drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Nototrichium humile* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes,

landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

### ***Life History***

#### **Food/Nutrient Resources**

#### **Breeding Season**

Adult: Flowering in *N. humile* is generally heaviest in the spring and summer, and the fruits mature a few weeks after flowering (USFWS, 2016).

#### **Reproduction Narrative**

Adult: Flowering in *N. humile* is generally heaviest in the spring and summer, and the fruits mature a few weeks after flowering. Pollination vectors for this species are not known, nor is it known if the plants are self-compatible. Based on observations of particular individuals, the plants live for at least one or two decades (Makua Implementation Team 2003). Other demographic information for *N. humile* in the wild is unknown, including number of seeds produced, age at sexual maturity, survivorship to sexual maturity, number of years in reproductive condition, survivorship during reproductive life, seed dispersal, vegetative reproduction and specific environmental requirements (USFWS, 2016).

#### **Habitat Type**

Adult: Dry forest gulch (USFWS, 2016)

#### **Habitat Narrative**

Adult: Open, remnant dry or mesic forest, on cliff faces, in gulches, or on steep slopes. (NatureServe, 2015). *Nototrichium humile* is found on gulch slopes and gulch bottoms in the understory of dry forests dominated by *Diospyros sandwicensis* or *Sapindus oahuensis*, dry shrublands near ridge tops, and open dry cliffs and cliff ledges sparsely vegetated with shrubs and grasses. Small groups or isolated plants sometimes occur in mesic habitats. On cliffs, *N. humile* is somewhat protected from feral ungulates, invasive alien weeds, and fire. This species usually is found on north-facing slopes at elevations of 60 to 700 m (197 to 2,298 ft) (Makua Implementation Team 2003) (USFWS, 2016).

### ***Dispersal/Migration***

#### ***Population Information and Trends***

#### **Population Trends:**

Increasing (USFWS, 2016)

#### **Number of Populations:**

10 (USFWS, 2020)

#### **Population Size:**

880-950 (USFWS, 2020)

**Population Narrative:**

Currently there are 880 to 950 wild individuals on O‘ahu, and this number has been steadily declining since listing. A landscape-based assessment of climate change vulnerability for native plants of Hawai‘i using high resolution climate change projections was made by Fortini et al. (2013) and their analysis showed that *Nototrichium humile* is highly vulnerable to the effects of climate change. A wildfire in 2018 approached populations. Wild and reintroduced populations are provided protection from feral ungulates by fencing and ungulate control. Nonnative plants are controlled within five managed areas. Seed collection, propagation, and reintroduction are ongoing, with three populations nearing the ANRP’s collection goals. Germination and seed storage studies are ongoing (USFWS, 2020). Currently, there are 880 to 950 wild individuals in 10 populations in the Wai‘anae mountains of O‘ahu (U.S. Army 2018, appendices; Army Natural Resources Program-O‘ahu (ANRP) 2019, Appendix 4-1).

**Threats and Stressors**

**Stressor:** Fire (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Threats include fires (USFWS, 2016)

**Stressor:** Climate change loss or degradation of habitat (USFWS, 2020)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawai‘i using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Nototrichium humile* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.675 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions may be needed to conserve this taxon into the future, such as locating key microsites that overlap with current and future climate envelopes for outplanting efforts. (USFWS, 2020)

**Recovery****Reclassification Criteria:**

Due to limited knowledge of life history requirements for short-term and long-term survival, the recovery plan for this species specifies interim objectives to downlisting and delisting that involve stabilization of all existing populations (Service 1995a, 1998a) (USFWS, 2016).

**Delisting Criteria:**

Due to limited knowledge of life history requirements for short-term and long-term survival, the recovery plan for this species specifies interim objectives to downlisting and delisting that involve stabilization of all existing populations (Service 1995a, 1998a) (USFWS, 2016).

**Conservation Measures and Best Management Practices:**

- Recommendations for Future Actions: Fire has increased in significance as a threat (after the previous 5-year review in 2013) since a large wildfire approached known populations in 2018. There is no other significant new information regarding the species' biological status since the last 5-year review in 2013. Thus, the following recommendations for future actions are added or reiterated for the 5-year review for 2020. • Surveys and inventories—Continue to conduct thorough surveys of all historical and suitable habitat for new occurrences. • Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect individuals from the negative impacts of browsing by ungulates. • Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species, and those that compete with *Nototrichium humile*. • Fire monitoring and control—Establish populations in areas where damage or destruction by fire is less likely. Continue to develop and implement fire prevention management plans and coordinate effective fire suppression efforts, especially for Mākaha and Wai'anae Kai. • Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species. • Slug control—Continue to develop and implement effective control measures for slugs. • Captive propagation for genetic storage and reintroduction—Continue collection and propagation efforts for maintenance of genetic stock and for reintroduction. • Reintroduction and translocation—Determine optimal sites and continue to reintroduce individuals into areas that are being managed for known threats. • Population biology research—
  - o Determine the number of genetically distinct plants in the populations of *N. humile*.
  - o Study *N. humile* with regard to population size and structure, geographical distribution, breeding system, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. Continue germination trials and seed storage studies.
  - o Determine suitability of habitat on Maui for reintroduction.• Alliance and partnership development—Continue to work with partners in planning and implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2020)
- New Management Actions: • Surveys and inventories—The ANRP continues to monitor wild and reintroduced populations of *Nototrichium humile* in the Wai'anae mountains of O'ahu, pursuant to the requirements of the Service's Biological Opinion for military training at Mākua Military Reservation of 2003 and the reinitiation in 2007 (USFWS 2007). • Ungulate monitoring and control—Ungulate monitoring and control is ongoing in the ANRP's population units and in the management units Kaluakauila, Wai'anae Kai, Mākua South, Manuwai, and Kolekole (U.S. Army Garrison Hawai'i 2010, pp. 2-141, 2-146-147; ANRP-O'ahu 2019, p. 16, Appendix 3-1). The Kahanahāiki and Palikea management units are ungulate-free with regular fence monitoring (ANRP-O'ahu 2019, Appendix 3-1). • Established ecosystem altering invasive plant species control—Nonnative plants are controlled within the exclosures at Kahanahāiki, Kaluakauila, Mākaha, Wai'anae Kai, and Manuwai (ANRP-O'ahu 2019, Appendix 4-7). • Fire threat control by ANRP includes removing fuel (nonnative grasses), marking areas for water drops, and installing fuel breaks in fallow lands along accessible roads (ANRP-O'ahu 2019, Appendix 4-7). Currently, one management unit, Kaimuhole-Palikea that includes *N. humile* has reached 100 percent of fire management goals and Wai'anae Kai has reached 92 percent of fire management goals. • Captive propagation for genetic storage and reintroduction—
  - o The ANRP reported collection of more than 4,500 seeds representing 19 founders from five populations in three locations (Punapōhaku, Kaimuhole-Palikea, Kolekole) and are close to collection goals (ANRP-O'ahu 2019, appendix 4-8). In 2018, 424 plants were propagated representing 124 founders from seven populations (U.S. Army 2018).
  - o The National Tropical Botanical Garden (NTBG) reported three individuals of *Nototrichium humile* in a living collection at the Southshore Garden (NTBG 2019).
  - o The Waimea Valley Arboretum

reported between 67 to 86 individuals of *N. humile* representing six wild individuals in refugia (Waimea Arboretum 2013, 2014, 2017, 2018). • Reintroduction and translocation—Between 2018 and 2019, the ANRP reported reintroduction or establishment of a living collection at botanical gardens of 435 plants representing approximately 190 individuals from seven populations (U.S. Army 2018). Currently, 256 of the individuals survive, 113 individuals in two reintroduction sites (one with 106 individuals), and the remaining of which are in the living collections at Schofield Barracks, Koko Crater Botanical Garden, and Waimea Valley Arboretum collections (U.S. Army 2018). • Population biology research—Germination trials are ongoing, currently with a minimum viability of 66 percent. Bulk seed collections provide material for processing protocol and for storage and longevity research (ANRP-O‘ahu 2019, pp. 124–125) (USFWS, 2020)

## SPECIES ACCOUNT: *Oenothera deltoides* ssp. *howellii* (Antioch Dunes evening-primrose)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

#### **Physical Description**

A biennial herb that forms tufts of coarse, heavily-branched, drooping stems. Lower leaves grayish, pubescent, form basal rosette. Flowers bell-shaped, acquiring a blush of pink with age (Smithsonian Institution 1980). (NatureServe, 2015)

#### **Taxonomy**

*Oenothera deltoides* subsp. *howellii* is a short-lived perennial in the primrose family (Onagraceae) (USFWS, 2019).

#### **Historical Range**

See current range/distribution.

#### **Current Range**

Endemic to the Antioch Dunes, known from Contra Costa County and introduced in Sacramento County, California (Skinner 1997). (NatureServe, 2015)

#### **Critical Habitat Designated**

Yes; 8/31/1978.

#### **Legal Description**

On August 31, 1978, the U.S. Fish and Wildlife Service, designated critical habitat for *Oenothera deltoides* ssp. *howellii* (Antioch Dunes evening-primrose) under the authority of the Endangered Species Act of 1973 (43 FR 39042 - 39044). Critical habitat was designated for one unit in California.

#### **Critical Habitat Designation**

One critical habitat unit is designated in California, described as: An area of land, water, and airspace in Contra Costa County with the following components: T. 2 N. R. 2 E. SW 1/4 section 17, E 2/3 of S 1/3 of section 18 (43 FR 39042 - 39044).

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements are not described (43 FR 39042 - 39044).

#### **Life History**

#### **Food/Nutrient Resources**

#### **Reproductive Strategy**

Adult: Self-incompatible, requiring cross-pollination for viable seed, insect pollinated (USFWS, 1984; 2019)

**Reproduction Narrative**

Adult: The Antioch Dunes evening-primrose is vespertine; the flowers open in early evening and close by mid-morning. In the garden, the plant flowers from "March to May and briefly in September" (Roof 1969). This *Oenothera* is self-incompatible (Klein 1970) and thus requires cross-pollination for sound seed. Arnold (pers. Comm. 1982) believes that bees are the primary pollinating agent at Antioch. Although hawkmoths were not known on the dunes until 1983, they have been reported as pollinators of other *Oenothera* species (Gregory 1963). Their role as pollinators of Antioch Dunes evening-primrose has not been documented. Studies are needed to determine the phenology, pollinators and seed dispersal mechanisms of this subspecies (USFWS, 1984).

**Habitat Type**

Adult: Interior dunes on the "Antioch Dunes" along the shore of the San Joaquin River in Contra Costa County, California, occurring in nearly pure and shifting sand (USFWS, 2019).

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits inland dunes; this species will not mature where adult plants have previously grown unless fresh sand is deposited (Smithsonian Institution 1980 and Skinner 1997 in NatureServe, 2015). O.d. subsp. *howellii* is considered almost entirely restricted to the remaining Antioch Dunes habitat at the Antioch Dunes Natural Wildlife Refuge, which encompasses 67 acres (the 41-acre Stamm Unit, owned by the Service and the 26-acre Sardis Unit, of which 14 acres are owned by the Service and 12 acres are owned by Pacific Gas and Electric)(USFWS, 2019).

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Declining (USFWS, 2019)

**Number of Populations:**

4 (Stamm Unit, Sardis Unit, transplanted location on Browns Island, and Brannan Island)(USFWS, 2019).

**Population Size:**

2,368 (as of 2017)(USFWS, 2019)

**Population Narrative:**

According to the CNDDDB (2018a), *Oenothera deltoides* subsp. *howellii* is known from 10 EOs, nine of which are presumed extant and one of which is considered likely extirpated (Table 2). Of

the nine presumed extant EOs, six are considered natural occurrences and three are considered transplanted outside of native habitat and/or range. The total population in 2017 was estimated at 2,368 individuals, with 2,334 plants counted at the ADNWR (2,008 at the Stamm Unit and 326 at the Sardis Unit) and 34 plants at one of the transplanted locations at Browns Island (Table 2). Population numbers have shown some improvement since the 2008 Five-Year Review, as illustrated by plant count numbers from ADNWR (Figure 5; Service 2018a, Service No Date). However, despite the improvement, the overall population is still not considered stable or self-sustaining due to the overall low population numbers, low redundancy of populations, and continuing and increasing threats (USFWS, 2019).

### ***Threats and Stressors***

**Stressor:** Habitat destruction from sand mining, industrial and urban/suburban development, and/or conversion to agriculture

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Habitat for the Lange's metalmark, O.d. subsp. howellii, E.c. var. angustatum, and pollinators, and area available for habitat restoration is threatened by destruction and conversion to other uses. This threat is largely ameliorated on the ADNWR and other properties with protection/management agreements in place, but not on properties without such agreements (USFWS, 2019).

**Stressor:** Habitat degradation due to loss of natural disturbance regime

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** The reduction in sand deposition in Antioch Dunes habitat as a result of water management/use (dams, levees, etc.) in the Sacramento/San Joaquin River Delta system and reduced effectiveness of wind-driven dispersal of sand and disturbance of dunes has and continues to reduce overall size and connectedness of the dune natural community (USFWS, 2019).

**Stressor:** Habitat degradation due to non-native and native invasive vegetation

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Invasive vegetation colonizes open sand habitat, reducing available suitable Lange's metalmark, O.d. subsp. howellii, E.c. var. angustatum, and pollinator, habitat. Invasive plants out-compete native species, including Lange's metalmark host and food plants, and O.d. subsp. howellii and E.c. var. angustatum, for sunlight, space, nutrients, and moisture. They also stabilize the sand/soil, eliminating the natural disturbance regime and may cause soils to become more eutrophic (Thomson 2005a, Thomson 2005b, Chin 2012, McNally 2014). The 2008 Five-Year Review notes that the proliferation of non-native invasive plants has been increasing rapidly since 1998 (Service 2008) and these conditions continue (Chin 2012, McNally 2014, Service 2018a, Service 2018b, Service 2018c, Service 2018d). The use of herbicides to control non-native and native invasive vegetation may also present potential threat to Lange's metalmark host and food plants, O.d. subsp. howellii, and E.c. var. angustatum occurring in the same vicinity. Applying

herbicides selected for the target species and using appropriate rates and technique should minimize effects to non-target Lange's metalmark host and food plants, *O.d. subsp. howellii*, and *E.c. var. angustatum*. These practices have been instituted at the ADNWR, so this threat is considered largely ameliorated there (Service 2008), but it may pose a risk to current and future occurrences of these listed species elsewhere. Additionally, some herbicides may pose threat directly to Lange's metalmark. In a study of Behr's metalmark, a close relative of Lange's metalmark butterfly, the herbicides triclopyr, sethoxydim, and imazapyr were found to reduce the number of adults that emerged from pupation by 24-36% after exposure to typical field application rates (Stark et al 2012 in Richmond et al 2015) (USFWS, 2019).

**Stressor:** Habitat degradation due to gypsum dust deposition from neighboring plant (facility)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The 2008 Five-Year Review reported that gypsum dust building up on plants may reduce exposure to sunlight and decrease photosynthesis. It may also alter soil chemistry due to introduction of calcium and sulphates, which may affect the growth of Lange's metalmark host and food plants, *O.d. subsp. howellii* and *E.c. var. angustatum* and promote colonization by invasive species. Deposition is noted as affecting mostly the Sardis Unit. The ADNWR staff have met with Georgia-Pacific (G-P) about concerns over the dust and G-P increased efforts to reduce airborne gypsum (beyond the standards for air pollution control) by keeping it wetted down when possible during production activities. At the time of the 2008 Five-Year Review, staff noted a reduction in dust from G-P efforts. The review noted that there was no evidence that gypsum dust was adversely affecting any of the three species (Service 2008). However, it also cited a study that demonstrated that dusts may adversely increase transpiration through the cuticle of insect larvae and cause desiccation and abrasion of the cuticle (Wigglesworth 1945 in Service 2008), which may affect Lange's metalmark and pollinators of *O.d. subsp. howellii* or *E.c. var. angustatum*. The ADNWR staff reported an increase in gypsum dust deposition at ADNWR in 2017-2018 (Susan Euing pers. comm. December 12, 2018). In 2018, staff noted that gypsum was being deposited on the refuge at concentrations that coats plants, leading to cancellation of surveys for the Lange's metalmark in some parts of the refuge (Susan Euing pers. comm. August 17, 2018). In 2019, after several weeks into the Lange's metalmark survey season, ADNWR staff confirmed that no surveys had been canceled due to concerns about gypsum dust deposition (Louis Terrazas pers. comm. September 10, 2019). The magnitude of this potential stressor requires further investigation and Service partnership with G-P is ongoing (USFWS, 2019).

**Stressor:** Habitat degradation due to rogue hiking/trails

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** This activity may cause direct injury or mortality to the Lange's metalmark, to its host and food plants, and to *O.d. subsp. howellii* and *E.c. var. angustatum* from trampling while also increasing potential for accidental introduction of wildfire from hikers. These threats and stressors were significantly reduced when ADNWR was fenced in 1986 and the 2008 Five-Year Review (Service 2008) no longer considered recreational and pedestrian traffic to be a significant threat. However, ADNWR staff note that incidence of trespassing and human encampments at ADNWR has increased in the past several years (Susan Euing pers. comm. December 12, 2018) (USFWS, 2019).

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes

**Exposure:**

**Response:**

**Consequence:** Extirpation

**Narrative:** These activities represent a threat to the Antioch Dunes species from direct mortality of any individual(s) collected and a reduction in annual recruitment by killing or injuring reproductive individuals (USFWS, 2019).

**Stressor:** Disease or predation

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Evidence exists of *O.d. subsp. howellii* infestation by beetles (possibly family Chrysomelidae), which feed on petals, pollen, and seed pods. Also, in the early 1980s up to 50% of *O.d. subsp. howellii* was infested with small mirid bugs (family Miridae of the insect order Hemiptera) that prey upon *O.d. subsp. howellii*, and these insect predators remained an identified threat in 2008 (Service 2008). The magnitude of this stressor requires further investigation (USFWS, 2019).

**Stressor:** Wildfire

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Wildfire may cause direct mortality of *O.d. subsp. howellii* and *E.c. var. angustatum* plants during vulnerable life stages. These stages include the period from germination during the beginning of the wet season in December through the deposition of seeds in mid-summer. However, historical evidence indicates that the native plants may recover rather quickly from a wildfire (Service 2008). Any mortality would also result in reduced annual recruitment by killing or injuring reproductive individuals. The threat extends to pollinators and other pollinator plant species (USFWS, 2019).

**Stressor:** Fuelbreak discing

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Fuelbreak discing may cause direct injury or mortality to Lange's metalmark, its host and food plants, and to *O.d. subsp. howellii*, and *E.c. var. angustatum*. However, it also creates open, disturbed, sand/soil that may be suitable for colonization by *O.d. subsp. howellii* and *E.c. var. angustatum*, as well as invasive vegetation. The net impact of this activity to listed plant resilience is unquantified (USFWS, 2019).

**Stressor:** Loss of pollinators

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Lange's metalmark is addressed as a pollinator for this discussion of the potential threat posed by possible insecticide drift from mosquito abatement spraying on neighboring

properties (Richmond et al 2015). The Mosquito Abatement District allows for spraying of insecticides to reduce the incidence of West Nile Virus at a wetland adjacent to the Stamm Unit of the ADNWR. The spray could drift on to the refuge and affect pollinators, such as Lange's metalmark and those that pollinate *O.d. subsp. howellii* or *E.c. var. angustatum*. While ADNWR staff have worked with county mosquito control staff to minimize effects from this potential threat, the magnitude of this stressor requires further investigation. As of the 2008 Five-Year Review, there was no evidence that lack or loss of pollinators has negatively impacted *O.d. subsp. howellii* or *E.c. var. angustatum* (Service 2008), but both species require cross-pollination, so an adequate pollinator population is necessary. Bees are suspected pollinators for both species and hawkmoths may also be pollinators for the primrose; however, actual pollinator taxa are unknown. This potential threat requires investigation (USFWS, 2019).

**Stressor:** Low population numbers

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** *Oenothera deltoides* subsp. *howellii* and *E.c. var. angustatum* are threatened by few and small populations that are limited to a small and localized distribution, which increases the risk of extirpation and extinction due to: (1) Reduced resiliency (the ability of a species to withstand stochastic disturbance; resiliency is positively related to population size and growth rate and may be influenced by connectivity among populations); (2) Low redundancy (spreading risk among multiple populations or a large area to minimize the potential loss of the species from catastrophic events); and (3) Low representation (the breadth of genetic and environmental diversity within and among populations that influences the ability of a species to adapt to changing environmental conditions over time) (USFWS, 2019).

**Stressor:** Climate change

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** *Oenothera deltoides* subsp. *howellii* and *E.c. var. angustatum* are threatened by multiple environmental effects anticipated with climate change, which may result in loss of habitat, altered temperature and moisture regimes causing direct mortality and/or impaired reproduction, and altered temperature and moisture regimes causing indirect mortality and/or impaired reproduction via phenological mismatches with pollinators and between pollinators and their host and/or other nectar plants (Richmond et al 2015) (USFWS, 2019).

## **Recovery**

### **Reclassification Criteria:**

There are at least five separate self-sustaining (all plants are naturally recruiting\*) populations, including: at least three populations, each with a 15-year moving median of at least 4,800 flowering plants; and at least two populations, each with a 15-year moving median of at least 1,500 flowering plants (USFWS, 2019).

A distance of at least 1,500 feet and a natural and/or man-made firebreak separates individual populations (USFWS, 2019).

Populations should be protected and have in place a long-term management plan for the conservation of *O.d. subsp. howellii* and commitment for implementation of the plan (USFWS, 2019).

**Delisting Criteria:**

There are at least seven separate self-sustaining (all plants are naturally recruiting (\*Any flowering individuals counted as naturally recruiting would have to be  $\geq$  two flowering seasons post-outplanting. This would indicate the individual has completed the life cycle in situ.)) populations including: at least five populations, each with a 15-year moving median of at least 4,800 flowering plants; and at least two populations, each with a 15-year moving median of at least 1,500 flowering plants. OR, population viability analysis determines that *O.d. subsp. howellii* has a range-wide 95% probability of persistence over a 100-year period. a. A distance of at least 1,500 feet and a natural and/or man-made firebreak separates individual populations. b. Populations should be protected and have in place a long-term management plan for the conservation of the *O.d. subsp. howellii* and commitment for implementation of the plan. (USFWS, 2019)

A post-delisting monitoring plan for the species has been developed (USFWS, 2019).

**Recovery Actions:**

- The final supporting actions for Primary Action 1 include identification of other essential habitat and developing an MOU with the landowner to develop protective alternatives and actions. Since listing, the only new habitat identified for conservation is the property owned by the Pioneer Companies, Inc., and currently occupied by the McCulloch-Kemwater North American Company. All three of the Antioch Dunes species have been surveyed on this property (USFWS 2005). Currently, this property is for sale and the Service is considering alternatives that include purchasing this valuable habitat (USFWS, 2008).
- The initial supporting actions for Primary Action 2 are essentially the same for all three endangered Antioch Dunes species, and include conducting annual census of population and habitat; captive breeding (Lange's metalmark butterfly) or propagation and outplanting (Antioch Dunes evening-primrose, Contra Costa wallflower); developing and implementing a habitat restoration plan; and conducting studies of the biology of the species which include life history (Lange's metalmark butterfly), autecological studies (Antioch Dunes evening-primrose, Contra Costa wallflower), habitat requirements (Lange's metalmark butterfly), population biology (Lange's metalmark butterfly), and reproductive studies (Antioch Dunes evening-primrose, Contra Costa wallflower). Out-planting buckwheat host plants is also needed for Lange's metalmark butterfly. All of these actions have been ongoing and are discussed below in section IIC. Another group of supporting actions includes rebuilding the natural dune substrate and topography to the degree feasible by negotiating with the Army Corps of Engineers (Corps) and the Port of Stockton for sandy dredged material, preparing the sites for deposition of dredged material, and surveying the sites for candidate and listed species in order to ameliorate any negative effects. Several sources of sand were used in restoration efforts since listing the three species. Dredged material was found to contain a substantial amount of fine non-silica sediment which proved to stabilize too quickly for use as a substitute for the original dune sand (C. Smith in litt. 2007). Antioch Dunes NWR staff recently located several sources of local high-silica content sand that should prove useful in the restoration; however, although funding sources are being sought for purchasing and delivering the sand, current plans tentatively include testing the composition of the

imported sand prior to using it to supplement the refuge. (C. Smith in litt 2007; L. Terrazas, USFWS, pers. comm. 2008). Other actions include removal of a vineyard and removal of other non-native invasive vegetation throughout the Antioch Dunes NWR. The vineyard was removed in 1983 and removal of non-native invasive vegetation has been an ongoing effort (see section IIC for updated status on the restoration) (USFWS, 2008).

- Supporting actions for this include erecting interpretive signs, printing and distribution of leaflets describing the Antioch Dunes NWR's unique dune ecosystem and the need for restoration, and the development of an environmental education program. These actions were completed in the early 1980s; however, the public awareness effort is a dynamic and ongoing process (USFWS, 2008).
- Continue restoration of riverine dune habitat at Antioch Dunes NWR (USFWS, 2008)
- Conduct controlled propagation of the Lange's metalmark butterfly until natural populations at Antioch Dunes NWR are at a self-sustainable level (USFWS, 2008)
- Continue research into life history, habitat requirements, and population studies, including annual population monitoring surveys (USFWS, 2008)
- Acquire the McCulloch/Kemwater property abutting the eastern boundary of the Sardis Unit of the Antioch Dunes NWR (USFWS, 2008)
- Consider revising the Recovery Plan for the three endangered species endemic to Antioch Dunes, California (USFWS, 2008)

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS** Several areas of future action are suggested over the next five years, which build on the actions articulated in the revised recovery plan (Service 1984) and the riverine dune ecosystem conservation strategies articulated in Service (2019b). These areas include: continuing to restore riverine dune habitat at ADNWR and considering nearby locations for restoration activities; continuing research on the habitat requirements, life history, and seed bank dynamics of Antioch Dunes evening-primrose; improving statistical analysis and numerical modeling related to Antioch Dunes evening-primrose; considering development of a publicly-accessible website for documents, literature, and data related to Antioch Dunes evening-primrose; and establishing an Antioch Dunes Recovery Implementation Team or recovery working group. Continued research on the habitat requirements and seed bank dynamics of Antioch Dunes evening-primrose could include identifying areas for possible development of new populations of Antioch Dunes evening-primrose. For example, the Service's experience with dune restoration at the Refuge in combination with the work of Jones et al. (2019) provides a strong foundation for expanding dune restoration work over the coming years. This future work could include an analysis of how environmental variables, such as precipitation and temperature patterns influence population dynamics in currently occupied areas and colonization of newly restored dunes. It is also not currently clear which invertebrate species are the most important pollinators of Antioch Dunes evening-primrose. A study of the current pollinators of primrose at Antioch Dunes would help add to our understanding of the natural history of this subspecies and identify which potential pollinators to monitor to ensure that healthy pollinator populations continue to occur at and near the Antioch Dunes ecosystem. Statistical and numerical modeling, such as with habitat suitability analysis and population dynamics modeling, can provide insights into possible future locations for development of Antioch Dunes evening-primrose populations, and future dynamics of these populations. Jones et al. (2019) began developing habitat suitability models for primrose using remote sensed vegetation metrics (NDVI; Normalized Difference Vegetation Index). It is possible that a continuation of this line of investigation will lead to improved insights into where and how to develop additional restored

sand dunes that will support the recovery of this subspecies. It may also be useful to consider developing population viability analyses (PVA) that are specifically developed for Antioch Dunes evening-primrose. For example, it is possible that the stagestructured matrix population model developed by Thomson (2005a) could be used to form a foundation for PVA analysis. It is also possible that building and parameterizing such a model, and then projecting this model into various possible futures, including under the influence of changing climate conditions, could help provide insights beyond the PVA's suggested by recovery criteria in Service (2019a). As part of efforts to improve statistical analysis and modeling, creating a well-vetted and archived dataset of all Antioch Dunes evening-primrose surveys, and resolving any discrepancies in counts identified during this review will be critical to progressing on this objective. In late 2019, staff of the Bay-Delta Fish and Wildlife Office met with the staff of the ADNWR and considered formally convening a recovery implementation team (RIT) for the listed species that occur at the Refuge, including Antioch Dunes evening-primrose. The primary purpose for convening this group would be to encourage Service biologist and managers and external experts to consider recovery priorities for these species and the Antioch Dunes ecosystem, and continue to stay abreast of emerging research related to primrose, riverine dune ecology, and other relevant topics. This group would also help develop a recovery implementation strategy for Antioch Dunes. (USFWS, 2020)

## SPECIES ACCOUNT: *Opuntia treleasei* (Bakersfield cactus)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

A flat-padded (beavertail) opuntia cactus, with the eye-spots (which are not sunken) having spines as well as bristles. Typically flowers in May. (NatureServe, 2015)

### **Taxonomy**

USFWS treats as *Opuntia treleasei* (8/93). (NatureServe, 2015)

### **Historical Range**

The distribution of Bakersfield cactus was not estimated historically. Based on written descriptions (Twisselmann 1967), historical photographs (Britton and Rose 1920; Benson 1982), topography, and deductions from plant morphology, the populations were likely more or less continuous east of Bakersfield (Service 1998). According to Twisselman (1967), Bakersfield cactus "once grew in dense almost impenetrable colonies on the mesas east of Bakersfield." Densely-spaced clumps of Bakersfield cactus once covered about two square miles from the Caliente Creek floodplain onto Sand Ridge. (USFWS, 2011)

### **Current Range**

California: San Joaquin Valley (central Kern County). Other reports are no longer considered to be this taxon (cf. Munz 1974; Benson 1982; Brown and Cypher 1997).

### **Critical Habitat Designated**

No;

### **Life History**

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Insect pollinated/Vegetative reproduction (USFWS, 1998)

### **Lifespan**

Adult: at least 48 years (USFWS, 1998)

### **Breeding Season**

Adult: Bakersfield cactus typically flowers in May (Munz and Keck 1959) (USFWS, 1998).

### **Reproduction Narrative**

Adult: Bakersfield cactus is a perennial. The life span of wild plants has not been determined, but clumps in cultivation at the Rancho Santa Ana Botanic Garden in Claremont, California, survived for 48 years, until extremely wet winter weather caused the pads to rot (R. van de Hoek pers. comm.). Bakersfield cactus typically flowers in May (Munz and Keck 1959). Reproductive biology of this taxon has not been studied, but certain other *Opuntia* species

require cross-pollination for seed-set and many are pollinated by bees (Benson 1982, Spears 1987, Osborn et al. 1988). One potential pollinator of Bakersfield cactus is the native solitary bee *Diadasia australis* ssp. *california*, which is known to occur in Kern County and which specializes in collecting pollen from *Opuntia* species (Thorp in litt. 1998). Vegetative reproduction, which is the production of new plants from sources other than seed, is typical in Bakersfield cactus and several related species (Benson 1982). Fallen pads root easily if sufficient water is available (Twisselmann 1967, Benson 1982, Mitchell 1988), but Bakersfield cactus does not survive prolonged inundation (ESA Planning and Environmental Services 1986a). Bakersfield cactus produces seeds infrequently. Van de Hoek (pers. comm.) noted that the frequency of seed set in extant populations is similar to the proportion of seeds he observed in herbarium specimens. Cactus seeds require warm, wet conditions to germinate, a combination which is extremely rare in the Bakersfield area (Benson 1982). Pads may be dispersed by flood waters (ESA Planning and Environmental Services 1986a), but seed dispersal agents are unknown (USFWS, 1998).

**Habitat Type**

Adult: Grasslands (USFWS, 1998)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits sandy soils or sand flats and low hills mostly in grassland at 120-550 m (Benson 1982; Brown and Cypher 1997). Characteristic in Sierra-Tehachapi Saltbush Scrub community, but also in Blue Oak Woodland and a riparian woodland. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on its specific habitat needs and low number of known populations.

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Pads may be dispersed by flood waters (ESA Planning and Environmental Services 1986), but seed dispersal agents are unknown (USFWS, 2011).

***Population Information and Trends*****Population Trends:**

Not available

**Number of Populations:**

51 (USFWS, 2020)

**Population Narrative:**

Twenty-nine occurrences are presumed extant; about half have not been surveyed for over 20 years (USFWS 2011; CNDDDB 2012). (NatureServe, 2015)

### ***Threats and Stressors***

**Stressor:** Agricultural Conversion and Urbanization (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The primary threats to Bakersfield cactus over its entire habitat range continue to be residential development and conversion to agriculture. Continuing threats to localized populations that were identified in the listing rule include urbanization events such as; road expansion and maintenance (Oildale Area (within the MBNKR Recovery Site), Wheeler Ridge, and Sand Ridge), expansion of the Kern River Power Plant (Kern Canyon), the county airport (MBNKR), and the Bena landfill (Caliente-Bena Hills); as well as oil and gas development (Oildale Area (within the MBNKR) and Wheeler Ridge), Off road vehicle use (MBNKR and Cottonwood Creek), sand and gravel mining (Sand Ridge) and California Aqueduct right-of-way maintenance (Wheeler Ridge) (Cypher pers comm. 2010). All of these activities continue to threaten Bakersfield cactus by the modification of its habitat, the removal of Bakersfield cactus clumps, and the further fragmentation of existing populations. Table 2 summarizes land ownership and protected status (USFWS, 2011).

**Stressor:** Oil and Gas Extraction and Conveyance (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Oil and gas extraction and conveyance continue to threaten Bakersfield cactus. Adverse effects of oil and gas development on Bakersfield cactus include the loss of habitat, change in habitat quality, destruction of individuals or populations and their seedbank, habitat fragmentation, and increased competition from nonnative plant species due to habitat degradation. According to our HCP database (Service 2010), there is one HCP that covers oil and gas production that includes Bakersfield cactus as a covered species. The Nuevo Energy Company and Torch Operating Company (Nuevo/Torch) HCP was permitted in 1999 for a 30-year permit term. The project size is 21,800 acres with 1,700 acres impacted. The mitigation includes 800 acres to be created, enhanced, or restored, and 840 acres to be protected. Approximately 1,328 acres of the total 21,900 acres in the Nuevo/Torch Plan Area may be suitable for Bakersfield cactus (Nuevo/Torch 1999). Only those Nuevo/Torch lands east of Highway 99 overlap with reported occurrences of Bakersfield cactus. Bakersfield cactus has a limited range and is only found in western Kern County. Therefore Nuevo/Torch proposed avoidance and minimization measures are particularly important for this species. Oil and gas development is often limited and linear in nature in terms of well pads and pipeline construction but where oil and gas fields are developed into production sites, the cumulative impact can be large. Three of the five largest U.S. oil fields are in Kern County and span more than one million acres (USFWS, 2011).

**Stressor:** Conservation Efforts (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Approximately 1068.40 acres (74.6 percent) of occupied presumed extant Bakersfield cactus habitat is on private land that is not protected from agricultural conversion, urbanization, oil and gas development, and off road vehicle use. About 144.35 acres (10.1 percent) of occupied presumed extant Bakersfield habitat is on private land that is protected. About 115.03 acres (8 percent) of presumed extant Bakersfield cactus habitat is on public land that is not protected from oil and gas development, off road vehicle use, and utility operation and maintenance; 104.37 acres (7.3 percent) is on protected public lands (USFWS, 2011).

**Stressor:** Overutilization for Commercial, Recreational, Scientific, or Educational Purposes (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** At the time of listing we stated that many cacti are collected and cultivated by plant collectors, or offered for sale or trade by cactus growers. Although there have been no reports of such trade in Bakersfield cactus, the species may still be collected and cultivated (Service 1990). Currently, we have no evidence whether this has occurred. Currently, the lack of monitoring means that we probably would not detect collection or vandalism, especially on private land (USFWS, 2011).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** In summary, the Endangered Species Act is the primary Federal law that provides protection for this species since its listing as endangered in 1990. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2011).

**Stressor:** Nonnative annual grasses and increased fire frequency (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Nonnative annual grasses directly threaten the survival of mature cactus plants and hinder the establishment of new plants (ESA Planning and Environmental Services 1986; Mitchell 1988). In 2002-2004, mortality of Bakersfield cactus clumps and low rates of vegetative and sexual reproduction at Sand Ridge Preserve were attributed to competition with nonnative annual grasses for water during years with below-average precipitation (Cypher and Fiehler 2006; Cypher pers. comm. 2006). Nonnative annual grasses also indirectly affect Bakersfield cactus in three ways. First, indirect effects from nonnative annual grasses include increased fire frequency (Service 1998; Brooks 1999; Brooks and Pyke 2001; Brooks 2003), damage from insects (Burger and Louda 1994), and rot of cactus pads during wet years (Service 1998). Fire suppression has allowed the extensive growth of nonnative grasses in some areas to the detriment of Bakersfield cactus (Moe 1989). Also, nonnative annual grasses, which are adapted to fire, increase the fuel load in fire-intolerant saltbush (*Atriplex* sp.) habitat, where Bakersfield cactus is found, resulting in an increase in fire frequency (Brooks 1999; Brooks and Pyke 2001; Brooks 2003). Although the

effect of repeated fires on Bakersfield cactus has not been determined, the survival of Bakersfield cactus plants was monitored following single fire events at Sand Ridge (R. Hewett, Sand Ridge Preserve Manager, in litt. 1987) and near the Rio Bravo Hydroelectric Power Plant in Kern Canyon (Lawrence 1987; George Lawrence and Associates 1988). All of the Bakersfield cactus clumps survived the fires at both sites, despite wilting and browning of the pads. During the following spring, Bakersfield cactus plants that were subjected to low-intensity flames flowered; however, those subjected to moderate-intensity flames produced only vegetative growth. Second, dense grass also may harbor insects that damage cactus, as was observed with related species of *Opuntia* in Nebraska grasslands (Burger and Louda 1994), but not yet studied in Bakersfield cactus. Third, the dense grass cover creates a moist microclimate which may promote the growth of decay organisms and cause cactus pads to rot more in years of above-average precipitation (Service 1998) (USFWS, 2011).

**Stressor:** Loss of genetic diversity (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Extirpation

**Narrative:** The destruction of Bakersfield cactus habitat by agriculture and urban sprawl has left the remaining populations highly fragmented and small. The small size of many of the populations (Moe 1989; CNDDDB 2010), presumed lack of gene flow between populations, and infrequent sexual reproduction (Menges 1986) may result in a lack of genetic diversity (Service 1998) although this has not been tested in Bakersfield cactus. Populations that are low in genetic variation are more vulnerable to diseases and parasites (Burdon and Marshall 1981) and to chance events, including environmental fluctuations, catastrophes, and genetic drift (Menges 1991). Several of the occurrences have few individuals (CNDDDB 2010) and could be subject to loss of genetic diversity (USFWS, 2011).

**Stressor:** Flooding (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Bakersfield cactus populations located in floodplains are threatened by flooding. Bakersfield cactus plants cannot survive long periods of inundation (ESA Planning and Environmental Services 1986; Service 1998). Populations within the Caliente Creek floodplain have been extirpated due to flooding, and flooding continues to be a threat for the Caliente - Bena Hills populations (Service 1998; CNDDDB 2010). Populations of Bakersfield cactus within the California Aqueduct right-of-way are also potentially threatened by flooding. Kern County identified earthquakes as highly significant hazard to all regions of Kern County. Large earthquakes can cause secondary hazards including landslides, fire, and flooding. The California Aqueduct crosses the White Wolf Fault at Wheeler Ridge and parallels the San Andreas Fault within 25 miles for most of its length in Kern County (Kern County Fire Department Office of Emergency Services 2005). The largest concentration of clumps in the Wheeler Ridge population is located adjacent to an overflow drain for the Aqueduct, which could lead to flooding if an earthquake occurred anywhere along its length (Service 1998) (USFWS, 2011).

**Stressor:** Air pollution (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Reduced reproduction

**Narrative:** The Recovery Plan cites Messick (1987) as stating that air pollution is suspected to have contributed to the decline of Bakersfield cactus. Messick noted that populations of Bakersfield cactus appeared to be reproducing less and losing vigor and that soft tissues may be adversely affected by acid deposition or ozone. He suggested that study of possible air pollution effects was needed (USFWS, 2011).

**Stressor:** Reproductive threats (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Reduced reproductive success

**Narrative:** Reproduction of Bakersfield cactus may be threatened by the loss of pollinators. The reproductive biology of Bakersfield cactus has not been studied, but other *Opuntia* species are known to require cross-pollination for seed-set and many are pollinated by bees (Benson 1982; Spears 1987; Osborn et al. 1988; Thorp in litt. 1998). Pollinators are threatened by the use of both regulated (e.g., malathion) and unregulated pesticides (e.g., pyrethroids) (Service 2000; DPR 2006; Keith 2006). Malathion, a broad spectrum insecticide, has been used to control the beet leaf-hopper (*Circulifer tenellus*) in rangeland habitat, fallow fields, oil fields, and cultivated areas on both public (BLM) and private lands in the San Joaquin Valley, and in adjacent valleys and foothills. Increasingly, malathion is used to kill agricultural pests and mosquitoes, which are documented as vectors of the West Nile Virus. Its application therefore, is not limited to agricultural areas but includes residential and commercial zones thereby increasing the regional areas in which it is used. Hymenopterans (ants, wasps, bees, etc.) are particularly susceptible to malathion exposure (Dobroski and Lambert 1984) (USFWS, 2011).

**Stressor:** Climate change (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Climate models predict for California an overall warming of 1.7 degrees to 5.8 degrees Celsius (3.0 degrees Fahrenheit to 10.4 degrees Fahrenheit) by 2100 (Cayan et al. 2006), but they vary in their predictions for precipitation. VanRheenen et al. (2004) predict a decrease in precipitation in the southern San Joaquin Valley. Bakersfield cactus seeds require warm, wet conditions to germinate (Benson 1982). Therefore, a sufficient decrease in precipitation could hinder Bakersfield cactus growth by sexual reproduction. Additionally, studies at Sand Ridge Preserve revealed increases in Bakersfield cactus mortality and lowered rates of vegetative and sexual reproduction in years of below-average precipitation due to competition for water with nonnative annual grasses (Cypher and Fiebler 2006; Cypher pers. comm. 2006). Conversely, increases in annual precipitation would possibly promote the growth of decay organisms resulting in the rot of cactus pads (Service 1998). Bakersfield cactus cannot tolerate prolonged periods of inundation as observed in the Caliente Creek floodplain (ESA Planning and Environmental Services 1986; Service 1998; CNDDDB 2010). The effect of such changes in climate on nonnative species and parasites is unknown, but could accelerate their establishment in Bakersfield cactus habitat. If such changes in climate occur, and the resulting changes in precipitation occur, Bakersfield cactus could be extirpated with no available refugia (USFWS, 2011).

## **Recovery**

**Reclassification Criteria:**

- 1) Secure and protect specified areas from incompatible uses A) 95 percent of occupied habitat on public lands; 75 percent of Bakersfield cactus clumps and 75 percent of occupied habitat in the Caliente-Bena Hills, Comanche Point, Kern Bluff, Sand Ridge, and Wheeler Ridge areas (addresses Listing Factor A) (USFWS, 2011);
- 2) A management plan has been approved and implemented for the recovery areas that includes survival of the species as an objective (addresses Listing Factors C and E) (USFWS, 2011);
- 3) Population monitoring in specified recovery areas shows: stable or increasing populations at all protected sites for a 5-year period (addresses Listing Factor E) (USFWS, 2011).

**Delisting Criteria:**

- 1) 90 percent of existing clumps and occupied habitat in the areas specified in the downlisting criteria (i.e. Caliente-Bena Hills, Comanche Point, Kern Bluffs, Sand Ridge, and Wheeler Ridge areas) and in the Fuller Acres, Cottonwood Creek, Granite Station, and Kern Canyon populations are protected (as defined in the downlisting criteria) (USFWS, 2011);
- 2) 100 or more clumps each in other populations north and south of the Kern River are protected (USFWS, 2011);
- 3) A management plan exists for all protected areas identified as important to the continued survival of the species; and (USFWS, 2011)
- 4) All protected populations show evidence of reproduction (USFWS, 2011)

**Recovery Actions:**

- 1. Protect populations within Bakersfield City limits in the Kern Bluff area and south of highway 178 (USFWS, 2011).
- 2. Work with willing land owners to establish a conservation easement or fee title to the property at the mouth of Kern Canyon (USFWS, 2011).
- 3. Complete the draft Department of Water Resources Habitat Conservation Plan (USFWS, 2011).
- 4. Conduct census of known populations and monitor the reproductive status of known populations (USFWS, 2011).
- 5. Determine suitable management methods for reducing nonnative annual grasses and increasing native perennials, including Bakersfield cactus, and communicate the benefits of such management to rangeland landowners (USFWS, 2011).

