What's the Problem with Dog Waste?

Dog waste left in our yards, forest areas and parks can have many adverse effects on the environment.

It's full of harmful bacteria and excess nutrients.

Besides being a neighborhood nuisance, dog waste can make people sick, especially children who are more likely to come into contact with it while playing.

Dog waste left on lawns can also kill or damage grass and other plants.

When dog waste is washed into lakes or streams, the waste decays, uses up oxygen in the water, and sometimes releases ammonia. This can kill fish!

Dog waste also contains nutrients that encourage weed and algae growth.

Too much of these nutrients turn water cloudy and green . . . imagine this in your backyard pond or stream!

Managing dog waste properly is something easy that everyone can do to make a difference in the quality of our surface waters.

Brought to you by the

Town of Sandown

PO Box 1756

Sandown, NH 03873

Information taken from

Mass DEP and dcr Massachusettts

DOG WASTE AND SURFACE WATER QUALITY

Did You Know?

There are over 1500 licensed dogs in our town.

Each of these dogs produces about $\frac{3}{4}$ pound of solid waste and over 7 billion bacteria daily!

Rainfall and snowmelt in the Town of Sandown goes untreated and ultimately goes into local streams, ponds, rivers and lakes.

As it flows, stormwater picks up contaminants and pollutants in its path.

That's why it's important to make sure that dog waste and its pollutants do not end up in our waterbodies.

What's So Bad About Dog Waste?

Bacteria and other parasites found in pet waste, such as Giardia and Cryptosporidium, can survive for long periods when left on the ground.

During a rain storm, these pollutants can be washed into local rivers and ponds and into local drinking water supplies.

Individual actions can result in significant water quality improvements when carried out by many people.

Unlike some forms of stormwater pollutants, individual people can easily and economically manage dog waste and help

keep our waters safe and aesthetically pleasing.

How You Can Help

BRING IT – Always bring a plastic bag when you walk your dog.

BAG IT – Use the bag as a glove to pick up the dog waste. Scoop it up and turn the bag inside out around the waste.

DISPOSE IT – Properly dispose of dog waste by putting it in a trash can.

AND REMEMBER

- Pick up after your pet in your yard
- Only bring your dog where dogs are allowed.

What lakeside homeowners can do to protect New Hampshire's surface waters?

- Design and site your septic system in accordance with DES rules.
- Keep your septic system maintained by inspecting and pumping every two to three years.
- Do not apply fertilizer closer than 25' from the shore—it's against the law.
- If you must fertilize, use low phosphate, slow release nitrogen fertilizer between 25' and 250' from shore.
- Keep a buffer zone of native plants along the shore.
- Minimize paving to reduce stormwater runoff.
- Reroute runoff from eroded paths, so it can slow down and soak into the soil, minimizing runoff.
- Use low phosphate cleaning supplies.
- Do not bathe in the water.
- Do not allow farm animals in the lake or stream—provide alternative water sources.

What boaters can do to keep New Hampshire's inland surface waters clean

- Use low-polluting outboard marine engines: four-stroke or direct fuel injected two-stroke.
- Make certain there are no overboard discharges of sewage or gray water into the water—it's against the law.
- Whenever possible, refuel personal watercraft and small boats on land, at gas stations and away from the shore.
- When boating in shallow areas or along the shoreline, minimize your wake.
- Clean boats, motors, and trailers of any clinging plant or animal material before launching in the lake or river. Dispose of all attached materials on land and away from shore.

Don't Drink Untreated Surface Water!

What lake and riverfront residents and renters should know about drinking untreated surface water

N.H. Dept. of Environmental Services
and
Rotary Club of Wolfeboro, NH

DO NOT USE Lakes or Streams for Domestic Water Supply

Some residents and visitors think of New Hampshire as relatively rural and pristine and believe it is safe to use surface water for drinking. Surface waters include lakes, ponds, streams, and some springs—and these waters naturally contain microorganisms.

Diseases that may be transmitted by surface water include gastroenteritis, dysentery, and giardiasis. Symptoms of ingesting contaminated surface water include nausea, vomiting, diarrhea, mild fever, and general malaise.

Populations of potentially harmful microorganisms are naturally occurring in all waterbodies. Weather and water conditions, poor human sanitary practices, feces from animals and waterfowl can result in an uncontrollable change in water quality that can make you sick, even though past bacterial tests of the water may have shown good water quality.

