905(b)(2). This same approach has been used in other NPDWRs (e.g., for SOC trigger levels).

Individual Public Comments

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045153)

Does § 141.902(a)(8) require quarterly monitoring based on individual detections at or above the trigger level during initial monitoring, or does this evaluation occur once initial monitoring is completed comparing the average of either the two or four samples to the trigger levels? What does it mean to "monitor quarterly…beginning in the next quarter." If a PWS collects its initial monitoring in the first year after final rule promulgation and exceeds the trigger, must they immediately begin quarterly monitoring even though the compliance date is still two years away? If so, this will cause most PWS to delay initial monitoring until the last year prior to the compliance date. MassDEP recommends that EPA clarify that quarterly monitoring must begin on the compliance date of the final rule.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. The EPA agrees that compliance monitoring does not begin until three years after the date of rule promulgation and has deleted the proposed text for § 141.902(a)(8). Thus, a system that performs initial monitoring in the first year after the rule is promulgated and identifies levels of regulated PFAS that exceed trigger levels would not need to begin quarterly compliance monitoring until three years following rule promulgation.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045751)

15. EPA should clearly define when compliance monitoring would begin under the final rule

PWD supports EPA's decision to allow the use of monitoring data collected before the compliance date of this rulemaking (such as UCMR5) for initial compliance monitoring. However, PWD is requesting that EPA clearly define when compliance monitoring would begin after the compliance date of the final rule. If the final rule compliance date is in the middle of a calendar year, would compliance monitoring begin at the start of the next quarter or at the start of the next year? EPA should provide this clarification so that PWS and primacy agencies can properly plan for the start of compliance monitoring.

EPA Response: As noted under the summary for section 8.1.1, the EPA added specific dates under 40 CFR § 141.900(b)(2), including the date when compliance monitoring will begin, which is three years following rule promulgation rather than at the start of a calendar year or quarter. For discussion of the use of existing data to fulfill initial monitoring requirements, please see section 8.3 of the EPA response in this *Response to Comments* document.

Sammamish Plateau Water and Sewer District (Doc. #1573, SBC-042461)

The proposed rule is particularly unclear in the following areas, and should be revised to provide clarity to water utilities by addressing the following:

• The rule should provide clarity on what initial PFAS detection/limit would result in the need for ongoing monitoring. The rule should clarify whether this based on an exceedance of the proposed MCL or a percentage of the MCL. Additionally, regardless of the percentage of the MCL requiring a response (.3 versus .5 MCL), it would be helpful to provide clarity as to what levels will require the need for treatment.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Under the final rule, all CWS and NTNCWS are required to conduct compliance monitoring at least every three years and potentially as often as quarterly. This frequency will be determined based on previous sampling results. Systems with RAA results above an MCL will be required to take actions, such as treatment, to reduce levels of regulated PFAS to at or below all MCLs to be in compliance with the rule.

Edward Cullen (Doc. #3075, SBC-047724)

EPA regulations should require providers of public drinking water to measure the levels of PFOA, PFOS, PFHxS, HFPO-DA, PFNA, and PFBS in drinking water, and to report the results to suitable authorities and to the public. Measurements should be made using available methods and sampling procedures approved by the EPA, as describe in the proposed rule (FR 88, 18638 (2023)). Also, for the sake of the health of US citizens and residents, the final EPA rule should require providers of public drinking water to remove PFOA, PFOS, PFHxS, HFPO-DA, PFNA, and PFBS whenever they are found to exceed the relevant Maximum Contaminant Level (MCL) or Hazard Index (HI), so that the drinking water meets the requirements of the rule.

I would like to congratulate and thank all the people at EPA who have worked on this program and put together the proposed rule.

Sincerely,

Edward Cullen

New Jersey

EPA Response: The EPA agrees with this commenter's recommendations, which are in alignment with the final rule. For more on the final rule compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document. Additionally, the final rule requires systems to measure levels of the six PFAS the commenter identified using EPA-approved methods. (Analytical methods are discussed in section VII of the preamble to the final rule.) Public water systems are required to comply with NPDWRs, including meeting MCLs. For a discussion of how compliance is assessed and the EPA's

responses to comments on that topic, please see section VIII of the preamble to the final rule and section 8.2 of the EPA response in this *Response to Comments* document. The Public Notice Rule requires public water system to notify persons served when there is a violation or situation with potential to have adverse health effects, and the CCR Rule requires CWSs to provide consumers with information about detected levels of PFAS in their reports. For more information about public notice and CCR requirements, please see section IX of the preamble and section 9.1 of the EPA response in this *Response to Comments* document.

Portland Water Bureau (PWB) (Doc. #1769, SBC-044541)

May 30, 2023

Michael S. Regan, Administrator

U.S. Environmental Protection Agency

Mail Code 2822IT

1200 Pennsylvania Avenue, NW Washington, DC 20460

RE: Comments on EPA Proposed PFAS National Primary Drinking Water Regulation Rulemaking (Docket ID No. EPA-HQ-OW-2022-0114)

Dear Administrator Regan,

The Portland Water Bureau (PWB) in Portland, Oregon appreciates the opportunity to review and provide comments on EPA's proposed PFAS National Primary Drinking Water Regulation and supports EPA's efforts to reduce exposure from PFAS in drinking water. These comments were submitted electronically via regulations.gov.

The PWB is the largest drinking water utility in Oregon, serving nearly one million Oregonians every day. Portland is fortunate to have invested in two high quality water supplies and, to date, has not detected PFAS chemicals in our water supplies. Portland's primary drinking water source is the highly protected Bull Run Watershed, the largest drinking water supply in Oregon. Portland also has a secondary groundwater source, which is used as needed for seasonal supply augmentation and as a backup to the Bull Run surface water supply.

Portland is among many public water systems in the Pacific Northwest that operate seasonal and/or backup water supplies, such as aquifer storage and recovery wells, to balance out the wet winters and dry summers. For supplies/entry points used on an intermittent or seasonal basis, the draft rule is not clear how compliance is determined when quarterly monitoring is required. We would like to request clarification of monitoring and compliance requirements for intermittent use of supplies in the regulation.

EPA Response: Systems that use multiple sources and blend the water at one location before it is routed to a single entry point are to collect samples during time periods representative of standard operating conditions, according to 40 CFR § 141.902(a)(2). Thus, for systems that