**Conservation Measures and Best Management Practices:**

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Protect existing habitat in the San Joaquin Valley for Bakersfield cactus. 2. Survey both extant and extirpated occurrences that have not been visited in the past few years to determine the status of these occurrences. Conduct yearly surveys at extant locations utilizing a standardized methodology to determine trends in the range-wide status as well as population/occurrence abundance. 3. Determine suitable management methods for reducing

nonnative annual grasses and increasing native perennials, including Bakersfield cactus, and communicate the benefits of such management to rangeland owners. (USFWS, 2020)

## SPECIES ACCOUNT: *Osmoxylon mariannense* (No common name)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 04/08/2004; Pacific Region (Region 1) (USFWS, 2016)

### **Physical Description**

*Osmoxylon mariannense* is a spindly, soft-wooded tree in the ginseng family (Araliaceae), which can reach 10 m (33 feet) in height. It has several upward-growing (ascending), gray-barked branches that bear conspicuous leaf scars. Leaves vary in size; mature leaves are palmately lobed (hand-shaped) and about 30 cm (1 foot) long and 50 cm (1.7 feet) wide. The seven to nine lobes are coarsely toothed, and each lobe has a conspicuous, depressed mid-vein. The leaves are alternate or whorled and grow only at the branch tips. The petioles are 35 to 40 cm (1 to 1.5 feet) long and based in distinctive, conspicuous green multiple “sockets” (Raulerson and Rinehart 1991). The flowers are yellow and have both male and female components. They are borne in many-branched, compact terminal cymes or umbels. The fruits are round and maroon in color when ripe (Raulerson and Rinehart 1991). (USFWS, 2007)

### **Taxonomy**

The species *Osmoxylon mariannense* (Kanehira) Fosberg and Sachet was first described as *Boerlagiodendron mariannense* by Kanehira. Fosberg and Sachet (1980) made the generic transfer to *Osmoxylon*. (USFWS, 2012)

### **Historical Range**

See current range/distribution.

### **Current Range**

Endemic to Rota in the Mariana Islands (USFWS 2004b).

### **Critical Habitat Designated**

Yes;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproduction Narrative**

Adult: The species is dioecious, with male and female flowers being produced on separate trees. Trees have been observed flowering in February, March, and October and fruiting in November, December, January, February, and March (Raulerson and Rinehart 1997; G. Hughes, in litt. 1998; G. Koob, in litt. 2005). The seeds of *O. mariannense* are difficult to germinate and this may be due to production of “false seeds” (structures that appear to be seeds but aren’t) or low viability rates (J. Manglona, CNMI, pers. comm. 2005; L. Raulerson, pers. comm. 2005). (USFWS, 2007)

### **Habitat Type**

Adult: Terrestrial (USFWS, 2007)

**Habitat Vegetation or Surface Water Classification**

Adult: Limestone forests, forest edges, cliffs (USFWS, 2012)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations of approximately 425 meters (1,400 feet) and higher; prefers partial shade and forest edges (USFWS, 2012)

**Environmental Specificity**

Adult: Medium, with some key requirements (USFWS, 2007; USFWS, 2012)

**Habitat Narrative**

Adult: *Osmoxylon mariannense* prefers partial shade or grows on the edges of forests, including areas near cliffs (Manglona no date [n.d.]). *Osmoxylon mariannense* is found in limestone forests at approximately 425 meters (1,400 feet) elevation and higher, where moisture and humidity levels are high (Koob 2005; Manglona n.d.). These forests occur in patches in the formerly mined Sabana and are dominated by *Hernandia labyrinthica* and *Elaeocarpus joga* (yoga) interspersed with *Pandanus* (kafu) thickets. Mixed with the *Elaeocarpus* and *Hernandia* are a few *Ficus* spp., *Artocarpus* spp., and *Hibiscus tiliaceus* (pago). Understory species include *Macaranga thompsonii* (pengua) and *Pipturus argenteus* (amahadyan). Epiphytes are abundant and include *Freycinetia reineckeii* (no common name), *Asplenium nidus* (galak), *Davalia solida* (pugua-machena), and other ferns; *Coelogyne guamensis* (no common name) and other orchids; and mosses (Falunruw et al. 1989). (USFWS, 2007; USFWS, 2012)

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: The fruit may provide food for birds and bats, which may also be the dispersal agents, though this is not confirmed (Raulerson and Rinehart 1991; Resources Northwest 1997; J. Manglona, pers. comm. 2005). (USFWS, 2007)

***Population Information and Trends*****Population Trends:**

Not available.

**Number of Populations:**

1 (USFWS, 2019)

**Population Size:**

135 (2 wild) (USFWS, 2019)

**Additional Population-level Information:**

There have been no systematic surveys for *Osmoxylon*, and very few field visits to known wild plant locations for several years (Estanislao Taisacan, pers. comm. 2016). During July-August of 2016, one wild *Osmoxylon* tree was observed alive along the north rim of the Mount Sabana plateau (James Manglona, pers. comm. 2016), and a second one further east along the rim was observed alive and bearing fruit (McBride, personal observation). Another *Osmoxylon* was found in the Assoro area on the south part of the Sabana plateau “five or six years ago” (Robert Ulloa,

pers. comm. 2016). Two other trees, in As Mundo and Fanlagon areas, were alive when last seen sometime between 2005 and 2010 (Estanislao Taisacan, pers. comm. 2016). Impediments to recruitment: wild reproduction has been limited or prevented by vegetative competition, as well as herbivory by Cuban slugs, which are pervasive throughout forested areas. Also, trampling and browsing by Philippine deer are now the principal ungulate issues for this species as hunters have suppressed or eliminated feral goat and pig populations (James Manglona, pers. comm. 2016). (USFWS 2017)

**Population Narrative:**

An unknown number of trees currently exist in cultivation, and 2 trees that were outplanted in 2002 adjacent to wild individuals of *Osmoxylon mariannense* continue to survive, bringing the total number of currently known individuals in the wild to 10. (USFWS, 2007). Currently, there is only 1 known population, with a total of 2 naturally occurring and 133 outplanted individuals. Fruit collection, propagation, and outplanting are ongoing. There is some protection from ungulates through fencing efforts.(USFWS, 2019)

**Threats and Stressors**

**Stressor:** Land-use activities (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Native vegetation, including Sabana limestone forest habitat for *Osmoxylon mariannense*, has undergone extreme alteration due to past and present land use practices, including ranching, deliberate and unintentional nonnative animal and plant introductions, agriculture, and military activities during World War II (Falanruw et al. 1989). Rota was subject to extensive agricultural development (particularly the cultivation of sugar cane in the lowland areas) by the Japanese prior to World War II. Currently, Rota retains less than 60 percent of its historical native forest (Falanruw et al. 1989). Continued loss of native forest is attributable to application of the Agricultural Homestead Act of 1990, which allows for the distribution of 1-hectare (2.5-acre) parcels of public land to eligible participants. (USFWS, 2007)

**Stressor:** Introduced ungulates (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Throughout the Mariana Islands, introduced goats (*Capra hircus*), pigs (*Sus scrofa*), cattle (*Bos taurus*), and Philippine deer (*Cervus mariannus*) have severely damaged forest vegetation by browsing on plants, causing habitat degradation and erosion (Kessler 1997; Wiles et. al. 1999, 2005; Worthington et. al. 2001) that then retards forest growth and regeneration (Lemke 1992). Of these nonnative ungulates, deer and feral pigs are degrading the forests of the Sabana (L. Williams, pers. comm. 2005, G. Wiles in litt. 2006). These animals may also directly browse on young individuals of *Osmoxylon mariannense*. (USFWS, 2007)

**Stressor:** Unidentified pests (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Defoliation (due to the poor health of the leaves), the lack of seedlings and juveniles of *O. mariannense*, and the death of several previously mapped older individual plants are suspected to be caused by unidentified invertebrate pests, mice (*Mus musculus*), rats (*Rattus* spp.), or disease (D. Grout, pers. comm. 1997). (USFWS, 2007)

**Stressor:** Deer browsing (USFWS, 2007; USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Deer are reported to browse on seedlings of *Osmoxylon mariannense* (USFWS 2004; L. Williams, pers. comm. 2004). The bark of *Osmoxylon mariannense* may be subject to stripping by deer before reaching reproductive age (Hess and Pratt 2006). Cooperative efforts between the U.S. Fish and Wildlife Service and the Rota Division of Fish and Wildlife have resulted in the construction of fenced exclosures around two individuals in the wild. The remaining eight individuals are not currently fenced (USFWS 2004). (USFWS, 2007; USFWS, 2012)

**Stressor:** Natural disasters (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** While *O. mariannense* is expected to have adapted to high winds and typhoons, its distribution and numbers have been reduced significantly due to human activities, making the few remaining individuals particularly susceptible to extirpation or extinction from a natural disaster. Destruction of the Sabana forest canopy by typhoons has adversely affected *O. mariannense*, altering sub-canopy vegetation conditions over the long term by opening up and drying out older, closed forest habitat (E. Taisacan, pers. comm. 1998; L. Williams, pers. comm. 2004). As discussed above for *Nesogenes rotensis*, all evidence points to the increasing frequency and intensity of the threat from typhoons in this region. (USFWS, 2007)

**Stressor:** Non-native plants (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** *Osmoxylon mariannense* is threatened by competition from invasive, nonnative plant species including *Momordica charantia* (bitter melon), *Mikania scandens* (climbing hempvine), and *Passiflora suberosa* (corky-stem passionflower). In opened forest areas, these opportunistic, weedy vines cover the ground (Fosberg 1960; G. Hughes, pers. comm. 1998) and may alter the conditions necessary for seed germination and seedling growth provided in closed-canopy, high-stature forests covered with mosses and various epiphytic species. (USFWS, 2007)

**Stressor:** Small population size (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Small population size and limited distribution make this species particularly vulnerable to extinction from reduced reproductive vigor or random environmental events. There are currently only 10 known individuals of *Osmoxylon mariannense* remaining in the wild, 2 of which were outplanted from past controlled propagation efforts. A single adverse environmental event

or a decline of successful reproduction in *O. mariannense* could lead to the extirpation of this species. (USFWS, 2007)

**Stressor:** Climate change (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Climate change may pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative (PICCC) has currently funded climate modeling that will help resolve these spatial limitations. The Service anticipates high spatial resolution climate outputs by 2013. (USFWS, 2007)

### ***Recovery***

#### **Reclassification Criteria:**

1. A total of two populations of *Nesogenes rotensis* are naturally reproducing and stable, or increasing in numbers. Each population of *N. rotensis* must consist of at least 300 mature, reproducing individuals. A total of two populations of *Osmoxylon mariannense* are naturally reproducing and stable, or increasing in numbers. Each population of *O. mariannense* must consist of at least 100 mature, reproducing individuals. A stable or increasing population is defined as having a finite rate of increase (known as  $\lambda$  or lambda) greater than or equal to 1 over the requisite 10-year time period. (USFWS, 2007)
2. Sufficient habitat is protected and managed to achieve criterion 1 above. (USFWS, 2007)
3. Management and control of nonnative species by local, regional, Commonwealth, and Federal authorities are demonstrated to be successful and sufficient to achieve criterion 1 above. (USFWS, 2007)

#### **Delisting Criteria:**

1. A total of four populations of *Nesogenes rotensis* are naturally reproducing and stable, or increasing in numbers. Each population of *N. rotensis* must consist of at least 300 mature, reproducing individuals. A total of four populations of *Osmoxylon mariannense* are naturally reproducing and stable, or increasing in numbers. Each population of *O. mariannense* must consist of at least 100 mature, reproducing individuals. A stable or increasing population is defined as having a finite rate of increase (known as  $\lambda$  or lambda) greater than or equal to 1 over the requisite 10-year time period. (USFWS, 2007)
2. Sufficient habitat is protected and managed to achieve criterion 1 above. (USFWS, 2007)
3. Management and control of nonnative species by local, regional, Commonwealth, and Federal authorities are demonstrated to be successful and sufficient to achieve criterion 1 above. (USFWS, 2007)

#### **Recovery Actions:**

- Coordinate and monitor recovery efforts. (USFWS, 2007)
- Address factors affecting viability of the wild populations. (USFWS, 2007)

- Monitor the extant *Nesogenes rotensis* and *Osmoxylon mariannense* populations, establish new populations, and augment existing populations. (USFWS, 2007)
- Provide educational and informational opportunities to build public support for conservation. (USFWS, 2007)
- Propagation and outplanting programs: through the Rota Rare Plants project (Partners Grant No. F14AC00510) from June 2015 through August 2016, 118 young *Osmoxylon* have been outplanted at locations on and around the Sabana; these plants are currently 1-2 years old, and are protected by fencing enclosures (Manglona 2016). Note also, that there are 35-40 older *Osmoxylon* (12-15 years old) that were outplanted in multiple locations (James Manglona, pers. comm. 2016). (USFWS 2017).
- Also in 2016, Lainie Berry of CNMI Department of Lands and Natural Resources began work on surveys and propagation of *Osmoxylon*, under a USFWS Section 6 grant (F16AP00687). In addition to surveys for previously unknown individuals as well as all previously-known natural and outplanted trees, efforts to propagate the species will also be undertaken. Anticipated propagation activities include seed collection, propagation via established techniques, outplanting in conservation areas, and initial monitoring. Existing fencing will be restored as needed, new fencing and signage established, and invasive plants hand-cleared where necessary to protect individual trees. This work is scheduled to conclude in 2018. Ongoing fence maintenance will be carried out by Rota Forestry, as well as longer-term monitoring if additional federal funding is secured (USFWS 2016). (USFWS 2017)
- Ungulate exclosure – Continue to construct and maintain ungulate-proof fenced exclosures around the remaining individuals or populations (USFWS 2017).
- Other currently-recognized herbivory concerns: develop and implement control programs for slugs and rodents (rats), at least within localized areas around established wild or outplanted trees (USFWS 2017).
- Threats research:
  - o Conduct research to determine the impact of invertebrates on *Osmoxylon mariannense* populations.
  - o Conduct research on methods to control invertebrates, if necessary.
  - o Develop and implement an invertebrate control and /or eradication program, if necessary. (USFWS 2017).
- Established invasive plant species control – Control invasive plant species around all populations (USFWS 2017).
- Mitigation of risks from potential disturbance factors:
  - o Evaluate whether there is evidence of typhoons being a significant risk factor for this species, at least in the current state of very limited population. If this is judged to be the case, develop and implement effective measures to mitigate the impact of typhoons, such as establishing multiple and relatively widelydistributed populations, to improve resiliency at the species level.
  - o Maintain fencing around individuals on the Sabana, as well as those that might be harmed by highway maintenance.
  - o Work with local DPW to ensure that road construction and maintenance activities do not harm existing individuals. (USFWS 2017)
- Population biology research: Identify the pollination mechanisms for the species, including flowering periods, specific pollinators, and other factors (USFWS 2017).
- General outreach:
  - o Develop public outreach programs to inform residents of Rota of the importance of native species and their habitat.
  - o Work with private landowners to help them conserve this species on their property. (USFWS 2017)
- Alliance and partnership development – Work with the CNMI Department of Lands and Natural Resources, Division of Forestry, Division of Fish and Wildlife, and other land managers to coordinate planning and support implementation of ecosystem level

- restoration and management to benefit *Osmoxylon* (USFWS 2017).
- Assess the modeled effects of climate change on this species, for which records of historic distribution suggest a very restricted elevational—and thus, areal—range on Rota. Consider trends suggested by available climate models when evaluating future landscape needs for the recovery of the species (USFWS 2017).
  - Regulatory protections – Work with CNMI authorities to ensure that federal and local regulations provide the necessary protections to support the recovery of *Osmoxylon mariannense*, whether by adding the species to the CNMI Threatened and Endangered Species list, or by other means (USFWS 2017).
  - Review the recovery plan (USFWS 2007) to determine if any new information suggests a need to update the plan to more effectively attain recovery goals (USFWS 2017).
  - Continue to collect cuttings or seed from tagged individuals, keeping close track of the maternal source for use in ex situ propagation. (USFWS, 2012)
  - Continue to collect seeds from all existing populations and send to at least two or three different venues for propagation and storage. (USFWS, 2012)
  - Determine where populations could be reintroduced on Rota. (USFWS, 2012)
  - Continue to reintroduce the species back into its known historical range. (USFWS, 2012)
  - Conduct surveys for *Osmoxylon mariannense* in potentially suitable habitat on Rota that may have been overlooked previously. (USFWS, 2012)
  - Survey all remaining individuals (native and reintroduced) to gain a better sense of the ratio of male to female trees. (USFWS, 2012)
  - Continue to construct ungulate-proof fenced exclosures around the remaining population and monitor the fences for any signs of breaching. (USFWS, 2012)
  - Protect all populations against disturbances from feral ungulates. (USFWS, 2012)
  - Implement effective control methods for rodents. (USFWS, 2012)
  - Develop and implement a slug control program, if necessary. (USFWS, 2012)
  - Conduct research to determine the impact of invertebrates on *Osmoxylon mariannense* populations. (USFWS, 2012)
  - Conduct research on methods to control invertebrates, if necessary. (USFWS, 2012)
  - Develop and implement an invertebrate control and /or eradication program, if necessary. (USFWS, 2012)
  - As individual wild trees begin the process of senescence they should be closely watched to determine what factors may be contributing to their demise. (USFWS, 2012)
  - Control invasive introduced plant species around all populations. (USFWS, 2012)
  - Develop and implement effective measures to reduce the impact of typhoons. (USFWS, 2012)
  - Maintain fencing around individuals near Sabana and those that might be harmed by highway maintenance. (USFWS, 2012)
  - Prevent the widening of the undeveloped roads that occur near individuals. (USFWS, 2012)
  - If fruit set begins to decline overall, then monitor the exact flowering times of each tree to determine whether there is a decrease in the overlap of flowering times between male and female trees. (USFWS, 2012)
  - Identify the pollination mechanisms and pollinators for the species. (USFWS, 2012)
  - Develop public outreach programs to inform residents of Rota of the importance of native species and their habitat. (USFWS, 2012)
  - Work with private landowners to help them conserve this species on their property. (USFWS, 2012)

- Work with private landowners, Mariana Public Lands Authority, the Division of Fish and Wildlife, and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2012)
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species. (USFWS, 2012)

***Conservation Measures and Best Management Practices:***

- Recommendations for Future Actions: With the historically-known wild population being so small, and the status of those trees being so poorly known today, all previously recommended future actions remain in effect, with a few additions or modifications:
  - Surveys / inventories – Resurvey the historical range of the species to determine if previously unknown or newly reestablished populations exist.
  - o Conduct surveys for *Osmoxylon mariannense* in potentially suitable habitat on Rota that may have been overlooked previously.
  - o Inventory all remaining individuals (wild and propagated) to assess survival, noting observable conditions or factors that appear to be accelerating the senescence or mortality of individual plants.
  - Continue propagation and outplanting programs to establish *Osmoxylon* in a range of locations, particularly within the known historic distribution around the Mount Sabana plateau on Rota.
  - o Continue to collect cuttings or seeds from tagged individuals, keeping close track of the maternal source for use in ex situ propagation.
  - o Continue to collect seeds from all existing populations and send to at least two or three different venues for propagation and storage.
  - o Evaluate seed viability under storage conditions, and develop protocols for effective storage parameters for propagation programs.
  - Ungulate exclosure – Continue to construct and maintain ungulate-proof fenced exclosures around the remaining individuals or populations.
  - Other currently-recognized herbivory concerns: develop and implement control programs for slugs and rodents (rats), at least within localized areas around established wild or outplanted trees.
  - Threats research: o Conduct research to determine the impact of invertebrates on *Osmoxylon mariannense* populations.
  - o Conduct research on methods to control invertebrates, if necessary.
  - o Develop and implement an invertebrate control and /or eradication program, if necessary.
  - Established invasive plant species control – Control invasive introduced plant species around all populations.
  - Mitigation of risks from potential disturbance factors: o Evaluate whether there is evidence of typhoons being a significant risk factor for this species, at least in the current state of very limited population. If this is judged to be the case, develop and implement effective measures to mitigate the impact of typhoons, such as establishing multiple and relatively widely-distributed populations, to improve resiliency at the species level.
  - o Maintain fencing around individuals on the Sabana, as well as those that might be harmed by highway maintenance.
  - o Work with local DPW to ensure that road construction and maintenance activities do not harm existing individuals.
  - Population biology research: Identify the pollination mechanisms for the species, including flowering periods, specific pollinators, and other factors.
  - General outreach: o Develop public outreach programs to inform residents of Rota of the importance of native species and their habitat.
  - o Work with private landowners to help them conserve this species on their property.
  - Alliance and partnership development – Work with the CNMI Department of Lands and Natural Resources, Division of Forestry, Division of Fish and Wildlife, and other land managers to coordinate planning and support implementation of ecosystem level restoration and management to benefit *Osmoxylon*.
  - Assess the modeled effects of climate change on this species, for which records of historic distribution suggest a very restricted elevational—and thus, areal—range on Rota. Consider trends suggested by available climate models when evaluating future landscape needs for the recovery of the species.
  - Regulatory protections – Work with CNMI authorities to ensure that federal and local regulations provide the necessary protections to support the recovery of *Osmoxylon mariannense*, whether by adding the species to the CNMI Threatened

and Endangered Species list, or by other means. • Review the recovery plan (USFWS 2007) to determine if any new information suggests a need to update the plan to more effectively attain recovery goals. (USFWS, 2019)

- New Management Actions: • Propagation and outplanting programs: through the Rota Rare Plants project (Partners Grant No. F14AC00510) from June 2015 through August 2019, 133 young *Osmoxylon* have been outplanted at locations on and around the Sabana; these plants are currently 1-5 years old, and are protected by fencing enclosures (Manglona 2016). Note also, that there are 35-40 older *Osmoxylon* (12-15 years old) that were outplanted in multiple locations (James Manglona, pers. comm. 2016). • In 2016, Lainie Berry of CNMI Department of Lands and Natural Resources began work on surveys and propagation of *Osmoxylon*, under a USFWS Section 6 grant (F16AP00687; USFWS 2016b). In addition to surveys for previously unknown individuals as well as all previously-known natural and outplanted trees, efforts to propagate the species has been ongoing since 2016. Seed collection, propagation via established techniques, outplanting in conservation areas with exclusion fencing has resulted in 133 outplantings of the species and 2 nursery stock plants representing two different wild trees from Fanlagon (James Bamba, CNMI Department of Lands and Natural Resources, pers. comm. 2020). (USFWS, 2019)

## SPECIES ACCOUNT: *Ottoschulzia rhodoxylon* (Palo de rosa)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 4/10/1990; Southeast Region (R4) (USFWS, 2015). Reclassified to Threatened on December 7, 2022.

### **Physical Description**

A small evergreen tree which has been reported to reach 15 meters in height and 41 centimeters in diameter. The average height of 178 trees measured was 6.21 meters and the average diameter was 8.94 centimeters. The leaves are alternate, glabrous, and elliptic to ovate, from 5 to 9 centimeters long, from 3 to 6 centimeters wide, rounded or blunt at the apex and the base, entire, thick and leathery. Flowers in this genus are bisexual, solitary or in clusters at the leaf bases, and composed of a cup-shaped corolla tube with five lobes. The fruit is a one-seeded drupe with a thin pericarp; the heartwood is reddish (USFWS, 1994).

### **Taxonomy**

Member of the Icacinaceae or the Icacinaceae family. This genus includes only three species (*O. rhodoxylon*, *O. domingensis* in Hispaniola, and *O. cubensis* in Cuba) (USFWS, 1994).

### **Historical Range**

In Puerto Rico, first collected near Mayaguez, Puerto Rico, in 1876; when listed in 1990, known on the north coast near Bayamon; in several sites in the Guanica Commonwealth Forest, and in the Maricao Commonwealth Forest (USFWS, 1990).

### **Current Range**

In Puerto Rico, known in the following areas of western Puerto Rico: Guaynabo; Quebradillas/Isabela; Cambalache Commonwealth Forest; Guanica Commonwealth Forest; Maricao Commonwealth Forest; Susua Commonwealth Forest; and the Sierra Bermeja in Cabo Rojo (USFWS, 1994).

### **Critical Habitat Designated**

Yes;

### **Life History**

### **Food/Nutrient Resources**

### **Breeding Season**

Adult: flowering and fruiting between May and July (USFWS, 2022)

### **Reproduction Narrative**

Adult: When the palo de rosa recovery plan was written, information about the flowering and fruiting pattern was limited due to the species not being well-studied and the infrequent observation of reproductive events, although flowering was observed in May and July 1993 (USFWS 1994, p. 5). The species bears hermaphrodite flowers, flowers for a short period at the beginning of the rainy season and develops fruits subsequently until November (Breckon and Kolterman 1993, p. 15; Santiago-Valenti'n and Viruet-Oquendo 2013, p. 62). Few buds and

flowers occur from April to May with an explosive flowering in June coinciding with the beginning of the rainy season in May. Herbarium specimens demonstrated flowering and fruiting between May and July (Santiago-Valentin and Viruet-Oquendo 2013, p. 62). Flower and fruit production are documented in individuals with diameters at breast height greater than 5 in (12.7 cm). Despite the high number of adult individuals reported, only a few reach that stem size (USFWS, 2022).

**Habitat Type**

Adult: Terrestrial (USFWS, 1994)

**Habitat Vegetation or Surface Water Classification**

Adult: Found in humid canyon bottoms (in Guanica) or on drier upper slopes and summits (in Quebradillas/Isabela) (USFWS, 1994)

**Dependencies on Specific Environmental Elements**

Adult: Well-drained, alkaline, rocky soils (USFWS, 1994)

**Geographic or Habitat Restraints or Barriers**

Adult: At elevations ranging from 10 to ~625 meters (USFWS, 1994).

**Environmental Specificity**

Adult: Narrow range of moisture tolerance (USFWS, 1994)

**Habitat Narrative**

Adult: Trees are limited to well-drained, alkaline, rocky soils derived from limestone or serpentine, as are trees of the other two members of the genus in Cuba and Hispaniola. In both Guanica and the Sierra Bermeja, palo de rosa is restricted to the bottom of canyons, where conditions are more mesic than might be expected given the extremely low annual precipitation. In SusLia, with greater rainfall than Guanica, the populations are restricted to the lower slopes of the mesic ravines. In the limestone hills of the north coast, receiving more precipitation than Guanica or Susua, palo de rosa occurs on the upper slopes and near the summits, where more xeric conditions prevail. Trees, therefore, are found in drier habitats (upper slopes and summits of hills) in the more mesic northern limestone hills and more mesic habitats (canyon bottoms) in the dry forests of Guanica and the Sierra Bermeja, an indication of a narrow range of moisture tolerance. Trees are located elevations ranging from 10 to ~625 meters (USFWS, 1994).

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Not available.

**Species Trends:**

Not available.

**Population Growth Rate:**

Low (inferred from USFWS 1994)

**Number of Populations:**

14 populations, 47 subpopulations (USFWS 2022).

**Population Size:**

The estimated number of adult individuals is at least 963 (USFWS 2017).

**Additional Population-level Information:**

As of the date of the publication of this 5-year review, we believe the status of *O. rhodoxylon* is improving. The species is currently known from the Guanica, Susua, Guajataca, Cambalache and the Rio Abajo Commonwealth Forests, and several areas managed for conservation along the northern coast (i.e., Hacienda Esperanza and Fort Buchanan). The species is widely distributed along the northern karst region of Puerto Rico, and despite previous impacts to the populations due to deforestation for agriculture and urban development, some localities show clear evidence of recruitment. However, since palo de rosa is considered a late successional species with a slow growth rate, the populations that lie on private lands remain vulnerable to habitat modification (i.e., deforestation, habitat intrusion by exotics, habitat fragmentation, etc.). (USFWS 2017)

**Population Narrative:**

Approximately 200 individual trees are known from 16 populations in 10 areas in western Puerto Rico (USFWS, 1994). Based on the above information, we have determined the palo de rosa to be distributed across Puerto Rico in 14 populations composed of 66 subpopulations containing 1,144 individuals (not including seedlings). Following this approach, 8 of the 14 current populations (containing 47 subpopulations with approximately 804 individuals) occur in the geographical areas associated with the 16 populations (now defined as subpopulations) included in the Service's 1994 recovery plan. Since 1994, we have identified 6 additional populations (as currently defined) composed of 19 subpopulations (342 individuals) ranging in size from 5 to 124 individuals in areas associated with remnants of forested habitat suitable for the species. Thus, these additional occurrences are key in understanding the current condition of the species (USFWS, 2022).

**Threats and Stressors**

**Stressor:** Habitat modification or destruction (USFWS, 1990)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Much of the island of Puerto Rico has been deforested, and today all of the known sites for *Ottoschulzia rhodoxylon* are found in areas of secondary forests. The north coast site lies just to the west of the San Juan metropolitan area, an area which is being rapidly developed. Undiscovered individuals in this area are likely to be destroyed before being discovered. Remaining individuals on the southwestern coast are found within the Guanica Commonwealth Forest, but they are found in sites such as dry stream beds and roadsides, which may be vulnerable to forest management practices that do not take the species into consideration (USFWS, 1990).

**Stressor:** Hurricanes and Climate Change (USFWS 2017)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Due to the low number of populations and individuals, flashfloods were identified as a threat to palo de rosa on its listing rule. As an endemic to the Caribbean, this species should be well adapted to tropical storms, and associated disturbances such as flashfloods. However, the low number of populations and individuals known at the time of listing posed a threat to the species by making it more susceptible to stochastic events such as hurricanes. Current information indicates that at least 22 (40%) of the known sites for the species harbor 5 or less individuals, and these sites basically show no natural recruitment, making them susceptible to extirpation by stochastic events such as storms and flashfloods. The Service has evidence of uprooted adult trees of palo de rosa within the natural populations at Hacienda La Esperanza and Higuillar "Sabanera" (both in northern Puerto Rico), suggesting damage caused by hurricane winds (Monsecur, USFWS, personal observations 2009 and Ilianet Morales, UPRM, 2006). Moreover, impacts to seedlings due to flashfloods occur on the populations located in drainages and canyons along the southern coast (i.e., Hoya Honda, Las Trichilias, CORCO and Yauco Landfill) of Puerto Rico (Monsecur, USFWS, personal observations 2006-2016). Climate change is predicted to increase the frequency and strength of tropical storms, but also cause severe droughts (Hopkinson et al. 2008). The vulnerability of species to climate change is a function of sensitivity to changes and exposure to those changes, and the adaptive capacity of the species (Glick et al. 2011). It is unlikely that small populations with little or no recruitment withstand the anticipated impacts of climate change and the shift in vegetation communities. Climate change may also compromise natural recruitment by affecting the establishment and survival of seedlings (USFWS 2017).

### **Recovery**

**Reclassification Criteria:**

Not available.

**Delisting Criteria:**

1. populations known to occur on privately owned land are placed under protective status (USFWS, 1994).
2. an agreement between the Service and the U.S. Army concerning the protection of the species on their land (Fort Buchanan) has been prepared and implemented (USFWS, 1994).
3. mechanisms for protection of palo de rosa have been incorporated into management plans (currently not existing for all forests) for the Maricao, Guanica, Susua, and Cambalache Commonwealth Forests. Given the recent discovery of additional populations, priority should be given to the enhancement and protection of existing populations in protected areas and the protection of privately owned sites (USFWS, 1994).

**Recovery Actions:**

- Protect habitat, through acquisition or conservation easements, for existing privately owned populations, and through the development of management plans for the species where it occurs on Federal or Commonwealth land (USFWS, 1994).

- Monitor known populations and continue to search for additional ones (USFWS, 1994).
- Continue to conduct research on the life history of the species and evaluate the necessity and feasibility of propagation (USFWS, 1994).
- If determined to be necessary and feasible, conduct propagation and enhance existing populations or establish new ones (USFWS, 1994).
- The recovery of palo de rosa should focus on the protection of known key populations that show evidence of natural recruitment. Protections may include the development of conservation easements with private landowners (USFWS 2017).
- Develop a refined GIS model is needed to identify remnants of pristine forest or old secondary forest areas along the northern karst belt that may harbor the species. Surveying those areas may result in the finding of additional populations of palo de rosa, and may also be used to identify areas for the reintroduction of the species (USFWS 2017).
- The populations that are actively reproducing need to be monitored for seed collection for propagation purposes. A species-specific seed collection protocol should be developed to avoid altering its natural recruitment, and to ensure that any propagation effort addresses the populations genetic variability and the species recovery (USFWS 2017).
- Since palo de rosa seems to require a long period for the establishment of seedlings and developing into an adult tree, it is recommended that all planted individuals are pennanently tagged and monitored for their survival (USFWS 2017).
- Cooperative Agreements (USFWS, 1994)

## SPECIES ACCOUNT: *Oxypolis canbyi* (Canby's dropwort)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 2/25/1986

### **Physical Description**

A perennial herb with strong, fleshy rhizomes. Plants have slender stems, often more than 1 m tall. Leaves are thin and quill-like. Herbage smells slightly of dill. From mid-August to October the plants bear compound clusters of small white flowers (sometimes tinged with red) (NatureServe, 2015).

### **Taxonomy**

Molecular and morphological studies have shown evidence that the genus *Oxypolis* as currently circumscribed, including compound-leaved and rachis-leaved species, is not monophyletic: the rachis-leaved species of *Oxypolis* (which include *O. canbyi*) are transferred to their own genus, *Tiedemannia* (Feist and Downie 2008 and Feist et al. 2012) (NatureServe, 2015).

### **Historical Range**

See Current

### **Current Range**

Native to the coastal plain, from southwestern Georgia through South Carolina to southeastern North Carolina (mostly in the middle and inner Coastal Plain), and from eastern MD to (historically) Delaware (Weakley 2008). (NatureServe, 2015)

### **Critical Habitat Designated**

No;

### **Life History**

### **Food/Nutrient Resources**

### **Reproduction Narrative**

Adult: Existing populations of *Oxypolis canbyi* are maintained mainly through asexual reproduction. This species is strongly clonal, reproducing vegetatively by means of stoloniferous rhizomes. Stems also become decumbent and root at the nodes, especially in drier sites where there is little or no water to support the stems. The flowers can be either unisexual or bisexual. Bisexual flowers may facilitate some self-pollination; however, the flowers are protandrous, which is indicative of some degree of outcrossing.; Existing populations of *O. canbyi* are maintained mainly through asexual reproduction. This species is strongly "clonalizing," reproducing vegetatively by means of stoloniferous rhizomes. Stems also become decumbent and root at the nodes, especially in drier sites where there is little or no water to support the stems. Perfect (bisexual) flowers are produced which may result in some self-pollination; however, the flowers are protandrous which may ensure some degree of outcrossing. The potential for outcrossing may be higher in those umbels which produce inner male flowers and outer female flowers. Outcrossing results in increased recombination and heterozygosity, thereby ensuring increased evolutionary potential. Sexual reproduction theoretically should act

as a sort of evolutionary buffer enabling the species to survive environmental changes. This may not be the case in *O. canbyi* due to a possible high selfing rate and/or the isolation of small populations. Predation by the caterpillar of the black swallowtail butterfly (*Papilio polyxenes asterius*) may be a factor in reducing the sexual reproductive potential of *O. canbyi*. This caterpillar chews through the stems just below the inflorescence (NatureServe, 2015).

**Habitat Type**

Adult: Coastal Plains (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: *O. canbyi* has been found in a variety of Coastal Plain habitats prone to long periods of inundation, including pond cypress ponds, grass-sedge dominated Carolina bays, wet pine savannahs, shallow pineland ponds and cypress-pine swamps or sloughs. The largest and most vigorous populations reported occur in open bays or ponds which are flooded throughout most of the year and which have little or no canopy cover. Many sites are on a sandy loam or loam soil which is underlain by a clay layer. Based on county soil surveys, known soil types which support populations of *O. canbyi* include Rembert loam, Portsmouth loam, McColl loam, Grady loam, Coxville fine sandy loam, and Rains sandy loam. These soil types are similar in that they have a medium to high organic content, high water table, and are deep, poorly drained, and acidic. Historically, fire was a key element maintaining the open nature of the habitat at many *O. canbyi* sites. The following species are frequently found associated with *O. canbyi*: *Ilex myrtifolia*, *Nyssa biflora*, *Taxodium ascendens*, *Pinus serotina*, *Stillingia aquatica*, *Rhynchospora tracyi*, *R. inundata*, *Manisuris rugosa*, *Rhexia aristosa*, *Polygala cymosa*, *Pluchea rosea*, *Lobelia boykinii* and *Hypericum denticulataum* (NatureServe, 2015). Moderate ecological integrity of the community, tolerance ranges and site fidelity are inferred based on the variety of habitat in which the species can be found.

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: The vectors of seed dispersal are not well understood, but at least some seed dispersal is by wind (USFWS, 1990).

***Population Information and Trends*****Population Trends:**

Decreasing (NatureServe, 2015)

**Number of Populations:**

18 (17 natural and 1 introduced) (USFWS, 2022)

**Population Size:**

10,000 - 100,000 total individuals (NatureServe, 2015)

**Population Narrative:**

Historically, Canby's dropwort occurred in Delaware, Maryland, North and South Carolina, and Georgia. Today, Canby's dropwort only occurs in three states: Maryland, South Carolina, and Georgia. Further, Canby's range within these states has been reduced greatly overtime with Canby's dropwort being extirpated from 11 counties since the time it was listed. Habitat loss and wetland degradation combined with lack of habitat management through natural or prescribed fire has resulted in a continued decline of this species since its listing. To date, seventeen populations remain extant, and one population has been introduced, bringing the total number of extant populations to 18. Eleven Canby's dropwort populations are partially protected. Because many populations are owned by several landowners, protection and management of populations is difficult to achieve. Species experts defined a self-sustaining population as having a minimum of 1000 stems for five years. Currently, only five Canby's dropwort populations have 1000 stems or more. These populations occur in a small part of the species' former range in Maryland, South Carolina, and Georgia with populations being extirpated from Delaware and North Carolina. Because of existing and future threats and the limited number of populations that appear to be self-sustaining, this species still meets the definition of an endangered species. (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Wetland draining (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The most significant threat to Canby's dropwort is the direct loss or alteration of its rare wetland habitat. Ditching and draining of wetland areas, primarily for agriculture and silviculture, have reduced the frequency, depth and duration of surface water, lowered the groundwater table, and changed the vegetative composition in many areas of the mid-Atlantic coastal plain where the species historically occurred. Reducing surface water, changing soil moisture levels and lowering of the water table enables other plants to become established, modifies vegetative succession, and makes sites less conducive overall to the plant's growth and reproduction (Murdock and Rayner 1990). As a result, many sites have been invaded by shrubs and some sites have been planted in pine. Other sites have been dredged thus breaking the clay hardpan and draining the wetland (Murdock and Rayner 1990, Gaddy 2006) (USFWS, 2015).

**Stressor:** Fire suppression (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** On sites that are not actively disturbed by logging, ditching or dredging, habitat management is often needed to prevent encroachment of shrubs or trees that increase evapotranspiration, lower the water table and shade out Canby's dropwort. Periodic fires probably limited this encroachment under natural conditions but many sites are no longer

surrounded by pine forest subject to regular fires and few sites are managed with prescribed burning. An example is the Big Cypress Meadow which is owned by The Nature Conservancy and is the only site in North Carolina. Young trees, shrubs and maidencane have invaded much of the meadow and the number of Canby's dropwort has declined from as many as 10,000 plants in 1986 to only a few plants in recent years and none in 2006 (Gaddy 2006) (USFWS, 2015).

**Stressor:** Predation (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:** Loss of plants

**Narrative:** Black swallowtail butterfly, grasshoppers, rabbits and rodents have all been known to damage/eat these plants (USFWS, 2015).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** There is currently little regulatory protection of Canby's dropwort habitat. The U.S. Army Corps of Engineers (Corps) generally does not regulate dredge and fill activities in isolated wetlands because of a 2001 U.S. Supreme Court opinion. The 2001 opinion was issued in the Solid Waste Agency of Northern Cook County (SWANCC) v. the U.S. Army Corps of Engineers et al. and ruled in favor of SWANCC. The Corps' requirement for a Clean Water Act Section 404 permit to fill isolated wetlands to construct a landfill was overturned. The Corps had asserted jurisdiction on the isolated intrastate waters based solely on use by migratory birds (Findlaw 2007). Since that ruling isolated wetlands are generally not considered jurisdictional by the Corps. Therefore, there is no Federal nexus and consultation under section 7 of the Endangered Species Act is not required. Because Canby's dropwort grows only in isolated wetlands, there is currently no Federal regulatory control of actions that would affect its habitat. In South Carolina and Georgia, where almost all Canby's dropwort populations occur, there are no State laws that protect the isolated wetlands that provide Canby's dropwort habitat. Maryland and North Carolina, with one Canby's dropwort population each, do regulate isolated wetlands and therefore offer some protection to the habitat (Maryland Department of the Environment 2010, North Carolina Department of Environment and Natural Resources 2010). The Endangered Species Act prohibits the taking of endangered plants from Federal lands without a permit and regulates trade of listed plants. In addition, the Endangered Species Act prohibits the malicious damage or destruction of plants on Federal lands; and, their removal, cutting, digging, damaging, or destroying in knowing violation of any state law or regulation, including criminal trespass law. The State of Maryland prohibits taking of the species from private property without the landowner's permission and from State property without a permit and regulates trade in the species (Code of Maryland regulations 08.03.08). The State of North Carolina prohibits taking of the plant without a permit and the landowner's permission and regulates trade (North Carolina General Statute 19-B, 202.12-202.19). The State of Georgia prohibits digging, removal, or sale of State listed plants from public lands without the approval of the State management authority, and regulates sale or transport of State listed plants from private property (Georgia Wildflower Preservation Act of 1973). The State of South Carolina does not have any regulations that protect endangered plants on private land. However, regulations prohibit the unauthorized taking of plants from South Carolina Heritage Preserves and State Parks (South Carolina Code of Laws: Sections 50-11-2200, 50-11-2210, and 51-3-140) (USFWS, 2015).

**Recovery****Delisting Criteria:**

Canby's dropwort (*Oxypolis canbyi*) will be considered for delisting when there are at least 19 self-sustaining populations in existence that are protected to such a degree that the species no longer qualifies for protection under the Endangered Species Act (see criteria below). A self-sustaining population is a reproducing population that is large enough to maintain sufficient genetic variation to enable it to survive and respond to natural habitat changes. The number of individuals necessary and the quantity and quality of habitat needed to meet this criterion will be determined as one of the recovery tasks. The populations should be distributed throughout the species' historic range. This recovery objective is considered an interim goal because of the lack of data on biology and management requirements of the species. As new information is acquired, the estimate of self-sustaining populations required for the species' survival may be readjusted. The recovery objective for *O. canbyi* will be reassessed at least annually in light of any new information that becomes available (USFWS, 1990).

**Recovery Actions:**

- Conduct surveys and habitat assessments at all surveyed sites by Gaddy (2006) that are not routinely monitored to determine the species presence and to assess habitat quality (USFWS, 2015).
- Protect known Canby's dropwort populations on private lands with conservation easements or Wetland Reserve Program easements (USFWS, 2015).
- Assess moribund and extirpated sites as well as other isolated wetlands for suitable habitat and resource availability (USFWS, 2015).
- Improve our understanding of the relationship between precipitation (and other parameters) and Canby's dropwort population viability (USFWS, 2015).
- Determine objective, quantitative criteria for self-sustaining populations (USFWS, 2015).
- For populations confined within roadside or powerline right-of-ways, promote management actions that shift Canby's dropwort populations away from right-of-ways and towards the interior of adjacent wetlands (USFWS, 2015).
- Conduct demographic studies that further examine genetic variability, population structures, reproduction, and indeterminate growth factors (USFWS, 2015).

**Conservation Measures and Best Management Practices:**

- RECOMMENDATIONS FOR FUTURE ACTIVITIES 1. Protect known Canby's dropwort populations on private lands with conservation easements or Wetland Reserve Program Easements such as Monkey Bay in Clarendon County, SC, Perrion Pond (Burke County), Layfield Pond (Dooly County), Forrester Flats (Lee County), Roadside Park (Lee County), West Daniels Pond (Burke County), Greater Unadilla Pond (Dooly County), and Harmony Church Pond (Dooly County), GA. 2. Improve extant populations with fewer than 1,000 individuals by removing shrub/tree encroachment with prescribed fire, canopy thinning, or other techniques: a. Crosby Heritage Preserve, Colleton County, SC. b. Monkey Bay, Clarendon County, SC. c. Black Pond, Jenkins County, GA. d. Harmony Church Road, Dooly County, GA. e. Greater Unadilla Pond, Dooly County, GA. 3. Search for new populations on property that has suitable habitat within the species range. 4. Propagate and reintroduce Canby's dropwort by rhizome cuttings in a way that retains genetic diversity (e.g., taking rhizome cuttings from multiple individuals). 5. Collect seeds from all populations across the range to safeguard at a Center

for Plant Conservation Site, such as North Carolina Botanical Garden (NCBG). (USFWS, 2022)

## SPECIES ACCOUNT: *Oxytheca parishii* var. *goodmaniana* (Cushenbury oxytheca)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

An annual herb with a small basal rosette of leaves and leafless, wiry stems, mostly 0.5-3 dm tall. Flowers (May-September) are white, pink, or greenish, borne in clusters of 3-12, with each cluster subtended by a funnel-shaped, long-awned involucre. (NatureServe, 2015)

### **Taxonomy**

At the time of listing, Cushenbury oxytheca was recognized as *Oxytheca parishii* var. *goodmaniana* first described by Ertter (1980, p. 90). Ertter recognized *O. parishii* as so distinct as to warrant its own section of the genus, *Acanthoscyphus*. An analysis of molecular as well as morphological data have shown that the sections recognized by Ertter (1980, pp. 70–102) are distinct from each other and in fact are more closely related to other taxa in the *Eriogonoideae* subfamily of the *Polygonaceae* (buckwheat family) than to each other (Pant 2000, pp. 1–94). In reviewing the taxonomic and nomenclatural status of the *Eriogonoideae*, Reveal (2004, p. 144) published names for the taxa found to be distinct from *Oxytheca* by Pant (2000, pp. 1–94). This systematic treatment was followed by Reveal (2005, p. 438) in his contribution to the *Flora of North America* and will be followed in the upcoming revision of the *Jepson Manual Higher Plants of California*. The name now recognized for Cushenbury oxytheca is *Acanthoscyphus parishii* (Parry) Small var. *goodmaniana* (Ertter) Reveal. The name change in no way changes the description or range of the taxon. The common name for the taxon will likewise remain the same. Based on Service convention and the need for continuity with the history of this taxon, 50 CFR 17.12 will be revised to read as follows “*Acanthoscyphus* (*Oxytheca*) *parishii* var. *goodmaniana*” (USFWS, 2009).