Regardless of the presumed safety of this practice in the past, drinking untreated water from lakes, ponds, and streams is not safe and DES strongly cautions against this practice.

Treating your own drinking water is not recommended, because:

- There are usually no restrictions on activities in the vicinity of the intake.
- Testing, inspections, record keeping, and maintenance of the system is usually sporadic.

- Routine chemical and bacteriological monitoring, as well as monitoring for other pathogens, is usually not done.
- Mixing time for the source water and the chlorine may be insufficient to kill some microorganisms, and others can only be removed by filtration.

While many municipalities and private companies take water from lakes or rivers for domestic use, sophisticated filtration and/or chlorination systems are always required. Many lakes that are used as a source of municipal water supply have restrictions on fishing, swimming, and boating activities, thus restricting the presence of man and lowering potential contamination. In addition, they are sampled daily.

For reliable drinking water, DES recommends the use of dug, point, or drilled wells, or municipal or small public water systems operated by a certified water system operator. Another option is to bring bottled water to a house that does not have clean, potable water.

VOLUNTEER LAKE ASSESSMENT PROGRAM INDIVIDUAL LAKE REPORTS

ANGLE POND, SANDOWN

2017 DATA SUMMARY

RECOMMENDED ACTIONS: Angle Pond water quality declined in 2017 and an algal bloom likely occurred in July due to excess nutrient (phosphorus) levels. The above average spring/early summer rainfall and associated stormwater runoff likely transported excess nutrients to the pond that fed algal growth. Stormwater management should be a main focus in the watershed and on waterfront properties. Consider joining NHDES' Soak up the Rain NH program to help implement stormwater management in the watershed. For more information visit www.soaknh.org. Sayre Inlet phosphorus and turbidity levels were extremely elevated and indicate upstream sources of pollution, and turbidity levels exceed state water quality standards. Work with the DES Watershed Management Bureau, the NH Dept. of Agriculture and the Town to address upstream sources of pollution. Keep up the great work!

OBSERVATIONS (Refer to Table 1 and Historical Deep Spot Data Graphics)

- ◆ **CHLOROPHYLL-A:** Chlorophyll levels were elevated in June, increased to levels indicative of an algal bloom in July, and then decreased to moderate levels in August. Average chlorophyll level increased greatly from 2016 and was much greater than the state median and the threshold for mesotrophic lakes. Historical trend analysis indicates highly variable chlorophyll levels since monitoring began.
- ◆ **CONDUCTIVITY/CHLORIDE:** Epilimnetic (upper water layer), Metalimnetic (middle water layer), Hypolimnetic (lower water layer), and Outlet conductivity levels remained elevated and much greater than the state median. Epilimnetic chloride levels were much greater than the state median however did not exceed the state chronic chloride standard. Historical trend analysis indicates relatively stable epilimnetic conductivity levels with moderate variability between years. Sayre Inlet conductivity and chloride levels continue to be elevated however chloride levels did not exceed the state standard.
- ◆ **COLOR:** Apparent color was measured in the epilimnion and indicates the pond is moderately tea colored, or brown.
- ◆ **E. COLI:** Sayre Inlet E. coli levels were within a low range in June and much less than the state standard of 406 cts/100 mL for surface waters.
- ◆ **TOTAL PHOSPHORUS:** Epilimnetic phosphorus levels were elevated in June following a significant storm event and above average spring/early summer rainfall, and then decreased to within a low to moderate range in June and August. Average epilimnetic phosphorus level increased from 2016 and was slightly greater than the state median and the threshold for mesotrophic lakes. Historical trend analysis indicates stable epilimnetic phosphorus levels since monitoring began. Metalimnetic phosphorus level was low in June, increased to an elevated level in July during the algal bloom, and then decreased to a moderate level in August. Hypolimnetic phosphorus levels increased from low to elevated as the summer progressed likely due to phosphorus release from bottom sediments under anoxic conditions. Outlet phosphorus levels were elevated in June and July. Sayre Inlet phosphorus levels remained greatly elevated in June and July.
- ◆ **TRANSPARENCY:** Transparency measured with (VS) and without (NVS) the viewscope was below average in June and July due to highly colored water flushed in from spring rains, as well as algal blooms. Transparency increased (improved) only slightly in August, and average NVS transparency decreased from 2016 and was the lowest (worst) measured since 2006. Historical trend analysis indicates highly variable transparency since monitoring began.
- ◆ **TURBIDITY:** Epilimnetic turbidity levels decreased as the summer progressed and remained within a low to moderate range for that station. Metalimnetic turbidity levels were within a low to average range. Hypolimnetic turbidity levels were low in June and July and elevated in August. Outlet turbidity levels remained within a low to moderate range. Sayre Inlet turbidity levels were greatly elevated in June and July.
- ◆ **pH:** Epilimnetic pH levels were within the desirable range 6.5-8.0 units and increased in 2017 likely due to photosynthetic by-products from elevated algal and/or cyanobacteria growth. Historical trend analysis indicates relatively stable epilimnetic pH levels with moderate variability between years. Metalimnetic, Hypolimnetic, Outlet, and Sayre Inlet pH levels were also within the desirable range.