### **Historical Range**

See Current

### **Current Range**

Restricted to a carbonate belt in the northeastern San Bernardino Mountains extending from White Mountain in the west to at least Terrace Springs in the east; from Terrace Springs to Rattlesnake Canyon, var. *goodmaniana* occurs with var. *cienengensis* and some morphological intermediates (potential hybrids) between the two (USFWS 2002). Distribution includes occurrences near Cushenbury Spring; Cushenbury, Marble, Arctic, Wild Rose, and Furnace Canyons; Blackhawk, Mineral, and Tip Top Mountains; Terrace Springs; Rose Mine and Green Lead gold mine (USFWS 2002). Range occurs in and adjacent to San Bernardino National Forest; San Bernardino County, California; using GIS tools, range extent was calculated to be approximately 165 square km. (NatureServe, 2015)

### **Critical Habitat Designated**

Yes; 12/24/2002.

**Legal Description**

On December 24, 2002, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Oxytheca parishii* var. *goodmaniana* (Cushenbury *oxytheca*) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in California (67 FR 78570-78610).

**Critical Habitat Designation**

The critical habitat designation for *Oxytheca parishii* var. *goodmaniana* includes one CHU (29 subunits) in San Bernardino County, California (67 FR 78570-78610).

Northeastern Slope Unit, San Bernardino County, California. (i) From USGS 1:24,000 quadrangle maps Butler Peak, Fawnskin, Big Bear City, Rattlesnake Canyon, and Onyx Peak, California.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Oxytheca parishii* var. *goodmaniana* critical habitat consists of three components (67 FR 78570-78610):

(i) Soils derived primarily from upslope limestone, a mixture of limestone and dolomite, or limestone talus substrates with parent materials that include Bird Spring Formation, Bonanza King Formation, middle and lower members of the Monte Cristo Limestone, and the Crystal Pass member of the Sultan Limestone Formation at elevations between 1,440 and 2,372 m (4,724 and 7,782 ft);

(ii) Soils with intact, natural surfaces that have not been substantially altered by land use activities (e.g., graded, excavated, recontoured, or otherwise altered by grounddisturbing equipment); and

(iii) Associated plant communities that have areas with a moderately open canopy cover (generally between 25 and 53 percent (Neel 2000)).

**Special Management Considerations or Protections**

The SBNF is planning a revision of their Resource Management Plan in the near future that, among other functions, would provide conservation benefits to the two carbonate plant species and their habitat in this unit. These lands, however, currently do not have approved management provisions for the carbonate plants and their habitat, and habitat degradation may still be occurring due to ongoing activities identified in the final listing rule for these species (see USFWS 2001b). Therefore, the subject lands continue to require special management and protection to ensure the conservation of these species and their habitat. The core occurrences of the two carbonate plants in this unit are important as potential sources for the colonization events (e.g., seed dispersal) necessary to maintain the natural population dynamics of the species. Every carbonate plant occurrence in this unit is important as a seed source to colonize unoccupied sites and therefore maintain an equilibrium between local colonization and extirpation events. Every carbonate plant occurrence in this unit potentially provides important genetic material through pollen and seed dispersal which may help maintain genetic diversity and reduce the likelihood of regional extirpation events.

**Life History**

**Food/Nutrient Resources****Breeding Season**

Adult: May through June is the flowering season (USFWS, 1997).

**Reproduction Narrative**

Adult: May through June is the flowering season (USFWS, 1997).

**Habitat Type**

Adult: Talus slopes (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species occurs on gentle talus slopes (approximately 10-25 degrees) with no apparent aspect preference. Typically found on soils derived from limestone, dolomite, or a mixture of limestone and dolomite; occupied habitat is mostly correlated with the Bird Springs Formation, Bonanza King Formation, Monte Cristo Limestone, and Sultan Limestone, and Crystal Pass substrate. Plant communities include singleleaf pinyon- Utah juniper woodland, singleleaf pinyon-mountain juniper woodland, singleleaf pinyon woodland, and canyon live oak woodland. Associated species include *Cercocarpus ledifolius* (Curl-Leaf Mountain-Mahogany), *Arctostaphylos glauca* (Big-Berry Manzanita), *Chrysothamnus viscidiflorus* (Green Rabbitbrush), and *Achnatherum coronatum* (Giant Rice Grass). 1440 - 2370 m. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the species unique habitat requirements and low number of known populations.

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Seed dispersal mechanisms need to be studied (USFWS, 2009).

***Population Information and Trends*****Population Trends:**

Not available

**Number of Populations:**

20 (USFWS, 2022)

**Population Size:**

2500 - 100,000 individuals (NatureServe, 2015)

**Population Narrative:**

May have 20,000 - 35,000 individuals in some years. However, because this taxon is an annual, the number and distribution pattern of individuals fluctuates greatly from year to year, depending on winter and spring rainfall and temperatures during the seed germination and seedling establishment season (USFWS 2002). Approximately 14 occurrences are believed extant, with another 1 historical and 1 of unknown status, when mapped using the separation distance of the California Natural Diversity Database (CNDDB). Other reports, using a much smaller separation distance, have broken the total population into a smaller number of "patches" (e.g. 93 patches reported by SBNF cited in USFWS 2002) (NatureServe, 2015). Low resiliency, representation and redundancy are inferred based on the low number of known population and the limited geography in which this species is found. In summary, we consider there to be 20 known occurrences of *Acanthoscyphus parishii* var. *goodmaniana*. Of the 20 occurrences, 6 are extant (i.e., the species was observed during the past 10 years) and 14 are presumed extant (i.e., the species was not observed during the past 10 years, but suitable habitat is present) (Table 1). Two occurrences are fully protected and seven are partially protected as part of the Carbonate Strategy's Habitat Reserve (Figure 2; Table 1). Portions of four occurrences are known to be under active mining (i.e., are being actively mined or have approved plans to be mined) (USFWS, 2022).

**Threats and Stressors****Stressor:** Off-highway vehicle (USFWS, 2009)**Exposure:****Response:****Consequence:** Loss of individuals

**Narrative:** The final listing rule indicated off-road vehicle use and energy development projects were a threat to Cushenbury oxytheca and its habitat. Such activities could impact the species' habitat through ground disturbance or dust creation. About 7 acres (3 hectares) of occupied habitat and 36 acres (15 hectares) of designated critical habitat for Cushenbury oxytheca overlap with roads and motorized vehicle trails (USFWS 2005a, p. 267). The San Bernardino National Forest closed road 3N77 and placed signs and barriers on the other roads (USFWS 2001, p. 18), which should limit impacts due to off-road vehicle use. Additionally, road 3N11A is proposed for decommissioning, and roads 3N03D, 3N54, 3N88, and 3N88B are proposed for reclassification as administrative use only (USFWS 2009, p. 2), which should reduce vehicle activity in the area and further reduce the threat to the species (USFWS, 2009).

**Stressor:** Hydroelectric project (USFWS, 2009)**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** We are unaware of any energy development projects occurring since listing that affect Cushenbury oxytheca (USFWS, 2009).

**Stressor:** Mining (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Mining activity remains the primary threat for Cushenbury oxytheca (USFWS 2005a, p. 246). Mining activities can impact habitat for the plants through the removal of mined materials, disposal of overburden, and road construction (USFWS, 2009).

**Stressor:** Dust/artificial lighting (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Other impacts to the plants are associated with dust and artificial lighting (USFWS 1997, pp. 13, 15–18). Dust can affect Cushenbury oxytheca's habitat by altering soil chemistry and light penetration into seedbanks (USFWS 1997, pp. 17–18). Artificial lighting may affect Cushenbury oxytheca's growing conditions by altering the photoperiod response or the behavior of pollinators or seed dispersers (USFWS 1997, p. 18) (USFWS, 2009).

**Stressor:** Recreational activities (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Several threats such as dispersed target shooting, dispersed camping areas, fuelwood collection, and fire suppression activities have been identified since listing (USFWS 2001, pp. 4–11). These activities can result in trampling of Cushenbury oxytheca and can impact its habitat through ground disturbance or dust creation (USFWS, 2009).

**Stressor:** Predation (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** The threat of predation from burro grazing was identified after listing (USFWS 2001). However, burros are expected to have minimal effects to Cushenbury oxytheca due to the low numbers of burros present (about 60), the dispersal of the burros across a large area, the burros preference for wetter habitats, and the short stature and scarce nature of carbonate plants, which makes foraging on them unlikely (USFWS 2001, p. 39) (USFWS, 2009).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** While both CEQA and NEPA may provide some discretionary conservation benefit to Cushenbury oxytheca, the Act is the primary regulatory mechanism mandating Cushenbury oxytheca conservation. With the majority of suitable and occupied habitat on U.S. Forest Service lands (Figure 1), the Act remains the primary regulatory mechanism for ensuring that Cushenbury oxytheca is addressed during planning efforts for land management actions potentially affecting this species (USFWS, 2009).

**Stressor:** Stochastic extinction (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Extinction

**Narrative:** The final rule indicates the risk of stochastic extinction of Cushenbury oxytheca resulting from random events was considered high due to the low numbers of plants (USFWS 1994, p. 43662). Because this species is restricted to certain, limited soils, it is likely that its population has always been small. Despite this, the population has persisted. This suggests even though the magnitude of this threat may be high, its immediacy is low. However, the potential for stochastic extinction could be increased by habitat loss, fragmentation, and drought. Habitat fragmentation can result in areas too limited and isolated to support pollinators or other seed dispersal agents (USFWS 1997, p. 16).

**Stressor:** Climate change (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Cushenbury oxytheca is endemic to isolated occurrences of particular carbonate soils in the San Bernardino Mountains. Therefore, any combination of environmental conditions, such as those attributed to climate change above, that force an upward shift in the distribution of the species, poses a profound threat to the taxon's persistence and recovery. If this species is affected by elevational shifts resulting from climate change, then there will be no suitable habitat when the elevational range exceeds the species' maximum elevation. As this occurs, the density and distribution may concentrate the species into a smaller area. This, in turn, may make the species even more susceptible to stochastic extinction. To date, no species-specific monitoring has been conducted to detect an elevational shift in its range (USFWS, 2009).

## **Recovery**

### **Reclassification Criteria:**

The priority ranked habitat areas have been protected. Priority for protection shall be determined according but not limited to: 1) population size; 2) habitat quality; 3) manageability/defensibility of site; and 4) connectivity. The initial preserve area should be 5,000 acres (2,000 hectares) based on known areas occupied by the plants and should include protection for the threatened species, *Erigeron parishii* (which is discussed separately under the delisting objective and criteria). Priority areas and populations include, but are not limited to, the following: 1) Sites within the White Mountain Management Unit; 2) populations just north/northeast of Hitchcock Spring; 3) upper Crystal Creek Drainage; 4) Upper Furnace Canyon and prioritized populations in the lower Furnace Canyon area; 5) populations just north of Holcomb Valley; 6) Arctic Canyon; 7) Marble Canyon; 8) Bertha Ridge and slopes to Big Bear Lake; 9) Monarch Flats and northern slopes; 10) eastern and western slopes of Cushenbury Canyon including the vicinity of Whiskey Springs; 11) Burnt Flat; 12) Blackhawk Mountain and slopes; 13) Round Mountain; 14) Grapevine Creek; 15) Top Spring/Lone Valley/Squirrel Spring; 16) Granite Spring; 17) Arrastre Creek/Rose Mine Valley; 18) Rattlesnake Canyon; 19) Sugarlump/Sugarloaf Mountain; and 20) the outlying populations of *Erigeron parishii* in the Little San Bernardino Mountains. The species and ecosystem-level attributes of these priority areas make them necessary for the survival and recovery of these species. Taxonomic assessment of

the eastern populations of *Oxytheca parishii* var. *goodmaniana* may affect the recovery priority and reserve needs of this variety. To count toward reclassification of the plants, reserves must have been designed to minimize or eliminate indirect threats due to adjacent land uses. This includes protection of carbonate plant habitat from human disturbance to hydrology, soil integrity, fire ecology, habitat microclimates, and light regimes. Appropriate management and restorative measures should reduce habitat-degrading effects such as surface disturbances, windblown sediments, fugitive night lighting, and off-highway vehicle use (USFWS, 2009).

Protect additional lands needed to complete otherwise isolated reserves, to protect new populations that may be discovered in the future, and to provide strategic buffer zones and potential population reintroduction and/or expansion areas. The interim estimate of additional lands needed to secure habitat connectivity, buffers, and natural community context is 4,600 acres (1,860 hectares), including lands to meet Delisting Criterion #2 for *Erigeron parishii*. This figure may be further refined as additional information becomes available (USFWS, 2009).

Adaptive population monitoring/adaptive management programs must be functioning so that early detection is assured for any population instability or other problems in the reserve system. Studies will have shown whether there is a need for reintroductions and/or augmentations of existing populations. Research results to support adaptive management will be available, including at least preliminary results on pollination ecology, seed dispersal mechanisms, population dynamics, microclimate effects of vegetation removal/bare areas, seedbank dynamics, and fire ecology (USFWS, 2009).

Recovery Priority Number: 9C

**Delisting Criteria:**

The reserve system designed to allow downlisting is intended to suffice for delisting, provided that monitoring and research demonstrate that the reserves work as planned to remove the threats identified during the listing process. As monitoring and research results become available, delisting criteria will be established (USFWS, 2009).

**Recovery Actions:**

- **Reclassification:** This criterion implicitly addresses listing Factors A (habitat loss) and E (stochastic events). The U.S. Forest Service and Bureau of Land Management have partnered to develop the Carbonate Habitat Management Strategy. The goals of the Carbonate Habitat Management Strategy are to: 1) protect the listed plants and the habitat components they require; 2) guide impact minimization and compensation for unavoidable impacts; 3) streamline reviews of mining activities in carbonate plant habitat; 4) guide habitat restoration; and 5) plan and provide for long-term needs of both the mining industry and listed species conservation. One of the primary goals of the Carbonate Habitat Management Strategy is the establishment of conservation areas for carbonate plants. The Carbonate Habitat Management Strategy provides parameters for allowing mining while ensuring the protection of listed carbonate plant species in perpetuity through the establishment of habitat reserves. The Service provided a programmatic nonjeopardy and no adverse modification biological opinion on May 2, 2005, for the Carbonate Habitat Management Strategy regarding potential effects to Cushenbury oxytheca and other federally listed carbonate plant species. Upon successful implementation of the Carbonate Habitat Management Strategy, habitat preservation will meet or exceed Downlisting

Criterion #1 (USFWS 2005a, p. 247). This includes preservation of at least 425 acres (172 hectares) (82 percent) of occupied habitat and 2,157 acres (873 hectares) (69 percent) of designated critical habitat for Cushenbury oxytheca (USFWS 2005b, pp. 24 and 27). However, the Carbonate Habitat Management Strategy is a programmatic strategy to allow mining and protect carbonate plants; participation by mining interests is voluntary. The reserve system under the Carbonate Habitat Management Strategy is not yet developed and future projects may or may not be implemented under the provisions of the Carbonate Habitat Management Strategy. This criterion has not been met at this time (USFWS, 2009). Delisting: As documented above, a reserve system is planned, but not established. Thus, the necessary monitoring and research associated with the reserve has not been completed. This criterion has not been met at this time (USFWS, 2009).

- **Reclassification:** This criterion implicitly addresses listing Factors A (habitat loss) and E (stochastic events). In addition to the protection of occupied areas, the Carbonate Habitat Management Strategy provides for the conservation of suitable habitat including about 14,709 acres (5,953 hectares) for Cushenbury oxytheca (USFWS 2005b, p. 28). Because the Carbonate Habitat Management Strategy is only a programmatic strategy, these lands are not yet conserved. This criterion has not been met at this time (USFWS, 2009).
- **Reclassification:** This criterion addresses listing Factors A (habitat loss) and E (stochastic events). Because the reserve system is not yet in place, this criterion is not yet applicable. Further, focused research on pollination ecology, seed dispersal mechanisms, population dynamics, microclimate effects of vegetation removal/bare areas, seedbank dynamics, and fire ecology of Cushenbury oxytheca has not yet occurred. This criterion has not been met at this time (USFWS, 2009).
- **Finalize Recovery Plan:** Prepare a new threats-based recovery plan specific to Cushenbury oxytheca that identifies a recovery strategy, objectives, and criteria for reclassification to threatened, objectives and specific criteria for removal from the list of endangered and threatened species, and prioritizes recovery actions. In the interim, seek implementation of elements of the Carbonate Habitat Conservation Strategy that have direct benefit to the conservation of Cushenbury oxytheca (USFWS, 2009).
- **Monitor Existing Populations:** Work with the San Bernardino National Forest to conduct systematic monitoring of Cushenbury oxytheca throughout known and potentially occupied sites as necessary to track the status of the species and identify management priorities. There is a need to continue to obtain quantitative information regarding the status of this species to evaluate the effectiveness of conservation efforts over time, especially in light of potential effects associated with global climate change (USFWS, 2009).
- **Management of Occupied Cushenbury Oxytheca Habitat:** Work with partners, such as the San Bernardino National Forest, to help conserve Cushenbury oxytheca by identifying opportunities to: a) Continue monitoring programs for the effectiveness of measures to protect Cushenbury oxytheca from recreational activities and make adjustments to signs, barriers, and roads as necessary. b) Avoid new developments in or near Cushenbury oxytheca habitat (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS** The recommended actions listed below are to be initiated over the next 5–10 years. Successful implementation of these actions will reduce threats to *Acanthoscyphus parishii* var. *goodmaniana* and provide information to better understand the biological and physical factors limiting population growth and distribution. We recognize that

conservation of this taxon will require cooperation and coordination with partners to minimize impacts from current threats and aid future restoration efforts. 1. Continue implementation of the Carbonate Strategy, particularly additions of *A. p. var. goodmaniana* habitat to the Habitat Reserve and withdrawal of mining claims on habitat with high conservation value. 2. Research the variety's susceptibility to climate change by determining climate tolerances (e.g., temperature, drought duration) and identify climate refugia to protect within carbonate habitat. 3. Determine appropriate monitoring frequency and implement a range-wide monitoring strategy that provides useful information about occupancy and population health. 4. Conduct a species status assessment to evaluate viability given climate change projections, conservation, and progress in threat reduction. The assessment may be used to revise recovery criteria, or to inform a downlisting or delisting decision. 5. Continue managing the threat of roads, off-road vehicle activity, or other recreational activities to carbonate habitat. This may be achieved through road decommissioning, installation and maintenance of signs and barriers, or other management. 6. Research the efficacy of restoring populations on reclaimed lands that have been restored after mining. 7. Finalize the establishment of the proposed Blackhawk Research Natural Area. 8. Collect additional seeds from different occurrences to expand the conservation seed bank (USFWS, 2022).

## SPECIES ACCOUNT: *Oxytropis campestris* var. *chartacea* (Fassett's locoweed)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened 09/28/1988; Great Lakes-Big Rivers Region (R3) (USFWS, 2015)

### **Physical Description**

A perennial herb with compound leaves and with herbage that is covered with dense, white-silky hairs, giving the plant a silvery-gray appearance. Spikes of rose-purple flowers, each about 2 cm long, bloom from late spring-early summer. (NatureServe, 2015)

### **Taxonomy**

A distinct taxon. (NatureServe, 2015)

### **Historical Range**

Historic populations in Bayfield and Waushara counties. (NatureServe, 2015)

### **Current Range**

Restricted to small inland lakes at eight sites in central and northwestern Wisconsin: Waushara, Portage, and Bayfield counties. (NatureServe, 2015)

### **Critical Habitat Designated**

No;

### **Life History**

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Sexual (USFWS, 2013)

### **Lifespan**

Adult: Mean 1-4 years; up to 14 years (USFWS, 2013)

### **Dependency on Other Individuals or Species**

Adult: Pollinated by bees and butterflies (USFWS, 2013)

### **Breeding Season**

Adult: Flowers primarily late May to mid-June (USFWS, 2013)

### **Other Reproductive Information**

Adult: Tippery (2015) found that seed germination in Fassett's locoweed is highly dependent on physical damage to the seed coat, similar to many other plants in the Fabaceae (legume) family. In germination experiments, seeds with an intact seed coat had a very low rate of germination (about 7.8%) when compared to germination rates of seeds cut with a razorblade (61.1%) or seeds rubbed between sandpaper (71.1%). Seeds with thicker seed coats will persist longer in

the seed bank, and since Fassett's locoweed relies on an extensive seed bank to recover from population crashes, this adaptation likely heavily contributes to the persistence of the species (Tipperry 2015). Seed germination is also predicted by the ability of seeds to absorb water. During a trial, locoweed seeds that did not increase in size after being soaked in water overnight, were determined to have insufficient damage to the seed coat. Seeds that did absorb water had a germination rate of almost 100% (Tipperry 2016). Ultimately, findings from these studies found that for germination to be successful, there must be absorption of water, which is not possible without scarification (nicking, breaking, softening, or weakening of the outer shell to speed up seed germination)(Tipperry 2015, Tipperry 2016). Tipperry (2016) found that during the early stages of germination, Fassett's locoweed seedlings grow a root of 4 centimeters (cm)(1.6 inches (in)) or more in length. In germination experiments, seeds that were planted at the soil surface grew a hypocotyl (the part of the stem of an embryo plant beneath the stalks of the seed leaves and directly above the root) of 1 cm in length. In wild populations, there is no visible hypocotyl, and cotyledons (the embryonic leaf, first leaves to appear from a germinating seed) are usually visible just at the soil surface. This indicates that naturally seeds germinate at a depth of 1 cm (0.4 in) or more. In germination experiments, the effect of water depth on seedling establishment was tested using different length pipes to plant seeds. There were no observed differences in germination of seeds in 5 cm (2.0 in), 10 cm (3.9 in), or 15 cm (5.9 in) under water depth setups (USFWS, 2022).

**Reproduction Narrative**

Adult: Fassett's locoweed blooms primarily at the end of May through mid-June, although occasional plants bloom as late as November (Tracy Feldman, pers. obs., 2009-2012). The mean lifespan of Fassett's locoweed appears to vary from 1-4 years depending upon the life stage, the lake from which data were used, and the year data were collected, but the maximum can range to potentially over 14 years (Tracy Feldman, pers. comm., 2013). Seed production is variable, having the potential to vary from zero (even in a "reproductive" plant) to well over 10,000 seeds per plant, but actual numbers range from fairly low in small plants to several hundred (or even in the 1000s) of seeds for larger plants, on average (Tracy Feldman, pers. comm., 2012) (Feldman 2012). Data suggest that the seed banks on Plainfield and Pickerel Lakes are patchy but could be very large (Feldman 2010). While seed banks may be large, seed germination rates vary, and in the field germination rates may be low, from 50-95%; however, only 0-1% of intact seeds germinated in greenhouse and field germination experiments. Seeds appear to germinate in bands along the shoreline at some range of distances above the water line. (Feldman 2012) (USFWS, 2013)

**Habitat Type**

Adult: Palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Open gravelly lake (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Fluctuating lake levels (USFWS, 1991)

**Spatial Arrangements of the Population**

Adult: Pure stands to scattered individuals (USFWS, 1991)

**Environmental Specificity**

Adult: Narrow. Specialist with key requirements common. (NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from USFWS, 1991)

**Habitat Narrative**

Adult: Fassett's locoweed occurs on sandy or gravelly shorelines of small landlocked seepage lakes. It is apparently intolerant of competition and shading and dependent on lake level fluctuations to eliminate competition and maintain an open habitat. (NatureServe, 2015) In all cases, Fassett's locoweed occurs in areas which are completely exposed to sunlight or receive only partial shade from other species. Particularly along the open shorelines but also throughout the sandy lakeside habitat, the soil surface is subjected to extreme temperature fluctuations, high solar radiation, strong winds, and soil moisture stress. However, it is in these areas, where competition from other plant species appears to be very low, that Fassett's locoweed occurs in the densest colonies. (USFWS, 1991)

***Dispersal/Migration*****Dispersal**

Adult: Low (USFWS, 1991)

**Dispersal/Migration Narrative**

Adult: The mature fruits release numerous, small black seeds which have no evident adaptation for dispersal. As in many other plant species (Harper 1977, Johnson and Anderson 1986), the seeds of Fassett's locoweed probably tend to disperse in a clumped pattern around the parent plant. However, they may be moved short distances by wind, rain, or lake water during periods of inundation. (USFWS, 1991)

***Population Information and Trends*****Population Trends:**

Fluctuating, but apparently increasing (USFWS, 2013)

**Species Trends:**

Fluctuating, but apparently increasing (USFWS, 2013)

**Population Growth Rate:**

Fluctuating (USFWS, 2013)

**Number of Populations:**

9 (USFWS, 2022)

**Population Size:**

Approximately 190,000 in 2012 (USFWS, 2013)

**Adaptability:**

Low (USFWS, 2013)

**Population Narrative:**

Of the 10 lakes that support Fassett's locoweed, the plant currently occurs in highest numbers (thousands) at four lakes; Pigeon, Mountain, Plainfield, and Pickerel lakes. Populations of Fassett's locoweed have fluctuated considerably over time. From 2009 to 2012, populations at Plainfield and Pickerel lakes have been stable or increasing due to increases in the number of seedlings (in the thousands) and small plants, most of which do not survive long enough to reproduce (Feldman 2009, 2010, 2011, 2012). Numbers of reproductive plants have decreased over the last four years at these two lakes. Predictions using projection matrix population models indicate that these populations have the potential to decrease in the near future (Feldman 2012). Up to 2000 plants were observed at Second Lake from 2006-2008, however the current population level is unknown. Populations number in the hundreds at Weymouth and Sherman (Marks) lakes. Very small populations (30 plants or less) have been consistently recorded at Lake Huron, Deer Print Lake, and Wolf Lake. (USFWS, 2013) Fluctuations in water levels maintain habitat but also determine population size from year to year. In one year, unusually high water levels may reduce populations to only a few plants and in the next year, lower water levels may result in thousands of plants (USFWS 2009). (NatureServe, 2015). Fassett's locoweed is a rare endemic species with a very limited distribution. Found in only a maximum of 9 sites (7 in central Wisconsin and 2 in northwest Wisconsin), any factor that impacts its habitat adversely could have major consequences (USFWS, 2022)

**Threats and Stressors**

**Stressor:** Development (USFWS, 1991; 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Development, primarily construction of homes and cottages, was considered a significant threat in the Recovery Plan (USFWS, 1991). This threat has been reduced through acquisition of locoweed sites, conservation education and agreements, protective signage, designation of State Natural Areas which are managed to protect and maintain native landscapes. Residential development is still an issue for the Lake Huron site, although many homeowners at this site are caging plants, distributing information and occasionally pulling invasive weeds. (USFWS, 2013)

**Stressor:** Human impacts (USFWS, 1991; 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** A county boat ramp on Pickerel Lake is a threat, along with fishing and swimming. A summer camp is also on this lake. In the past, Fassett's locoweed areas on camp property had been roped off (Darcy Kind, pers. comm., 2012), however no ropes were in place as of at least 2009. ATV use and hiking may trample plants. (USFWS, 1991; 2013)

**Stressor:** Other vegetation (USFWS, 1991; 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Invasive plants, such as the non-native sweet clover can spread readily in open areas. It is considered a threat to recovering prairies, because it may compete with native species for resources or otherwise alter the edaphic conditions of the plant community (Eckardt 1987). The invasive orange hawkweed is quite abundant a few meters above the high waterline and grows in association with Fassett's locoweed in that zone. This species is of concern because of its possible allelopathic properties and the potential impact on Fassett's locoweed (Waller 1989). Trees and other vegetation may grow sufficiently to block out sunlight required by the locoweed. (USFWS, 1991; 2013)

**Stressor:** Nutrient enrichment (USFWS, 1991; 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The Fassett's locoweed recovery plan (USFWS 1991) identified nutrient enrichment of shorelines supporting Fassett's locoweed resulting from run-off as a threat, as this may result in loss of habitat due to competition from other plant species that would not typically be able to compete with Fassett's locoweed in its nutrient poor habitat. (USFWS, 2013)

**Stressor:** Reduced groundwater levels (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Fassett's locoweed is found on sandy-gravel lakeshores of seepage lakes, fed by groundwater, with fluctuating lake levels. Fluctuating lake levels are critical in maintaining suitable open shoreline habitat for the species. Aggressive plant competitors may be eliminated during periods of high water. Fluctuating water levels also help maintain low substrate fertility (preferred by the species) and distribute seeds within the site. The amount of available habitat at each site depends on current and recent lake levels. Generally, lower lake levels expose more shoreline area which provides more suitable habitat for the species, resulting in higher population numbers, especially of seedlings. However, continued low water conditions may decrease habitat due to succession. High lake levels which eliminate shoreline habitat, generally reduce overall population numbers. In addition, water level fluctuations within seasons may cause mortality of plants through submersion or desiccation (Tracy Feldman, UW-SP, pers. comm., 2012.) Lake levels may be affected by the use of high capacity wells used for crop irrigation. (USFWS, 2013)

**Stressor:** Herbivory (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Flowers have been eaten from a number of plants at one site, possibly by deer (WDNR, unpublished data). At Plainfield and Pickerel lakes in 2009-2012, Feldman observed racemes removed from Fassett's locoweed plants, potentially by deer. Insect herbivores may also affect Fassett's locoweed plants and seeds. At Plainfield and Pickerel lakes between 2009 and 2012, Tracy Feldman (UW-SP) observed caterpillars on racemes, spittlebugs on leaves, and occasional chewed leaves or racemes. At Pickerel Lake in 2012 he also observed holes in mature Fassett's locoweed fruits, reminiscent of weevil damage. (USFWS, 2013)

**Stressor:** Herbicides (USFWS, 1991; 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Herbicide and pesticide use is heavy in the agricultural areas. In addition, many of the lakes with Fassett's locoweed are lined with residential properties and lawns. Problems are possible from spray drift or run-off onto Fassett's locoweed habitat. Any decrease in the protective wooded buffer around each lake could result in increased overland flow of sediment-laden run-off into the water. (USFWS, 1991) The threat from herbicides is ongoing. (USFWS, 1991; 2013)

### ***Recovery***

**Reclassification Criteria:**

Recovery Priority Number: 9

**Delisting Criteria:**

Removal of Fassett's locoweed from the list of US. Endangered and Threatened Species will be considered when six populations are permanently protected and managed, and monitoring indicates the populations to be self-sustaining. (USFWS, 1991)

**Recovery Actions:**

- Protect and manage Fassett's locoweed at all sites with naturally-occurring populations. This includes the six extant [now 10 (USFWS, 2013)] populations as well as any new occurrences which might be found. Adequate protection will be accomplished not only through legal agreements with landowners but by increasing public awareness on the high-use lake shorelines. Education must be seen as integral to protection. (USFWS, 1991)
- Management to maintain appropriate habitat, including such activities as fencing populations in certain areas or removing invading, nonnative species, will be necessary at some sites. (USFWS, 1991)
- It is essential to conduct research which will contribute to recovery. Included here are seed bank research and genetic studies. (USFWS, 1991)
- Introduction of the species may become a future priority if protection of extant populations cannot be achieved. (USFWS, 1991)
- Land protection and site monitoring (USFWS, 2013)
- Site protection (USFWS, 2013)
- Population monitoring at Plainfield and Pickerel lakes (USFWS, 2013)
- Population augmentation (USFWS, 2013)
- Searches for new sites and potential reintroductions (USFWS, 2013)
- Actions to address threats due to continued low lake levels (USFWS, 2013)
- Pollinator studies (USFWS, 2013)
- Seed storage (USFWS, 2013)
- Seed bank studies (USFWS, 2013)

## **SPECIES ACCOUNT: *Packera franciscana* (San Francisco Peaks ragwort)**

---

### ***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 11/22/1983; Southwest Region (Region 2) (USFWS, 1983)

### **Physical Description**

A dwarf alpine perennial, 3.1-10.2 cm tall, with deeply lobed leaves; upper leaves smaller than lower leaves. Small yellow-gold flower heads, composed of 1-6 flowers. (NatureServe, 2015)

### **Taxonomy**

The San Francisco Peaks ragwort was listed as *Senecio franciscanus*. (USFWS, 1983)

### **Historical Range**

It is believed that the plant inhabits much of the same area it occupied when it was first described in 1884 (USDA 1987). (USFWS, 2010)

### **Current Range**

Endemic to the San Francisco Peaks, a high altitude mountain range in Coconino County, northern Arizona; range about 4.44 sq km. (NatureServe, 2015)

### **Critical Habitat Designated**

Yes; 11/22/1983.

### **Legal Description**

On November 22, 1983, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Astragalus holmgreniorum* (Holmgren milk-vetch) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Arizona (48 FR 52743-52747).

### **Critical Habitat Designation**

The critical habitat designation for *Astragalus holmgreniorum* includes one CHU in Coconino County, Arizona (48 FR 52743-52747).

Coconino County; Coconino National Forest, Agassiz Peak and Humphreys Peak, T22N, R7E, N½ of NW¼ Sec. 5; T23N, R7E, W½ Section 32 and W½ Section 29.

### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Astragalus holmgreniorum* critical habitat consists of one component (48 FR 52743-52747):

Primary constituent elements are the loose cinder talus slopes of the alpine tundra system of the San Francisco Peaks and the absence of disturbance and damage from hikers.

### ***Life History***

### **Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Primarily vegetative by rhizomes, but also sexual (NatureServe, 2015)

**Breeding Season**

Adult: August to mid-September (USFWS, 1987)

**Reproduction Narrative**

Adult: Reproduction is primarily vegetative by mat-forming rhizomes although sexual reproduction also occurs from matures achenes. (NatureServe, 2015)

**Habitat Type**

Adult: Scree/talus slopes (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Alpine tundra (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clustered (inferred from USFWS, 1987)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Site Fidelity**

Adult: High (USFWS, 1987)

**Habitat Narrative**

Adult: The San Francisco Peaks groundsel occurs in alpine tundra areas on sparsely vegetated loose talus slopes, at 3350-3750 m. It is usually just above southwestern montane spruce-fir or bristlecone pine (*Pinus aristata*) forests. (NatureServe, 2015)

***Dispersal/Migration*****Dispersal**

Adult: Low (inferred from USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: Personal observations indicate that the plant does occur in avalanche-disturbed areas and it is possible that these disturbances may allow for the plant to spread and/or take root in new areas. (USFWS, 2010)

***Population Information and Trends*****Population Trends:**

Stable (USFWS, 2021)

**Species Trends:**

Stable (USFWS, 2021)

**Population Growth Rate:**

Unknown (NatureServe, 2015)

**Number of Populations:**

5 (USFWS, 2021)

**Population Size:**

90,000 to 135,000 ramets (USFWS, 2021)

**Adaptability:**

Low (USFWS, 2010)

**Population Narrative:**

On the San Francisco Peaks, there are approximately 1,200 acres of tundra and *P. franciscana* occurs in a patchy distribution across approximately 213 acres within the lpine zone (Dexter 2007). On the San Francisco Peaks, ragwort plants occur on Humphreys, Agassiz, Fremont, and Doyle peaks, and along the north rim that extends northeast from Humphreys Peak. *P. franciscana* surveys have estimated a total population of 90,000 to 135,000 ramets (USFWS 2014). The species appears to be stable based upon the apparent persistence and density of ramets, the continuous occupancy of monitored areas, and implementation of conservation measures to protect the plant and its habitat (USFWS 2010, Fowler and Sieg 2011, Fowler et al. 2015, USFS 2018). (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Trampling (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** At the time of listing, the greatest threat to the species was thought to be the activity of summer hikers using a multitude of user-created trails and the lack of a designated trail to minimize effects to the San Francisco Peaks ragwort (USFWS 1983). Since the species was listed, trails, or plans for them, have been modified to avoid impacting areas where the plant occurs. Off trail use is expected to be minimal because of the steep and loose terrain. (USFWS, 2010)

**Stressor:** Ski area expansion (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** When the ragwort was listed, the expansion of the Arizona Snowbowl, a local ski area located on Humphreys Peak, was predicted to have a serious detrimental effect on *P. franciscana* (USFWS 1983). However, after listing, the planned improvements to the ski area were adjusted to not affect known populations or individual *P. franciscana* plants, but some activities will occur within designated critical habitat. (USFWS, 2010)

**Stressor:** Avalanches (USFWS 2010)

**Exposure:**

**Response:****Consequence:**

**Narrative:** Avalanches tend to create disturbance areas that can impact existing vegetation. However, the plant seems to be adapted to some amount of disturbance, and it is not understood if this is a disturbance that results in negative, positive, or neutral impacts to the plant. Negative results may occur if plants are uprooted and destroyed. Personal observations indicate that the plant does occur in avalanche-disturbed areas and it is possible that these disturbances may allow for the plant to spread and/or take root in new areas. (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)

**Exposure:****Response:****Consequence:**

**Narrative:** Global climate change may be the greatest threat to this alpine tundra-dependent species. Studies have shown that since 1950, the snowmelt season in some watersheds of the western U.S. has advanced by about 10 days (Dettinger and Cayan 1995, Dettinger and Diaz 2000, Stewart et al. 2004). In alpine habitats, climate change intensifies natural drought cycles and the ensuing stress placed upon high elevation specialist species (IPCC 2007, Cook et al. 2004, Breshears et al. 2005, Mueller et al. 2005). The San Francisco Peaks ragwort may be threatened with extinction in the future if climate change results in the loss of tundra habitat on the San Francisco Peaks. Since the highest peak on the mountain is at 3,850 m (12,633 ft), there is little habitat available for the plant to migrate upward in a warming climate scenario, and we have speculated that the species may be vulnerable to extinction due to climate change. (USFWS, 2010)

**Recovery****Delisting Criteria:**

Demonstrated long-term stability in population levels and habitat size and quality at current levels or greater through monitoring studies. (USFWS, 1987)

Actions identified in Alpine Tundra Management Plan are implemented. (USFWS, 1987)

Extend the improved trail system to the top of Humphrey's Peak; provide an alternate exit from the alpine zone. (USFWS, 1987)

Develop a cooperative agreement between the Forest Service and the Fish and Wildlife Service on monitoring and enforcement of closure. (USFWS, 1987)

**Recovery Actions:**

- Remove threats to San Francisco Peaks groundsel by enforcement of existing regulations and by management for protection. (USFWS, 1987)
- Study populations in their natural habitat. (USFWS, 1987)
- Establish and maintain an ex situ population of *Senecio franciscanus*. (USFWS, 1987)
- Develop public awareness, appreciation, and support for preservation of San Francisco Peaks Groundsel. (USFWS, 1987)
- We recommend that the USFWS, U.S. Forest Service Rocky Mountain Research Station, and Coconino National Forest establish a statistically robust, baseline population size estimate

- for the entire mountain and within the San Francisco Peaks Recreation Natural Area. This is necessary for us to better understand the true status and to accurately document responses and trends of the *P. franciscana* population. (USFWS, 2010)
- We recommend that the USFWS initiate revision of the Recovery Plan (which is 23 years old) and develop specific delisting criteria for *P. franciscana*. (USFWS, 2010)
  - We recommend that the USFWS, U.S. Forest Service Rocky Mountain Research Station, and Coconino National Forest conduct long-term monitoring of the *P. franciscana* population centroid determined by Fowler et al. (2009) to allow detection of altitudinal migration. (USFWS, 2010)
  - We recommend that the USFWS, U.S. Forest Service Rocky Mountain Research Station, Coconino National Forest, and other partners conduct research on the reproductive biology of *P. franciscana* evaluating the genetic diversity within and between colonies, the breeding system involved with sexual reproduction, pollination, and fertilization. (USFWS, 2010)
  - We recommend that the USFWS, U.S. Forest Service Rocky Mountain Research Station, Coconino National Forest, and other partners conduct research on *P. franciscana* seed viability, seedling establishment, survivorship, and fecundity to better understand the life history characteristics of this species. (USFWS, 2010)
  - We recommend that the USFWS, U.S. Forest Service Rocky Mountain Research Station, Coconino National Forest, and other partners conduct research examining the effect of natural and manmade disturbance on *P. franciscana* persistence and distribution. (USFWS, 2010)

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS** The foremost recommendation for action is that, if possible, given workloads, we conduct a Species Status Assessment for *P. franciscana* to guide the development of a recovery plan revision. In addition, the following recommendations for future actions are the result of discussions and/or published information regarding the species' needs with recognized experts from the RMRS, The Arboretum at Flagstaff, and managers from the Coconino National Forest. 1. We recommend that the Service, RMRS, and Coconino National Forest conduct longterm monitoring of the *P. franciscana* population centroid determined by Fowler et al. (2015) to allow detection of altitudinal migration. 2. We recommend that the Service, RMRS, Coconino National Forest, and other partners conduct research examining the effect of natural and human-caused disturbance on *P. franciscana* persistence and distribution, including damage potentially caused by trampling and habitat destruction by hikers and potential effects from the Arizona Snowbowl Ski Resort. 3. We recommend that the Service, RMRS, Coconino National Forest, and/or other partners conduct research on the reproductive biology of *P. franciscana* evaluating the genetic diversity within and between clones, and the breeding system involved with sexual reproduction, pollination, and fertilization. 4. We recommend that the Service, RMRS, Coconino National Forest, and other partners conduct research on ragwort seed viability, seedling establishment, survivorship, and fecundity to increase our understanding of the life history characteristics of this species. 5. We recommend that the Service work with The Arboretum at Flagstaff, and other partners to collect additional seed to replenish the seed in storage as well as for germination trials. 6. We recommend that the Service work with The Arboretum at Flagstaff, or other interested partners, to conduct a thorough population genetic analysis of *P. franciscana* to assess the extent of the hybrid zone with *P. werneriifolia* on the San Francisco Peaks, and to investigate whether phenology or elevational distribution of one or both species is changing due to climatic shifts. 7. We recommend that, if possible, given workloads, the Coconino National Forest work with us to develop a current

Wilderness Management Plan for the San Francisco Peaks wilderness that identifies management actions to protect *P. franciscana* and its habitat. (USFWS, 2021)

## SPECIES ACCOUNT: *Paronychia chartacea* (Papery whitlow-wort)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 2/20/1987; Southeast Region (R4)

### **Physical Description**

The papery whitlow-wort is mat-forming with many bright yellowish-green branches radiating flatly from a strong taproot (Kral 1983, Small 1933). The stems are 5 to 20 cm long and are wiry. The leaf blades are sessile, 1.5 to 3.0 mm long, ovate to triangular-ovate in shape, and strongly revolute. It has numerous small cream-colored to greenish flowers (Small 1933, FWS 1996) that produce a very thin-walled utricle (Kral 1983). There are two geographically isolated subspecies of this small herb: *P. chartacea* ssp. *chartacea* in central Florida and *P. chartacea* ssp. *minima* L. Anderson in the Florida panhandle. Much of the distinction between the two subspecies is a matter of degree (Anderson 1991). The *P. chartacea* ssp. *minima* is somewhat less pubescent than ssp. *chartacea*. There are also differences in their base stems, leaf width, and flower cluster (Anderson 1991). (USFWS, 1999)

### **Taxonomy**

The papery whitlow-wort was first named by Small (1925) as *Nychia pulvinata*. In 1936 Fernald transferred the species to the genus *Paronychia* as *P. chartacea* because the name *P. pulvinata* was pre-empted (Anderson 1991). In 1991 Anderson formally described two geographically distinct subspecies, *P. chartacea* ssp. *chartacea* and *P. chartacea* ssp. *minima*. The subspecies *P. chartacea* ssp. *minima* was formally described by Anderson (1991), several years after *P. chartacea* had been listed as a threatened species. Because the entire species was listed as threatened, the newly described subspecies is also protected. (USFWS, 1999)

### **Historical Range**

See current range/distribution.

### **Current Range**

*P. chartacea* ssp. *chartacea* occurs in the Lake Wales Ridge in Highlands, Polk, Osceola, Orange, and Lake counties, Florida. *P. chartacea* ssp. *minima* occurs in the karst region of the Florida panhandle, Washington and Bay counties. (USFWS, 1999)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproduction Narrative**

Adult: Flowering and fruiting occur in late summer or fall (Anderson 1991) and the seeds mature in September or October (T. Race, Bok Tower Gardens, personal communication 1996). This species is a short-lived perennial (Anderson 1991 and observations by staff at the Historic Bok Sanctuary).

**Habitat Type**

Adult: Sand scrub/rosemary balds

**Environmental Specificity**

Adult: Narrow (Inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Papery whitlow-wort is most frequently seen in open, sunny gaps in rosemary balds within scrub vegetation (Abrahamson et al. 1984, Christman 1988, Menges and Kohfeldt 1995). At Archbold Biological Station, rosemary scrubs are found only on the higher ridges and knolls surrounded by scrubby flatwoods with dense oaks. The main soil types are St. Lucie and Archbold (Abrahamson et al. 1984), which are both well-drained white sands (U.S. Dept. of Agriculture, Soil Conservation Service 1989). The fire cycle in rosemary scrub can range from 10 to as long as 100 years (Johnson 1982, Myers 1990). Rosemary scrub has abundant Florida rosemary (*Ceratiola ericoides*) and scrub oaks including Chapman oak (*Quercus chapmannii*), sand live oak (*Q. geminata*), Archbold oak (*Q. inopina*) and occasional sand pine (*Pinus clausa*). The open sandy areas of rosemary scrub contain small herbs and lichens (Abrahamson et al. 1984, Hawkes and Menges 1996). These gaps in the dense vegetation are more persistent in rosemary scrubs than in scrubby flatwoods (Hawkes and Menges 1996). Papery whitlow-wort also occurs in high pineland (upland longleaf pine vegetation, also called “sandhill”) in the Walk in the Water tract of LWR State Forest (A. Cox, Florida Division of Forestry, personal communication 2002), at TNC’s Crooked Lake Sandhill Preserve (B. Pace-Aldana, TNC, in litt. 2002), and at the Tiger Creek Preserve. In studies of the responses of plants to fire in rosemary balds, Johnson and Abrahamson (1990) and Ostertag and Menges (1994) identified two groups of scrub plants—those that resprout after a fire and those that return from seed. They found that papery whitlow-wort appeared in rosemary balds after fires, even though it had been rare or absent prior to the burn. This strongly indicates that papery whitlow-wort maintains seed banks in the soil, waiting for suitable germination conditions. Within about 9 to 12 years after a fire, papery whitlow-wort was displaced by Florida rosemary and reindeer lichens (*Cladonia* and *Cladina*) (Johnson and Abrahamson 1990). Some gap plants such as snakeroot and Highlands scrub hypericum disappear relatively quickly after fires and require large populations consisting of tens of thousands of plants to persist (Quintana-Ascencio and Menges 2000), but papery whitlow-wort persists longer after fire and it has many large populations over a relatively large geographic range, compared to other LWR endemic plants. The density of papery whitlow-wort increases in relation to available open space (Hawkes and Menges 1996; Menges and Kohfeldt 1995), so the species is most abundant in disturbed, sandy areas such as road rights-of-way and recently cleared high pine (Abrahamson et al. 1984; Christman 1988; Service 1996). Papery whitlow-wort can become very abundant after a fire or on disturbed sites such as along fire lanes or trails (Service 1996; Johnson and Abrahamson 1990) and is least likely of the federally-listed scrub plants to suffer local extirpations as open areas become covered by shrubs. Loose sand affects papery whitlow-wort. According to research by Petru and Menges (2004), “the demographic responses of the species to sand movements indicate that mobile sands create constantly shifting arrays of microsites that can influence post-dispersal seed germination, survival, and growth of Florida scrub herbs. Roadside habitats have more dynamic patterns of sand movement than natural gaps and may alter selection regimes important for demographic variation of endemic Florida scrub plants.” Papery whitlow-wort persists on road edges in the absence of fire in the vegetation. These roadside sandy areas constitute habitats that are significantly different from the bare areas within the vegetation, and may be less suitable for

persistence of the species. This research bolsters the already-substantial evidence that prescribed fire is essential to maintain Florida scrub vegetation and its biota, including other federally listed plants and animals. Management for papery whitlow-wort requires burning regimes that mimic the natural fire cycles of rosemary scrub. Relationships among fire, open space, and plant distributions within a xeric scrub are complex and need to be studied further (Hawkes and Menges 1996). Management practices for rosemary scrub should include fire at intervals suitable for a variety of plants and animals, rather than at intervals optimized for just a single species (Hawkes and Menges 1996; Quintana-Ascencio et al. 2003).

### ***Dispersal/Migration***

### ***Population Information and Trends***

#### **Number of Populations:**

< 24 EORs ( Element Occurrence Records) (USFWS, 2021)

#### **Population Size:**

2500 - 10,000 individuals (NatureServe, 2015)

#### **Adaptability:**

Found in disturbed sites; can tolerate and probably promoted by fire. (NatureServe, 2015)

#### **Population Narrative:**

Papery whitlow-wort occurs on the Lake Wales and at least one smaller nearby ridge (Kral 1983), in Highlands, Polk, Osceola, Orange, and Lake Counties (Anderson 1991). It is present on the small ridge at the Lake McLeod tract of LWR National Wildlife Refuge, but not on the Bombing Range Ridge on Avon Park Air Force Range. On the LWR, it is present in essentially all of the scrub conservation lands. Since the last comprehensive survey (Schultz et al. 1999), it has been found in high pineland at the Walk in Water tract of LWR State Forest (Anne Cox, LWR State Forest, personal communication 2002). It is also present in high pineland on the Tiger Creek Preserve, owned by The Nature Conservancy. The northern range limit of papery whitlow-wort is in Lake County, where it occurs on the north side of Lake Louisa at Crooked River Preserve, owned by the Lake County Water Authority. It was possibly present at a nearby site, Schofield Sandhill, which had been proposed for acquisition under the Florida Forever program, but the acquisition proposal did not come to fruition. The only site on conservation lands in Orange County (also at the northern range limit) is the small Shadow Bay Park (formerly Lake Cane-Marsha Park) near where the Florida Turnpike crosses Interstate 4. The species was reported from localities in western Orange County, but the area has since become urbanized, and there are few if any opportunities for setting aside conservation lands in this area. The only papery whitlow-wort site in Osceola County for that has been proposed for State acquisition is at Lake Davenport, in the northwestern corner of the County. It has not been purchased (Florida Natural Areas Inventory 2005). Papery whitlow-wort is present on essentially all conservation lands with scrub on the LWR in Polk and Highlands Counties. The southernmost sites on conservation lands are Gould Road (part of the LWR Wildlife and Environmental Area operated by the FWC) and Archbold, both in Highlands County south of Lake Placid (Schultz et al. 1999). During 2003, the Florida Fish and Wildlife Conservation Commission and Archbold Biological Station purchased adjoining portions of a ranch that bordered the Biological Station's preserve to the west. The recently-acquired land provides an important buffer for Archbold, and it protects

additional habitat for this species, both occupied and restorable. Although FNAI data provide the best available overall view of the distribution of this species, intensive local inventories add important detail. The LWR State Forest is represented in the FNAI database by nine element occurrences, yet the Arbuckle tract of the Forest has 188 records of this plant in its GIS database, based upon an inventory by K. DeLaney in 1988 (data provided by A. Cox, LWR State Forest). Of the 188 records, 23 represented more than 100 individuals. Archbold Biological Station has not monitored this plant because it thrives in fire lanes that usually do not have exotic plant problems (E. Menges and M. Deyrup, Archbold, personal communication 1995, in Service 1996). The propensity of this species to occupy fire lanes, roadsides, and other artificially disturbed areas is a primary conservation concern for the papery whitlow-wort, because it tends to be far more abundant in such disturbed areas than within the vegetation itself. This situation was researched by Petru and Menges (2004), and they confirmed that prescribed fire is essential to create and restore open, sandy habitat for this and other plants. The papery whitlow-wort occurs in association with several other federally listed species: in scrub, Florida bonamia, Highlands scrub hypericum, wireweed, Florida perforate cladonia, snakeroot, and scrub blazing star. In high pineland at the Tiger Creek Preserve, pygmy fringe tree, pigeon wings, scrub buckwheat, Britton's beargrass, scrub plum, and Carter's mustard. Papery whitlow-wort is the most abundant and widespread of the listed LWR scrub and high pineland plants, and it has benefited greatly from acquisition of conservation lands in its range. Like several other scrub species, including Highlands scrub hypericum, is particularly abundant in human-disturbed areas such as road edges and fire lanes. Researchers based at Archbold Biological Station are interested in finding ways to lessen these plants' dependence on such artificial habitats through restoration of fire regimes.

### ***Threats and Stressors***

**Stressor:** Habitat destruction or modification

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** For subspecies chartacea, about 30% of FNAI EORs are not protected from threats that are range-wide in scope. Fire suppression is pervasive at unprotected sites and gradually alters habitat over a period of years. Habitat loss through agricultural and residential development is immediate, ongoing, and cumulative. Seventy percent of FNAI EORs occur within one of the 26 managed areas listed in C(1)(d) above. Loss of populations off the LWR in Orange, Polk, and Glades Counties would constitute a significant curtailment of the historic range of chartacea (Turner et al. 2006). Some of these sites may already have been lost. For subspecies minima, it is unknown how many populations have already been lost and its historical range has apparently not been documented. Eight of 12 extant sites appear to be in imminent danger of being lost; all are on privately owned land and could be destroyed if development or habitat modification occurs on those lands. For both subspecies a range-wide survey is needed to determine the current status of populations and the threats to each. (USFWS, 2008)

**Stressor:** Inadequacy of existing regulatory mechanisms

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Papery whitlow-wort is listed as endangered by the State of Florida on the Regulated Plant Index (Florida Department of Agriculture and Consumer Services Rule 5B-40). This law regulates the taking, transport, and sale of listed plants. Property owners are not prohibited under this law from destroying populations of listed plants nor are they required to manage habitats to maintain populations. Existing federal and state regulations prohibit the removal or destruction of listed plant species on public lands. However, they afford no protection to listed plants on private lands. In addition, state regulations are less stringent than federal regulations on land management practices that may adversely affect populations of listed plants. Existing regulatory mechanisms are inadequate to protect this species. (USFWS, 2008)

**Stressor:** Inadequate management (fire or mechanical disturbance)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Maintenance of viable populations of imperiled plant species depends largely on the determination of the appropriate management regime of populations on managed areas. For subspecies *chartacea*, inadequate use of fire or the use of mechanical treatments as a surrogate for fire may reduce population sizes or adversely affect demographic performance. For subspecies *chartacea*, appropriate management means burning Florida rosemary scrub often enough to maintain large gaps within the rosemary shrub matrix. In the absence of data on the biology and autecology of subspecies *minima*, its management needs cannot be determined. The preferred habitat of subspecies *minima* on the margins of karst ponds suggests that disturbances other than fire may be required for the maintenance of its populations. (USFWS, 2008)

### ***Recovery***

**Reclassification Criteria:**

Not relevant. (USFWS, 1999)

**Delisting Criteria:**

1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to ensure 95% probability of persistence for 100 years. (USFWS, 1999)

2. When these sites, within the historic range of *P. chartacea*, are adequately protected from habitat loss, degradation, and fragmentation. (USFWS, 1999)

3. When these sites are managed to maintain the rosemary phase of xeric oak scrub communities to support *P. chartacea*. (USFWS, 1999)

4. When monitoring programs demonstrate that these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. (USFWS, 1999)

**Recovery Actions:**

- Determine current distribution of *P. chartacea*. Some portions of *P. chartacea*'s range have been well surveyed yet a total distribution has not been ascertained for this species. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)

- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, has been isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics of *P. chartacea*. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species, more specific biological information is needed. (USFWS, 1999)
- Monitor populations of *P. chartacea*. Develop monitoring protocol to assess population trends for *P. chartacea*. Develop a quantitative description of the population structure of *P. chartacea*. (USFWS, 1999)
- Provide public information about *P. chartacea*. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about *P. chartacea*. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of *P. chartacea* and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Manage and enhance habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)
- A taxonomic study evaluating the distinctiveness of the two subspecies should be conducted. (USFWS, 2008)
- A study of the reproductive biology of the two subspecies should be conducted to determine the degree of floral dimorphism/sexual gender and sex ratios of populations. (USFWS, 2008)
- For *P. c. chartacea*, surveys should be conducted to assess the status of the FNAI EORs that occur on unprotected sites and to evaluate the feasibility of protecting additional populations. Following Turner et al. (2006), extant parcels in the Green Swamp and at Fisheating Creek, Avon Park Lakes, Lake Davenport and other sites should be targeted for acquisition. Acquisition of these sites would also extend protection to other federally listed plants. (USFWS, 2008)
- For *P. c. minima*, it is unclear how well existing FNAI EORs reflect the historic range of the taxon. It is possible that additional surveys of areas with appropriate habitat are needed. The possibility of acquiring additional populations also needs to be assessed. (USFWS, 2008)
- Habitat maintenance requirements of *P. c. minima* need to be investigated. (USFWS, 2008)
- For both subspecies, the minimal monitoring should be establishment of level 2 monitoring (sensu Menges and Gordon 1996) to track changes in population sizes over time. Level 2 monitoring requires that surveys be repeated at defined intervals (e.g., annually, biannually, every five years, or both before and after imposition of management treatments) and that surveys take place within well-defined areas (e.g., within plots small enough to be searched thoroughly within a minimum of effort). ABS' s Population Dynamics of Endemic Plants (PDEP) project was designed as a model of level 2 monitoring that can be deployed by other

- agencies. Presence/absence data (level 1 monitoring sensu Menges and Gordon 1996) or the periodic accumulation of GPS points cannot provide meaningful data for determining population trends or for quantifying responses to prescribed fire or other management activities. (USFWS, 2008)
- To conduct population viability analyses, detailed demographic data (level 3 monitoring sensu Menges and. Gordon 1996) should be collected from multiple populations of both subspecies. These data need to be collected across the full geographic range of both subspecies, from populations in contrasting habitats (e.g., rosemary scrub vs. roadsides for subspecies chartacea, pond margins vs. sandhill for subspecies minima), and in sites with differing management histories. (USFWS, 2008)
  - Studies should be conducted to understand the genetic diversity of both subspecies; this may aid in the identification of new acquisition needs. (USFWS, 2008)
  - Where monitoring is being conducted, data should be collected on fire management activities to aid in the interpretation of trends and identifying the most favorable treatments. (USFWS, 2008)
  - A revised recovery plan should be developed to address the existence of two subspecies with separate geographic ranges and their potential need for differing management practices to ensure recovery. (USFWS, 2008)
  - Habitat for *P. c. chartacea* needs to be maintained through burning Florida rosemary scrub within the modal fire return interval defined by other gap specialists and by Florida rosemary (Menges 2007). (USFWS, 2008)

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS** • Conduct surveys for *P. c. var. minima* in areas with appropriate habitat and unknown occupancy to assess the possibility of additional populations and help identify the historic range of the variety. This could include a habitat suitability analysis to help guide surveys. • Purchase for conservation or work with private landowners to develop conservation agreements for unprotected lands with *P. c. var. minima*. • Manage Florida rosemary scrub habitat for *P. c. chartacea* through prescribed fire within a fire return interval of 10 to 30 years (Menges et al. 2019). • Investigate the habitat maintenance requirements of *P. c. minima*, particularly with respect to hydrology. • Institute or continue Level 1 monitoring for *P. c. var. chartacea* between August and November when plants are most abundant. • Conduct more intensive monitoring of *P. c. var. minima*. However, its short lifespan and the very dynamic nature of pond hydrology at most sites will make this monitoring challenging. Understanding seed dormancy in *P. c. var. minima* will be key to understanding its limits with respect to hydrological variation. • Conduct population viability analyses, including detailed demographic data (level 3 monitoring sensu Menges and Gordon 1996) collected from multiple populations of both subspecies. Collect data across the full geographic range of both varieties, from populations in contrasting habitats (e.g., rosemary scrub vs. roadsides for subspecies *P. c. var. chartacea*, pond margins vs. sandhill for subspecies *P. c. var. minima*), and in sites with differing management histories. Relate demographic research on *P. c. var. chartacea* to fire management parameters, including fire frequency, time-since-fire, fire intensity, and fire patchiness. Couple such data for *P. c. var. minima* with current and historical data on pond hydrology. • Conduct studies to understand the genetic diversity of both varieties; this may aid in the identification of new acquisition needs. • Conduct a study of the reproductive biology of the two varieties to determine the degree of floral dimorphism/sexual gender and sex ratios of populations. (USFWS, 2021)

## **SPECIES ACCOUNT: *Parvisedum leiocarpum* (Lake County stonecrop)**

---

### ***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

A low annual herb, generally only 1-3.5 cm tall, with fleshy leaves that fall off the stem by flowering time. Flowers (April-May) are small and yellow. (NatureServe, 2015)

### **Taxonomy**

USFWS tracks as *Parvisedum leiocarpum* (9/93). (NatureServe, 2015)

### **Historical Range**

See current range/distribution.

### **Current Range**

Known from only a small number of populations within a 10-square-mile area. This species occurs on more or less level sites in shallow depressions that retain water seasonally. Known microhabitats include Northern Basalt Flow and Northern Volcanic Ashflow vernal pools (Sawyer and Keeler-Wolf 1995), low areas in meadows and gravelly flats, and hollows in exposed rocks. A few plants were found on a man-made berm within a flat area that supported a large population. Substrates on which *S. leiocarpa* occur frequently are of volcanic origin and often are gravelly (Patterson 1986). The species occurs at elevations of 518 to 793 meters (1,700 to 2,600 feet). (USFWS, 2009)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Habitat Type**

Adult: Terrestrial, palustrine (NatureServe, 2015)

### **Habitat Vegetation or Surface Water Classification**

Adult: Vernal pools and margins (NatureServe, 2015)

### **Environmental Specificity**

Adult: Very narrow (inferred from NatureServe, 2015)

### **Habitat Narrative**

Adult: Inhabits margins of vernal pools and depressions in bedrock which act as shallow vernal pools and volcanic substrates (NatureServe, 2015).

### ***Dispersal/Migration***

***Population Information and Trends*****Population Trends:**

Decreasing (NatureServe, 2015)

**Population Narrative:**

At least 50% of the known populations have been destroyed in the last 60 years. Decline of 50-70% (NatureServe, 2015). Low resiliency, representation and redundancy are based on the low number of known populations and individuals.

***Threats and Stressors***

**Stressor:** Altered hydrology (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Altered hydrology is listed as a threat to this species (USFWS, 2009).

**Stressor:** Road maintenance/widening (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Road maintenance/widening is listed as a threat to this species (USFWS, 2009).

**Stressor:** Agricultural land conversion (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Agricultural land conversion is listed as a threat to this species (USFWS, 2009).

**Stressor:** Off-highway vehicle use (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Off-highway vehicle use is listed as a threat to this species (USFWS, 2009).

**Stressor:** Trampling by cattle (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Trampling by cattle is listed as a threat to this species (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The final rule finds inadequacies with the Federal Clean Water Act, the California Environmental Quality Act, and the California Endangered Species Act in addressing threats to

this species (USFWS, 2009).

**Stressor:** Likelihood of Stochastic Extinction (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Extinction

**Narrative:** The combination of restricted range, few populations, and highly specific and vulnerable habitat makes this species vulnerable to destruction of all, or a significant part, of any population from random events such as floods or droughts (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Climate change is listed as a possible threat to this species (USFWS, 2009).

### **Recovery**

#### **Delisting Criteria:**

Habitat protection: Accomplish habitat protection that promotes vernal pool ecosystem function sufficient to contribute to population viability of the covered species. Suitable vernal pool habitat within each prioritized core area for the species is protected. Species localities distributed across the species geographic range and genetic range are protected. Protection of the extreme edges of the population protects the genetic differences that occur there. Reintroduction and introductions must be carried out and meet success criteria. Additional localities that are detected (and determined essential for recovery goals) are permanently protected. Habitat protection results in protection of hydrology essential to vernal pool ecosystem function, and monitoring indicates that hydrology that contributes to population viability has been maintained through at least one multi-year period that includes above average, average, and below average local rainfall as defined above, a multi-year drought, and a minimum of 5 years of post-drought monitoring (USFWS, 2009).

Adaptive habitat management and monitoring. Habitat management and monitoring plans that facilitate maintenance of vernal pool ecosystem function and population viability have been developed and implemented for all habitat protected, as previously discussed in sections 1A-E. Mechanisms are in place to provide for management in perpetuity and long-term monitoring of 1A-E, as previously discussed (funding, personnel, etc.). Monitoring indicates that ecosystem function has been maintained in the areas protected under 1A-D for at least one multi-year period that includes above average, average and below average local rainfall, a multi-year drought, and a minimum of 5 years post drought monitoring. Seed banking actions have been completed for species that would require it as insurance against risk of stochastic extirpations or that will require reintroductions or introductions to contribute to meeting recovery criteria (USFWS, 2009).

Status surveys: Status surveys, 5-year status reviews, and population monitoring show populations within each vernal pool region where the species occur are viable (e.g., evidence of reproduction and recruitment) and have been maintained (stable or increasing) for at least one multi-year period that includes above average, average, and below average rainfall, a multi-year

drought and a minimum of 5 years of post drought monitoring. Status surveys, status reviews, and habitat monitoring show that threats identified during and since the listing process have been ameliorated or eliminated. Site-specific threats identified through standardized site assessments and habitat management planning must be ameliorated or eliminated (USFWS, 2009).

**Research:** Research actions necessary for the recovery and conservation of the covered species have been identified. Research actions on species biology and ecology, habitat management and restoration, and methods to eliminate or ameliorate threats have been completed and incorporated into habitat protection, habitat management and monitoring, and species monitoring plans, and refinement of recovery criteria and actions. Research on genetic structure has been completed and results incorporated into habitat protection plans to ensure that within and among population genetic variation is fully representative by populations protected in the Habitat Protection section of this document as previously described in sections 1A-E. Research necessary to determine appropriate parameters to measure population viability for each species have been completed (USFWS, 2009).

**Participation and outreach:** Recovery Implementation Team is established and functioning to oversee rangewide recovery efforts. Vernal pool regional working groups are established and functioning to oversee regional recovery efforts. Participation plans for each vernal pool region have been completed and implemented. Vernal pool regional working groups have developed and implemented outreach and incentive programs that develop partnerships contributing to achieving recovery criteria 1-4 (USFWS, 2009).

**Recovery Actions:**

- Protect habitat. Currently none of the known localities of the species are protected. Preservation of Zone 1 core area should be pursued to preserve known localities (USFWS, 2009).
- Control erosion (USFWS, 2009).
- Conduct research at as many of the extant localities as possible (USFWS, 2009).
- Collect seeds for future introduction and/or reintroductions into suitable habitat (USFWS, 2009).
- Formally change the name in the Code of Federal Regulations from *Parvisedum leiocarpum* to *Sedella leiocarpa* (USFWS, 2009).
- Correct the downlisting criteria, if necessary, to also apply to the Dry Lake core area (USFWS, 2009).

## SPECIES ACCOUNT: *Pectis imberbis* (Beardless chinch weed)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered (USFWS, 2021)

#### **Physical Description**

*Pectis imberbis* is an erect, many-branched, perennial herb growing 3-12 decimeters (dm) (12 to 47 inches (in)) from a woody caudex (stem base). The glabrous (without hairs) leaves are 1 to 5 cm (0.4 to 2 in) in length and 1 to 2 millimeters (mm) (0.04 to 0.08 in) wide with pointed tips, becoming smaller toward the tips. The leaves have a row of narrow, oval-shaped glands on the underside surface near each margin and a single, oval-shaped gland on the upper surface. Daisy-like flower heads containing yellow ray and disk flowers are solitary or in open, flat-topped clusters at the tips of the branches. The petals are also dotted with oil glands. Unlike other species in this genus, *P. imberbis* has no fine hairs fringing the base of the upper leaves; instead, it has a single pair of trichomes (hair-like growth) on the lower leaves.

#### **Taxonomy**

The beardless chinchweed is an erect, many-branched perennial of the Asteraceae (sunflower) family (USFWS, 2021).

#### **Current Range**

The beardless chinchweed is an erect, many-branched perennial of the Asteraceae (sunflower) family. It occurs on sunny, south-facing slopes in natedominated grasslands, oak savannas, and oak woodlands in southern Arizona and northern Mexico. The species is particularly susceptible to competition from other plants and is impacted by nonnative, invasive grasses, which outcompete this species for light, water, nutrients, and space, and exacerbate unnatural high-severity fires. Nine populations have been extirpated since 1962, leaving 12 extant populations in Arizona and Mexico. The extirpated sites have high levels of invasion by nonnative grasses. Most populations are very small, with 92 percent of populations throughout the range of the species supporting fewer than 50 individuals. These small populations are particularly vulnerable to extirpation. The beardless chinchweed occurs between elevations of 3,799 to 5,699 ft. It requires steep, south-facing, sunny to partially shaded hillslopes with open areas and little competition from other plants. To maintain species' viability, populations with multiple subpopulations and overall high abundance must be distributed across the species range and represent a range of environmental conditions. These populations must experience recruitment that exceeds mortality. Beardless chinchweed requires habitat consisting of native-dominated plant communities on eroding limestone or granite bedrock substrate with precipitation adequate for germination, growth and reproduction. The natedominated plant communities include plains, great basin, and semi-desert grasslands, oak savanna, or Madrean evergreen woodlands and communities dominated by bunchgrasses with open spacing and little competition from other plants. In addition, these communities must support sufficient beardless chinchweed pollinators (e.g., flies, bees, and butterflies) including plants for pollinator foraging and nesting within pollinator flight distance of beardless chinchweed populations (USFWS, 2021).

#### **Critical Habitat Designated**

Yes; 7/15/2021.

***Life History*****Food/Nutrient Resources****Habitat Type**

Adult: grasslands, oak savannas, and oak woodlands (USFWS, 2021)

**Dependencies on Specific Environmental Elements**

Adult: Plants need space on steep, south-facing, sunny to partially shaded hillslopes, with eroding bedrock and open areas with little competition from other plants (USFWS, 2021).

**Habitat Narrative**

Adult: The beardless chinchweed is an erect, many-branched perennial of the Asteraceae (sunflower) family. It occurs on sunny, south-facing slopes in native dominated grasslands, oak savannas, and oak woodlands in southern Arizona and northern Mexico. The species is particularly susceptible to competition from other plants and is impacted by nonnative, invasive grasses, which outcompete this species for light, water, nutrients, and space, and exacerbate unnatural high-severity fires. Nine populations have been extirpated since 1962, leaving 12 extant populations in Arizona and Mexico. The extirpated sites have high levels of invasion by nonnative grasses. Most populations are very small, with 92 percent of populations throughout the range of the species supporting fewer than 50 individuals. These small populations are particularly vulnerable to extirpation. The beardless chinchweed occurs between elevations of 3,799 to 5,699 ft. It requires steep, south-facing, sunny to partially shaded hillslopes with open areas and little competition from other plants. To maintain species' viability, populations with multiple subpopulations and overall high abundance must be distributed across the species range and represent a range of environmental conditions. These populations must experience recruitment that exceeds mortality. Beardless chinchweed requires habitat consisting of native-dominated plant communities on eroding limestone or granite bedrock substrate with precipitation adequate for germination, growth and reproduction. The native-dominated plant communities include plains, great basin, and semi-desert grasslands, oak savanna, or Madrean evergreen woodlands and communities dominated by bunchgrasses with open spacing and little competition from other plants. In addition, these communities must support sufficient beardless chinchweed pollinators (e.g., flies, bees, and butterflies) including plants for pollinator foraging and nesting within pollinator flight distance of beardless chinchweed populations (USFWS, 2021).

***Dispersal/Migration******Population Information and Trends*****Resiliency:**

Our analysis of the past, current, and future stressors on the resources that the beardless chinchweed needs for long-term viability revealed that there are a number of stressors influencing this species. All beardless chinchweed populations likely contain nonnative grasses with a competitive advantage over native grasses during periods of drought. Further, altered fire regime has the potential to affect all populations. This altered fire regime enhances the spread of nonnatives, and all populations of beardless chinchweed contain nonnatives. Consequently,

fire will aid in the spread of nonnatives, is currently a risk to all populations of the beardless chinchweed, and will be further exacerbated by nonnative grasses in the near future (approximately 10 years). Altered precipitation, increased temperatures, increased evapotranspiration, decreased soil moisture, and decreased winter and spring precipitation are current and ongoing environmental conditions impacting all populations of the beardless chinchweed and exacerbating an altered fire regime. Road maintenance is likely resulting in the loss of individuals in three populations (Ruby Road, Scotia Canyon, and Coronado National Memorial). In addition, all individuals in these three populations are currently being impacted by dust from the road. The Ruby Road and Scotia Canyon populations exhibit low resiliency, and the Coronado National Memorial population exhibits moderate resiliency. Two additional populations (McCleary Canyon-Gunsight Pass and McCleary Canyon-Wasp Canyon) will be impacted by Rosemont mining operations and dust in the near future (approximately 10 years; Westland 2010, p. iv). One of these populations currently exhibits low resiliency, and the other exhibits moderate resiliency. Rangeland (including Mexico), 11 of the 12 populations (83 percent) are small (fewer than 50 individuals). Synergistic interactions among wildfire, nonnative grasses, decreased precipitation, and increased temperatures cumulatively and cyclically impact the beardless chinchweed, and all stressors are exacerbated in small populations. Of the six extant populations in the United States, two exhibit moderate resiliency and four exhibit low resiliency (see table 1, below). A population with moderate resiliency is one in which abundance ranges from 100–300 individuals the population contains 2 subpopulations, and spatial distribution is limited with few groupings; seed production is moderate; recruitment and mortality are equal such that the population does not grow; the ability to withstand stochastic events or recover from stochastic events is limited due to low abundance and recruitment and to a reduced seed bank; and there is some suitable habitat. A population with low resiliency is one in which abundance is less than 100 individuals, the population contains a single subpopulation, and spatial distribution is limited; seed production is low; mortality exceeds recruitment such that the population is declining; the ability to withstand stochastic events or recover from stochastic events is unlikely due to low abundance and recruitment and to a limited seed bank; and there is limited suitable habitat. The categories of conditions used to determine population resiliency are further described in the SSA report (Service 2020, Table 5.10) and the proposed listing rule (84 FR 67060, December 6, 2019, p. 84 FR 67065) (USFWS, 2021).

**Representation:**

No genetic studies have been conducted within or among the 21 historical populations of the beardless chinchweed in southern Arizona and Mexico. Mountain ranges that have only one or two populations, or have only have one subpopulation per population, or low numbers of individuals per population with several miles between mountain ranges, may not be as genetically diverse because pollination or transport of seeds between populations may be very limited or nonexistent. Five of the six extant U.S. populations do not have multiple subpopulations. The Coronado National Memorial population has two subpopulations. The six extant U.S. populations are separated geographically into four ranges separated by 16 to 61 km (9.9 to 37.9 mi). There is likely genetic diversity among mountain ranges, but reduced genetic diversity within populations. Further, overall genetic diversity is likely reduced given that some populations are extirpated. Extant U.S. populations of the beardless chinchweed range in elevation from 1,158 m (3,799 ft) to 1,737 m (5,699 ft). Of the 15 historical U.S. populations, 8 (approximately 53 percent) fall below 1,457 m (1,500 ft) elevation. Of these eight, six have been extirpated in recent decades. This loss of lower elevation populations may mean the loss of

some local adaptation to warmer or drier environments and genetic differentiation among populations. In the Ruby Road, Scotia Canyon, and Coronado National Memorial populations, and the Tributary of O'Donnell subpopulations, plants have been reported over many decades, indicating that these populations may have the genetic and environmental diversity needed to adapt to changing conditions. However, both the Ruby Road and Scotia Canyon populations have been reduced in size in the past 30 years, and we have no previous count data at Coronado National Memorial for comparison (USFWS, 2021).

**Redundancy:**

The beardless chinchweed populations in the United States and Mexico are naturally fragmented between mountain ranges. Currently, six extant U.S. populations of the beardless chinchweed are spread across the Atascosa-Pajarito, Huachuca, and Santa Rita Mountains and the Canelo Hills. The Atascosa-Pajarito Mountains and the Canelo Hills have only one extant population each, while the Santa Rita and Huachuca Mountains have two extant populations each. Range separation makes natural gene exchange or re-establishment following extirpation very unlikely. In addition, six historical populations of the beardless chinchweed are distributed across two general areas in northern Chihuahua and Sonora, Mexico. Their status is unknown, but we expect they are small populations with poor habitat based on populations in the United States, which are small and dominated by nonnative species. Although this may imply some level of redundancy across the range of the beardless chinchweed, five of the six extant populations in the United States contain fewer than 50 individual plants. Further, nine populations and one subpopulation have been extirpated in recent decades, largely from the lower elevations of the species' range, and several populations have been reduced in size in recent decades. We note that, by using the SSA framework to guide our analysis of the scientific information documented in the SSA report, we have not only analyzed individual effects on the species, but we have also analyzed their potential cumulative effects. We incorporate the cumulative effects into our SSA analysis when we characterize the current and future condition of the species. Our assessment of the current and future conditions encompasses and incorporates the threats individually and cumulatively. Our current and future condition assessment is iterative because it accumulates and evaluates the effects of all the factors that may be influencing the species, including threats and conservation efforts. Because the SSA framework considers not just the presence of the factors, but to what degree they collectively influence risk to the entire species, our assessment integrates the cumulative effects of the factors and replaces a standalone cumulative effects analysis (USFWS, 2020).

**Number of Populations:**

12 extant populations in Arizona and Mexico (USFWS, 2021)

**Population Size:**

In Arizona, there are currently 387 individual beardless chinchweed spread across less than 2 ha (5 ac) within six extant populations spread across the four mountain ranges (USFWS, 2021).

**Minimum Viable Population Size:**

General conservation biology indicates that at least 500 individual are needed for a minimum viable population (USFWS, 2021).

**Population Narrative:**

The beardless chinchweed is an erect, many-branched perennial of the Asteraceae (sunflower) family. It occurs on sunny, south-facing slopes in native dominated grasslands, oak savannas, and oak woodlands in southern Arizona and northern Mexico. The species is particularly susceptible to competition from other plants and is impacted by nonnative, invasive grasses, which outcompete this species for light, water, nutrients, and space, and exacerbate unnatural high-severity fires. Nine populations have been extirpated since 1962, leaving 12 extant populations in Arizona and Mexico. The extirpated sites have high levels of invasion by nonnative grasses. Most populations are very small, with 92 percent of populations throughout the range of the species supporting fewer than 50 individuals. These small populations are particularly vulnerable to extirpation. The beardless chinchweed occurs between elevations of 3,799 to 5,699 ft. It requires steep, south-facing, sunny to partially shaded hillslopes with open areas and little competition from other plants. To maintain species' viability, populations with multiple subpopulations and overall high abundance must be distributed across the species range and represent a range of environmental conditions. These populations must experience recruitment that exceeds mortality. Beardless chinchweed requires habitat consisting of native-dominated plant communities on eroding limestone or granite bedrock substrate with precipitation adequate for germination, growth and reproduction. The native-dominated plant communities include plains, great basin, and semi-desert grasslands, oak savanna, or Madrean evergreen woodlands and communities dominated by bunchgrasses with open spacing and little competition from other plants. In addition, these communities must support sufficient beardless chinchweed pollinators (e.g., flies, bees, and butterflies) including plants for pollinator foraging and nesting within pollinator flight distance of beardless chinchweed populations (USFWS, 2021). The minimum viable population size for this species is unknown. General conservation biology indicates that at least 500 individual are needed for a minimum viable population. Currently, 11 of the 12 populations have fewer than 50 individuals. In Arizona, there are currently 387 individual beardless chinchweed spread across less than 2 ha (5 ac) within six extant populations spread across the four mountain ranges. Space, in the form of habitat described above, is needed for an increase in the number of populations and the number of individuals per population (USFWS, 2021). Space for individual and population growth is needed for the beardless chinchweed, including sites for germination, pollination, reproduction, pollen and seed dispersal, and seed banks in the form of open, native dominated plains, great basin, and semidesert grasslands, oak savannas, and Madrean evergreen or oak woodlands at 1,158 to 1,737 m (3,799 to 5,699 ft) in elevation (SEINet, entire) representing the ecosystems where beardless chinchweed occurs. In addition, plants need space on steep, south-facing, sunny to partially shaded hillslopes, with eroding bedrock and open areas with little competition from other plants. Native-dominated habitats have diverse assemblages of vegetation, each with different-shaped and -sized canopy and root system, which creates heterogeneity of form, height, and patchiness and provides openness. The diverse vegetation is dominated by bunchgrasses with open spacing (adjacent to and within 10 m (33 ft) of beardless chinchweed plants), providing beardless chinchweed with the necessary open habitat with little competition. The beardless chinchweed is presumed to be a poor competitor due to its preference for this open habitat and the inability to find the species under dense vegetation conditions (USFWS, 2021).

## ***Recovery***

### **Reclassification Criteria:**

Recovery Priority Number: 5C

1. Downlisting Criteria The following are objective, measurable criteria which, when met, would result in a determination that beardless chinchweed will be considered for reclassification as a threatened species: 1. Fifteen or more populations (see Justification for Recovery Criteria below for definitions of populations and subpopulations) occur throughout the species' geographic range in the U.S. and Mexico, including populations in the three representation areas as follows: a.i. Northern Representation Area in Arizona – at least eight populations, including: 1) McCleary Canyon - Gunsight Pass, 2) McCleary Canyon - Wasp Canyon, 3) Audubon Research Ranch, 4) Scotia Canyon, 5) Coronado National Memorial, 6) Copper Canyon, 7) Lampshire Well, 8) Ruby Road 1: Peña Blanca Canyon, or 9) up to two newly discovered populations in lieu of any two of the above-named populations. and a.ii. Northern Representation Area in Arizona – at least two populations fulfilled by any combination of the following: rediscovered or reintroduced populations within unoccupied critical habitat (Harshaw Creek, Washington Camp, and Ruby Road 2: Peña Blanca Canyon), newly discovered, rediscovered, or successfully introduced or reintroduced populations in other strategic sites. and a.iii. Central Representation Area in Sonora, Mexico – at least two populations. These populations may include newly discovered, rediscovered, successfully introduced, reintroduced, or augmented populations in strategic sites. and a.iv. Southern Representation Area in Sonora and Chihuahua, Mexico – at least three populations. These populations may include newly discovered, rediscovered, successfully introduced, reintroduced, or augmented populations in strategic sites. Of the fifteen populations referenced above, at least: a. One population needs to support a minimum of 2,500 individuals within two or more subpopulations. b. Six populations need to support a minimum of

over 300 individuals within three or more subpopulations. c. Eight populations need to support a minimum of 100 individuals within at least two subpopulations. These population numbers will be maintained for a total of at least 15 years over a 20-year period, as indicated by monitoring every 1 to 3 years during the flowering season, including during the three most recent monitoring events. To count toward achieving this criterion, existing, introduced, or re-introduced populations that are used to evaluate this criterion may be augmented for the first 10 years to achieve population and subpopulation numbers. To show that populations are viable, no augmentation can occur within populations being evaluated under this criterion in the last 10 years of the 20-year period for populations considered as contributing to possible downlisting (USFWS, 2023).

2. All of the populations referenced in downlisting criterion #1 above must have documented natural recruitment that is greater than or equal to documented plant loss during three or more monitoring events (every 1 to 3 years) of the 20-year period (USFWS, 2023).

3. A collection of seed representing the geographical, morphological, and genetic diversity of beardless chinchweed is regularly collected following Center for Plant Conservation guidelines (2019, p. 1-14) during the period of recovery and maintained in at least one Center for Plant Conservation partner botanical or seed storage institution for conservation purposes (USFWS, 2023).

4. A living collection of plants representing the geographical, morphological, and genetic diversity of beardless chinchweed and following Center for Plant Conservation guidelines (2019, p. 3-13) is established within 10 years of the finalization of this recovery plan and is maintained in perpetuity in at least one botanical institution for educational and conservation purposes (USFWS, 2023).

5. The land within a 500-meter radius around each of at least six populations supports  $\geq 80$  percent cover of native plant species. The land within a 1,000-meter radius around each of at least an additional five populations supports  $\geq 65$  percent cover of native plant species. The land within a 1,000-meter radius around each of at least the remaining four populations support  $\geq 50$  percent cover of native plant species (USFWS, 2023).

6. To ensure the continued existence of beardless chinchweed and to help meet populationbased criterion number one, conservation and management plans address the threat of desert grassland, oak savanna, and oak woodland habitat loss and degradation and the direct threats to beardless chinchweed and their pollinators. Specifically, the following must be met, as further quantitatively described in the 2023 Beardless Chinchweed Recovery Implementation Strategy: a. In areas supporting beardless chinchweed populations, land management and site-specific plans are developed and partially implemented, such that over a 20-year period: i. there is a reduction in nonnative vegetation and promotion of native vegetation and a natural fire regime to a level that ensures beardless chinchweed viability is not affected by competition or fires outside the normal fire regime, and that their vigor is not negatively affected (Factors A and E), ii. there is a reduction in beardless chinchweed herbivory by wildlife and grazing by livestock that ensures  $>80$  percent of branches are intact and with seedheads (Factor C), iii. there is a reduction in erosion, sedimentation, burial, trampling, and removal of beardless chinchweed and associated native plants caused by border related activity, mining activity, livestock grazing activity, recreation activity, and other activities to a level that ensures beardless chinchweed

viability is not affected by these activities and their vigor is not negatively affected (Factor A), and iv. there is habitat restoration using locally sourced native plants and seed on lands impacted by the before mentioned threats to a level that ensures beardless chinchweed viability is not affected from nonnative plant competition and their vigor is not negatively affected (Factors A and E). b. data on the conservation and management of beardless chinchweed is collected and shared regularly among land managers and researchers (USFWS, 2023).

**Delisting Criteria:**

1. Fifteen or more populations occur throughout the species' geographic range in the U.S. and Mexico, including populations in the three representation areas as follows: a.i. Northern Representation Area in Arizona – at least eight populations, including: 1) McCleary Canyon – Gunsight Pass, 2) McCleary Canyon – Wasp Canyon, 3) Audubon Research Ranch, 4) Scotia Canyon, 5) Coronado National Memorial, 6) Copper Canyon, 7) Lampshire Well, 8) Ruby Road 1: Peña Blanca Canyon, or 9) up to two newly discovered populations in lieu of any two of the above-named populations. And a.ii. Northern Representation Area in Arizona – at least two populations fulfilled by any combination of the following: rediscovered or reintroduced populations within unoccupied critical habitat (Harshaw Creek, Washington Camp, and Ruby Road 2: Peña Blanca Canyon), newly discovered, rediscovered, or successfully introduced or reintroduced populations in other strategic sites. And a.iii. Central Representation Area in Sonora, Mexico – at least two populations. These populations may include newly discovered, rediscovered, successfully introduced, reintroduced, or augmented populations in strategic sites. And a.iv. Southern Representation Area in Sonora and Chihuahua, Mexico – at least three populations. These populations may include newly discovered, rediscovered, successfully introduced, reintroduced, or augmented populations in strategic sites. Of the fifteen populations referenced above, at least: a. One population needs to support a minimum of 2,500 individuals within two or more subpopulations. b. Six populations need to support a minimum of over 300 individuals within three or more subpopulations. c. Eight populations need to support a minimum of 100 individuals within at least two subpopulations. These population numbers will be maintained for a total of at least 25 years over a 30-year period, as indicated by monitoring every 1 to 3 years during the flowering season, including during the three most recent monitoring events. Note the down- and delisting criteria are the same with the exception that there is a longer period of recovery for delisting. To count toward achieving this criterion, existing, introduced, or re-introduced populations that are used to evaluate this criterion may be augmented for the first 10 years to achieve population and subpopulation numbers. To show that populations are viable, no augmentation can occur within populations being evaluated under this criterion in the last 20 years of the 30-year period for populations considered as contributing to possible delisting (USFWS, 2023).

2. All of the populations referenced in delisting criteria #1 above must have documented natural recruitment that is greater than or equal to documented plant loss during three or more monitoring events (every 1 to 3 years) of the 30-year period (USFWS, 2023)

3. A collection of seed representing the geographical, morphological, and genetic diversity of beardless chinchweed is regularly collected following Center for Plant Conservation guidelines (2019, p. 1-14) during the period of recovery and maintained in at least two Center for Plant Conservation partner botanical or seed storage institutions for conservation purposes (USFWS, 2023)

4. A living collection of plants representing the geographical, morphological, and genetic diversity of beardless chinchweed and following Center for Plant Conservation guidelines (2019, p. 3-13) is established within 10 years of the finalization of this recovery plan and is maintained in perpetuity in at least two botanical institutions for educational and conservation purposes (USFWS, 2023)

5. The land within a 500-meter radius surrounding at least six populations supports  $\geq 80$  percent cover of native plant species. The land within a 1,000-meter radius surrounding an additional five populations supports  $\geq 65$  percent cover of native plant species. The land within a 1,000-meter radius surrounding the remaining at least four populations support  $\geq 50$  percent cover of native plant species (USFWS, 2023).