Station Name	Table 1. 2017 Average Water Quality Data for ANGLE POND-SANDOWN										
	Alk. mg/l	Chlor-a ug/l	Chloride mg/l	Color PCU	Cond. uS/cm	E. Coli MPN/100ML	Total P ug/l	Trans. m		Turb. ntu	pH
								NVS	VS		
Epilimnion	18.4	12.74	54	73	254.0		14	2.42	2.83	0.87	7.46
Metalimnion					251.7		14			0.89	6.84
Hypolimnion					243.0		16			3.14	6.51
Outlet					270.5		23			0.76	6.72
Sayre Inlet			100		417.0	30	193			16.65	6.76

NH Median Values: Median values for specific parameters generated from historic lake monitoring data.

Alkalinity: 4.9 mg/L

Chlorophyll-a: 4.58 mg/m³

Conductivity: 40.0 uS/cm

Chloride: 4 mg/L

Total Phosphorus: 12 ug/L

Transparency: 3.2 m

pH: 6.6

NH Water Quality Standards: Numeric criteria for specific parameters. Results exceeding criteria are considered a water quality violation.

Chloride: > 230 mg/L (chronic)

E. coli: > 88 cts/100 mL – public beach

E. coli: > 406 cts/100 mL – surface waters

Turbidity: > 10 NTU above natural level

pH: between 6.5-8.0 (unless naturally occurring)

HISTORICAL WATER QUALITY TREND ANALYSIS

Parameter	Trend	Explanation	Parameter	Trend	Explanation
Conductivity	Stable	Trend not significant; data moderately variable.	Chlorophyll-a	Stable	Trend not significant; data highly variable.
pH (epilimnion)	Stable	Trend not significant; data moderately variable.	Transparency	Stable	Trend not significant; data highly variable.
			Phosphorus (epilimnion)	Stable	Trend not significant; data show low variability.

Fanwort

The Waterbody Report Card tables are generated from the DRAFT 2016 305(b) report on the status of N.H. waters, and are based on data collected from 2006-2015. Detailed waterbody assessment and report card information can be found at www.des.nh.gov/organization/divisions/water/wmb/swqa/index.htm

Designated Use	Parameter	Category	Comments
Aquatic Life	Phosphorus (Total)	Slightly Bad	Data exceed water quality standards or thresholds for a given parameter by a small margin.
	pH	Slightly Bad	Data periodically exceed water quality standards or thresholds for a given parameter by a small margin.
	Oxygen, Dissolved	Encouraging	Limited data for this parameter predicts water quality standards or thresholds are being met; however more data are necessary to fully assess the parameter.
	Dissolved oxygen saturation	Cautionary	Limited data for this parameter predicts exceedance of water quality standards or thresholds; however more data are necessary to fully assess the parameter.
	Chlorophyll-a	Slightly Bad	Data exceed water quality standards or thresholds for a given parameter by a small margin.
Primary Contact Recreation	Escherichia coli	Very Good	All sampling data meet water quality standards or thresholds for this parameter.
	Cyanobacteria hepatotoxin	Slightly Bad	Cyanobacteria bloom(s).
	Chlorophyll-a	Good	Sampling data commonly meet water quality standards or thresholds for this parameter.

BEACH PRIMARY CONTACT ASSESSMENT STATUS

PHILLIPS POND - SEELEY TOWN BEACH	Escherichia coli	Good	Sampling data commonly meet water quality standards or thresholds for this parameter.
PHILLIPS POND - SEELEY TOWN BEACH	Cyanobacteria	Slightly Bad	Cyanobacteria bloom(s).