6. To ensure the continued existence of beardless chinchweed and to help meet populationbased delisting criterion #1, conservation and management plans address the threat of desert grassland, oak savanna, and oak woodland habitat loss and degradation and the direct threats to beardless chinchweed and their pollinators. Specifically, the following must be met, as further quantitatively described in the 2023 Beardless Chinchweed Recovery Implementation Strategy: a. In areas supporting beardless chinchweed populations, land management and site-specific plans are developed and fully implemented, such that over a 30-year period: i. there is further reduction in nonnative vegetation and promotion of native vegetation and a natural fire regime to a level that ensures beardless chinchweed viability is not affected by competition or fires outside the normal fire regime, and that their vigor is not negatively affected (Factors A and E), ii. there is further reduction in beardless chinchweed herbivory by wildlife and grazing by livestock that ensures  $>90\%$  of branches are intact and with seedheads (Factor C), iii. there is a further reduction in erosion, sedimentation, burial, trampling, and removal of beardless chinchweed and associated native plants caused by border related activity, mining activity, livestock grazing activity, recreation activity, and other activities to a level that ensures beardless chinchweed viability is not affected by these activities and their vigor is not negatively affected (Factor A), and iv. there is further habitat restoration using locally sourced native plants and seed on lands impacted by the before mentioned threats to a level that ensures beardless chinchweed viability is not affected from nonnative plant competition and their vigor is not negatively affected (Factors A and E). b. data on the conservation and management of beardless chinchweed continues to be collected and shared regularly among land managers and researchers (USFWS, 2023).

## SPECIES ACCOUNT: *Pedicularis furbishiae* (Furbish lousewort)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Northeast Region (R5) (USFWS, 2015). Reclassified to Threatened June 9, 2023.

### **Physical Description**

A perennial herb in the Scrophulariaceae (snapdragon family) that produces 1 or more flowering stems, up to 1 m tall, from a basal rosette of leaves. Leaves are deeply divided and have toothed edges. Yellow, 2-lipped flowers bloom in a spike at the top of the flowering stalk from mid-July to late-August. (NatureServe, 2015)

### **Taxonomy**

The genus *Pedicularis* contains over 600 species, most of which are common in tundra, alpine, and subalpine floras in Asia, Europe and North America (Robart et al. 2015, p. 229). The center of *Pedicularis* species diversity is in the northern Himalayas, China, and Siberia. The Furbish's lousewort has the most restricted distribution of any species of the genus *Pedicularis* (Gawler 1983, p. 28). The Furbish's lousewort (*Pedicularis furbishiae* Sereno Watson 1882) is a member of the broomrape family, Orobanchaceae (formerly from the snapdragon family Scrophulariaceae)(Olmstead et al. 2001). The taxonomic identity of the Furbish's lousewort as a distinct species is unquestioned, but its taxonomic position within the genus *Pedicularis* is not certain (Macior pers. comm. in Stirrett 1980, p. 21) and has been a topic of considerable conjecture and discussion (Gawler 1983, pp. 28-29, Robart et al. 2015, p. 253). Dr. Peter Nelson at the University of Maine at Fort Kent and Rick Ree at the Field Museum in Chicago are continuing genetic research to identify the "sister species" and document the unique phylogeny of the Furbish lousewort. Dr. Nelson has collected samples at numerous subpopulations in Maine and New Brunswick to evaluate the genetic structure and variation within the Furbish's lousewort metapopulation. Similar to the electrophoretic genetic results published by Waller et al. (1987, entire), preliminary results indicate low genetic variability in the Furbish's lousewort population (P. Nelson email November 11, 2017). Additional results will be available in 2018. (USFWS, 2018)

### **Historical Range**

See current range/distribution.

### **Current Range**

Endemic to the Saint John River Valley of northern Maine and adjacent New Brunswick. The entire range of *Pedicularis furbishiae* covers 225 km of the St. John River, extending from a point 1.5 miles upriver of the confluence with the Big Black River in Aroostook County, Maine to the town of Andover, New Brunswick in Canada. (NatureServe, 2015)

### **Critical Habitat Designated**

Yes;

### **Life History**

### **Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (outcrossing) and asexual (USFWS, 1991)

**Dependency on Other Individuals or Species**

Adult: *Bombus vagans*, a common bumblebee which also forages on other co-flowering species such as red clover, is the exclusive pollinator of *Pedicularis furbishiae* (Macior 1978a). (USFWS, 1991)

**Breeding Season**

Adult: July to August (USFWS, 1991)

**Reproduction Narrative**

Adult: *Pedicularis furbishiae* is a herbaceous perennial which takes several years to reach sexual maturity. Reproduction is solely by seed. Louseworts flower from mid-July to mid-August, with seeds dispersing in early September. Recent experiments (Waller et al. 1988) have shown that selfed and outcrossed flowers are equally successful at setting capsules, contradicting Macior's (1978) conclusion that *Pedicularis furbishiae* is self-incompatible. The success of capsule maturation varies widely among populations and years. On average an inflorescence will produce 7—17 capsules, each averaging 25 seeds (Menges et al. 1985, 1986; Gawler et al. 1986). (USFWS, 1991)

**Habitat Type**

Adult: Palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Herbaceous wetland, riparian, scrub-scrub wetland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: High soil moisture; flooding is essential for habitat (USFWS, 1991)

**Geographic or Habitat Restraints or Barriers**

Adult: Ice scouring and succession can limit habitat; low vegetative cover (USFWS, 1991)

**Environmental Specificity**

Adult: Narrow. Specialist or community with key requirements common. (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (USFWS, 1991)

**Habitat Narrative**

Adult: This species inhabits the riverbanks of the Saint John River, mostly in the steep, highly diverse shrub- or forb-dominated zone between open river cobbles and boreal forest. The habitat is notable for the high frequency and the severity of disturbance by ice scour and vertical river bank slumping. (The Saint John River drains one of the largest watersheds in the northeast, yet it has relatively little headwater storage, making it subject to dramatic seasonal and longer-term fluctuations in water level and to severe ice-jams.) The zone in which *Pedicularis furbishiae* occurs bears the brunt of regular ice scouring - tree establishment does not occur here and

vegetation cover tends to be moderate. Plants grow on glacial lacustrine or till deposits. (NatureServe, 2015) *Pedicularis furbishiae* is a fugitive species, succeeding in early— to mid—successional vegetation, and relying on disturbance to open up new areas for colonization. The growth rate of a lousewort population depends largely on site characteristics, principally soil moisture and time since disturbance. Excluding effects of succession, populations on saturated soils grow most rapidly, those on moist soils grow moderately fast, and those on dry soils grow slowly or even decline (Gawler 1988). (USFWS, 1991; NatureServe, 2015)

### ***Dispersal/Migration***

#### **Dispersal/Migration Narrative**

Adult: Seeds appear to be dispersed by wind and water (Waller et al. 1988).

### ***Population Information and Trends***

#### **Population Trends:**

Long-term trends suggest declines of 30 to 50%, whereas short-term trends indicate declines of 10 to 30% (NatureServe, 2015)

#### **Species Trends:**

Declining (NatureServe, 2015)

#### **Resiliency:**

Narrow endemic species with only two small populations and limited geographical ranges. Count data from surveys over almost two decades indicate both are declining 9-12% annually. Occupancy of shoals has declined in the Conasauga, and fish in both systems have been extirpated or greatly reduced in abundance in the lower reaches of the historic range. Resiliency = low to very low (USFWS, 2018).

#### **Representation:**

Two declining populations genetically-isolated by Lake Allatoona. Representation = Low to Moderate (USFWS, 2018).

#### **Redundancy:**

Only two populations are known historically, and neither appears resilient to stochastic or catastrophic events and/or to current anthropogenic stressors. Redundancy = low (USFWS, 2018).

#### **Number of Populations:**

20 subpopulations distributed across 140 river-miles (USFWS, 2019)

#### **Population Size:**

~2397 (USFWS, 2018)

#### **Adaptability:**

Low (inferred from USFWS, 1991)

#### **Additional Population-level Information:**

All subpopulations at or near lowest recorded numbers since 1980. Two subpopulations good condition, 2 subpopulations fair/good, 3 subpopulations fair, and 8 subpopulations poor condition. Six upriver subpopulations maintaining resiliency and redundancy. Fourteen downriver populations losing resiliency and redundancy; absent from 6 subpopulations. Largest contiguous habitats upriver; smallest, fragmented, eroded habitats downriver. One upriver subpopulation partially protected. One downriver subpopulation partially protected and one New Brunswick site protected. Habitat degradation (erosion, poor riparian buffer) greatest in downriver habitats. (USFWS, 2018)

**Population Narrative:**

Although Furbish's Lousewort is adapted to this highly dynamic riparian habitat, the species is vulnerable to high degrees of the annual ice scouring and flooding. Little genetic variability has been detected in this species. Populations of Furbish's Lousewort have declined since historic times. Long-term population trends suggest declines of 30 to 50%, whereas short-term trends indicate declines of 10 to 30%. The number of stems fluctuate widely with varying hydrological or environmental changes but in Maine have ranged from over 6000 plants to just over 2000 plants over a 25-year period. In New Brunswick the numbers of plants have ranged from 68 to over 1000 plants. Two element occurrences (one historic & one extant) are known in New Brunswick, whereas it is estimated that about three or four extant EOs occur in Maine. Lousewort populations are notoriously difficult to delineate, because the linearity and dynamism of the habitat dictate that populations are rarely discrete units. (NatureServe, 2015)

**Threats and Stressors**

**Stressor:** Alterations in hydrology (USFWS, 1991)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The cycle of intermittent disturbance by floods is crucial to the survival of the species. Damming free-flowing waters of the St. John would not only inundate some populations, but would affect all populations by preventing the ice scour and floods which now shape riverbank vegetation. New Brunswick Power is still pursuing possible modification of the existing dam at Grand Falls, New Brunswick as well as the creation of an additional hydropower facility near Morrill, New Brunswick. Potential and known populations in Canada and the United States from Madawaska to Hamlin would be eliminated by implementation of these projects. (USFWS, 1991)

**Stressor:** Land use (USFWS, 1991)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Aside from the continuing, albeit muffled, potential for dam construction on the St. John, widespread effects on lousewort populations resulting from changing land uses along the river as well as from increased river flows are the major concern at this time. changes in land use on the banks of the St. John River have occurred through the clearing of vegetation, especially trees, for individual houselots, views, and agricultural fields. The removal of trees to the river's edge eliminates shade conducive to lousewort growth and reproduction, while the subdivision of the riverbank into residential and commercial building lots increases the difficulty of implementing conservation strategies. These land use practices within the St. John River

watershed appear to affect Furbish lousewort habitat and populations. (USFWS, 1991)

**Stressor:** Increased runoff (USFWS, 1991)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In addition, there is evidence that the spring flows of the St. John River have been increasing since the 1940's (Menges and Gawler 1986), possibly due to excess runoff. Increased runoff (Gawler and Menges 1984), perhaps caused by accelerated timber harvesting within the watershed, may exacerbate the disturbance impacts to lousewort habitat. For instance, deforested areas can reduce the water retention capability of the watershed; increased river flows and resultant bank slumping may then eliminate habitat and populations at an artificially high rate. (USFWS, 1991)

**Stressor:** Habitat alteration (USFWS, 1991)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** More localized activities such as direct habitat alteration and the burial of individual plants by the dumping of refuse and slash continue to be minor threats to particular lousewort populations. Causes of habitat degradation associated with shorefront developing include dumping of refuse, slash, and fill; motorized vehicles, vegetation clearing, ATV use along the river bank, personal boat access, and impermeable surfaces that focus runoff. (USFWS, 1991; USFWS, 2007)

**Stressor:** All-terrain vehicles (USFWS, 1991)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Impacts from all—terrain vehicle traffic and bank use by recreationists may become threats as these activities increase in the area. (USFWS, 1991)

**Stressor:** Residential development (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The conversion of farms for residential development, which alters the riparian forest or riverbank vegetation, is an increasing conservation concern. (USFWS, 2007)

**Stressor:** Invasive species (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Competition for invasive species is a threat to the unique riverbank ecosystem in the lower river segments. Phragmites, Japanese knotweed, non-native grasses, and purple loosestrife have all been documented in lousewort habitat. These invasive plant species are linked to human activities such as riverbank clearing, trails, and mowing, and spread of invasive species is one consequence of shorefront development. (USFWS, 2007)

**Stressor:** Forest management (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Forest management in the watershed could increase siltation and run-off (Menges and Gawler 1986). (USFWS, 2007)

**Stressor:** Climate change (USFWS, 2007; USFWS, 2019)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Climate change is expected to affect the ice regime of northern rivers, including the St. John, by increasing the frequency of severe ice-scour events and patterns of spring ice breakup (Beltaos 1997, Beltaos and Prowse 2001). Beltaos (1999) did a hydroclimatic analysis for the upper St. John River using long-term climate and flow records and documented that a small rise in winter air temperatures over the past 80 years has already resulted in a substantial increase in the number of mild winter days and the amount of winter rainfall- previous rare occurrences in this region. These two factors have augmented river flows, causing increased breakup of ice cover and flow peaks in late winter and the frequency of spring ice jams and flooding. (USFWS, 2007); The Furbish's lousewort is identified as one of Maine's plant species most vulnerable to climate change (Jacobson et al. 2009, p. 33). The species depends on periodic disturbance of the riverbank from ice scour; not too frequent or too infrequent and not too severe (section 2.4). Climate change is expected to affect the ice regime of northern rivers, including the St. John, by increasing the frequency and severity of severe ice-scour and flood events (Beltaos 1997, entire; Beltaos and Prowse 2001, entire; Beltaos and Prowse 2009, entire). In summary, there is evidence suggesting that climate change is indirectly affecting the ice dynamics of the St. John River and these factors have the potential to increase the severity of the spring breakup and increased severity of flooding (Beltaos 2002, entire). We will evaluate climate change as a stressor further in our assessment of future scenarios. (USFWS, 2018)

**Stressor:** Increased frequency of ice jam events (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The increased frequency of ice jam events is a particular concern. The frequency of flooding events on the St. John River has increased since the 1940s (Menges and Gawler 1986). Lousewort biology suggests that a disturbance interval of less than 6 to 10 years would interfere with maturation and seed production (Menges 1990). (USFWS, 2007)

**Stressor:** Development (USFWS, 2018)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Changes in land use on the banks of the St. John River in downriver areas have occurred through the clearing of vegetation, especially trees, for agriculture, individual house lots, roads, and river views. These land use changes within the St. John River valley may have negatively affected some of Furbish's lousewort subpopulations' habitat through removal or

reduction of the forested riparian buffer and subsequent loss of shade critical to lousewort growth and reproduction. Areas cleared of forest and impermeable surfaces associated with development have led to erosion and subsidence of the unconsolidated glacial till soils, and caused slumping and erosion of Furbish's lousewort habitat. We will evaluate development as a stressor further in our assessment of future scenarios. (USFWS, 2018)

## **Recovery**

### **Reclassification Criteria:**

In light of the recommendation to reclassify the Furbish's lousewort as threatened, downlisting criteria in the 1991 Recovery Plan (USFWS 1991) are now obsolete. (USFWS, 2019)

### **Delisting Criteria:**

Criterion 1. The metapopulation is viable, comprising a 30-year median of 4,400 flowering stems or greater, and distributed as follows: Upriver: a 30-year median of 2,800 flowering stems or greater in at least 6 subpopulations with at least 3 good and 3 fair subpopulations; Downriver: a 30-year median of 1,600 flowering stems or greater in at least 9 subpopulations with at least 3 good and 6 fair subpopulations. Once the upriver and downriver criteria are reached, the median number of flowering stems for each respective river section will remain stable or increase over a period of at least 30 years (three generations) without augmentation, reintroduction, or hand pollinating of plants. Additionally, in New Brunswick there is a 30-year median of 1,100 plants distributed among at least 5 subpopulations (Resiliency and Redundancy). (USFWS, 2019)

Criterion 2. There is long-term habitat protection for all subpopulations in Maine that provides for the species' needs throughout its life cycle. Long-term habitat protection mechanisms must assure important species' needs: forest overstory shade conditions (about 50-percent sunlight) by protecting or restoring a forested riparian buffer of 250 feet adjacent to suitable habitat; moist soil conditions and seeps by limiting further shoreline erosion and bank slumping, and restoring suitable habitat where it has been damaged from past events; native vegetation that newly germinated Furbish's lousewort plants can parasitize; site conditions without excessive plant competition, especially from tall shrubs and robust herbs; populations of the half-black bumble bee sufficient to assure pollination and subsequent seed production. (USFWS, 2019)

### **Recovery Actions:**

- 1. Monitor the Furbish's lousewort population and demographics and periodically assess the status of the bumble bee pollinator to document trends. (USFWS, 2019)
- 2. Improve the health and viability of extant subpopulations and restore extirpated subpopulations throughout the historical range. (USFWS, 2019)
- 3. Achieve long-term habitat protection for each subpopulation. (USFWS, 2019)
- 4. Conduct scientific investigations to improve understanding of stressors, viability, propagation, restoration, and genetic needs. (USFWS, 2019)
- 5. Periodically review progress toward achieving recovery criteria and employ strategic conservation and adaptive management to address threats. (USFWS, 2019)
- Contingency recovery strategies will be implemented if the metapopulation in Maine falls below 1,200 flowering stems OR if there are 4 or fewer upriver subpopulations OR if there are 2 or fewer downriver subpopulations OR if seed production is not sufficient to achieve a

- stable or increasing metaoooooulation. (USFWS, 2019)
- 6. Establish new subpopulations in unoccupied areas having suitable habitat. (USFWS, 2019)
- 7. Store seeds and establish captive populations. (USFWS, 2019)
- 8. Enhance seed production. (USFWS, 2019)
- 9. Work with Canadian partners to implement strategies that prevent extinction. (USFWS, 2019)
- To be considered for delisting in the near future, the Service needs specific information on: 1) the degree of threat from residential development in river segments 2, 3, and 4; 2) the degree of threat from climate change and severe ice jams and flooding; and 3) population viability in the context of a dynamic environment. (USFWS, 2007)
- New recovery criteria should be developed based on current information on population viability and responses to habitat perturbations, specifically related to improving municipal shoreland zoning, addressing habitat restoration caused by catastrophic ice scour events, and controlling invasive species. (USFWS, 2007)
- Efforts to protect lousewort habitat in the lower river reaches should be emphasized. (USFWS, 2007)

Recommendations for Future Actions: Continue to monitor the subpopulations of the species and document population trends. Maintain current long-term habitat protections for subpopulations in Maine. Work with Maine landowners and municipalities to develop conservation easements or fee title opportunities to protect additional subpopulations. Continue to evaluate the effects of climate change and development. (USFWS, 2019)

## SPECIES ACCOUNT: *Pediocactus (=Echinocactus,=Utahia) sileri* (Siler pincushion cactus)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 11/26/1979; Southwest Region (Region 2) (USFWS, 2016)

### **Physical Description**

The Siler pincushion cactus is a small, solitary or occasionally clustered, globose cactus about 10 cm (4 in) tall and 7.5-10 cm in diameter. Each areole contains 3-7 brownish-black straight or slightly curved central spines, becoming pale gray or nearly white with age. There are, in addition, 11-16 whitish radial spines per areole. The central spines are about 2.5 cm long, the radials slightly less. Flowers are about 2.5 cm in diameter, with yellowish marginally scarious petals with maroon veins. Fruits are greenish-yellow, somewhat enlarged upwards, with scales toward the top. They are dry at maturity; seeds are gray. (USFWS, 1986)

### **Taxonomy**

This species has been through several nomenclatural changes and has two recognized synonyms: *Echinocactus sileri* and *Utahia sileri*. This species was originally described as a species of *Echinocactus* (Coulter 1896), and was later placed in the genus *Utahia* by Britton and Rose (1922). Lyman Benson combined into the genus *Pediocactus* various species that formerly had been placed in six different genera due to their diversity in spination, body proportion, and flower color. This combination includes *P. sileri*. (USFWS, 1986)

### **Historical Range**

See current range.

### **Current Range**

The geographic range of Siler pincushion cactus extends from southeast of Fredonia, extreme northwestern Coconino County, Arizona, west for about 70 air miles in north-central Mohave County, Arizona. It also includes about 3 miles of southern Utah in Washington and Kane Counties (USFWS, 2008).

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Breeding Season**

Adult: Blooms April-mid May. (USFWS, 1986)

### **Reproduction Narrative**

Adult: Little variation exists within populations. These populations can be separated by distances of several miles even when there is suitable habitat. Further, dispersal within populations appears to be staggered throughout the growing season from shortly after seeds are produced

in June to fall. This dispersal strategy may be disadvantageous for the genus, however, populations in the genus when left undisturbed seem to be healthy with all age classes represented (Heil et al. 1981). Flowers bloom from April to May. (NatureServe, 2015)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Desert, forest/woodland, grassland/herbaceous, woodland- conifer (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Elevations between 2,800 and 5,400 ft (USFWS, 2008)

**Spatial Arrangements of the Population**

Adult: Solitary or occasionally clustered (USFWS, 1986).

**Environmental Specificity**

Adult: Narrow. Specialist or community with key requirements common. (NatureServe, 2015)

**Habitat Narrative**

Adult: Siler pincushion cactus grows on gypsiferous clay and sandy soils derived from the Moenkopi Formation. The majority of the plants are associated with the Shnabkaib Member of this particular formation. The Shnabkaib Member is composed of 65 percent siltstone, 25 percent gypsum, and 10 percent limestone and dolomite (Stewart et al. 1972). Siler pincushion cacti are also found scattered on the Middle Red Member of the formation, which is a reddish siltstone with thin to thick layers of gypsum. The cacti are found growing on elevations between 2,800 and 5,400 feet, in the Great Basin Desert Shrub community (USFWS, 2008).

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Members of *Pediocactus* produce dry, dull-colored fruit which are presumed not to be dispersed by birds or rodents, but rather wind or water. (NatureServe, 2015)

***Population Information and Trends*****Species Trends:**

Short-term trends indicate declines of 10-30% (NatureServe, 2015)

**Number of Populations:**

~ 25 NatureServe, 2015)

**Population Size:**

~10,000 or more individuals (USFWS, 2008)

**Population Narrative:**

Short-term population trends indicate declines of 10-30%. Several 100, possibly 10,000 or even more plants. In 2006, BLM estimated there were over 10,000 individuals (BLM 2006 cited by

USFWS 2008). BLM has documented approximately 22 occurrences in Arizona, and populations in the Kanab and St. George areas of Utah. In the NatureServe central database, there are approximately 25 extant occurrences (EO data in the NatureServe central database as of August 2013). (NatureServe, 2015)

### ***Threats and Stressors***

**Stressor:** Habitat modification from uranium mining and prospecting (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** From 1980-1985, 81 of 246 uranium mining plans of operations (MPOs) were located in Siler pincushion cactus habitat. Of those, 30 were modified to avoid or minimize impacts to Siler pincushion cactus. Only one of the MPOs occurred in a dense P. sileri area near Atkin Well; no cacti were damaged as a result of the drilling. The Service does not know how much Siler pincushion cactus habitat was affected or modified by these activities. The BLM reports that since 1990, there has been no uranium mining and very little gypsum exploration. The 2005-2006 resurgence in uranium mining was limited to Kaibab limestone near uranium mines that were already active since the 1980s and 1990s. In the Draft Environmental Impact Statement (DEIS), there is a map of uranium resource potential (U.S. Department of Interior 2005). There are two areas characterized on the map: 1) Sandstone uranium (SSU) high potential, abundant direct evidence, and 2) breccia pipe uranium (BPU) high potential, abundant direct evidence. All areas known to support Siler pincushion habitat are within these units. Based on this information, there is still potential for Siler pincushion plants and their habitat to be negatively affected by new uranium mining claims. (USFWS, 2008)

**Stressor:** Habitat modification from oil and gas leases (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In the DEIS for the revised RMP, BLM states that known oil and gas reserves within the Planning Area are not significant and no economic occurrences of gas or oil have been encountered to date (U.S. Department of Interior 2005). The BLM rated oil and gas potential within the Planning Area; areas in the north central and extreme western portions were rated as moderate potential. Good potential was assigned to the Shnabkaib Member of the Moenkopi Formation, which corresponds to the geologic formation that supports habitat for Siler pincushion cactus. Although we do not consider oil and gas production to be a threat at this time, the Service cannot rule it out as a future threat due to the increasing interest in domestic sources of oil production. All areas that are mapped as having moderate potential for oil and gas are within Siler pincushion habitat. (USFWS, 2008)

**Stressor:** Habitat modification from gypsum mining (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In the 2005 DEIS, BLM states that within the Planning Area potentially favorable areas for the occurrence of gypsum include sabkha environments associated with marine regressions in Permian and Triassic-aged rocks (U.S. Department of Interior 2005). Large gypsum deposits

occur in the northwestern portion of the Planning Area, associated with the Harrisburg Member of the Kaibab Formation (does not support Siler pincushion cactus) and the Moenkopi Formation. Again, the entire area beneath Siler pincushion habitat is classified as high gypsum potential, with abundant direct evidence. According to the BLM (2006), gypsum deposits within areas supporting Siler pincushion cactus were considered non-economically viable, at least in the 1980's when the mineral feasibility report was completed. While the Service does not consider gypsum mining a threat at this time, given the rapidly changing market for saleable minerals, the Service cannot rule it out as a future threat for Siler pincushion. (USFWS, 2008)

**Stressor:** Off-highway vehicles (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** This type of use has killed tagged Siler pincushion cactus within the Warner Ridge plot (Utah). The threat from OHV activity is very high in this area due to the proximity of St. George, which is experiencing rapid urban growth. There is increased use of open space around the city for recreational activities. The BLM (Dixie Resource Area) (1999) and the Arizona Strip RMPs established the Fort Pierce and Warner Ridge areas as Areas of Critical Environmental Concern (ACEC). The areas are closed to OHV use and are signed. The areas are patrolled regularly and on peak high-use weekends. The Warner Ridge ACEC is 4,281 acres in size and 1,790 acres are fenced. (USFWS, 2008)

**Stressor:** Livestock trampling (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Siler pincushion cacti can be trampled by livestock. A total of five Siler pincushion cacti mortalities attributable to livestock trampling were documented in all of the BLM monitoring plots for years 1986-2006. This number is small in comparison to the 258 and 322 mortalities attributed to rodent herbivory and natural causes (likely drought related), respectively. The highest mortality from livestock trampling (3) occurred in the Atkins Well grazed plot; the plot is located near a water tank, which typically receives high use. The Service assumes that additional plants are trampled outside of the monitoring plots, because almost all of Siler pincushion habitat is within grazing allotments. However, the Service suspects that the numbers trampled are small. (USFWS, 2008)

**Stressor:** Water pipeline (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** FWS has recently become involved with a permit request from the Utah Board of Water Resources to the Federal Energy Regulatory Commission (FERC) to construct a water pipeline from Lake Powell to St. George. This proposed pipeline plan is in the preliminary stages of development, and there are 3 alignments being considered at this time. One of the alignments would cross through the northern portion of BLM land on the Arizona Strip, which would go through Siler pincushion cactus habitat. Preliminary engineering studies were started in the summer of 2007, and by summer 2009, a completed license application will be submitted to FERC. Under the current timeline, construction would begin in 2013. The project will require

section 7 consultation with FWS, but the effects to Siler pincushion cactus and its habitat could be substantial, depending on which alignment is chosen. In addition, the assured water supply to St. George may contribute to increasing development in the general area, which would likely affect Siler pincushion cactus and its habitat near St. George. (USFWS, 2008)

**Stressor:** Herbivory and insect predation (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Herbivory and insect predation on Siler pincushion cacti are addressed in the HMP under "Natural Factors". Herbivory and insect predation result in death to individual cacti. Actions taken or recommended were the construction of raptor perches near dense populations of Siler pincushion cacti in order to reduce rodent herbivory and continued monitoring of the species. There were no actions described for reducing or eliminating insect predation. There have been observations of insect predation on Siler pincushion cactus. The BLM (2006) report indicates that insect larvae hollow out plants, resulting in cacti death. There are six species of *Moneilema* beetles recognized in North America, which were thought to be specialists on *Opuntia* spp. However, recent observations indicate the genus predated other cacti species as well. The *Opuntia* borer beetle (*Moneilema semipunctatum*) has been observed feeding on and killing the endangered Wright fishhook cactus (*Sclerocactus wrightiae*) in south central Utah (Kass 2001), and the threatened Mesa Verde cactus (*Sclerocactus mesa-verdae*) in New Mexico and Colorado (Smith 2001). Adult beetles feed on cacti and females lay eggs near the base of the plant. Once hatched, larvae tunnel into the plant, often causing death of the infested plant. *Moneilema corrugans* (no common name) has been known to kill the threatened Cochise pincushion cactus (*Coryphantha robbinsorum*) in southeastern Arizona (Zimmerman 1985). Additional research needs to be done to identify insects that infest Siler pincushion cactus and determine effects that insects have on cacti population dynamics. Insect infestations may be correlated with drought cycles; additional work is needed to examine if there is a relationship. The majority of mortalities (over 98 percent) observed in BLM monitoring plots were attributed to natural causes (likely drought), mammal herbivory, and insect predation. (USFWS, 2008)

**Stressor:** Drought (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Ongoing drought, which has been in place in much of the southwest since the late 1990's, has affected Siler pincushion cactus populations. Increased mortality and reduced or non-existent germination and recruitment have been observed on the monitoring plots. Other populations in Utah seem to have disappeared, likely due to drought. There are no recovery criteria that address this threat. The only action called for in the HMP is continued monitoring on BLM lands to quantify the effect. There are no actions to minimize or alleviate this threat to Siler pincushion cacti populations outside of BLM lands. (USFWS, 2008)

**Stressor:** Climate change (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Periods of drought in the southwest are not uncommon. But, the frequency and duration of droughts may be altered by climate change. Global warming, and associated effects on regional climatic regimes, is not well understood, but weather predictions for the southwestern United States include less overall precipitation and longer periods of drought. Seager et al. (2007) predict, based on broad consensus among 19 climate models, that the southwest will dry in the 21st century and that this drier climate change is already occurring. Increased aridity associated with the current on-going drought and the 1950's drought will become the norm for the American southwest within a timeframe of years to decades if the models are correct. The 2007 Intergovernmental Panel on Climate Change (IPCC) report outlines several scenarios that are virtually certain or very likely to occur in the 21st century. These are: 1) over most land, there will be warmer and fewer cold days and nights, and warmer and more frequent hot days and nights, 2) areas affected by drought will increase, and 3) the frequency of warm spells/heat waves over most land areas will likely increase. The IPCC makes equally sobering predictions for ecosystems; the resilience of many ecosystems is likely to be exceeded this century by an unprecedented combination of climate change, associated disturbances (e.g. flooding, drought, wildfire, insects), and other global drivers (IPPC 2007). With medium confidence, IPPC predicts that approximately 20-30% of plant and animal species assessed so far are likely to be at an increased risk of extinction if increases in global average temperature exceed 1.5 – 2.5°C (IPPC 2007). Almost certainly this species, along with its habitat, will be affected in some manner by climate change; the magnitude and extent of the change cannot be quantified at this time. (USFWS, 2008)

### **Recovery**

#### **Reclassification Criteria:**

Not applicable; species was downlisted to Threatened status in 1993 (USFWS, 2008).

#### **Delisting Criteria:**

1. All known populations are maintained at a level that demonstrates stable or increasing plant abundance and maintain the current distribution of locations within each population. Plant abundance (measured by the number of plants) may fluctuate within locations and populations, but the defined populations should be stable or increasing over a consecutive 15-year period. (USFWS, 2019)

2. Ensure no more than two percent of the suitable gypsiferous and calcareous clay soil habitat (as defined in the Recovery Plan and final rule to reclassify the species: 58 FR 68476) within each of the populations is disturbed over a 15-year period. This disturbance will result in short-term modification of no more than 2,671 hectares (6,600 acres) rangewide and be of short-term duration such that habitat restoration is achievable, including the formation of biological crusts. (USFWS, 2019)

#### **Recovery Actions:**

- The development and implementation of habitat management plans that alleviate the threats of collecting and habitat modification. (USFWS, 1986)
- The enforcement of existing regulations on collecting and trade. (USFWS, 1986)
- The study of population biology to develop the understanding needed to sustain healthy populations in their natural habitat. (USFWS, 1986)

- The development of public awareness, appreciation and support for preservation of the Siler pincushion cactus. (USFWS, 1986)
- The 1986 Recovery Plan should be updated. The recovery criteria need to be measurable and threats based. In addition, the BLM has better maps and location information that should be in the Plan. (USFWS, 2008)
- Assistance (technical and monetary) should be provided to the Kaibab Paiute Indian Tribe to conduct surveys and develop conservation measures for Siler pincushion cactus on their lands. (USFWS, 2008)
- The BLM monitoring protocol should be revised in order to quantify seedling survivorship. Random plots/transects should be used in order to make estimates for the population as a whole. (USFWS, 2008)
- The Siler pincushion cactus population in Utah should be monitored on a regular basis, especially to quantify and address threats from climate change related drought. An adaptive management plan should be developed to address this issue. (USFWS, 2008)
- The BLM should pursue mineral withdrawals on the established ACECs or in the areas that support dense concentrations of Siler pincushion cactus. (USFWS, 2008)
- The BLM should close areas that support dense concentrations of Siler pincushion cactus to off-road vehicle use. (USFWS, 2008)
- Research to examine insect predators on Siler pincushion cactus should be conducted. (USFWS, 2008)
- Recovery Criteria The Service downlisted Siler pincushion cactus to threatened on December 27, 1993, and an explanation of how reclassification criteria were met can be found in the final reclassification rule (58 FR 68476). We will not be carrying forward any of the original downlisting criteria identified in the original Recovery Plan due to the 1993 reclassification of the species. Current recovery criteria The prime objective is to manage the essential habitat of *Pediocactus sileri* so that populations can be sustained in their natural habitat. Actions identified as necessary for meeting the prime objective and for delisting include: 1. Demonstrated long-term stability (or increase) in population levels and habitat through monitoring studies. 2. Suitability of downlisting actions demonstrated; plant stabilized in its habitat. 3. Continued assurance of no mining or new claims in known habitat. 4. Implementation of actions identified in Habitat Management Plan. (USFWS, 2019)

## SPECIES ACCOUNT: *Pediocactus bradyi* (Brady pincushion cactus)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 11/26/1979; Southwest Region (Region 2) (USFWS, 2016)

### **Physical Description**

*Pediocactus bradyi* is a small, semiglobose cactus with single stems (although rare, 2 to 4), 3.2 to 6.2 cm long and 2.6 to 4 cm in diameter. The spines are dense (typically no central spine) with each elliptic areole (white or yellow-villous) numbering 13 to 16 radial spines, 3 to 5 mm long (white or yellowish tan). The straw-yellow flowers are 2 cm long and 1.5 cm in diameter and its smooth green fruit (7 to 10 mm long and 10 mm diameter) turns reddish-brown at maturity. The fruit is top-shaped and constricted at the base, the apex slightly convex, dehiscent by a vertical slit. Seeds are brownish black, 2.8 mm long and 1.7-2.0 mm wide (Heil and Porter 2001). (USFWS, 2012)

### **Taxonomy**

In 1961-1962, Lyman Benson combined into the genus *Pediocactus* (including *p. bradyi*) species that formerly were distributed over six different genera due to their great diversity in spination, body proportions, and flower color. Benson recognized an overriding similarity; the structure and method of dehiscence of the fruits (dry at maturity and dehiscent usually both by a dorsal slit and by a ring around the circumscissile apex), as well as several other common characteristics (Benson 1962c). *Pediocactus bradyi* can readily be distinguished from its closest relative, *p. winkleri*, by the latter's peach-colored flowers and fewer spines (mostly g-11). Also, the radial spines of *p. winkleri* are less pectinate than those of *p. bradyi*. (USFWS, 1985)

### **Current Range**

Restricted to a specific and limited limestone soil type and known only from Coconino County, in northern Arizona, along Marble Canyon. The species' range comprises an area approximately 23 kilometers (km) in length, north to south, and varies in width from 1.6 km to 4.58 km (USFWS 2012).

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Sexual (NatureServe, 2015)

### **Lifespan**

Adult: 10-20 years (USFWS, 2012)

### **Breeding Season**

Adult: March to April (USFWS, 2012)

**Reproduction Narrative**

Adult: Little variation exists within populations. These populations can be separated by distances of several miles even when there is suitable habitat. Further, dispersal within populations appears to be staggered throughout the growing season from shortly after seeds are produced in June to fall. This dispersal strategy may be disadvantageous for the species, however, populations in the genus when left undisturbed seem to be healthy with all age classes represented (Heil et al. 1981). *P. bradyi* breeding system as cross-pollinated and self-incompatible. Tepedino (2000) also found the cactus to be insect-pollinated, and sweat bees (*Dialictus* spp.) were observed to be the primary pollinators. Vegetative reproduction has not been documented in literature reviewed. If the conditions are favorable the cacti will flower typically between March and April (Spence 2008). The longevity of *P. bradyi* was not clearly understood in 1985. Information provided in the Recovery Plan indicates the cactus has a lifespan of 10 to 15 years (USFWS 1985). Spence (2008) describes the species as long-lived and suggests recruitment occurs perhaps once every 10 to 20 years. Roth estimates the cactus may live approximately 20 years. Long-lived and exhibits relatively low fecundity, which would increase the potential for a genetic bottleneck in conjunction with its isolated and restricted distribution (USFWS, 2012; NatureServe, 2015)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Desert, shrubland/chaparral (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Prefers exposed, sunny locations; responds to summer rainfall events by expanding above soil (USFWS, 2012)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations between 1170 and 1,370 m; vegetation is open and sparse (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Habitat Narrative**

Adult: Navajoan Desert on benches and terraces made up of Kaibab limestone chips overlying Moenkopi shale and sandstone-derived soils. The plants grow in gravelly alluvium on the gently sloping (0-10") benches, in exposed, sunny situations. The cactus occurs between 1,177 and 1368 meters (m) (3,861 and 4,488 feet [ft]) in elevation, which is the altitude of the Kaibab Formation (USFWS 1985). In the summer and winter months, *P. bradyi* spends most of its time below ground level covered by loose limestone fragments along the Marble Canyon plateaus of the Colorado River. The cacti typically respond to summer rainfall events by expanding above the soil (Heil et al. 1981). The vegetation where *P. bradyi* occurs is generally open and sparse, and characterized by low shrubs, grasses, and annuals. Associated plants include shadscale (*Atriplex confertifolia*), snakeweed (*Gutierrezia sarothrae*), and Mormon tea (*Ephedra viridis*). (USFWS, 1985; USFWS, 2012; NatureServe, 2015)

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Members of *Pediocactus* produce dry, dull-colored fruit which are presumed not to be dispersed by birds or rodents, but rather wind or water. (NatureServe, 2015)

***Population Information and Trends*****Population Trends:**

Short-term trends indicate a decline of 10-30% (NatureServe, 2015)

**Number of Populations:**

8 (NatureServe, 2015)

**Population Size:**

<2,500 (USFWS, 2012)

**Population Narrative:**

Long-lived and exhibits relatively low fecundity, which would increase the potential for a genetic bottleneck in conjunction with its isolated and restricted distribution, and limited micro-habitat (USFWS 2012). Navajo Nation populations are typically found in small widely scattered groups of 2 to 15 cacti. In 2004, only one population contained over 100 plants (Roth 2004). Scattered populations throughout its limited range. Short-term population trends indicate a decline of 10-30%. There are approximately 8 extant occurrences in Arizona (EO data in the NatureServe central database as of August 2013). Total population abundance is still unknown. There are less than 2500 individuals (Butterworth and Porter 2013). (USFWS, 2012; NatureServe, 2015).

**Distribution** The cactus occurs only in scattered populations along the rim of Marble Canyon, near Lees Ferry, in northern Arizona on lands administered by the Bureau of Land Management (BLM) and National Park Service (NPS), and on the Navajo Nation. The Arboretum at Flagstaff (Arboretum) conducted surveys to increase understanding of the population and distribution the cactus using 200 randomly selected plots within appropriate soil types that covered the known distribution of the cactus as well as suitable habitat (Haskins and Murray 2017, p. 4). The plots were distributed across BLM and NPS-managed lands (90 plots on BLM, 5 plots on NPS), and 105 plots located on the Navajo Nation. The Arboretum-led study located cacti at 18 of the 200 plots and found 80 occurrences of cacti (724 individuals) outside of survey plots (Haskins and Murray 2017, p.5). Including cacti at the survey plots, they located over 850 individuals, but of more significance, they located new occurrences of the cactus south of its previously known range. The U.S. Geological Survey (USGS) and Arizona Strip District Office of the BLM compiled 22 years' worth of monitoring and demographic data (Shryock et. al. 2014, entire). They tagged and measured 1,049 cacti over the study period, with annual population size ranging from a low of 152 cacti in 1992 to a high of 311 cacti in 2002 (Shryock et al. 2014, p. 1947). The cactus' survivorship was lowest during the first five years of life and after 15 years, with increased survivorship of cacti in between these ages. They found that the median survival age was eight years. Thirty-one cacti survived at least 20 years and 14 cacti were present for the entire length of the study, indicating that some cactus may live longer than 22 years. The growth rate ( $\lambda$ ) was below unity (0.961), meaning the population is declining (a stable population is equal to 1 and a growing population is greater than 1). Within plots, the cacti generally occur in small, widely spaced clumps, surrounded by sparse vegetation dominated by low shrubs and grasses.

Vegetation in these occupied areas include shadscale (*Atriplex confertifolia*), broom snakeweed (*Gutierrezia sarothrae*), and Indian ricegrass (*Achnatherum hymenoides*) (Shryock et al. 2014, p. 1945; Haskins and Murray 2017, p. 8). Annual non-native grasses, including invasive species of *Bromus* spp. and *Schismus* spp., are also common (Shryock et al. 2014, p. 1945; Haskins and Murray 2017, p. 9). Non-native grasses can reduce native plant diversity and reduce pollinator availability (Aslan 2017, p. 15). Haskins and Murray (2017, p. 5) found some overlap between the cactus and the federally endangered Fickeisen plains cactus (*Pediocactus peeblesianus* var. *fickeiseniae*). They observed 28 Fickeisen plains cacti within and nearby their cactus survey plots (USFWS, 2022).

### ***Threats and Stressors***

**Stressor:** Off-highway vehicles (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Several reports discuss the current or potential threat from OHV use on BLM, NPS, and NN lands. Historically, the threat from OHV activity was described by BLM as random and sparse (BLM 1986); Spence (1992) mentions that the most immediate threat at the time was OHV traffic on NPS lands; and since the early 1990s NN has documented unauthorized public vehicles accessed in areas where *P. bradyi* and its habitat occur (Roth 2008). For BLM, improvements were made through road closures, and monitoring reports (2002, 2004, and 2007) have not documented any recent OHV activity that resulted in effects to *P. bradyi* (Hughes 2009). For the NPS, the location of *P. bradyi* near the Lee's Ferry road suggests that the potential for OHV damage could exist; however, there is no current monitoring or documentation of such occurrence. Unauthorized vehicle access to *P. bradyi* habitat on the NN has been a problem in the past. In 2008, the NDFW installed a low running cable to prevent vehicle access to the area. Provided the cable on the NN is effective and additional road closures on BLM lands remain in place, the Service believes the threat from OHVs to *P. bradyi* is low and are no longer considered significant. (USFWS, 2012)

**Stressor:** Uranium mining (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Historically, uranium mining and exploration were considered potential threats due to a number of exploration and mining permits near *P. bradyi* populations that were submitted for review in the mid-1980s (USFWS 1985). As stated previously, no active uranium mining occurs within *P. bradyi* habitat and the Secretary of the Interior approved a withdrawal of approximately one million acres of public land surrounding Grand Canyon National Park from mineral entry for 20 years (DOI 2012). No mines will occur in the House Rock Valley and, therefore, will not pose a threat to *P. bradyi*. Thus, the Service believes uranium mining has become an insignificant threat to the species and is not expected to occur in the foreseeable future. (USFWS, 2012)

**Stressor:** Livestock grazing (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Historical livestock use, prior to the 1930s, on the BLM's Portion of the Kane Ranch was estimated to have about 3,000 head of cattle until the Grand Canyon Cattle Company became the operators and the herd was increased to 20,000 head. By 1934, the Taylor Grazing Act set into motion public lands grazing regulations (BLM 1999). Currently, management actions such as the 1992 ACEC plan and subsequent 1994 plan, and the Biological Opinion for the Kane Ranch Allotment Management Plan provided actions to protect *P. bradyi*, including moving livestock waters, closing areas to vehicles, and monitoring to determine livestock trampling effects on the cactus (Hughes 2005). The most recent RMP (BLM 2007) provides management actions for special status plants (including *P. bradyi*) where disturbance, injury, or mortality of such plants from livestock grazing will be minimized or eliminated through the implementation of conservation measures. As discussed previously in section 2.2.3, livestock trampling transects on the Kane Ranch Allotment (completed in 2001, 2002, and 2003) identified a total of 15 cacti that were stepped on and only 1 of those resulted in mortality (Hughes 2005). Although livestock trampling is possible, BLM recognizes that the occurrence is infrequent to uncommon (BLM 2007). Thus we believe as long as grazing continues where *P. bradyi* occur, the threat from livestock will remain but the severity of impact is considered low and is not considered to increase in the foreseeable future due to current management practices on BLM lands. As of 1992, the NPS lands were not grazed by cattle, and no sign of livestock activity was seen in the area (Spence 1992). There is no additional information available to suggest that the status of livestock activity in the area has changed to date. Thus the Service believes livestock grazing on NPS lands will continue to be an insignificant threat to *P. bradyi*. (USFWS, 2012)

**Stressor:** Collection (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Threats related to collection of *P. bradyi* were discussed in reports from BLM (HMP 1986), NPS (Spence 1992), and the Recovery Plan (USFWS 1985). Historically collections were considered a serious threat; however, annual monitoring of the cactus indicates collection is rare on BLM and NPS lands (Hughes 2005 and Spence 2008) and Roth (2008) indicates illegal collection appears to be a minor threat on NN lands. Thus the Service believes the threat from collection is low and is no longer considered a significant threat to *P. bradyi*. (USFWS, 2012)

**Stressor:** Recreational off-highway vehicles (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Off-road vehicle recreational use has been reduced to a minimum on BLM and NPS lands but NN lands may continue to have violations if the low running cable to deter vehicles in *P. bradyi* habitat is ineffective. As stated previously, provided the cable on the NN is effective and additional road closures on BLM lands remain in place, the Service believes the threat from OHVs to *P. bradyi* is low and are no longer considered a significant threat. (USFWS, 2012)

**Stressor:** Filming crews and movie set locations (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** On the NN, the Navajo Office of Broadcasting Services (Navajo Nation Department of Parks and Recreation [NDFW]) regularly gives out permits for filming along the picturesque rims of Marble Canyon. These permits do not require film crews to clear an area through biological assessments or evaluations. Because of the short timeframe of the filming activities and the remoteness of the habitat, the NDFW may not be aware of all ground-disturbing activities in the habitat of *P. bradyi* (Daniela Roth, former NN botanist, summary of email communication, July 27, 2010). At this time the Service is not aware of any resolutions or changes in communication between the two departments, and threats from filming crews will likely continue in the future. As stated previously (section 2.2.3) disturbance occurred in 1993 and 1994 from a film crew and in 2001 from a stunt jumper. These ground disturbing activities resulted in mortality and in soil compaction which restricts recovery and seedling recruitment. The Service concludes that recreational and commercial filming activities are having and will continue to have impacts on *P. bradyi* on the NN. (USFWS, 2012)

**Stressor:** Predation (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Disease is not mentioned as a new threat; however, there have been instances where predation by rodents has impacted populations during times of drought. Significant mortality attributed to rodents reduced the total population in the North Canyon plot (on BLM lands) from 240 individual cacti in 1989 to 81 in 1990 with an additional 40 cacti removed through predation in 1991. Future interactions with climate could increase the likelihood of predation for the cactus. We believe the potential threat from rodents is significant and is likely to have adverse impacts to populations of *P. bradyi* in the future, particularly under drought conditions, when other sources of moisture for rodents become scarcer. (USFWS, 2012)

**Stressor:** Climate change (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Based on the unequivocal evidence of warming of the earth's climate from observations of increases in average global air and ocean temperatures, widespread melting of glaciers and polar ice caps, and rising sea levels recorded in the Intergovernmental Panel on Climate Change Report (IPCC 2007), climate change is now a consideration for Federal agency analysis (GAO 2007). The earth's surface has warmed by an average of 0.74 C (1.3 F) during the 20th century (IPCC 2007) and, since 1960, the annual average temperature across the United States has increased by more than 2 F (1.1C) (Global Climate Change Impacts in the United States [GCCIOUS] 2009). The IPCC (2007) projects that there will very likely be an increase in the frequency of hot extremes, heat waves, and heavy precipitation events as a result of climate change. Overall effects from climate change to *P. bradyi* are unknown, but diminished seedling recruitment and overall population numbers described above could be exacerbated by recent temperature increases and precipitation decreases. Depending on the specialization of the native bee pollinators of this cactus, changes in climate could alter the blooming and foraging phenologies between the cactus and its insect pollinators, leading to changes in pollination occurrence and efficiency, and ultimately, impacts to sexual reproduction. Interactions among population demographics should be monitored in conjunction with climate changes to understand and track the status of this cactus. Although the effects of climate change are not

clearly understood at this time, the Service believes the impacts to the populations of *P. bradyi* could be severe in the future. (USFWS, 2012)

**Stressor:** Invasive plant species (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The rapid increase in the exotic species Mediterranean grass (*Schismus barbatus*) in the locality *P. bradyi* may have been triggered by recent changes in climate. Spence (2008) states the proliferation of this exotic grass could negatively affect soil moisture within suitable habitat for *P. bradyi*, and increase the potential for fire in high density years. This information described by Spence (2008) is anecdotal and speculative in theory and there are no current data available to confirm or dispute the potential influences of exotic grasses to cacti at this time. But, as we describe above, other nonnative invasive grasses outcompete native species for soil nutrients and water (Melgoza et al. 1990, Aguirre and Johnson 1991, Brooks 2000) and we expect that Mediterranean grass could have the same impact to *P. bradyi*. The impacts from altered pollinator behavior and a reduction of soil nutrients and water could adversely affect *P. bradyi* populations; however, the extent of these impacts is unknown at this time. Thus, we believe the threat is low to moderate and may continue to affect *P. bradyi* in the future. The potential for increased fire frequency and severity is a significant threat to *P. bradyi* since the habitat in which they reside is not fire adapted. Invasions of annual, nonnative species are well documented to contribute to increased fire frequencies (Brooks and Pyke 2002, Grace et al. 2002, Brooks et al. 2003). The disturbance caused by increased fire frequencies creates favorable conditions for increased invasion by nonnative grasses. The end result is a downward spiral where an increase in invasive species results in more fires, more fires create more disturbances, and more disturbances lead to increased invasive species densities. The risk of fire is expected to increase from 46 to 100 percent when the cover of cheatgrass (*Bromus tectorum*) increases from 12 to 45 percent or more (Link et al. 2006). The invasion of nonnative grasses into the Mojave Desert of western North America poses similar threats to fire regimes, native plants, and other federally protected species (Brooks et al. 2004). Brooks (1999) also found that high interspace biomass of nonnative grasses resulted in greater fire danger in the Mojave Desert. Brooks (1999) goes on to state that the ecological effects of nonnative grass-driven fires are significant because of their intensity and consumption of perennial shrubs. Although *P. bradyi* does not grow in the Mojave Desert, the studies above include Mediterranean grass. Furthermore, the Great Basin Desert Scrub community that *P. bradyi* occur in does not receive much more rainfall; therefore, the effects of Mediterranean grass on *P. bradyi* are anticipated to be similar to those described in the Mojave Desert. Although specific information on the genus *Pediocactus* and fire adaptations are unknown, we expect the invasion of annual, nonnative species will likely increase the frequency and severity of fire beyond historical conditions within the *P. bradyi* habitat. For example, the Paradine plain cactus (*Pediocactus paradine*) was impacted by the Warm Fire in 2006. The area burned experience high vegetation mortality and the Forest Service expects many of the cacti were killed since surveys did not produce any live cacti (USDA 2007). It was suggested that the modification of historical management practices resulted in vegetation changes and the spread of nonnatives that altered the fire behavior from low intensity to more severe fires (USDA 2007). Thus, we believe the threat from nonnative grasses and the potential for increased fire behavior is a severe threat to *P. bradyi* and is likely to increase in the future. (USFWS, 2012)

**Stressor:** Small population size and limited genetic mixing (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The species' low population level, restricted gene pool, and geographic limitations were described as natural factors affecting the population in the Recovery Plan (USFWS 1995). Although the reason for small population sizes and the potentially limited genetic mixing between *P. bradyi* has not been confirmed or evaluated, Benson (1982) suggests that the species of *Pediocactus* we have today are relicts of a more variable group of plants that once occupied suitable intervening sites between the present areas of distribution. For these relictual populations, the structural differences, extremely disjunct distribution, together with the lack of special means of seed dispersal and the physiological limitation of each species to a specific underlying rock or soil type, indicate long evolutionary periods of isolation. Although the specific reasons for small population sizes are unknown, the isolated distribution could create conditions of lowered connectivity among *P. bradyi* locations and depauperate genetic diversity. Thus, we believe small populations and potentially limited genetic mixing are likely a severe threat to *P. bradyi*; however, additional research is needed to determine the extent of the threat. (USFWS, 2012)

### ***Recovery***

**Reclassification Criteria:**

1. Permanent protection of 75 percent of the known habitat. (USFWS, 1985)

Recovery Priority Number: 2

**Delisting Criteria:**

1. All known populations are maintained at a level that demonstrates stable or increasing plant abundance and maintain the current distribution of locations within each population. Plant abundance (measured by the number of plants) may fluctuate within locations and populations, but the defined populations should be stable or increasing over a consecutive 15-year period. (USFWS, 2019)
2. No more than 10 percent of the Moenkopi shale and sandstone habitat (as defined in the Recovery Plan and final rule to list the species: 44 FR 61784) within each of the populations is disturbed over a consecutive 15-year period. This disturbance should occur outside of the habitat that occurs within the 75 percent permanent protection area and be of short-term duration such that habitat restoration is achievable, including formation of biological crusts. (USFWS, 2019)

**Recovery Actions:**

- Management of ORV use, livestock grazing, and mining within habitat of populations on Federal lands. (USFWS, 1985)
- Inventory for new populations of *P. bradyi* (USFWS, 1985)
- Monitor and study existing populations. (USFWS, 1985)
- Development of a cactus trade management plan for all cacti. (USFWS, 1985)
- The 1985 Recovery Plan should be updated with recovery criteria that reflect current threats to *P. bradyi*. Objective, measurable criteria for downlisting and delisting should be

- established. (USFWS, 2012)
- Studies should be conducted to evaluate the climate data for each plot or plots at various elevations. Studies should focus on site specific climate changes such as precipitation, snowfall, and temperature that influence reproduction, retraction, and seed germination. Appropriate climate gauges should be installed throughout P. bradyi habitat within BLM, NPS, and NN lands. (USFWS, 2012)
  - Studies should be conducted to evaluate the effectiveness of seed germination and seedling establishment and if new populations can be established by seed or require transplants of already established plants (Spence 2008). (USFWS, 2012)
  - Studies should be conducted to evaluate the pollination ecology of P. bradyi and evaluate whether the species is pollinator limited due to its early flowering (March-April) (Spence 2008). (USFWS, 2012)
  - Identify and implement the control or eradication of nonnative species where needed. (USFWS, 2012)
  - Improve coordination and communication between the NDFW and Navajo Office of Broadcast Services for actions permitted within P. bradyi habitat. (USFWS, 2012)
  - Establish consistent monitoring protocols that allow comparison of data for population trend analyses. (USFWS, 2012)
  - Work with the NN to develop a grazing plan within P. bradyi habitat. (USFWS, 2012)
  - Construct fencing exclosures with educational signage around P. bradyi populations that appear to be more exposed to film sets or that need protection from OHV use. (USFWS, 2012)
  - Studies specific to genetics or trends in genetic variation should be completed. (USFWS, 2012)

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS** • We recommend the Service and partners, the Navajo Nation, BLM, NPS, USGS, and Arboretum, develop a monitoring plan to detect population trends for the cactus (USFWS 2019). This action would address Delisting Recovery Criteria 1. • We recommend land managers implement management actions to protect cacti and their habitat from dispersed recreation. This action would address Recovery Action 1. • We recommend researchers collect cactus demographic information (e.g., survival, fecundity) to understand how the cactus has responded to past climatic fluctuations and enable predictions for how future climatic changes will affect demographic processes. This action would address Recovery Action 2. • We recommend researchers continue to bank seeds so that this material is available for propagation research and genetic analysis, especially for research of genetic variance across cactus populations. This action would address Recovery Actions 2 and 5. • We recommend further study of the zone of overlap between Brady pincushion cactus and Fickeisen plains cactus. The known area of overlap is relatively small, but does exist, so increasing our understanding of the respective species' microhabitats may provide valuable information for management and conservation. This action would address Recovery Action 2. • We recommend mapping and estimating the size of existing and potential suitable habitat, as well as the conservation status of these areas. This would include cooperation with the Navajo Nation Department of Fish and Wildlife, as well as federal land managers. This information would allow for better interpretation of the estimates of stochastic growth rates and quasi-extinction risks that Shryock et al. (2014, p. 1950) calculated as well as for tracking habitat disturbance. This action would address Recovery Action 2 and Delisting Recovery Criteria 2. • We recommend creating and conducting additional public outreach and education to reduce the risk of

illegal collection (poaching), and public awareness, appreciation, and support for the cactus. This action would address Recovery Action 4 (USFWS, 2022).

## SPECIES ACCOUNT: *Pediocactus despainii* (San Rafael cactus)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 09/16/1987; Mountain-Prairie Region (R6) (USFWS, 2016)

### **Physical Description**

A small, spiny succulent. Stems can swell to up to 6 dm in height, but during dry or cold weather the plants may not appear above ground at all; the species is easily overlooked except in the spring, when bronze-tinted, yellow to peach-colored flowers are in bloom (NatureServe, 2015).

### **Taxonomy**

The plant genus *Pediocactus* contains nine species (eFloras 2014). Winkler cactus and San Rafael cactus are very closely related with a blending of morphological characteristics where their ranges meet (Porter et al. 1999) (USFWS, 2015).

### **Historical Range**

Endemic to south central Utah (USFWS, 2015).

### **Current Range**

San Rafael cactus is found exclusively in Emery County, Utah. Overall, the known San Rafael cactus populations are found from Dripping Spring in the north, to Big Ridge South/Keesle Country to the south (approximately 122 km (78.5 mi) north to south), and from Mussentuchit Mine in the west, near the border of Sevier to the Humbug population in the east (approximately 88 km (48.5 mi) east-west) (USFWS, 2015).

### **Critical Habitat Designated**

Yes;

### **Life History**

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2015)

### **Lifespan**

Adult: 20+ years (USFWS, 2015)

### **Breeding Season**

Adult: March - May (USFWS, 2015)

### **Key Resources Needed for Breeding**

Adult: Bee pollinators (USFWS, 2015)

### **Reproduction Narrative**

Adult: It is reported to have low fruit/seed output (USFWS 2007; NatureServe, 2015). Some monitored cacti lived at least 20 years after tagging, although the age of the cacti at the time of

tagging was unknown (Clark et al. 2015). The species reproduces sexually, is self-incompatible; cross pollination is needed to produce viable seeds (Tepedino 2000). Pollinators visiting San Rafael cactus include many species of bees, from multiple families. Flowering occurs from March to May with fruiting from May to June (Heil 1984) (USFWS, 2015).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Semi-arid grassland, desert pavements in pinyon-juniper woodlands (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 4,760-6,820 ft. elevation (USFWS, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2015)

**Habitat Narrative**

Adult: Inhabits desert pavements of cobble or pebble in pinyon-juniper woodlands (Flora of North America Editorial Committee 2003). Hills, benches and flats, of open, semi-arid grassland with scattered junipers and pinyon pines. (NatureServe, 2015). San Rafael cactus grows in a wide variety of soils, although it may favor fine textured mildly alkaline soils rich in calcium and derived from limestone substrates of the Carmel Formation and the Sinbad member of the Moenkopi formation. It has also been found on shale barrens of the Brushy Basin member of the Morrison, Carmel, Mancos and Dakota geologic formations and in areas of primarily alluvial and colluvium soils. It is found hill tops, and gentle slopes, and most abundantly on sites with a south exposure at elevations of 1450-2080 m (4760-6820 ft.). San Rafael cactus requires intact habitats relatively free of invasive species. This species also requires the presence of native plants which support their pollinators in order to successfully reproduction (USFWS, 2015).

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Members of *Pediocactus* produce dry, dull-colored fruit which are presumed not to be dispersed by birds or rodents, but rather wind or water. Further, dispersal within populations appears to be staggered throughout the growing season from shortly after seeds are produced in June, to fall (NatureServe, 2015).

***Population Information and Trends*****Population Trends:**

Not available

**Species Trends:**

10 - 30% decline (NatureServe, 2015)

**Number of Populations:**

21 (USFWS, 2015)

**Population Size:**

~8,200 (USFWS, 2015)

**Minimum Viable Population Size:**

Unknown; probably 500 individuals per population (USFWS, 2015)

**Adaptability:**

Low (inferred from NatureServe, 2015)

**Population Narrative:**

Little variation exists within populations. The fragile habitat makes the species vulnerable to disturbances. USFWS 2007). The short term population trend is decreasing (10 - 30%) (Butterworth and Porter 2013) (NatureServe, 2015). There are 20 populations of San Rafael cactus, with a total of approximately 8,200 documented individuals (BLM 2012, 2012a, 2013a; Truman 2014, 2015). Based on the most recent survey data, the estimated area of the known populations is approximately 152,971 ha (378,000 ac) (USFWS 2014). The minimum viable population size for this cacti species is unknown. It is likely that population sizes of at least 500 individuals per population are necessary to avoid extirpation (USFWS, 2015).

***Threats and Stressors***

**Stressor:** Recreation (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The majority of the known San Rafael cactus individuals occur near established unpaved roads and are subject to dust effects. Pressures from recreation, including OHV use and biking are extremely high at the two largest known San Rafael cactus populations. All recorded individuals of San Rafael cactus occur on BLM (85 percent) or SITLA (15 percent) land that is open to OHV use on designated routes only. Two heavily used, unofficial OHV recreational areas are located adjacent to or within occupied habitat areas and are impacting individual plants and their habitat. In addition to OHV use, other forms of recreation, including camping and bike riding, exert pressure on some San Rafael cactus populations, particularly the Wedge and Millsite populations (USFWS, 2015).

**Stressor:** Livestock disturbance (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Trampling by livestock has been recognized as a threat to San Rafael cactus since at least 1981, with impacts to cacti documented regularly since that time (Heil et al. 1981; Spector 2013). Grazing is permitted throughout the known range of San Rafael cactus and evidence of livestock has been recorded in every population, although grazing pressure is not equal at every population or every surveyed site within a population. San Rafael cactus occurs on 19 grazing allotments managed by the BLM Price Field office (USFWS, 2015).

**Stressor:** Ungulate disturbance (USFWS, 2015)

**Exposure:****Response:****Consequence:**

**Narrative:** Deer prints have been documented within 15 cm (5.9 in) of San Rafael cactus at several sites and can locally be more abundant than livestock tracks but are not as widespread (Spector 2013). For example, in the Millsite/Clawson population, deer disturbance within 15 cm (5.9 in) was found in places at rates over 20 percent, including one survey site with a rate of 95% (BLM 2012); the survey sites are located near an area called Diversion Hollow (BLM 2012; Truman 2014). Deer winter in the area and spring use is high in some parts of the Millsite/Clawson population area. Impacts and disturbance to plants and habitat from wild horses and burros can be very similar to those of cattle and other livestock grazing. Wild horses and burros occur within a portion of San Rafael cactus range in the BLM Price Field Office planning area (BLM 2008a). (USFWS, 2015).

**Stressor:** Energy and mineral exploration and development (USFWS, 2015)

**Exposure:****Response:****Consequence:**

**Narrative:** Approximately 86 percent of the total population San Rafael cactus occurs on BLM land that is open to oil and gas leasing either with no additional constraints or subject to minor constraints, including the entirety of the two largest populations (The Wedge and Millsite/Clawson). Previous energy development activity in the Millsite area has destroyed individual plants and occupied habitat (BLM 2008a; Clark 2011). There is a high level of interest in development throughout the range and the majority of the species' occupied habitat is open to leasing. The negative impacts on cactus habitat from oil, gas, and mining development, are well documented (USFWS, 2015).

**Stressor:** Paleontological exploration (USFWS, 2015)

**Exposure:****Response:****Consequence:**

**Narrative:** San Rafael cactus may be subject to some impacts from paleontological exploration and excavation. Emery County is the location of a number of paleontological sites, including the Cleveland-Lloyd Dinosaur Quarry near Price. Paleontological interest in the area has been increasing with recent finds on BLM land (Truman 2014). Disturbance to plants from paleontological activities can include direct injury or mortality of plants situated at an excavation site, effects from dust due to surface disturbance at excavation sites, and impacts from associated activities such as camping near and hiking into sites by paleontological field crews (USFWS, 2015).

**Stressor:** Invasive plants (USFWS, 2015)

**Exposure:****Response:****Consequence:**

**Narrative:** Non-native invasive species are known throughout the ranges of San Rafael cactus, the most common of which are cheatgrass (*Bromus tectorum*), halogeton (*Halogeton glomeratus*), and Russian thistle (*Salsola tragus*). San Rafael cactus inhabits sparsely vegetated areas that are not prone to fire, but the presence of invasive plants can alter local fire regimes

(Stoddart et al. 1951; Harper et al. 1996; Brooks and Pyke 2001; Brooks et al. 2003; Duda et al. 2003). Cacti are not adapted to frequent fires in their habitats and are therefore not expected to persist through more frequent and intense fire cycles. In addition, fires may produce intense heat that can kill seeds, thereby reducing seedbank viability (Brooks and Pyke 2001) (USFWS, 2015).

**Stressor:** Collection (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** This species is highly desired in cactus collections and gardens and are sought by hobby and commercial cactus collectors (Hochstatter 1990; Heil 1984). The fact that this species is difficult to maintain in garden settings stimulates a continual demand for replacement plants as cultivated garden and greenhouse plants die. Cactus collectors are active in the Colorado Plateau, going from the habitat of one species of *Pediocactus* to the next to collect a complete set of the genus (Heil 1994; 52 FR 32914, September 16, 1987; 63 FR 44587, August 20, 1998) (USFWS, 2015).

**Stressor:** Predation (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The species is susceptible to infestations and mortality of insect larvae, including the flightless cactus borer beetle (*Moneilema semipunctatum*). The cactus borer beetle larvae enter the plant by eating tunnels, usually at ground level in the stem of the plant and ultimately ingest most of the plant stems' succulent cortex. Cactus-borer beetle predation can result in 25 to 30 percent mortality in cacti populations, and episodic die offs of significant portions of this species populations due to cactus borer beetles were observed within the past 25 years (Kass 1990; Neese 1987; USFWS 1995; 52 FR 32914, September 16, 1987; 63 FR 44587, August 20, 1998). San Rafael cactus is also predated by weevils. At the Wedge population, 3 percent were found to be infested with weevils which consume the flower buds thereby preventing reproduction. An additional 5 percent were noted to have damage from an unidentified rodent or insect, and several were observed to be infested with the cactus borer beetle (Robinson 2011) (USFWS, 2015).

**Stressor:** Small population size (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Of the known populations of San Rafael cactus, more than half consist of less than 100 recorded individuals and all but three consist of less than 500 individuals (even if the five populations in the McKay flats allotment were shown to be connected, that population would still consist of less than 500 individuals based on current data). This means a majority of populations of this species are moderately to extremely vulnerable to extirpation from known threats and stochastic events. Very little data on genetic diversity within this species exists, and none at all for many of these populations. The loss of any one population could constitute a major loss of genetic diversity for the species (USFWS, 2015).

**Stressor:** Climate change (USFWS, 2015)

**Exposure:****Response:****Consequence:**

**Narrative:** climate change and its impacts to the region are well documented and projected to continue and increase. There was a documented decline of Winkler cactus during the 1999-2003 drought, and the similarity of San Rafael to Winkler cactus suggests a comparable response. (Clark and Clark 2008). Additionally, rare plants have a negative response to drought (Roth 2003, 2004; Van Buren and Harper 2003, 2004), and drought severity and frequency is set to increase due to climate change (IPCC 2007; Karl et al. 2009) (USFWS, 2015).

**Recovery****Reclassification Criteria:**

Not available

**Delisting Criteria:**

1. Based on analysis and modeling implemented under the recovery actions, trends for San Rafael cactus populations are shown to be stable or improving according to the following measures: a) Species presence is maintained at all known San Rafael cactus populations; and b) Within at least three-quarters of the known populations that represent the majority of the total known individuals (and including the Wedge, Millsite/Clawson, and all of the McKay Flats populations) and represent the range of geographical, morphological, and genetic diversity of San Rafael cactus, plant density within occupied habitat is stable or improving over a 20-year period. These populations would be designated as Recovery Populations and this measurement would be based on a standardized, long term monitoring protocol developed by the Recovery Team and managing agencies; and c) Predictive modeling using data from an additional 10-year period (30 years total), collected in accordance with a standardized monitoring protocol, provides an indication of long-term demographic stability as well as a projected survival probability of at least 95 percent over 100 years for the species (USFWS, 2015).
2. Based on best available data, the available habitat base for each recovery population of the species is of sufficient quality and large enough to allow for natural population dynamics, population expansion where needed, and the continued presence of pollinators, with sufficient connectivity to allow for needed gene flow within and, where possible, among populations (USFWS, 2015).
3. Population and habitat management is implemented for all populations of the species in accordance with management plans developed under Recovery Action 1 (Section 3.4). The management plan will include a course of action that addresses the following needs: habitat protection and management, threats abatement, biological and threats monitoring, and reporting and evaluation (USFWS, 2015).
4. Federal land protection through long-term management agreements or plans is achieved for all known San Rafael cactus populations. Protection considerations from grazing impacts, development, mining, oil and gas, and recreation must be included in the management agreements and the protected areas must meet the size and connectivity parameters determined through research to be adequate to sustain those populations. These may include but are not limited to resource management plans, conservation agreements, recreation

management plans, and travel management plans (USFWS, 2015).

5. Management agreements or plans in place and being implemented for all San Rafael cactus populations on all federal lands must include measures to address and curtail illegal collection activities. These plans should include criteria for appropriate law enforcement at correct times and places to prevent illegal collection and sales of plants or any plant parts (USFWS, 2015).

6. Adverse population-level effects from herbivory, disease, or predation, if any, are identified, monitored and abated to the extent that at least three quarters of known San Rafael cactus population trends are stable or increasing, as evidenced by demographic monitoring results from studies that have adhered to monitoring protocols developed under Recovery Action 2.4 (Section 3.4). Programs to control excessive herbivory or predation will be developed to adaptively manage each population per criterion P-3, and must take into consideration the degree which climate change may impact disease or herbivory levels in the future (USFWS, 2015).

7. Land protection covering the habitat of all populations for the species and/or statutory and regulatory protections for plants are such that the protections of the ESA are no longer needed to compensate for regulatory inadequacies (USFWS, 2015).

8. A long-term ex-situ conservation program is ongoing for all extant San Rafael cactus populations. This would include seed collection and storage, germination and viability trials, and development of a protocol for successful reproduction under greenhouse conditions. This would help avert the risk of extinction from stochastic events or environmental catastrophes (USFWS, 2015).

9. In conjunction with recovery criterion P-2 (criterion 2), the available habitat base for each of the populations designated under criterion P-1 (criterion 1) is of sufficient quality and large enough to offset the threat of loss or restriction of the species' pollinators. Effective measurement criteria will be developed through research under Recovery Action 3 (USFWS, 2015).

**Recovery Actions:**

- Protect and conserve known extant Winkler cactus and San Rafael cactus populations and their habitat (USFWS, 2015).
- Survey for additional populations, and monitor all populations in order to apply conservation measures where and when needed (USFWS, 2015).
- Conduct in depth research into the biology, requirements, threat responses, and life histories of both species in order to develop and implement appropriate management practices for the purposes of achieving recovery (USFWS, 2015).
- Promote communication by encouraging and creating dialog regarding these species between managing agencies, land owners, developers, and the public in order to raise awareness and aid recovery (USFWS, 2015).
- Coordinate and work together with all stakeholders to achieve recovery (USFWS, 2015).
- Survey and repeat inventory efforts were completed throughout the range of the species beginning in 1987. These were a responsibility of the Interagency team from 1998 through 2008, which then transferred to individual managing agencies from 2011-2013. Because of

these efforts, there is a better understanding of the status and distribution of the species as well as habitat requirements. Although many more occupied sites and populations are now known than at the time of listing, not all suitable habitat has been surveyed. There is currently no comprehensive, funded plan from any of the managing agencies for continued inventory and monitoring of the species (USFWS, 2015).

- A habitat modelling project for the species has been initiated by the USGS, with funding from USFWS and the support of the BLM and CRNP, which will use existing inventory and site data to help determine potential suitable habitat and delineate the range of San Rafael cactus. The model will identify the most influential environmental factors of presence/absence for the species. This will be useful in locating additional sites and populations, as well as helping determine the need for cactus surveys prior to proposed projects that impact potential habitat (USFWS, 2015).
- Seeds of San Rafael cactus have been collected for conservation purposes, most recently in 2013. Seeds are currently stored and maintained at the National Center for Genetic Resource Preservation in Ft. Collins, CO and at Red Butte Garden in Utah. No plants are currently being propagated (USFWS, 2015).

***Conservation Measures and Best Management Practices:***

- Recommended future actions: We recommend rangewide surveys of known populations for Winkler cactus and San Rafael cactus, and that survey results be used to compile a robust, updated population estimate. Additional research that provides a better understanding of current population demographics, population trends, and the impact of and response to the primary threats is vital to evaluating these species' status in the future and to developing updated and meaningful recovery criteria and actions. The designation and management of protected areas that reduce impacts from identified threats may be necessary to facilitate this species' recovery. Additionally, we recommend updating and finalizing the draft recovery plan and specifically reevaluating the recovery goals and criteria based on new population numbers, habitat requirements, connectivity analysis, and recent and upcoming changes in management and conditions that may result in changes to threat intensity and scope (USFWS, 2019)

## SPECIES ACCOUNT: *Pediocactus peeblesianus fickeiseniae* (Fickeisen Plains cactus)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 10/31/2013; Southwest Region (Region 2) (USFWS, 2013)

### Physical Description

The Fickeisen plains cactus is a small, unbranched to occasionally branched, globose (globular) cactus. At maturity, many plants are the size of a quarter making them difficult to locate even when their location is known. The stems of mature Fickeisen plains cactus are 2.5 to 6.5 cm (1.0 to 2.6 in) tall and up to 5.5 cm (2.2 in) in diameter; covered with tubercles (knoblike projections on the main stem) that form a spiral pattern around the plant. Each tubercle has 6 to 7 radial spines per areole (tip where spines develop), 4 to 7 millimeters (mm) (0.15 to 0.27 in) in length, and 1 central spine (15 to 18 mm (0.59 to 0.70 in) long) that is straight to strongly curved. Spines are soft and corky (spongy) and white to pale gray in color. Flowers are 2.5 cm (0.98 in) in diameter, cream-yellow or yellowish-green in color, and produced on the apex (top) of the stem. Fruits are turbinate (top-shaped), and turn reddish-brown at maturity. The seeds are dark brown to black, 3 mm (0.11 in) long, and 2 mm (0.08 in) wide. (USFWS, 2013)

### Taxonomy

The Fickeisen plains cactus was first discovered near Cameron, Arizona, in the late 1950s. It was originally described in the scientific literature by Benson (1969), then later by Heil et al. (1981), who recognized the name and taxon in a review of the genus *Pediocactus*. The Flora of North America treats the taxon as a subspecies of *Pediocactus peeblesianus*, finding that the name "*Pediocactus peeblesianus* var. *fickeiseniae*" was not validly published by Benson. The Service considers *Pediocactus peeblesianus* var. *fickeiseniae* to be a valid taxon since it was classified as a candidate species in 1980. Our previous documentation referring to the Fickeisen plains cactus used the name "*P. peeblesianus* var. *fickeiseniae*", and we will continue to use this name. Other synonyms of *Pediocactus peeblesianus* var. *fickeiseniae* that have been used are *Navajoa fickeisenii* and *Toumeyia fickeisenii*.

### Historical Range

Very little is known about its historical range. It has been described as widespread along the ledges of the Little Colorado and Colorado Rivers to the hills of the lower House Rock Valley; also with a range northern Arizona from the hills in northeast Mohave County to the vicinity of the Colorado and Little Colorado rivers near the Grand Canyon National Park and southeast Coconino County. (USFWS, 2013)

### Current Range

The current range is in Coconino and Mohave Counties in northern Arizona, extending from Mainstreet Valley of the Arizona Strip (i.e., the area north of the Colorado River to the Arizona-Utah border) to House Rock Valley; along the canyon rims of the Colorado River and Little Colorado River; the area of Gray Mountain; and along the canyon rims of Cataract Canyon on the Coconino Plateau. (USFWS, 2013)

### Critical Habitat Designated

Yes; 9/19/2016.

**Legal Description**

On August 18, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective September 19, 2016) for *Pediocactus peeblesianus fickeiseniae* (Fickeisen Plains cactus) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in three counties in Arizona (81 FR 55266--55313).

**Critical Habitat Designation**

The critical habitat designation for *Pediocactus peeblesianus fickeiseniae* (Fickeisen plains cactus) includes six CHUs (including 10 sub-units) in Maricopa, Pima, and Pinal Counties, Arizona. This species' critical habitat encompasses approximately 17,456 acres (ac) (7,062 hectares (ha)). Brief descriptions are presented below. Maps depicting the CH units are available in the Final Rule. (81 FR 55266--55313)

**Unit 1: Hurricane Cliffs:** The Hurricane Cliffs Unit is located on the Arizona Strip in the north-central area of Mohave County, Arizona. The unit lies predominantly on the Shivwits Plateau and is bounded to the west by Mainstreet Valley and to the east by the Hurricane Cliffs. The unit consists of four subunits totaling 3,044 ha (7,524 ac) and includes small areas of private land, lands owned by the State of Arizona, and federally owned land managed by the BLM. The entire unit occurs within the area referred as the Arizona Strip that is managed by the BLM for multiple land use purposes such as livestock grazing, fuels management, energy, and recreation. The BLM manages grazing leases for large allotments comprised of a mix of their lands as well as State lands. Occupancy of the Hurricane Cliffs Unit by the Fickeisen plains cactus has been documented since 1986 (BLM 1986, p. 1). The taxon was considered generally rare, but in abundant numbers at Dutchman Draw with a few scattered individuals located in small clusters adjacent to Dutchman Draw populations. These smaller clusters include the Navajo, Ward, Salaratus Draw I, Salaratus Draw II, Temple Trail, and Toquer Tank populations. This entire unit helps to maintain the geographical range of the species and provide opportunity for population growth. This unit also provides a core population of the species. **Subunit 1a: Dutchman Draw—** Subunit 1a consists of 1,527 ha (3,774 ac) of land near Dutchman Draw in Mainstreet Valley. The subunit occurs within the Shivwits Plateau and along an exposed fault. Lands within this subunit were occupied at the time of listing. A monitoring plot was established at this site in 1986. The BLM has visited the plot regularly since then. Monitoring information has shown fluctuations in plant numbers between years, but among all years, there is an overall decline in plant numbers from a peak of 219 individuals in 1992 to 5 individuals in 2012. This subunit also includes the Navajo and Ward cluster plots that were established to note presence or absence of the cactus. These small plots were last visited in 2001, and 10 plants were found at each of the plots. This subunit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. Occupied habitat areas in this subunit occur predominantly within the Plains and Great Basin grassland with a small portion in the Great Basin desertscrub vegetation communities. Plants occur amongst tall, dense clumps of grama grass with some desert shrubs. The subunit is located at the foot of a gently sloping hill in fine alluvium deposits. Most of the bedrock surface is limestone, siltstone, and gypsum of the Kaibab Formation. **Subunit 1b: Salaratus Draw—**Subunit 1b consists of 724 ha (1,789 ac) of land near Salaratus Draw. The subunit overlies an active fault on the Shivwits Plateau. Lands within this subunit were occupied at the time of listing and include Salaratus Draw I and Salaratus Draw II

populations. This site was visited only three times between 1986 and 2001. At most, 44 plants were located in this subunit when last visited in 1994. This subunit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. Subunit 1c: Temple Trail—Subunit 1c consists of 443 ha (1,096 ac) of land in Lower Hurricane Valley. This subunit lies on the Hurricane Cliffs. It is bounded by the Shivwits Plateau to the west and the Uinkaret Plateau to the east, separated by an active fault that runs north along the Hurricane Cliffs. Lands within this subunit were occupied at the time of listing. This site was last visited in 2001 when seven individuals were found. This subunit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. Subunit 1d: Toquer Tank—Subunit 1d consists of 350 ha (865 ac) of land in Lower Hurricane Valley. Lands within this subunit were occupied at the time of listing. This site was regularly monitored from 1986 to 1991, when abundance counts ranged from 7 to 13 plants. This site was last visited in 1994, and seven individuals were found. This subunit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. The features essential to the conservation of the species within this unit are threatened by livestock grazing; nonnative, invasive species issues; small mammal predation on the cactus; and long-term drought coupled with increased minimum winter temperatures. Special management considerations or protection may be required to minimize habitat disturbance to Fickeisen plains cactus individuals, soil, and associated native vegetation; and to prevent or remove nonnative, invasive species within its habitat.

Unit 2: Sunshine Ridge: The Sunshine Ridge Unit is located on the Arizona Strip and lies on the Kanab Plateau in Mohave County, Arizona. The unit totals 754 ha (1,863 ac). This unit contains land that is federally and State owned. The entire unit is managed primarily by the BLM for multiple land use purposes such as livestock grazing, fuels management, energy, and recreation. Plants are located east of the Uinkaret Plateau and east of the range of the *Pediocactus sileri* (Siler pincushion cactus). Occupancy of the Sunshine Ridge Unit by the Fickeisen plains cactus has been documented since 1977 (AGFD 2011b, entire). This population has been regularly monitored since 1986, and has 34 plants as of 2011. Land within this unit was occupied at the time of listing and contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. This unit helps to maintain the geographical range of the species and provide opportunity for population growth. This unit also provides a core population of the species. The features essential to the conservation of the species within this unit are threatened by livestock grazing; nonnative, invasive species issues; small mammal predation on the cactus; and long-term drought coupled with increased minimum winter temperatures. Special management considerations or protection may be required to minimize habitat disturbance to Fickeisen plains cactus individuals, soil, and associated native vegetation; and to prevent or remove nonnative, invasive species within its habitat.

Unit 3: Clayhole Valley: The Clayhole Valley Unit is located in Upper Clayhole Valley on the Arizona Strip and lies within the Uinkaret Plateau in Mohave County, Arizona. The unit consists of 414 ha (1,024 ac) of land that is federally and State owned. The entire unit is managed primarily by the BLM for multiple land use purposes including livestock grazing. Occupancy of the Clayhole Valley Unit by the Fickeisen plains cactus has been documented since 1980 (AGFD 2011b, entire). The population has been monitored annually since 1986. As of 2011, the population contains 42 plants. Land within this unit was occupied at the time of listing and contains all of the primary constituent elements of the physical or biological features essential to the conservation of the

Fickeisen plains cactus. This unit helps to maintain the geographical range of the species and provide opportunity for population growth. This unit also provides a core population of the species. The features essential to the conservation of the species within this unit are threatened by livestock grazing; nonnative, invasive species issues; small mammal predation on the cactus; and long-term drought coupled with increased minimum winter temperatures. Special management considerations or protection may be required to minimize habitat disturbance to Fickeisen plains cactus individuals, soil, and associated native vegetation; and to prevent or remove nonnative, invasive species within its habitat.

Unit 4: South Canyon: The South Canyon is located on the eastern boundary of the North Kaibab Ranger District of the Kaibab National Forest in Coconino County, Arizona. It is bounded by the Colorado River near Marble Canyon at House Rock Valley. It includes land originally designated as the Grand Canyon National Game Preserve that is now referred to as the Buffalo Ranch Management Area. It contains 110 ha (272 ac) of federally owned land that is administered by the Kaibab National Forest. This unit contains at least 62 individual Fickeisen plains cactus scattered among 6 areas along the rim of South Canyon Point. This unit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. This unit helps to maintain the geographical range of the species and provide opportunity for population growth. This unit also provides a core population of the species. The primary land uses within this unit include big game hunting and recreational activities throughout the year. The area is very remote and may receive limited numbers of hikers, hunters, or campers. Under a memorandum of understanding, the Kaibab National Forest and the AGFD commit to managing the natural resources of this area, mainly big game species, to ensure that sensitive resources are not impacted and desired conditions are achieved (USFS 2012, p. 92). Livestock grazing by cattle and mining activities are not authorized within the Buffalo Ranch Management Area. Special management considerations or protection may be required within the unit to minimize habitat disturbance to the soil and associated native vegetation, and prevent invasion of nonnative plants. The features essential to the conservation of the species within this unit are threatened by nonnative, invasive species issues and long-term drought coupled with increased minimum winter temperatures. Special management considerations or protection may be required to minimize conditions that may promote or encourage encroachment and establishment of nonnative, invasive species; and reduce the likelihood of wildfires affecting the population and nearby plant community.

Unit 5: House Rock Valley: The House Rock Valley is located on the eastern edge of the Arizona Strip near the North Rim of the Grand Canyon National Park in Coconino County, Arizona. The unit consists of four subunits totaling 1,893 ha (4,678 ac) of land. The unit consists of land that is federally and State owned. The entire unit is managed primarily by the BLM, mainly for livestock grazing. Lands within this unit were occupied at the time of listing and contain all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. This entire unit helps to maintain the geographical range of the species and provide opportunity for population growth. This unit also provides a core population of the species. Occupancy of the Fickeisen plains cactus in the House Rock Valley Unit was first documented in 1979 (Phillips 1979, entire; AGFD 2011b, entire), at Beanhole Well, Marble Canyon, and South Canyon. These sites have not been visited for more than 21 years. However, we have no reason to believe these sites were not occupied at the time of listing for reasons provided in the "Distribution and Range" section of the final listing rule (78 FR 60608). Occupancy at the North Canyon Wash site was documented in 1986, and it has been regularly

monitored since. The House Rock Valley Unit is bounded by the Colorado River to the east, U.S. Highway 89A to the north, and the Kaibab National Forest to the west. Subunit 5a: Beanhole Well—Subunit 5a consists of 745 ha (1,841 ac) of federally owned land that is managed by the BLM, and 126 ha (312 ac) of Stateowned land. Lands within this subunit were occupied at the time of listing. Three plants were documented at Beanhole Well in 1979, and the site has been visited by Hughes since then, and while occupied habitat was observed, no plant numbers were reported to us (Calico 2012, pers. comm.). This subunit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. Subunit 5b: North Canyon Wash— Subunit 5b consists of 472 ha (1,166 ac) of federally owned land that is managed by the BLM. Lands within this subunit were occupied at the time of listing. This site has been regularly monitored since 1986. As of 2011, the site contains 39 Fickeisen plains cacti. This subunit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. Subunit 5c: Marble Canyon—Subunit 5c consists of 214 ha (528 ac) of federally owned land that is managed by the BLM. Lands within this subunit were occupied at the time of listing. Eight plants were documented at Marble Canyon in 1979. This site has not been visited for many years. This subunit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. Subunit 5d: South Canyon—Subunit 5d consists of 336 ha (831 ac) of Federal land in House Rock Valley along the rim of Marble Canyon. Lands within this subunit were occupied at the time of listing. A total of 52 plants have been documented at this site historically. This subunit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. The features essential to the conservation of the species within this unit are threatened by livestock grazing; nonnative, invasive species issues; small mammal predation on the cactus; and long-term drought coupled with increased minimum winter temperatures. Special management considerations or protection may be required to minimize habitat disturbance to Fickeisen plains cactus individuals, soil, and associated native vegetation; and to prevent or remove nonnative, invasive species within its habitat.

Unit 6: Gray Mountain: The Gray Mountain Unit is located in the vicinity of the town of Gray Mountain, Arizona, on Highway 89 in Coconino County. The unit consists of two subunits totaling 847 ha (2,095 ac). The unit includes a checkerboard mix of private land, lands owned by the State, and federally owned land managed by the BLM. Lands within this unit are considered occupied at the time of listing. Occupancy at the Gray Mountain unit was first documented in 1962, and consists of two very small populations on both sides of Highway 89. Occupied sites were visited in 2013, and a few plants in flower were observed. This unit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. This entire unit helps to maintain the geographical range of the species and provide opportunity for population growth. This unit also provides a core population of the species. Subunit 6a: Mays Wash—Subunit 6a is located southeast of Highway 89 and consists of 326 ha (807 ac) of land. The subunit includes private land, land owned by the State, and federally owned land managed by the BLM. The entire subunit lies within a cattle ranch and is managed privately for livestock grazing. Lands in this subunit are considered occupied at the time of listing. Occupancy at this site was documented in 1981 and 1984, when 31 plants were found (AGFD 2011b, entire). A site visit to BLM land in 2013 located a few plants in flower. This subunit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. Subunit 6b: Gray Mountain—Subunit 6b is located west of Highway 89 and borders the boundary of the Navajo Nation. This subunit

consists of 521 ha (1,288 ac) of land that is owned by the State and privately owned land. The entire subunit lies within a cattle ranch and is managed privately for livestock grazing. Lands in this subunit are considered occupied at the time of listing. Occupancy was documented in 2009 when three individuals were found (NNHP 2011a, p. 2). An individual in bloom was observed in 2013. This subunit contains all of the primary constituent elements of the physical or biological features essential to the conservation of the Fickeisen plains cactus. The features essential to the conservation of the species within this unit are threatened by livestock grazing by horses and sheep; nonnative, invasive species issues; mineral development and associated infrastructure; and long-term drought coupled with increased minimum winter temperatures. Special management considerations or protection may be required to minimize disturbance or destruction to the bedrock substrate and associated limestone soils; to prevent or remove nonnative, invasive species within its habitat; and protect the native vegetation communities.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Pediocactus peeblesianus fickeiseniae* critical habitat consists of the following components (81 FR 55266--55313):

- (i) Soils derived from limestone that are found on mesas, plateaus, terraces, the toe of gentle sloping hills with up to 20 percent slope, margins of canyon rims, and desert washes. These soils have the following features: (A) They occur on the Colorado Plateau in Coconino and Mohave Counties of northern Arizona and are within the appropriate series found in occupied areas; (B) They are derived from alluvium, colluvium, or eolian deposits of limestone from the Harrisburg member of the Kaibab Formation and limestone, siltstone, and sandstone of the Toroweap and Moenkopi Formations; (C) They are nonsaline to slightly saline, gravelly, shallow to moderately deep, and well-drained with little signs of soil movement. Soil texture consists of gravelly loam, fine sandy loam, gravelly sandy loam, very gravelly sandy loam, clay loam, and cobbly loam.
- (ii) Native vegetation within the Plains and Great Basin grassland and Great Basin desertscrub vegetation communities from 1,310 to 1,813 m (4,200 to 5,950 ft) in elevation that has a natural, generally intact surface and subsurface that preserves the bedrock substrate and is supportive of microbotic soil crusts where they are naturally found.
- (iii) Native vegetation that provides for habitat of identified pollinators within the effective pollinator distance of 1,000 m (3,280 ft) around each individual Fickeisen plains cactus.