VOLUNTEER LAKE ASSESSMENT PROGRAM INDIVIDUAL LAKE REPORTS

PHILLIPS POND, SANDOWN

2017 DATA SUMMARY

RECOMMENDED ACTIONS: Pond conductivity levels have significantly increased (worsened) since monitoring began, and chloride levels are elevated for NH surface waters. This indicates the impacts of winter de-icing materials applied to local roads, parking lots, driveways and walkways. Encourage local road agents and winter maintenance companies to obtain a NH Voluntary Salt Applicator license through UNH Technology Transfer Center's Green SnowPro Certification program to help reduce conductivity and chloride levels. Hypolimnetic phosphorus levels continue to be indicative of internal loading from bottom sediments and/or milfoil management activities. This highlights the importance of minimizing external sources of phosphorus from the watershed. DES' "NH Homeowner's Guide to Stormwater Management" is a great resource to help manage stormwater runoff and reduce nutrient (phosphorus) loading to the pond. Apparent color was measured to better understand how tea colored the water is, or how much dissolved organic matter is present, and how this affects water clarity throughout the season. There appears to be a relationship between color and clarity and we recommend monthly color analyses continue to better understand this relationship. Keep up the great work!

OBSERVATIONS (Refer to Table 1 and Historical Deep Spot Data Graphics)

- ▲ **CHLOROPHYLL-A:** Chlorophyll levels were elevated in May and then decreased to a low level in June, and fluctuated between a low to moderate range from July to September. Average chlorophyll levels decreased slightly from 2016 however were slightly greater than the state median and threshold for mesotrophic lakes. Historical trend analysis indicates relatively stable chlorophyll levels with moderate variability between years.
- ▲ **CONDUCTIVITY/CHLORIDE:** Epilimnetic (upper water layer), Hypolimnetic (lower water layer), Inlet, Metacomet Inlet, and Outlet conductivity and chloride levels remained elevated and much greater than the state medians. However, chloride levels remained less than the state chronic chloride standard. Historical trend analysis indicates significantly increasing (worsening) epilimnetic conductivity levels since monitoring began.
- ▲ **COLOR:** Apparent color was measured in the epilimnion and was highest in May and June during spring rains and snowmelt and then decreased slightly as the summer progressed. Color levels indicate the pond water is highly tea colored, or dark brown.
- ▲ **TOTAL PHOSPHORUS:** Epilimnetic phosphorus levels were slightly elevated on each sampling event. Average epilimnetic phosphorus increased from 2016 and was greater than the state median and threshold for mesotrophic lakes. Historical trend analysis indicates stable epilimnetic phosphorus levels since monitoring began. Hypolimnetic phosphorus levels were elevated from June to September and the turbidity was also elevated indicating the release of phosphorus from bottom sediments in hypolimnetic waters when dissolved oxygen levels are depleted below 1.0 mg/L, a process called internal phosphorus loading. Tributary phosphorus levels were generally slightly elevated from July through September when flow levels were stagnant or very low.
- ▲ **TRANSPARENCY:** Transparency measured without the viewscope was lower from May through July when water color was darkest, and then increased (improved) in August and September as water color became lighter. Average transparency decreased (worsened) in 2016 and was much less (worse) than the state median. Historical trend analysis indicates highly variable transparency since monitoring began. Transparency measured with the viewscope (VS) was generally higher (better) than NVS transparency and likely a better measure of actual conditions.
- ▲ **TURBIDITY:** Epilimnetic, Inlet, Metacomet Inlet, and Outlet turbidity levels fluctuated within a low to average range from May through September. Hypolimnetic turbidity levels were elevated from June through September due to the formation and accumulation of organic compounds under anoxic (no oxygen) conditions.
- ▲ **PH:** Epilimnetic and Inlet pH levels were within the desirable range 6.5-8.0 units and historical trend analysis indicates stable epilimnetic pH levels since monitoring began. Hypolimnetic and Outlet pH levels were slightly acidic, and Metacomet Inlet pH levels were acidic and potentially critical to aquatic life.

NH Water Quality Standards: Numeric criteria for specific parameters. Results exceeding criteria are considered a water quality violation.

Chloride: > 230 mg/L (chronic)