#### **Special Management Considerations or Protections**

When designating critical habitat, the Services assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features which are essential to the conservation of the species and which may require special management considerations or protection. All areas designated as critical habitat as described below may require some level of management to address the current and future threats to the physical or biological features essential to the conservation of the Fickeisen plains cactus. In all of the described units, special management may be required to ensure that the primary constituent elements for the cactus are conserved and the habitat provides for the biological needs of the cactus. Some of the management activities that could ameliorate these threats include, but are not limited to, those discussed below. (1) Practice livestock grazing in a manner that maintains, improves, and expands the quantity and quality of desertscrub and grassland habitat. Special

management considerations or protection may include the following: Manage livestock grazing sustainably with the natural landscape by determining appropriate areas, seasons, and use consistent within the carrying capacity of rangeland in response to current and future drought and warming trends; improve monitoring and documentation of grazing practices; manage cattle and feral hoofed mammals (ungulates) (e.g., horses, burros) to reduce the risk of plants trampled and soil compaction; and manage for other small mammal species to restore desired processes to increase habitat quality and quantity. (2) Manage for nonnative, invasive species, such as *Bromus tectorum* (cheatgrass), *Bromus rubens* (red brome), or *Erodium cicutarium* (redstem filaree), by minimizing conditions that may promote or encourage encroachment or establishment of nonnative, invasive species and restore or reestablish conditions that allow native plants to thrive. Within the range of the Fickeisen plains cactus, the establishment and success of nonnative, invasive species has been a result of historic land use and management practices such as logging, grazing, wildfire suppression actions, mining, and ORV use. Actions have been taken by land management agencies to reduce the spread of invasive species and reduce the risk of wildfire they pose from creating fine fuel loads. Nonnative, invasive species occur near Fickeisen plains cactus habitat and may pose a threat through competition for resources or increase the risk of fire. Special management considerations or protection may include the following: Prevent or restrict establishment of nonnative, invasive species; minimize ground-disturbing activities that may facilitate their spread; implement post-disturbance restoration activities such as native plant propagation; practice active removal of nonnative, invasive plant species and targeted herbicide application (provided herbicides can be shown not to negatively impact the Fickeisen plains cactus or the native pollinators); and improve monitoring and documentation on a site-by-site basis where nonnative, invasive species are present in occupied habitat to assess any effect (beneficial or negative) they pose of the cactus. (3) Protect bedrock surfaces and associated limestone soils that provide suitable habitat from mineral development and associated infrastructure (new roads). Numerous breccia pipes (vertical, pipe-shaped bodies of highly fractured rock that collapsed into voids created by dissolution of underlying rock) are located across the Colorado Plateau and are expressed as circular collapse structures, minor folds, and other surface irregularities associated with the Kaibab and Toroweap Formations. Exploration and development of uranium has peaked and waned in accordance with market values. Areas of interest and oil and gas leasing/exploration overlap Fickeisen plains cactus habitat. These activities could result in direct habitat loss or alteration by removing or degrading limestone soils to such an extent that the soils would no longer support the growth of the Fickeisen plains cactus. Special management considerations or protection may include the following: Protect lands that support suitable habitat and site future development such that the destruction or removal of limestone from the Kaibab, Toroweap, and Moenkopi formations is minimized and depositional areas are preserved. (4) Manage or protect native desertscrub and plains grassland vegetation communities from recreational impacts. Special management considerations or protections may include the following: Managing trails, campsites, and ORVs; and reduce the likelihood of wildfires affecting the population and nearby plant community. These management activities will protect the physical or biological features essential to the conservation of the Fickeisen plains cactus by reducing the direct and indirect effects of habitat loss, alteration, or fragmentation; preserving the bedrock surfaces and associated limestone soils that form the basis of its habitat; and maintaining the native vegetation communities and its pollinators. In summary, the primary constituent elements of the Fickeisen plains cactus habitat may be impacted by livestock grazing; nonnative, invasive species; mineral development and associated transportation infrastructure; and recreation. We find that these activities may not be direct threats to the species as a whole, but may negatively impact

the primary constituent elements. The areas designated as critical habitat within the geographical area occupied by the taxon at the time of listing contain the physical or biological features essential to the conservation of the Fickeisen plains cactus. Special management considerations or protection may be required to eliminate, or reduce to a negligible level, the threats affecting each unit or subunit and to preserve and maintain the essential features that the critical habitat units and subunits provide to the cactus.

***Life History*****Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual (NatureServe, 2015)

**Lifespan**

Adult: The lifespan of the Fickeisen plains cactus is estimated to be between 10 to 15 years. (USFWS, 2013)

**Breeding Season**

Adult: Mid-April for flowering with fruiting in June (USFWS, 2013)

**Other Reproductive Information**

Adult: Reproduction has not been specifically studied on the Fickeisen plains cactus. For other species in the genus *Pediocactus*, reproduction occurs through cross-pollination by native bees. Insects observed visiting flowers of the Fickeisen plains cactus include species of hover flies (family Syrphidae) and bee flies (family Bombyliidae), mining bees (family Andrenidae), and sweat bees (family Halictidae). Although flies may pollinate flowers of the Fickeisen plains cactus, the primary pollinators of the plant are believed to be halictid bees from the genera *Lasioglossum*, *Halictus*, and *Agapostemon*, based on several studied species of *Pediocactus*. (USFWS, 2013)

**Reproduction Narrative**

Adult: *Pediocactus peeblesianus* var. *fickeiseniae* flowers in April to May and fruits mature in May to June. The cacti tend to produce abundant flowers (1-5 per plant) but not many seeds. Flowers generally open mid-morning (10-10:30 am) on fair, warm days but fail to open or only partially open in cold, cloudy or extremely windy weather (Navajo Natural Heritage Program 1994). Rainfall is very variable in the regions where Fickeisen Plains cactus grows and it exhibits episodic germination that is tied to the amount of precipitation. (NatureServe, 2015)

**Habitat Type**

Adult: Terrestrial (USFWS, 2013)

**Habitat Vegetation or Surface Water Classification**

Adult: Shallow, well-draining, gravelly loam soils derived from limestone (USFWS, 2013)

**Dependencies on Specific Environmental Elements**

Adult: Rainfall is very variable in the regions where it grows and it exhibits episodic germination that is tied to the amount of precipitation. (USFWS, 2013)

**Geographic or Habitat Restraints or Barriers**

Adult: 1200 - 1600 m elevation, 0 - 20 % slope (USFWS, 2013)

**Environmental Specificity**

Adult: Narrow endemic (USFWS, 2013)

**Habitat Narrative**

Adult: The Fickeisen plains cactus is a narrow endemic restricted to exposed layers of Kaibab limestone on the Colorado Plateau. Plants are found in shallow, well-draining, gravelly loam soils formed from alluvium, colluvium, or Aeolian deposits derived from limestone of the Harrisburg Member the Kaibab Formation and Toroweap Formation; Coconino Sandstone; and the Moenkopi Formation. Most populations occur on the margins of canyon rims, flat terraces, limestone benches, or on the toe of well-drained hills. Plants are found primarily on slopes of 0 to 5 percent but some also occur on slopes up to 20 percent at elevations between 1,280 to 1,814 m (4,200 to 5,950 ft). (USFWS, 2013)

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: The mechanisms of seed dispersal in the Fickeisen plains cactus have not been investigated and are poorly understood. Most site visits to areas occupied by the Fickeisen plains cactus have observed seedlings established very close to the adult plant. The general shared belief is that most species of *Pediocactus*, including the Fickeisen plains cactus, lack a good mechanism for seed dispersal, which is a contributing factor to its endemism and isolated, localized populations. (USFWS, 2013)

***Population Information and Trends*****Population Trends:**

Short-term trends indicate a decline of 10-30% (NatureServe, 2015)

**Number of Populations:**

37 (USFWS, 2020)

**Population Size:**

1,572 estimated in 22 pops on the Navajo Reservation (USFWS, 2020)

**Population Narrative:**

We received little information that changes our basic understanding about the Fickeisen plains cactus since we listed it in 2013. At listing, we knew of 33 populations (78 FR 60629) and currently we are aware of 37 populations range-wide, with two possibly extirpated. Also, while some populations are regularly monitored (such as those on the BLM Arizona Strip District), many are not monitored, or are evaluated infrequently or irregularly (78 FR 60629). We are encouraged by the recent increased survey and monitoring attention from the Navajo Natural Heritage Program and Babbitt Ranches/Landsward Foundation. Population sizes within the BLM Arizona Strip District monitoring plots appear to have declined by almost 50% since 2013. The enlargement of the Dutchman Draw plot in 2017 to include 22 additional plants complicates our

understanding of long-term trends. The BLM did not elaborate on the new plot size or reasons for the decline in total numbers. Their tally for recruitment, death, and/or missing plants does not explain what could be attributing to the decline. The Navajo Nation's comprehensive 2015 survey effort resulted in more discovered plants. Still, most of the Navajo Nation's populations are small and there is concern for low reproduction rates and seedling numbers, as well as the persistence of two populations. (USFWS, 2020)

### ***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The Fickeisen plains cactus and its habitat is threatened by direct loss of plants and habitat loss and modification due to the direct and indirect effects of livestock grazing and drought and climate change. These threats, in and of themselves, may not result in significant population-level impacts to the Fickeisen plains cactus. However, the above factors appear to be acting synergistically, placing a major stress on the known plants monitored rangewide with little indication of population growth and age-class diversity (USFWS, 2013).

**Stressor:** Herbivory (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Small mammal herbivory on cactus species is known to occur during dry conditions when animals seek available moisture from the plant or available food from cactus fruit. Although clear evidence is lacking of the scope of the impact that rodent predation has had on the Fickeisen plains cactus and its seeds, taken in conjunction with other habitat disturbances occurring across its range, low recruitment, and small population size, we find that rodent or rabbit predation is likely to rise to the level where it becomes a significant threat to the plant (USFWS, 2013)..

**Stressor:** Small population size (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Small populations that are restricted by habitat requirements are more vulnerable to the effects of climate change, such as prolonged droughts and increased fire frequencies. Although small population size makes the species intrinsically more vulnerable, it is uncertain whether this alone would rise to the level of threat. However, when combined with the threats from livestock grazing, drought and climate change, and rodent and rabbit predation, small population size likely exacerbates the effects of these threats on the Fickeisen plains cactus (USFWS, 2013).

**Stressor:**

**Exposure:**

**Response:**

**Consequence:**

**Narrative:****Recovery****Reclassification Criteria:**

Reclassification criteria are not available.

**Delisting Criteria:**

Delisting criteria are not available.

**Recovery Actions:**

- Recovery actions are not available.
- Conservation measures are not available.

**Conservation Measures and Best Management Practices:**

- **RECOMMENDATIONS FOR FUTURE ACTIONS** • Develop a recovery plan for the Fickeisen plains cactus to incorporate new information on biology, ecology, and management recommendations. Establish objective and measurable recovery criteria for down and delisting to address all relevant listing factors. • Continue to improve coordination and collaboration among all parties conducted land management actions or permitted activities in Fickeisen plains cactus habitat. • Continue to seek out new Fickeisen plains cactus populations and improve the monitoring of known populations using standardized methodology. • Conduct genetic studies between populations to determine variability and demographic studies to examine if low pollinator visits effects population size and if gene flow is limited. • Develop an off-site conservation program for seed banking and propagation techniques. Conduct studies to evaluate the effectiveness of seed germination and seedling establishment and whether new populations can be established by seed or require transplants of already established plants. • Investigate the need for pollinator restoration practices to increase abundance and diversity of pollinators and supporting habitat. • Examine the ability for the Fickeisen plains cactus to naturally disperse into unoccupied suitable habitat. Also, examine whether the quality of these unoccupied habitats can remain suitable under future climactic conditions. Develop management plans to conserve and protect those future habitats for the taxon's continuing persistence. Develop a systematic and standardized monitoring protocol to gather and collect long-term demographic information that improves the quality of data and helps formulate rangewide conservation practices to improve the taxon's status. • Establish coordination meetings with BLM Arizona Strip Field Office to discuss monitoring methods, results, and future management of the cactus. (USFWS, 2020)

## **SPECIES ACCOUNT: *Pediocactus peeblesianus* var. *peeblesianus* (Peebles Navajo cactus)**

---

### ***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** PNC

**Listing Status:** Endangered; 11/28/1979; Southwest Region (Region 2) (USFWS, 2016)

### **Physical Description**

Peebles Navajo cactus is a very small, solitary globose cactus. Mature stems range from 13 to 35 millimeters (mm) in diameter and up to 29 mm in height above ground (Butterwick 1986; Phillips et al. 1985). Individual plants have 3 to 5 (commonly 4) spongy or corky radial spines that are 2 to 9 mm long, 0.5 to 1 mm wide, white to pale gray in color (Heil et al. 1981) and may appear as a twisted cross (AZGFD 2009) (Figure 1). The upper radial spine is often longer than the other radial spines, extending up to 7.5 mm in length (AZGFD 2009). Peebles Navajo cactus lacks a central spine which distinguishes this subspecies from its closest relative, Fickeisen plains cactus (*Pediocactus peeblesianus* ssp. *fickeiseniae*) (USFWS, 2022).

### **Taxonomy**

The species that Lyman Benson combined into the genus *Pediocactus* in 1961-1962 formerly were in six different genera due to their great diversity in spination, body proportions, and flower color. Benson recognized an overriding similarity: the structure and method of dehiscence of the fruits (dry at maturity and dehiscent usually both by a dorsal slit and by a ring around the circumscissile apex) as well as several other characteristics in common (Benson 1962b). The Peebles Navajo cactus is separated from its nearest relative, *P. peeblesianus* var. *fickeiseniae*, primarily on the basis of spine characters, size, and distribution. Peebles Navajo cactus lacks a central spine, and has fewer of the corky radials [4 (3-5) versus 6 (7)] characteristic of the other variety. It is also smaller in all parts and grows in the vicinity of Holbrook, whereas var. *fickeiseniae* grows to the west in the vicinity of the Little Colorado and Colorado rivers and on the Arizona Strip (Benson 1962a). (USFWS, 1984)

### **Current Range**

Endemic to Navajo County, Arizona near Joseph City and Holbrook (USFWS 2008). Its range is very small, approximately 7 miles in length by 1 mile in width (USFWS 2008). (NatureServe, 2015)

### **Critical Habitat Designated**

Yes;

### ***Life History***

### **Food/Nutrient Resources**

### **Lifespan**

Adult: The life span of a Peebles Navajo cactus is estimated to be at least 30 years (USFWS, 2022).

**Breeding Season**

Adult: Late April (NatureServe, 2015)

**Other Reproductive Information**

Adult: Pollinators of *Pediocactus* species are solitary native bees from the genera *Agapostemon* (metallic sweat bees) and *Ashmeadiella*, as well as *Dialictus*, a subgenus of sweat bees from the genus *Lasioglossum* (Peach et al. 1993; Tepedino et al. 1996; Tepedino 2000). The primary pollinators of the Peebles Navajo cactus have not been identified. Insects observed visiting open flowers have included a single, native bee of *Lasioglossum*, thrips (Order Thysanoptera), and ants (*Forelius pruinosus*) (Butterwick 1986). In 2021, the Museum of Northern Arizona placed insect traps near the Joseph City plots during the flowering period to document the arthropod diversity in association with Peebles Navajo cactus (Phillips 2021). This will help identify or elaborate on insects observed visiting its flowers. Approximately 80 to 120 arthropod specimens were collected and data will be analyzed in the near future (USFWS, 2022).

**Reproduction Narrative**

Adult: Flowers (late April) are yellow-green. Growth rates are slow and reproduction does not occur until plants are > 8 years old. (NatureServe, 2015; USFWS, 2008). Reproductive potential varies among individual Peebles Navajo cacti. Based on monitoring data, most plants become reproductive when they reach a diameter of 13 to 14 mm (Butterwick 1986). The smallest reproductive plant documented was 7 mm in diameter and produced a single flower bud (USFWS, 2022).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Desert, grassland/herbaceous (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Prefers sunny exposed areas (USFWS, 2008)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs between 5,100 and 5,650 feet in elevation (USFWS, 2008)

**Spatial Arrangements of the Population**

Adult: Widely scattered, sometimes in clumps (USFWS, 2008)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: High (inferred from USFWS, 2008)

**Site Fidelity**

Adult: High (inferred from USFWS, 2008)

**Habitat Narrative**

Adult: Habitat requirements for the PNC have been determined to include well to extremely well drained soils that formed in mixed alluvium belonging to the Gypsiorthids-Torriorthents-Haplargids Association, low soil microelement values, and the presence of vesicular-arbuscular endomycorrhizae, such as *Glomus deserticola*, for colonization of the roots (Phillips and Phillips 1995). The PNC occurs between 5,100 and 5,650 feet above sea level on gentle slopes on all facing aspects (Stuart et al. 1972; USFWS 1984; AGFD 2004). This species prefers exposed sunny weakly alkaline, gravelly soils of the Little Colorado paleochannels (Taylor, 2008), and above the Shinarump in weakly alkaline, very coarse sand to cobble gravel deposits that unconformably overlie the finer grained facies of the Chinle Formation (Burch and Anderson, 2002). It is found in Great Basin desert scrub and desert grasslands (Flora of North America Editorial Committee 2003). PNC occurs at low to moderate densities that are often widely scattered, sometimes in clumps, even when apparently suitable habitat is contiguous (Heil et al. 1981). (USFWS, 2008; NatureServe, 2015)

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends*****Population Trends:**

Unknown (NatureServe, 2015)

**Population Growth Rate:**

Slow (NatureServe, 2015)

**Number of Populations:**

2 (USFWS, 2022)

**Population Size:**

>150 (USFWS, 2022).

**Additional Population-level Information:**

We compiled count information on the Peebles Navajo cactus between 2021 and 2022. There are at least 150 Peebles Navajo cacti (Phillips 2021; Phillips et al. 2022) (Table 2). Some additional plants were found in 2022 but no numbers were provided so we assume it was a few individuals. Not all areas where the taxon has been found are searched annually. Many years may pass before an area is re-surveyed making it difficult to verify continued occupancy of an area. Earlier population estimates of approximately 1,000 individual plants rangewide cannot be substantiated with available information (Phillips et al. 1979; USFWS 1984). Based on abundance data from 1985 to 2022, the highest number of reported cacti among three monitoring plots peaked at 522 individuals in 1995, with 498 alive and 24 dead. Numbers of live cacti thereafter have continuously declined to 42 individuals presently (USFWS, 2022).

**Population Narrative:**

Growth rates are slow and reproduction does not occur until plants are > 8 years old. During the dry months, the cacti retreat below soil surface level. "Reproduction may be insufficient to maintain populations over the long term" (Arizona Ecological Services 2009). Less than 1,000 plants are known to exist in six small populations (three occurrences), in a tiny area in northern Arizona. (NatureServe, 2015). Peebles Navajo cactus is known from two core populations in Navajo County, Arizona (USFWS 2008). One population occurs on BLM-administered land near Joseph City and the second on private land near Holbrook (Figure 8). Both populations are within the Tanner Wash Area of Critical Environmental Concern (ACEC), which encompasses 4,650 acres of federal (950 acres), state trust (1,280 acres) and private (2,420 acres) lands (USFWS, 2022).

### ***Threats and Stressors***

**Stressor:** Habitat loss (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Progress has been made in identifying and protecting habitat on public and private lands that supports PNC populations since the Federal listing of this species. However, residential and commercial development, and its infrastructure, remains a potential threat to the PNC on private lands. To date, there are no long-term conservation programs, such as conservation easements, in place for these key parcels; but, stakeholders remain optimistic that such programs may be implemented in the future. Non-government organizations continue to negotiate with private property owners to this end. A total of 40 acres have been fenced from livestock, OHV, and gravel mining activities in the Tanner Wash ACEC which has effectively reduced risks to cacti from trampling or crushing. (USFWS, 2008)

**Stressor:** Non-native species (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Nonnative species, most notably camelthorn (*Alhagi maurorum*), have been identified as a potential future threat to the PNC (pers. comm. Dr. Barbara Phillips, Zone Botanist, Coconino, Kaibab, and Prescott National Forests). Commonly observed with other nonnative invasive plant species in the southwest, camelthorn may out-compete the PNC and other native species. A secondary risk of increased ground cover caused by a nonnative species is the enhanced risk of fire. The habitat in which the PNC occurs is not fire adapted and has not experienced significant fire losses to date (pers. comm. Dr. Barbara Phillips, Zone Botanist, Coconino, Kaibab and Prescott National Forests). Camelthorn has not been identified in habitat on the mesas that is occupied by PNC, but it has been observed "down below the mesas very abundantly, however, and spreading" (pers. comm. Dr. Barbara Phillips, Zone Botanist, Coconino, Kaibab and Prescott National Forests). (USFWS, 2008)

**Stressor:** Herbivory (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Small mammalian herbivores such as rabbits and/or rodents have been observed eating PNC as vegetative preferences in diet shift in response to drought conditions (Phillips and Phillips 1997; 2004). Due to the importance of precipitation on germination and recruitment of PNC cohorts, drought conditions not only adversely affect the PNC by limiting these key life history events, but synergistically amplify adverse effects of herbivory. This has the potential to appreciably affect populations of PNC because of the inherent risks associated with this species' limited recruitment potential. Predicted warming and increased drought conditions in the southwest due to global climate change are likely to accelerate and exacerbate these effects (see discussion under 2.3.2.5, below). As stated previously, predator control may also positively influence populations of rabbits and rodents, which could heighten levels of rabbit and rodent herbivory on PNC, especially during drought conditions. However, more research is necessary to confirm these relationships. (USFWS, 2008)

**Stressor:** Climate change (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Drought is identified above as a significant concern for the conservation and recovery of the PNC. Philips and Thomas (2005) provided streamflow records that indicate that the drought Arizona experienced between 1999 and 2004 was the worst drought since the early 1940s and possibly earlier. Prolonged drought conditions have been observed in the immediate region where the PNC occurs as well as other areas statewide (Phillips and Phillips 2004). Should current drought conditions persist for several years into the future, the recovery potential for the PNC may become severely compromised. The Intergovernmental Panel on Climate Change (IPCC) stated, "Warming of the climate system is unequivocal, as is now evident from observations of increases in global average air and ocean temperatures, widespread melting of snow and ice, and rising global average sea level" (IPCC 2007). According to 18 of 19 regional climate models, the levels of aridity of recent drought conditions and perhaps those of the 1950s drought years will become the new climatology for the southwestern United States within years or decades and annual mean precipitation levels will continue to decrease over the next century (Seager et al. 2007). Persistent drought conditions over years are likely to reduce the frequency and duration of flowering and/or germination events, lower the recruitment of individuals, compromise the viability of populations, lessen the recovery potential for this species, and therefore adversely affect the long-term persistence of the PNC. Increased risk of invasive species such as camelthorn and an associated increased risk of wildfire in PNC habitat, as well as increased herbivory by rabbits and rodents are identified threats that may be exacerbated by long-term drought conditions associated with climate change. (USFWS, 2008)

**Stressor:** Alternative energy (NatureServe, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Future alternative energy development needs to be considered a threat as well. For example, a large wind farm is located about 2 miles north of the northern and western most occurrence. (NatureServe, 2015)

**Stressor:** Off-highway vehicles OHVs) (NatureServe, 2015)

**Exposure:**

**Response:****Consequence:**

**Narrative:** The two western populations are about 1 mile east of Joseph City north of I-40 with the northern site potentially impacted by off-road highway use. (NatureServe, 2015)

**Stressor:** Gravel mining NatureServe, 2015)

**Exposure:****Response:****Consequence:**

**Narrative:** The eastern population, is located in close proximity to a gravel mining operation. (NatureServe, 2015)

**Recovery****Reclassification Criteria:**

1. The protection, maintenance, and enhancement of existing natural populations. (USFWS, 1984)
2. An increase in the numbers of the cactus from the present approximately 1,000 to 10,000. (USFWS, 1984)
3. Establishment of a program to curtail collecting through enforcement and through a commercial artificial propagation program. (USFWS, 1984)

Recovery Priority Number: 6

**Delisting Criteria:**

Delisting criteria are not available.

**Recovery Actions:**

- Removal of off-road vehicle use, livestock grazing, and mining from the habitat of populations on Federal lands. (USFWS, 1984)
- Designation of a restricted use area (ACEC) on BLM lands. (USFWS, 1984)
- Development of management plans for all populations. (USFWS, 1984)
- Protection of habitat for privately owned populations. (USFWS, 1984)
- Monitoring and study of existing populations. (USFWS, 1984)
- Development of an artificial propagation program to provide stock for reintroductions and to provide techniques for use in the commercial cactus trade. (USFWS, 1984)
- The recovery plan for this species requires revision. The number of plants and populations referenced in the current recovery plan that are required for long-term viability of the species are unrealistic and should be revised. Recovery criteria should focus on habitat protection and acquisition, seed banking, researching dispersal mechanisms, seed collection and long-term storage, as well as inclusion of this species into the Center for Plant Conservation Collection. (USFWS, 2008)
- In addition, coordination with species experts needs to occur with an emphasis on conservation planning with respect to implementation of actions in the event of continuing long-term drought. These activities may include, but are not limited to, exploring new areas

- for transplants, captive propagation and reintroduction, or other means to help secure existing populations using artificial means (water supplementation, etc.). (USFWS, 2008)
- Because the known historical and current distribution of the PNC is limited, the Service views these actions as essential, in conjunction with continued management and enforcement of protection measures. The Service also recommend concerted efforts be implemented to ensure long-term viability of this species on private lands through various conservation incentive programs available to private landowners. (USFWS, 2008)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. If possible, given workloads, a Species Status Assessment could be conducted to guide the development of a revised recovery plan. We recommend revision of Peebles Navajo cactus recovery criteria. Specifically, the number of plants and populations referenced in the current recovery plan as necessary for long-term viability of the species are unrealistic, based on our knowledge of the species, and should be revised. The recovery criteria for downlisting and delisting should be adjusted accordingly. 2. Improve coordination with BLM and develop creative approaches to protect the Peebles Navajo cactus, including investing necessary resources in mitigating bottom-ash deposition, ensuring exclosure fences are maintained, and working with local partners to increase conservation efforts aimed at recovery the cactus. 3. Continue to survey areas within the species' revised range to verify the presence or absence of suitable habitat. Surveys should also focus on areas that may support future reintroductions of the Peebles Navajo cactus for recovery purposes. 4. Establish an off-site conservation program to develop captive propagation techniques that follow the Center for Plant Conservation best management practices. Conduct studies to evaluate the effectiveness of seed germination and seedling establishment. Establish a new population within Peebles Navajo cactus native habitat as a pilot project to ensure the taxon remains extant. 5. Develop incentives in the Tanner Wash ACEC to manage livestock grazing and OHV use or other recreational activities in a manner that does not result in habitat disturbance to the Peebles Navajo cactus. 6. Investigate the pollination system of Peebles Navajo cactus to identify and understand potential factors that are contributing to low recruitment, poor seed set, and fruit abortion. 7. Evaluate and test new technologies that improve the detection of rare, cryptic plants. 8. Implement concerted efforts to ensure long-term viability of this species on private lands through various conservation incentive programs available to private landowners. 9. Establish coordination meetings with the USFWS, BLM Safford District Office, and Museum of Northern Arizona to improve collaboration, discuss annual monitoring results, and proactive management of the cactus. 10. Develop public awareness and support for the conservation of the Peebles Navajo cactus (USFWS, 2022)..

## SPECIES ACCOUNT: *Pediocactus winkleri* (Winkler cactus)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 08/20/1998; Mountain-Prairie Region (R6) (USFWS, 2016)

### **Physical Description**

Winkler cactus (*Pediocactus winkleri*) was first discovered by Agnes Winkler in the late 1960's. It is a small, sub-globose cactus. Individuals range in size from 0.5 to 7 cm tall and 0.5 to 8 cm in diameter. Stems, which are ribbed with tubercles 0.4 - 0.7 cm long, are normally solitary but may be multi-stemmed, especially if damaged. Spine-bearing areoles are borne at the apex of the tubercles. The areoles are elliptic and densely wooly pubescent with spines obscuring or partially obscuring the stem. Central spines are lacking; radial spines commonly number 9 to 11. The spines are 1.5 - 4 millimeters (mm) long. Flowers are 1.7 to 2.2 cm in length with peach to pink color. Stamens are yellow and stigmas are green. The fruit is 0.7 to 1.0 cm long with a smooth surface, initially green turning reddish-brown with age. Seeds are shiny black. For a complete technical description of the Winkler cactus, please refer to Heil (1979) and Welsh et al. (2008).

### **Current Range**

Winkler cacti grow on fine textured alkaline soils derived primarily from the following geologic formations: Dakota, Morrison, Summerville, Entrada and Emery sandstone member of the Mancos formation (Heil 1984, Neese 1987, Clark 1998b, Clark 1999). It is generally found at elevations between 1,500 and 2,130 meters (4,900 and 7,000 feet) on rocky, alkaline hill tops and benches, and gentle slopes on barren, open sites in salt desert shrub communities. Heil (1984) describe it as typically occurring on the tops and sides of rocky hills or benches in *Atriplex* (saltbush) dominated desert shrub communities. Winkler cactus is endemic to Wayne, Emery and Sevier counties in south central Utah. Populations of the species occur primarily on lands managed by the Utah BLM through the Richfield Field Office and by the NPS at CRNP. The range of Winkler cactus extends approximately 48 km (30 miles) in a narrow band from Notom in central Wayne County to the Last Chance Desert in southwestern Emery County, Utah. Plants are estimated to occupy only 80 hectares (200 acres) within this band (Spector 2013b). The majority of the known populations occur on lands managed by BLM.

### **Critical Habitat Designated**

Yes;

### **Life History**

#### **Food/Nutrient Resources**

#### **Lifespan**

Adult: ~ 14 years

#### **Breeding Season**

Adult: Flowering occurs from April through mid-May and fruits are set mid-May to June.

#### **Reproduction Narrative**

Adult: Winkler cacti are typically only above ground during the growing season. When temperatures increase in mid-February or early March and rainfall is adequate, cacti emerge from below ground to flower. The cactus stem emerges up to 5 cm above ground. Flowering occurs from April through mid-May and fruits are set mid-May to June. The specific time varies from year to year apparently due to temperature and moisture conditions of late winter and early spring. After flowering, the plants shrink back to ground surface or below defending themselves against an annual cycle of extreme heat, drought and cold. Resurfacing in the spring appears to be dependent on winter and spring moisture (Clark 1999). Winkler cactus can survive underground for up to two years during drought conditions (Clark and Clark 2008a). We do not fully understand the factors leading to dormancy in Winkler cactus. Reproduction is presumed to be primarily sexual. No research has been conducted on pollination mechanisms, pollinators or seed germination success for Winkler cactus. Work conducted on the closely related San Rafael cactus found that species to be self-incompatible and pollinated by several native bee species. Pollination of species that reproduce sexually and are self-incompatible is necessary to produce viable seeds. Seedling ecology is unknown (San Juan College 1994). Winkler cactus is a long lived species. The lifespan of Winkler cactus is unknown but we know they live at least 14 years and most likely even longer. Information from a long-term study shows that Winkler cactus can survive at least 12-14 years (Clark and Clark 2008a). We do not know how old the Winkler cacti were when they were marked for the study and we do not know how long they lived after the study ended so it is highly likely the species can live longer than 14 years.

#### **Environmental Specificity**

Adult: Alkaline soils

#### **Habitat Narrative**

Adult: Winkler cactus is endemic to specific, fine textured soils derived from the Dakota formation and Morrison formation in the lower Fremont River in Wayne County and southeast Sevier Counties of south-central Utah. It is generally found at elevations between 1,500 - 2,130 meters (m) (4,900 - 7,000 feet (ft)) on rocky, alkaline hill tops and benches, and gentle slopes on barren, open sites in salt desert shrub communities. These communities are associated with species such as Indian rice grass (*Achnatherum hymenoides*), blue grama (*Bouteloua gracilis*), curly grass (*Pleuraphis jamesii*), alkali sacaton (*Sporobolus airoides*), sand hill muhly (*Muhlenbergia pungens*), prickly pear cactus (*Opuntia polyacantha*), Mormon tea (*Ephedra torreyana*), little-leaf mountain mahogany (*Cercocarpus intricatus*), shadscale (*Atriplex confertifolia*), four-wing salt bush (*Atriplex canescens* var. *canescens*), phlox (*Phlox* spp.), locoweed (*Astragalus* spp.), halogeton (*Halogeton glomeratus*), snakeweed (*Gutierrezia sarothrae*), and viscid rabbitbrush (*Chrysothamnus viscidiflorus*). It is also found among piñonjuniper (*Pinus edulis*-*Juniperus osteosperma*) woodland stands (Clark 2008; Welsh et al. 2003). (USFWS, 2015)

#### ***Dispersal/Migration***

#### ***Population Information and Trends***

##### **Number of Populations:**

4 (USFWS, 2019)

**Population Size:**

5700 (USFWS, 2019)

**Population Narrative:**

In 2016, we documented 5,700 individual Winkler cactus in 4 populations (USFWS 2016). Since that time, five new occurrences were documented within the Park, as well as additional individuals within existing occurrences. The total number of new individuals documented within the Park since 2016 is 244 (Borthwick 2017, pers. comm.). However, the Park and the BLM also documented declines in Winkler cactus at monitoring sites 2017 and 2018, but no mortality numbers are available (Borthwick and Livensperger 2019; Rooks 2019). (USFWS, 2019)

**Threats and Stressors**

**Stressor:** Off-highway vehicle (OHV) use and other recreational activities, and impacts associated with roads (USFWS, 2015)

**Exposure:** Moderate

**Response:** Basic need inhibited/injury/mortality

**Consequence:**

**Narrative:** In summary, and based on available information regarding OHV use in Winkler cactus habitat, OHV use has a documented detrimental effect on cactus and cactus habitat. Although direct impacts from OHV appears to be low, the little amount of compliance data for OHV use on BLM and SITLA land over the entire range where Winkler cactus occurs and the proximity of significant percentages of the population to unpaved roads and OHV routes is cause for concern. Therefore, we designate the threat level from OHV use and impacts associated with roads for Winkler cactus as moderate. This level may be reassessed if more detailed OHV use and compliance data near Winkler cactus occurrences is collected showing high rates of compliance. (USFWS, 2015)

**Stressor:** Livestock grazing (USFWS, 2015)

**Exposure:** Moderate

**Response:** Basic need inhibited/injury/mortality

**Consequence:**

**Narrative:** In summary, the negative effects to Winkler cacti from livestock grazing increase with increasing livestock use. Very few to no cacti were recorded as trampled during low to moderate livestock activity. As livestock activity increases, so does disturbance levels near cacti (Clark 2008b). There is extremely high grazing pressure throughout the majority of the species' range. The negative impacts of livestock grazing on the species and the habitat are well documented. Additionally, livestock grazing exacerbates other threat factors (including response to drought potentially caused by climate change and predation). Therefore, we designate a high threat level to Winkler cactus from livestock grazing and trampling. This threat level may be reassessed if changes in land use and grazing pressure on Winkler cactus populations occur. (USFWS, 2015)

**Stressor:** Native Ungulate Disturbance (USFWS, 2015)

**Exposure:** Small

**Response:** Basic need inhibited/injury/mortality

**Consequence:**

**Narrative:** Monitoring shows that elk and deer prints near listed cacti at Capitol Reef National Park are not as severe or regularly occurring as that from livestock. Elk prints within 15 cm (5.9

in) of Winkler cacti ranged from 2-10 percent of cacti surveyed in 2011-2012. Deer prints were found within 15 cm (5.9 in) of only 1-1.7 percent of Winkler cactus (NPS 2013). Between 2011 and 2013, five survey sites in the Hartnet population within CRNP had greater than 5 percent disturbance rates by native ungulates (22-31 percent), which correlated with the survey sites that had lower amounts of disturbance by livestock. Of the 2,380 plants surveyed in CRNP between 2011 and 2013, 15 were recorded as being trampled by elk (NPS 2013). In the Hartnet population outside of CRNP and in the Notom population, native ungulate disturbance was found at only 1 percent of surveyed cacti and no damage was recorded. This discrepancy may be due to the higher elevations of some of the survey sites at CRNP. Surveys for native ungulate disturbance have not been performed at the Blue Bench population. Due to the localized nature of native ungulate impacts, we designate a low threat level for native ungulate disturbance at this time. This level may be reassessed if native ungulate patterns change or additional populations in areas of high use by native ungulates are discovered. (USFWS, 2015)

**Stressor:** Energy and Mineral Exploration and Development (USFWS, 2015)

**Exposure:** Moderate

**Response:** Basic need inhibited/mortality

**Consequence:**

**Narrative:** In summary, the detrimental effects of energy and mineral exploration and development are well documented, but there is a general lack of current and historic mining activity and oil and gas development within the range of the species and low potential in the foreseeable future. Therefore, we designate a low threat level for energy and mineral exploration and development on Winkler cactus at this time. Surface disturbance permitting on active mining claims or the sale of leases for fluid or non-energy solid minerals within the range in the future could cause the threat level to increase, as could discovery of additional populations in areas with more active mineral development. (USFWS, 2015)

**Stressor:** Road and Utility Corridor Development or Other Construction (USFWS, 2015)

**Exposure:** Small

**Response:** Basic need inhibited/mortality

**Consequence:**

**Narrative:** Unauthorized utility and road development within the Notom population of Winkler cactus caused individual plant mortality and habitat degradation in 1995 (63 FR 44587, August 20, 1998). Currently, no plans for road or utility corridor development intersect with known San Rafael or Winkler cactus populations. One construction project exists that will impact San Rafael cactus. The Natural Resources Conservation Service is proposing to raise the level of the Millsite Reservoir Dam and this will affect several individual San Rafael cacti by flooding and increased recreational impacts; however, impacts from this project to the range-wide population of San Rafael cactus will be minimal (NRCS 2015). There are many existing roads within both species' habitat, primarily unpaved. Several populations or portions of populations of both species are located directly along dirt roads. Maintenance of these roads may impact individuals and care should be taken by local authorities to avoid cactus populations when performing this maintenance. Because there is no currently pending construction, road, or utility corridor development projects within known occupied habitat of Winkler cactus and only one pending project in known occupied habitat of San Rafael cactus, we designate a low threat level for road and utility corridor development or other construction for Winkler cactus and San Rafael cactus at this time. This level may be reassessed if new projects are put forward that would impact known cacti populations, or if new populations are discovered that would be impacted by road

and utility corridor development projects. (USFWS, 2015)

**Stressor:** Invasive Species (USFWS, 2015)

**Exposure:** Moderate

**Response:** Basic need inhibited

**Consequence:**

**Narrative:** In summary, there is a low incidence of invasive species in cacti habitat. There is also and the lack of high risk level at this time to any particular population or portion of a population, although there is legitimate concern that predation from insects or rodents on cacti may increase in the future. (USFWS, 2015)

**Stressor:** Commercial and Hobby Collecting (USFWS, 2015)

**Exposure:** High

**Response:** Mortality

**Consequence:**

**Narrative:** In summary, there is a known historic impact on these species from illegal collect. The current scale of illegal collection is unknown, although many populations have locations well known to cactus collectors. However, new sites and populations have been discovered recently which are less accessible and not well known to collectors. Therefore, we designate a moderate threat level from illegal commercial and hobby collecting for Winkler cactus and San Rafael cactus. This threat level may be reassessed if hard data on collecting activities is obtained or new methods of protection for cactus at vulnerable sites are implemented (Factor D). (USFWS, 2015)

**Stressor:** Small mammal and insect predation (USFWS, 2015)

**Exposure:** Moderate

**Response:** Basic need inhibited/injury/mortality

**Consequence:**

**Narrative:** In summary, despite the potential for the cactus borer beetle to impact the cacti, we have found no conclusive information to indicate that it is having an unprecedented, population level effect on Winkler cactus or San Rafael cactus. The recently documented die-offs from beetle borer may be part of the species' natural life cycle. The recent levels of recorded damage or mortality to San Rafael cactus and Winkler cactus from insects and rodents during recent surveys are relatively low. Also, the predators thus far recorded have been species native to the ecosystem. Therefore, we designate a low threat level for insect and rodent predation on Winkler cactus and San Rafael cactus at this time. This threat level will be reassessed if data shows pressure from predation to be increasing due to climate change or other factors, or that predation poses a substantial threat to particular populations. (USFWS, 2015)

**Stressor:** Inadequacy of Federal, State, and Local Laws and Regulations ( USFWS, 2015)

**Exposure:** Moderate

**Response:** Basic need inhibited/injury/mortality

**Consequence:**

**Narrative:** In summary, existing regulatory mechanisms, secured through the ESA, have reduced some threats on Federal lands. In the absence of the ESA's protective regulatory mechanisms, we believe the threats to the species would be amplified and cause further declines to both species. There are no state laws specifically protecting the species in Utah. Without the protection of the ESA, impacts to the species from OHV use, livestock grazing, and recreational activities would likely increase. These activities can kill or damage cacti, and degrade cactus habitat. In addition,

the lack of monitoring data makes it difficult to determine the species' needs and provide long-term protection. Reducing pressure on the species from collection and unauthorized access is difficult because of limited law enforcement resources and the remoteness of the habitat. Continued efforts are needed through law enforcement and habitat protection to ensure the species is protected over the long-term and the ESA provides the legal protection to the species to enforce unauthorized harvest. We therefore determine the inadequacy of regulatory mechanisms is a moderate threat to Winkler cactus and San Rafael cactus. This threat level may be reassessed if management policies that specifically address the protection of Winkler cactus and San Rafael cactus independent of the ESA are enacted throughout significant portions of their range. (USFWS, 2015)

**Stressor:** Climate Change (USFWS, 2015)

**Exposure:** High

**Response:** Basic need inhibited/mortality

**Consequence:**

**Narrative:** In summary, climate change and its impacts to the region are well documented and projected to continue and increase. There was a documented decline of Winkler cactus during the 1999-2003 drought, and the similarity of San Rafael to Winkler cactus suggests a comparable response. (Clark and Clark 2008). Additionally, rare plants have a negative response to drought (Roth 2003, 2004; Van Buren and Harper 2003, 2004), and drought severity and frequency is set to increase due to climate change (IPCC 2007; Karl et al. 2009). Therefore, we designate a high threat level from global climate change on Winkler cactus and San Rafael cactus. There are uncertainties in our threat evaluation since downscaled climate projections are not available for our specific location, and a vulnerability assessment has not been performed for these species. We will re-assess the degree of threat climate change poses when more specific information becomes available. (USFWS, 2015)

## ***Recovery***

### **Delisting Criteria:**

P-1. Based on analysis and modeling implemented under the recovery actions trends for San Rafael cactus and Winkler cactus populations are shown to be stable or improving according to the following measures: Species presence is maintained at all known Winkler cactus populations and (1) These criteria must be met for all known Winkler cactus populations due to the low number of known populations at this time. If additional Winkler cactus populations are discovered in the future, it may be determined that delisting is appropriate even if some populations are not stable or increasing, and (2) Predictive modeling using data from an additional 10-year period (30 years total), collected in accordance with a standardized monitoring protocol, provides an indication of long-term demographic stability as well as a projected survival probability of at least 95 percent over 100 years for each species. (USFWS, 2015)

T-1. Federal land protection through long-term management agreements or plans is achieved for all known Winkler cactus populations. Protection considerations from grazing impacts, development, mining, oil and gas, and recreation must be included in the management agreements and the protected areas must meet the size and connectivity parameters determined through research to be adequate to sustain those populations. These may include but are not limited to resource management plans, conservation agreements, recreation

management plans, and travel management plans. (USFWS, 2015)

P-2. Based on best available data, the available habitat base for each recovery population of each species is of sufficient quality and large enough to allow for natural population dynamics, population expansion where needed, and the continued presence of pollinators, with sufficient connectivity to allow for needed gene flow within and, where possible, among populations. (USFWS, 2015)

T-2. Management agreements or plans in place and being implemented for all Winkler cactus populations on all federal lands must include measures to address and curtail illegal collection activities. These plans should include criteria for appropriate law enforcement at correct times and places to prevent illegal collection and sales of plants or any plant parts. (USFWS, 2015)

T-3. Adverse population-level effects from herbivory, disease, or predation, if any, are identified, monitored and abated to the extent that all known Winkler cactus population trends are stable or increasing, as evidenced by demographic monitoring results from studies that have adhered to monitoring protocols developed under recovery action 2.4. Programs to control excessive herbivory or predation will be developed to adaptively manage each population per criterion P-3, and must take into consideration the degree which climate change may impact disease or herbivory levels in the future. (USFWS, 2015)

T-4. Land protection covering the habitat of all populations for each species and/or statutory and regulatory protections for plants are such that the protections of the ESA are no longer needed to compensate for regulatory inadequacies. (USFWS, 2015)

T-5. A long-term ex-situ conservation program is ongoing for all extant Winkler cactus populations. This would include seed collection and storage, germination and viability trials, and development of a protocol for successful reproduction under greenhouse conditions. This would help avert the risk of extinction from stochastic events or environmental catastrophes. (USFWS, 2015)

T-6. In conjunction with recovery criterion P-2, the available habitat base for each of the populations designated under criterion P-1 is of sufficient quality and large enough to offset the threat of loss or restriction of the species' pollinators and impacts from climate change, if feasible. Effective measurement criteria will be developed through research under Recovery Action 3. (USFWS, 2015)

**Recovery Actions:**

- Protect and conserve known extant Winkler cactus and San Rafael cactus populations and their habitat.
- Survey for additional populations, and monitor all populations in order to apply conservation measures where and when needed.
- Conduct in depth research into the biology, requirements, threat responses, and life histories of both species in order to develop and implement appropriate management practices for the purposes of achieving recovery.
- Promote communication by encouraging and creating dialog regarding these species between managing agencies, land owners, developers, and the public in order to raise awareness and aid recovery.

- Coordinate and work together with all stakeholders to achieve recovery.

***Conservation Measures and Best Management Practices:***

- Recommended future actions: We recommend rangewide surveys of known populations for Winkler cactus and San Rafael cactus, and that survey results be used to compile a robust, updated population estimate. Additional research that provides a better understanding of current population demographics, population trends, and the impact of and response to the primary threats is vital to evaluating these species' status in the future and to developing updated and meaningful recovery criteria and actions. The designation and management of protected areas that reduce impacts from identified threats may be necessary to facilitate this species' recovery. Additionally, we recommend updating and finalizing the draft recovery plan and specifically reevaluating the recovery goals and criteria based on new population numbers, habitat requirements, connectivity analysis, and recent and upcoming changes in management and conditions that may result in changes to threat intensity and scope. (USFWS, 2019)

## SPECIES ACCOUNT: *Penstemon debilis* (Parachute beardtongue)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 08/26/2011; Mountain-Prairie Region (R6) (USFWS, 2016)

#### **Physical Description**

A mat-forming perennial herb with thick, blue-green leaves, each about 2 cm long and 1 cm wide. Funnel-shaped, white to pale lavender flowers bloom June-July (NatureServe, 2015).

#### **Taxonomy**

Parachute beardtongue was discovered in 1986, and was first described by O’Kane and Anderson in 1987 (USFWS, 2016). Traditionally, the genus *Penstemon* was included in the Scrophulariaceae (figwort) family. However, *Penstemon* is now considered to be within the Plantaginaceae (plantain) family due to recent research using DNA sequences (Oxelman et al. 2005, p. 415) (USFWS, 2013).

#### **Historical Range**

The historical range and distribution for this species is unknown (USFWS, 2016). *Penstemon debilis* is endemic to Garfield County, Colorado (NatureServe, 2015).

#### **Current Range**

All of the currently known occurrences occupy about 91.8 ac (37.2 ha) on the Green River geologic formation in Garfield County, Colorado (USFWS, 2016).

#### **Critical Habitat Designated**

Yes; 8/13/2012.

#### **Legal Description**

On August 13, 2012, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Penstemon debilis* (Parachute beardtongue) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes four critical habitat units (CHUs), in Colorado (77 FR 48356-48415).

#### **Critical Habitat Designation**

The critical habitat designation for *Penstemon debilis* includes four CHUs in Garfield County, Colorado. This species critical habitat encompasses approximately 15,510 acres (ac) (6,277 hectares (ha)) (77 FR 48356-48415).

Unit 1, the Brush Mountain Unit, consists of 1,437 ac (582 ha) of federally owned lands, managed by BLM through the Grand Junction Field Office. It is located approximately 16 mi (26 km) northwest of the town of DeBeque in Garfield County, Colorado. It is northwest of the intersection of Roan Creek Road (County Road 204) and Brush Creek Road (County Road 209). This Unit is not currently occupied. This Unit has all the physical and biological features essential to the conservation of the species, including the Rocky Mountain Cliff and Canyon plant community (NatureServe 2004, spatial data) with less than 10 percent plant cover, suitable elevational ranges of 6,234 to 8,222 ft (1,900 to 2,506 m), outcrops of the Parachute Creek Member of the Green River Formation, steep slopes of these soil outcrops that lend to the

appropriate disturbance levels, pollinator habitat, and a climate with between 12 to 18 in. (30 and 46 cm) in annual rainfall and winter snow. Because of the presence of these features, we believe this may make a good introduction area for *Penstemon debilis* in the future and is needed to ensure conservation of the species. The primary threat to *Penstemon debilis* in this Unit is energy development and associated activities. *Penstemon debilis* consists of only 4,100 known individuals (little redundancy), and all occur within 2 concentrated areas (little resilience). For adequate redundancy and resiliency, we believe it is necessary for survival and recovery that additional populations be established. Therefore, we have identified this Unit as critical habitat for *P. debilis*.

Unit 2, the Cow Ridge Unit, is 4,819 ac (1,950 ha) of federally owned lands managed by BLM through the Grand Junction Field Office. It is located approximately 8 mi (13 km) northwest of the town of DeBeque in Garfield County, Colorado, and north of Dry Fork Road. This Unit is not currently occupied. This Unit has all the physical and biological features essential to the conservation of the species, including the Rocky Mountain Cliff and Canyon plant community (NatureServe 2004, spatial data) with less than 10 percent cover, suitable elevational ranges of 6,273 to 8,284 ft (1,912 to 2,525 m), outcrops of the Parachute Creek Member of the Green River Formation, steep slopes of these soil outcrops that lend to the appropriate disturbance levels, habitat for pollinators, and a climate with between 12 to 18 in (30 and 46 cm) in annual rainfall and winter snow. Because of the presence of these features, we believe this may make a good introduction area for *Penstemon debilis* in the future and is needed to ensure conservation of the species. The primary threat to *Penstemon debilis* in this Unit is energy development and associated activities. *Penstemon debilis* consists of only 4,100 known individuals (little redundancy) and all within 2 concentrated areas (low resilience). For adequate redundancy and resiliency, we believe it is necessary for survival and recovery that additional populations be established. Therefore, we have identified this Unit as a CHU for *P. debilis*.

Unit 3, the Mount Callahan Unit, consists of 4,369 ac (1,768 ha) of Federal and private land. It is located approximately 2 mi (3 km) west of the town of Parachute on the south-facing slopes of Mount Callahan and westward along the cliffs of the Roan Plateau. Fifty-five percent of Unit 3 is managed by the BLM under the management of two field offices: 80 Percent of these Federal lands are managed by the Colorado River Valley Field Office and 20 percent are managed by the Grand Junction Field Office. Oxy has been a partner in the conservation of *Penstemon debilis* since 1987. We have excluded all Oxy lands based on: (1) This continuing partnership, (2) existing CNA Agreements (674 ac (273 ha)) for two CNAs (the Mount Callahan and Mount Callahan Saddle), (3) commitments to create a third CNA (the Logan Wash Mine Natural Area) totaling 82 ac (33 ha), (4) already-implemented and further commitments to develop Best Management Practices for the CNAs as well as other adjacent lands, and (5) commitments on Oxy lands to conserve newly discovered *P. debilis* populations with more than 75 individuals. This exclusion totals 3,350 ac (1,356 ha). These exclusions are discussed in further detail below under Exclusions. Three percent of this Unit falls on private lands. This Unit is currently occupied. Once Oxy lands were excluded, four parcels (two BLM and two private) of land remained along the northern edge of the CHU, as proposed. We have elected not to include three (both BLM and one of the two private parcels) of these four parcels in our critical habitat designation because: (1) They would be isolated from the rest of Unit 3; (2) they contain no suitable habitat for *Penstemon debilis* (only pollinator habitat); (3) the pollinator and habitat protection measures on Oxy lands will provide adequate protections for the pollinators on their lands, making these three parcels less important; and (4) they are distant (at least 2,133 ft (650 m)) from occupied

and suitable habitat; and (5) we believe they are not necessary for the conservation of the species. The remaining private parcel (137 ac (55 ha)) is closer to occupied habitat, contains suitable habitat, and, therefore, is included in our critical habitat designation. This Unit currently has all the physical and biological features essential to the conservation of *Penstemon debilis*, including the Rocky Mountain Cliff and Canyon plant community (NatureServe 2004, spatial data) with less than 10 percent cover, suitable elevational ranges of 5,413 to 8,809 ft (1,650 to 2,685 m), outcrops of the Parachute Creek Member of the Green River Formation, suitable pollinators and habitat for these pollinators, steep slopes of these soil outcrops that lend to the appropriate disturbance levels, and a climate with between 12 to 18 in (30 and 46 cm) in annual rainfall and winter snow. The primary threat to *Penstemon debilis* and its habitat in this Unit is energy development and associated activities.

Unit 4, the Anvil Points Unit, consists of 4,885 ac (1,977 ha) of Federal and private land. It is located approximately 1 mi (2 km) north of the town of Rulison in Garfield County, Colorado. Seventy percent of this Unit is managed by the BLM, Colorado River Valley Field Office. Twenty-three percent of the Unit (1,102 ac (446 ha)) is within several potential BLM Areas of Critical Environmental Concern (ACECs). If these become ACECs, they would have several stipulations to protect *Penstemon debilis*, particularly from oil and gas development. These areas are discussed further in the proposed (75 FR 35732; June 23, 2010) and final listing rules (76 FR 45054). Thirty percent of this Unit is on private lands. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of *Penstemon debilis*, including the Rocky Mountain Cliff and Canyon plant community (NatureServe 2004, spatial data) with less than 10 percent plant cover, suitable elevational ranges of 6,318 to 9,288 ft (1,926 to 2,831 m), outcrops of the Parachute Creek Member of the Green River Formation, suitable pollinators and habitat for these pollinators, steep slopes of these soil outcrops that lend to the appropriate disturbance levels, and a climate with between 12 to 18 in (30 and 46 cm) in annual rainfall and winter snow. The primary threat to *Penstemon debilis* and its habitat in this Unit is energy development and associated activities. This Unit falls within the boundary of the BLM's Roan Plateau RMP. The RMP has two lease stipulations that directly address endangered, threatened and candidate plants. A no surface occupancy lease stipulation (NSO-12) protects occupied habitat and adjacent potential habitat from ground disturbing activities, with narrow exceptions. A controlled surface use stipulation (CSU-12) protects special status plant species and plant communities by authorizing BLM to impose special design, operation, mitigation and reclamation measures, including relocation of ground disturbing activities by more than 200 meters, with some exceptions. Special management considerations and protections are thus contemplated.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Penstemon debilis* critical habitat consists of five components (77 FR 48356-48415):

(i) Suitable soils and geology. (A) Parachute Member and the Lower Part of the Green River Formation. (B) Appropriate soil morphology characterized by a surface layer of small to moderate shale channers (small flagstones) that shift continually due to the steep slopes and below a weakly developed calcareous, sandy to loamy layer with 40 to 90 percent coarse material.

(ii) Elevation and climate. Elevations from 5,250 to 9,600 ft (1,600 to 2,920 m). Climatic conditions similar to those of the Mahogany Bench, including suitable precipitation and temperatures.

(iii) Plant community. (A) Barren areas with less than 10 percent plant cover. (B) Other oil shale endemics, which can include: *Mentzelia rhizomata*, *Thalictrum heliophilum*, *Astragalus lutosus*, *Lesquerella parviflora*, *Penstemon osterhoutii*, and *Festuca dasyclada*. (C) Presence of *Penstemon caespitosa* for support of pollinators and connectivity between sites.

(iv) Habitat for pollinators. (A) Pollinator ground, twig, and mud nesting areas. Nesting and foraging habitats suitable for a wide array of pollinators and their life-history and nesting requirements. A mosaic of native plant communities and habitat types generally would provide for this diversity (see paragraph (2)(iii) of this entry). These habitats can include areas outside of the soils identified in paragraph (2)(i) of this entry. (B) Connectivity between areas allowing pollinators to move from one population to the next within units. (C) Availability of other floral resources such as other flowering plant species that provide nectar and pollen for pollinators. Grass species do not provide resources for pollinators. (D) A 3,280-ft (1,000-m) area beyond occupied habitat to conserve the pollinators essential for plant reproduction.

(v) High levels of natural disturbance. (A) Very little to no soil formation. (B) Slow to moderate but constant downward motion of the oil shale that maintains the habitat in an early successional state.

### **Special Management Considerations or Protections**

The features essential to the conservation of this species (plant community and competitive ability, elevation, slope, soils, climate, reproduction, and disturbance regime) may require special management considerations or protection to reduce threats. Extremely low numbers and a highly restricted geographic range make *Penstemon debilis* particularly susceptible to becoming endangered in the foreseeable future. Threats to the species and its habitat include energy development, road maintenance, and inadequacy of existing regulatory mechanisms (76 FR 45054). Special management considerations or protections are required within critical habitat areas to address these threats. Management activities that could ameliorate these threats include (but are not limited to): The introduction of new *Penstemon debilis* populations; the establishment of permanent conservation easements or the acquisition of land to protect the species on private lands; the continuation and adequate management of *P. debilis* through the CNA Agreement with Oxy (see Exclusions section below); regulations and/or agreements that balance conservation with energy development in areas that would affect the species and its pollinators; the designation of protected areas with specific provisions and protections for the plant; the elimination or avoidance of activities that alter the morphology and status of the shale slopes; and avoidance of placing roads in habitats that would affect the plant or its pollinators. These management activities would protect the PCEs for the species by preventing the loss of habitat and individuals, maintaining or restoring plant communities and natural levels of competition, protecting the plant's reproduction by protecting its pollinators, and managing for appropriate levels and types of disturbance.

### **Life History**

### **Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2016); asexual: vegetative (inferred from NatureServe, 2015)

**Lifespan**

Adult: Long-lived (NatureServe, 2015)

**Dependency on Other Individuals or Species**

Adult: *Osmia brevis* (NatureServe, 2015)

**Breeding Season**

Adult: June - July (NatureServe, 2015)

**Key Resources Needed for Breeding**

Adult: Bee pollinators, several months of moist chilling (NatureServe, 2015)

**Reproduction Narrative**

Adult: This species is long-lived and thought to be slow to reach reproductive maturity. It is also thought that species with these life history characters have low reproductive rates (O'Kane and Broderick 2004). *Penstemon debilis* flowers from mid-June to mid-July (Scheck 1994) and fruits in mid July - August (CNHP 1998). The plants are bee pollinated and *Osmia brevis* is the primary pollinator. Amy McMullen at Utah State University is currently researching the biology of *P. debilis*. The following was compiled from her 1997 field season findings, unless otherwise stated: *P. debilis* requires several months of moist chilling to break dormancy. Breeding system experiments found low fruit production. This species does seem to be well adapted to its habitat, producing long rhizomes in response to a shifting substrate (NatureServe, 2015). Parachute beardtongue plants require cross pollination, and have many different pollinators that vary between occurrences (USFWS, 2016).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Parachute Creek Member of the Green River Formation (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: < 10% plant cover, > 15% slope, shifting slopes that maintain early successional habitat (USFWS, 2012); high insolation (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 5,250 to 9,600 ft. elevation (USFWS, 2013); > 10% plant cover (inferred from USFWS, 2012)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits oil shale outcrops, on south-facing, steep white shale talus on the Mahogany Zone of the Parachute Creek Member of the Green River Formation. The substrate is a mixture of thin shale fragments and clay. The barren, white surface of the slopes creates a very high insolation. Vegetation is sparse but other species, including at least 4 other oil shale endemics, occur as scattered individuals on the slopes. Associated species include: *Agropyron spicatum*, *Cercocarpus montanus*, *Chrysothamnus viscidiflorus*, *Cymopterus hendersonii*, *Eriogonum lonchophyllum*, *Galium coloradoense*, *Holodiscus dumosus*, *Machaeranthera grindeliodes*, *Monardella odoratissima*, *Astragalus lutosus*, *Festuca dasyclada*, *Mentzelia argillosa*, *Thalictrum heliophilum* (O'Kane and Anderson 1987), *Penstemon caespitosus*, and *P. mensarum* (A. McMullen, pers. comm. 1998). The environmental specificity is narrow; the substrate is relatively common in the region, but the plant is rare and may have other specific requirements (NatureServe, 2015). The Service has identified a suitable elevation range from 5,250 to 9,600 ft. (1,600 to 2,920 m) that allows for pollinator habitat and changing climate (77 FR 48368) (USFWS, 2013). Sparse vegetation (with less than 10 percent plant cover), assembled of other oil shale specific plants, including *P. caespitosus*, and not dominated by any one species; moderate to steep slopes, generally over 15 percent slope; slow to moderate, but constant, downward motion of the oil shale that maintains the habitat in an early successional state are physical or biological features for this plant (USFWS, 2012).

**Dispersal/Migration****Dispersal**

Adult: Low (inferred from USFWS, 2016)

**Dispersal/Migration Narrative**

Adult: Parachute beardtongue plants produce a small number of seeds that are dispersed by gravity (USFWS, 2016).

**Population Information and Trends****Population Trends:**

Unknown (NatureServe, 2015)

**Species Trends:**

10 - 30% decline (NatureServe, 2015)

**Representation:**

Representation describes the ability of a species to adapt to changing environmental conditions. A genetic study of the species suggests moderate levels of inbreeding, but no inbreeding depression (Wolfe et al. 2014). Genetic diversity among subpopulations is moderate. However, diversity within subpopulations is low, suggesting that the smaller, more isolated subpopulations may be at risk for inbreeding depression. The small geographic area and nearly identical geological substrate where Parachute beardtongue is found suggests that subpopulations exhibit little ecological variability and the species may not tolerate changes in habitat or climatic conditions. Therefore, maintaining genetic diversity within and among

subpopulations is especially important to preserve Parachute beardtongue representation. (USFWS, 2020)

**Redundancy:**

Redundancy describes the number and distribution of the populations and the ability of a species to withstand catastrophic events. Species with a greater number of populations that are more widely distributed are generally at lower risk to catastrophic events than species with fewer populations that are closely distributed. The six subpopulations of Parachute beardtongue we see today are what remain of a once larger continuous population. They are distributed across a very small geographic range, where a catastrophic event could impact multiple subpopulations. (USFWS, 2020)

**Number of Populations:**

5 subpopulations (USFWS, 2024)

**Population Size:**

4,546 individual plants rangewide (USFWS, 2024)

**Adaptability:**

Low (inferred from USFWS, 2013)

**Population Narrative:**

There are six known subpopulations of Parachute beardtongue, with an estimated total of 6,954 - 7,404 individual plants rangewide. Of the six known subpopulations of Parachute beardtongue, two have low resiliency and four are considered to have moderate resiliency. The small subpopulation sizes of Anvil Points Transplant Site and Mount Logan Road (one and three plants, respectively) play a large role in the low resiliency of these two subpopulations. The Mount Callahan subpopulation contains the vast majority of plants with an estimated 81 to 86 percent of the entire rangewide population. Although this subpopulation has more than 500 individuals, pollinator connectivity is low, average annual precipitation is low, and average annual temperature is moderate. (USFWS, 2020). The largest effort that has occurred for Parachute beardtongue since the 2019 5-year status review is the implementation of small Unmanned Aerial Systems (sUAS; drone) surveys for the Parachute beardtongue across the five occupied populations and the discovery of two new populations using those drone surveys. These efforts were conducted by CNHP, Aridlands, and EcoloGIS. These survey efforts were explored in 2019 but were not fully implemented until 2020 and 2021, in which drone surveys were flown over current occupied habitat and several areas of potentially suitable habitat based on similar geological characteristics. Drone surveys are particularly useful for surveying this plant species because of the cliffy, often inaccessible habitats upon which it grows. The sUAS took over 60,000 red, green, blue (RGB) photos, and 40,000 multispectral photos, that were then processed to identify 4,546 individual Parachute beardtongue across the study sites, including new detections in existing populations at Mount Logan, Logan Wash Mine, and Anvil Points. New detections in new populations were found at the Red Pinnacle and Anvil Creek study areas, where the group found 426 and 218 individuals, respectively. Abundance results from the drone surveys, when compared to an existing photo quadrat method, were found to be statistically significantly different, indicating that the drone surveying method, while useful for monitoring Parachute beardtongue, especially in remote populations, cannot provide complete census population estimates at a site (Swayze and Handwerk 2022) (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Oil and gas development (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Natural gas wells on Mt. Callahan and the Mt. Callahan Saddle have been developed and managed according to Natural Areas agreements and best management practices, which have been effective in avoiding impacts to the plants and habitat (see II. C.). These 2 natural areas support 40 percent of the occupied habitat and 69 percent of the plants. The Smith Gulch population is not included in the Natural Areas agreement or the designated critical habitat. It has 15 percent of the occupied habitat and about 1 percent of the plants (76 FR 45064). The persistence of plants in Smith Gulch near a well pad on BLM land is uncertain because the plants are subject to natural erosion within an ephemeral (short-lived) streambed (USFWS, 2013).

**Stressor:** Oil shale extraction and mine reclamation (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Anvil Points mine and Logan Wash mine were oil shale mines, which are now closed. Logan Wash mine road maintenance and reclamation activities have impacted habitat and destroyed plants on private and BLM land, and some of these activities are ongoing (76 FR 45054, CNAP 2012, p. 3) (USFWS, 2013).

**Stressor:** Vehicle access through occupied habitat (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Continuing use of the Anvil Points mine road to access a Garfield County communications facility prevents natural reclamation of the road by young plants on shifting shale. The road cuts through the middle of this largest population of plants on BLM land (USFWS, 2013).

**Stressor:** Climate change, drought, and impacts to the vegetative community (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Climate change is likely to affect long-term survival of native species, including beardtongue, especially if longer or more frequent droughts occur. However, species' response to climate change are complex and current information does not allow strong conclusions regarding the effects of climate change on Parachute beardtongue. Critical habitat for this species has been extended 328 ft. (100 m) upward and downward from the known occupied range in an attempt to provide areas where the plant could migrate, given shifting climates (77 FR 48368) (USFWS, 2013).

**Stressor:** Invasive species (USFWS, 2013)

**Exposure:**

**Response:****Consequence:**

**Narrative:** Invasive weeds are often able to out-compete native species under drought conditions (Everard et al. 2010). An invasion of large thistles among the beardtongue plants was observed one year on the bank above the Logan Mine road (USFWS, 2013).

**Recovery****Reclassification Criteria:**

Not available - recovery plan not yet developed.

Recovery Priority Number: 8C.

**Delisting Criteria:**

1. At least four subpopulations of Parachute beardtongue maintain stable or increasing growth rates ( $\lambda$  equal or greater than 1), as described below: a. Four subpopulations of Parachute beardtongue maintain a stable or increasing growth rate ( $\lambda$  equal or greater than 1) over a consecutive 10-year period. The abundance of Parachute beardtongue may fluctuate within individual sites, but overall, each subpopulation would have a stable or increasing growth rate over the 10-year time period. This 10-year period may start retroactively if existing monitoring data can be used to inform a consecutive 10-year period. b. Subpopulations used to meet this criterion could be any of the currently known subpopulations (the Anvil Points, Logan Wash Mine and Natural Area, Mount Callahan Natural Area, and Mount Callahan Saddle Natural Area subpopulations), or any new subpopulations identified through surveys and monitoring (Recovery Actions 1 and 4, below). Any new subpopulations that are discovered and used to meet this criterion must also maintain a stable or increasing growth rate over a consecutive 10-year time period, as described above under Criterion 1a. (USFWS, 2022)

Recovery Criterion 2: 2. At least four subpopulations, including the four subpopulations used to achieve Criterion 1, meet or exceed abundance estimates of at least 500 Parachute beardtongue individuals over the entire same 10-year time period applied to Criterion 1 (USFWS, 2022).

Recovery Criterion 3: 3. At least four subpopulations, including the four subpopulations used to achieve Criterion 1, have regulatory mechanisms or other protective measures in place that reduce or ameliorate threats to the Parachute beardtongue associated with habitat loss and fragmentation such that Parachute beardtongue habitats in each of the four identified subpopulations are of sufficient quantity and quality to support the demographic thresholds identified under Criteria 1 and 2. Examples of regulatory mechanisms or protective measures could include, but are not limited to, designated management areas, conservation plans, conservation easements, and conservation agreements (USFWS, 2022)

Recovery Criterion 4: 4. All known subpopulations, including currently known subpopulations and any newly discovered subpopulations, of Parachute beardtongue are represented in at least one exsitu (off site) seed collection that is managed according to the Center for Plant Conservation guidelines (Guerrant et al. 2004, entire). The ex-situ seed collection should be updated to represent genetic diversity across the range of the species if and when new subpopulations are discovered (USFWS, 2022).

**Recovery Actions:**

- Completion of a comprehensive plant survey on suitable habitat throughout the species' range (USFWS, 2013).
- Continue ongoing trend monitoring efforts and expand monitoring to include areas impacted by reclamation activities and invasive species (USFWS, 2013).
- Identify sites in urgent need of habitat protection, set protection priorities, and implement protective measures. Land management agencies should establish formal land management designations and stipulations to provide for long-term protection of important populations and habitat (USFWS, 2013).
- Oil and gas leasing and oil shale extraction activities should avoid occupied, critical, and suitable habitat (USFWS, 2013).
- Closed oil shale mines in plant habitat should remain closed (USFWS, 2013).
- Develop and implement standard conservation recommendations to minimize future project and use impacts on both private and federal lands (USFWS, 2013).
- Coordinate with land management agencies, project proponents, private landowners and other partners early in the planning process to limit direct and indirect impacts of planned activities (USFWS, 2013).
- Continue to implement Colorado Natural Areas agreements and extend best management practices for habitat adjacent to the CNAs to protect pollinators and habitat (USFWS, 2013).
- The Garfield County communications site on Anvil Points mine road should be moved out of occupied habitat and the site reclaimed in a manner that will allow recolonization of Parachute beardtongue (USFWS, 2013).
- Continue research into Parachute beardtongue life history and ecology, including pollinators (USFWS, 2013).
- Experiment with propagation techniques, soil (shale) and habitat conditions, and management needed to maximize the success of Parachute beardtongue introduction efforts with seeds, soil seed banks, seedlings, and transplants (USFWS, 2013).
- Study population dynamics and conduct a population viability analysis (USFWS, 2013).
- Encourage investigations that project the species' vulnerability and response to climate change (USFWS, 2013).
- Monitor changes in invasive species prevalence and impacts on Parachute beardtongue; explore approaches to minimize the risk posed by invasives and associated remediation actions (USFWS, 2013).
- Oil and gas development, reclamation or other activities on the Natural Areas will be conducted in accordance with best management practices (BMPs) included in the agreement. Termination of the agreements must be preceded by 2 years notice. These BMPs include specific provisions to minimize impacts to the species, pollinators, and habitat by the following measures: • Controlled collection of plant materials • Controlled surface disturbances • Reclamation and revegetation • Updated rare plant surveys, monitoring, and reporting • Noxious and invasive weed management and revegetation • Pollinator promotion –maintenance of nesting habitat • Placement of surface facilities • Fugitive dust control (USFWS, 2013).
- At Anvil Points mine BLM worked with the Service and contractors to minimize impacts to plants during closure of several mine tunnel openings, transplant unavoidable individuals, and monitor the effects to plants and habitat. One section of the road through plant habitat was ripped up to make it impassable to vehicles. The majority of transplants survived, some marked plants were buried by sliding shale, and the ripped road surface is not being

- recolonized because too much soil is mixed in with the shale (DeYoung 2012, pers. comm.) (USFWS, 2013).
- Surveys and monitoring of plants at the Mt. Callahan populations and Anvil Points mine are conducted annually. Surveys at Logan Wash mine may not be complete; monitoring is not yet implemented. The current draft BMPs for Logan Wash may differ from those at Mt. Callahan because reclamation must continue around the mine site. In 2008, BLM designated the Anvil Points Area of Critical Environmental Concern (ACEC), as an area for management of sensitive resources including Parachute beardtongue (BLM 2008b, p. 4) (USFWS, 2013).
  - Priority 1 Actions 1. Maintain or expand at least four viable Parachute beardtongue subpopulations. The total of four subpopulations may include any of the currently known subpopulations (Anvil Points, Logan Wash Mine and Natural Area, Mount Callahan Natural Area, Mount Callahan Saddle Natural Area), or any new subpopulations that may be discovered (Criteria 1, 2, and 3). 1.1. Analyze recovery potential of subpopulations and prioritize according to recovery potential. 1.2. Conduct research and develop biologically-relevant avoidance buffers and surface disturbance caps to protect plants, subpopulations, habitat function, and seedbanks. 1.3. Develop or improve conservation measures specifically for Parachute beardtongue in land management plans and other protective agreements or plans to reduce habitat loss and fragmentation. 1.4. Restore habitats or develop new habitats. 1.5. Develop and implement a rangewide strategy for subpopulation augmentation and introductions, if necessary. This action should be considered if subpopulation decline or loss has occurred. 2. Monitor all subpopulations (Criteria 1 and 2). 2.1. Develop standardized methodology for data collection and analysis. 2.2. Determine subpopulation abundance and trends. 2.3. Monitor quantity and quality of available habitat. 2.4. Evaluate stressors (USFWS, 2022).
  - Priority 2 Actions 3. Develop ex-situ (off-site) collections of seeds and tissues to preserve Parachute beardtongue's genetic diversity (representation) and provide the capability to augment existing subpopulations or introduce new subpopulations in the wild, if necessary (Criterion 4). 3.1. Select and contract with organizations to collect and preserve seeds and tissues. 3.2. Investigate seed viability, germination requirements, and tissue propagation. 4. Survey for additional subpopulations of Parachute beardtongue (Criteria 1 and 2). 4.1. Perform surveys of suitable habitat to inform land management, project planning, and recovery efforts (USFWS, 2022).
  - Priority 3 Actions 5. Maintain consistency and momentum of conservation efforts for Parachute beardtongue through Service communication and collaboration across jurisdictions and agencies with partners and stakeholders (Criteria 1, 2, 3, and 4). 5.1. Conduct meetings (virtual or in-person as appropriate) a minimum of twice yearly. 5.2. Complete and share status reports with partners (USFWS, 2022)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: We recommend updating the SSA report (Service 2020, entire) to incorporate the addition of new populations and the likely extirpation of the Anvil Points Mine Transplant Site population. Additionally, an examination of the metrics used to assess population resiliency may lead to improvements in this analysis. Other future actions could be to expand drone surveying across more suitable habitat, monitoring with drones, and conducting trend monitoring in more populations using drones or photo quadrats to better understand abundance trends across the range (USFWS, 2024).

## SPECIES ACCOUNT: *Penstemon haydenii* (Blowout penstemon)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 09/01/1987; Mountain-Prairie Region (R6) (USFWS, 2016)

### **Physical Description**

The blowout penstemon (*Penstemon haydenii*), a member of the snapdragon family, is a hairless perennial that grows 1 to 2 feet high. The stems are often decumbent, simple, or branched, and very leafy. The stem leaves are linear to lanceolate, entire, 3 to 5 inches long by 1 to 3 inches wide, sessile and clasping. The inflorescence is a compactly crowded thyrse. A thyrse is composed of (1) a main axis of an inflorescence made up of flowers born on stalks of about equal length along an elongated axis that continues to grow during flowering and open in succession from below and (2) secondary and later axes of the inflorescence that terminate in single flowers. Floral bracts are ovate to lanceolate, nearly equaling the flowers. The corolla is milky blue to pale lavender (rarely pink or white) and 1.5 to 2 inches long. The sterile staminode is glabrous and/or hairy. Fruits are 0.5 to 0.6 inch long capsules, acute, with light brown, disc-shaped seeds having winged margins (Heidel 2005, USFWS 1987).

### **Current Range**

Blowout penstemon is a regional endemic of the Nebraska Sandhills, the largest sand dune system in North America, located in north central Nebraska (Stokes and Swinehart 1997, Forman et. al 2001). The Nebraska Sandhills is an area of stabilized sand dunes covering 5 million hectares (approximately 12.4 million acres). In 2008, 32 blowout penstemon subpopulations (10 native and 22 introduced) were known to occur in the Sandhills (Stubbendieck 2008). In Wyoming, 3 populations (in addition to 6 subpopulations) of blowout penstemon are located in the Ferris Dunes of northwestern Carbon County, separated from the Nebraska Sandhills by about 175 miles (282 km). The Ferris Dunes cover an area less than 124,000 hectares (50,000 acres). See Figure 1 Geography below.

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Breeding Season**

Adult: flowers from mid-May to late June in Nebraska

### **Reproduction Narrative**

Adult: The species flowers from mid-May to late June in Nebraska. The flowers have a strong, persistent fragrance that lures several kinds of bees and other pollinators. The fruit (capsule) matures and splits in early to mid-August and the seeds either fall near the base of the plant or are transported primarily by wind to other areas within the blowout or outside of the blowout. All healthy flowering plants are thought to produce seed (USFWS 1992). Most blowout penstemon plants begin to bloom at 2 to 3 years of age (Stubbendieck et al. 1993) and have been successfully cultivated in the greenhouse (Flessner and Stubbendieck 1989, 1992).

Flowering in Wyoming occurs later than in Nebraska (late June to early July), probably in response to drier and cooler climatic conditions (Fertig 2001). Each fruit of the blowout penstemon contains an average of 25-35 seeds with as many as 1500 seeds per plant. The seeds are winged presumably to aid in wind dispersal although, given the high degree of herbivory of this plant, some questions have been raised that animals might also be an important avenue of seed dispersal (Heidel 2005). Seeds are released from late August through September. The seeds, potentially remaining dormant in the sand for 20 years, have a thick outer coat and germination is enhanced after some degree of scarification. Axillary root branching may be an adaptation to survive burial by wind-blown sand rather than a common form of reproduction. By digging around individual blowout penstemon plants, Heidel (2005, 2012) did not find evidence of long-distance underground connectivity between adjacent plants.

**Habitat Type**

Adult: Sand dunes

**Environmental Specificity**

Adult: Very Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Characterized as a "primary" blowout species (Pool 1914) on active sand dunes in Nebraska sandhills prairie (Stubbendieck et al. 1989, Kuchler 1964). The term 'blowout' refers to a naturally occurring depression in the Nebraska Sandhills. These depressions are caused when vegetation at the upper slope of a hill is disturbed, typically by fire or grazing animals. The 'blowout' may take as many as ten years to become a full scale and active blow out. The process is started when sand is deposited from the windward side of the slope to the leeward side, and this process continues until eventually the roots of the surrounding vegetation are exposed and finally ripped up by the force of the wind. Eventually, a crater is created where there is constant wind action, so succession is continually taking place (Stubbendieck et al. 1989). For a detailed description of blowout ecology, see Stubbendieck et al. (1989). *Penstemon haydenii* occurs within the blowout usually near the leeward side only after the sand has stabilized, and it declines once vegetation is established. All sites have less than 10% basal ground cover (Heidel 1981). Initial colonization of dunes is by *Redfieldia flexuosa*. *Psoralea lanceolata* is locally common where *P. haydenii* is found (Heidel 1981). Other common associates include: *Andropogon hallii*, *Artemisia campestris*, *Asclepias arenaria*, *Astragalus longifolia*, *Calamovilfa longifolia*, *Cirsium plattensis*, *Helianthis* spp., *Hymenopappus corymbosus*, *Lathyrus polymorphus*, *Linum sulcatum*, *Lithospermum incisum*, *Lygodesmia rostrata*, *Oenothera serrulata*, *Oryzopsis hymenoides*, *Petalostemum villosum*, *Rume venosus*, *Tradescantia occidentalis*, and *Yucca glauca* (Heidel 1981; Lichvar 1982). (NatureServe, 2015). Blowout penstemon was first collected along the North Loup River in the Sandhills area of Nebraska by Ferdinand V. Hayden, probably in 1857 (Sutherland 1988). This specimen was without flowers or fruits and was referred to as sharp leaf penstemon, *Penstemon acuminatus*. Senner Watson originally named and described the species as *Penstemon haydeni*, based on a collection made by H. L. Webber near the Dismal River in Thomas County, Nebraska in 1891 (Watson 1891). Later, Francis W. Pennell could not locate the original 1857 Hayden specimen, and he substituted the Webber specimen as the type collection (Pennell 1920). Both the Hayden specimen and type specimen were deposited at the Gray Herbarium at Harvard. A second "i" was later added to the specific epithet "haydeni" to make it etymologically correct (Sutherland 1988). The most recent morphological descriptions report a deep taproot and

stems which root adventitiously in shifting sand (Great Plains Flora Association 1991). No other populations of blowout penstemon were known outside of Nebraska until 1996. In 1996, the Bureau of Land Management (Frank Blomquist) discovered a small colony of blowout penstemon south of the Ferris Dunes (Fertig 1999). Plant samples were later collected and verified by Dr. Noel Holmgren of the New York Botanical Gardens for verification in 1999. Field identification was subsequently confirmed by additional specimens sent to Dr. James Stubbendieck of the University of Nebraska and Dr. Holmgren. There has been some reason to question whether the populations in Wyoming and Nebraska should be considered members of the same species. Blowout penstemon individuals in Wyoming have divergent flower traits that had not been previously reported (Heidel 2007). At the time of the Five year review, there were still questions as to whether the morphological differences between the Nebraska and Wyoming populations are due to phenotypic plasticity, genetic differences, or a combination of these factors affecting populations. Further consultation with taxonomic experts is ongoing. All known blowout penstemon sites are well-developed blowouts in dune complexes with active sand and accompanying environmental extremes in wind, temperature, evapotranspiration, and soil moisture stress. Blowout penstemon plants are most frequently in microsites that are, or recently have been, zones of sand accumulation. The plant apparently is successional and is a pioneer species that does not persist when a blowout becomes completely vegetated. The species survives burial in sand by sending off shoots at successively higher nodes. It withstands initial erosion and has a rhizomatous system with extensive lateral roots to survive erosion that may uncover much of its root length (USFWS 1987).

### ***Dispersal/Migration***

### ***Population Information and Trends***

#### **Population Narrative:**

Blowout penstemon is a short-lived perennial plant, which requires actively moving sand in blowouts to thrive. It grows from a tap root, initially producing a single stem that often becomes decumbent. The stem roots readily where nodes are buried in the sand. Buds located at the base of the stem break dormancy in the second spring, often producing multi-stemmed plants. These plants typically flower in the second or third year (Kottas 2009), and individual plants live for six to eight years (Stubbendieck et al. 1997). The lavender (or occasionally blue or white) flowers produce two-sided capsules (ovaries) bearing 14 to 35 discoid brown to black seeds (USFWS 1992; Kottas 2009). Seeds have a thick, hard seed coat and germination in the field is typically very low. The seeds are adapted to dispersal by wind, which often distributes seed downwind across the edge of the blowout into the area of sand accumulation. Wind and animals aid in the seed dispersal (Stubbendieck, pers. comm. 2009). Seed numbers are highly variable among years and sites (Kottas 2009). Individual plants may produce approximately 1,400 to 1,500 seeds (Kottas 2009; USFWS 1992), but seed viability can reduce reproductive potential to an average of approximately 530 viable seeds per plant (Kottas 2008). The number of seeds in the seedbank is typically low, due mainly to predation by small mammals at the time of seed rain (Kottas 2009; Stubbendieck, pers. comm. 2009). Kottas (2009) investigated the effects of floral herbivory by insects and fungal infection on seed production and viability. She reported that treatments of plants with insecticide or fungicide did not significantly affect total seed output, weight or viability (Kottas 2009). Consequently, site specific herbivore, granivore and fungal impacts may be important when seed production is low or when the surrounding vegetation invades blowout penstemon habitat, bringing additional herbivory with it (Kottas

2009). The genus *Penstemon* is endemic to North America. Of 275 species in the *Penstemon* genus, only the blowout penstemon and one other species are fragrant (Kottas 2009). The common name of the blowout penstemon comes from the blowouts in the Sandhills of Nebraska. Blowouts are round or conical eroded areas, depressions formed in the sand when prevailing northwesterly winds scoop out the sides of the hills (Pool 1914 in Kottas 2009). These eroded areas form on the sides of dunes when vegetative cover is removed or disturbed and wind action further exposes the slopes (Stubbendieck et al. 1989). Blowout penstemon is a pioneer species in these blowouts, frequently found among blowout grass (*Redfieldia flexuosa*) which is often the first pioneer in a blowout (Kottas 2009). Neither blowout grass nor blowout penstemon persists after other grasses begin to invade the blowout. The amount of suitable, active blowout habitat has declined markedly since settlement of the Sandhills region in the early 20th century (USFWS 2012). In Wyoming, blowout penstemon is found primarily on the rim and lee slopes of blowouts, or the rim and steep faces of sandy slough slopes. These deposits are found at the base of mountains or ridges, which represent topographic barriers. Shifting sand dunes are prevented from becoming fully stabilized and overgrown because of wind and gravity. The dunes may be 60 to 120 feet high at elevations between 5860-7440 feet (Heidel et.al 2007). The blowout penstemon is found in the early stages of plant community development which can be composed of blowout grass, lemon scurfpea, and thickspike wheatgrass or Indian ricegrass (Heidel 2005). The Wyoming sites differ from Nebraska Sandhills in that the populations occur at higher elevations, the mean annual precipitation is lower, and Wyoming has cooler minimum and maximum summer temperatures.

### ***Threats and Stressors***

**Stressor:**

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** At the time of listing in 1987, the species was known to exist in only six population centers in four counties of the Nebraska Sandhills. Approximately 7000 plants occurred on less than 10 hectares (25 acres). Improved range management practices and fire suppression which promote blowout healing, were a major cause of the species decline in Nebraska and that remains a major threat today. Given the nature of the different habitats occupied by blowout penstemon plants in Nebraska as compared to those in Wyoming, the degree of threat to populations in these two states may differ. When the blowout penstemon was listed as endangered under the Act, only the Nebraska populations were known, therefore only the threats to populations in Nebraska were considered. In Nebraska, despite conservation strategies to increase numbers of plants and populations within the range, two main areas hamper recovery: 1) Continual loss of blowout habitat due to the stabilization of sand dunes (and lack of habitat management) 2) Lack of plans to guide habitat management and a way to include written agreements to implement such habitat management into conservation plans that could protect the species where it primarily occurs (private land). Additional threats identified and discussed in the 5 year review include: drought, overgrazing, ORV use, construction practices, pesticides, and natural outbreaks of the pyralid moth. In Wyoming, populations have basically been preserved in more or less a natural state because of the isolated, currently inaccessible nature of the sites. However, there is potential moderate to significant impacts from future energy development to the species. As with other forms of development, wind energy facilities, have the potential to affect the natural dynamics of a dune system by directly or

indirectly causing changes to the erosion and deposition of sand. Blowout penstemon may be negatively impacted by changes in the dynamics of the dune system (i.e. loss of key habitat attributes, competition, etc.).

**Stressor:** Mining

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Sand mining is currently not occurring in close proximity to any blowout penstemon sites, however more accessible sand deposits in the Rawlins Resource Area are currently being mined. The sand mined from those locations is used for golf courses and road maintenance. Presently, it seems impractical for sand mining to occur near blowout penstemon sites because of their relative isolation, rugged terrain, and limited access. Blowout penstemon populations in Wyoming are located over 7 miles from primary unpaved county roads to the north and east, and at least 15 miles from primary county roads to the west. Future changes in the accessibility to these habitats could affect the profitability and establishment of sand mines near blowout penstemon sites. Other valuable minerals located near the Seminoe Mountains to the south of the blowout penstemon populations include iron, copper, and gold (from Hausel 1989, in Heidel 2012).

**Stressor:** • Water Development

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Near blowout penstemon habitat at Bradley Peak, Bear Mountain, and Junk Hill in Wyoming are excavated ponds, as well as natural ponds and springs used for sources of livestock water. It would not be feasible to develop these water sources as irrigation water for cultivated fields or central pivot irrigation as is done in Nebraska. Nevertheless, further livestock water sources developed near blowout penstemon populations could potentially concentrate livestock near these habitats causing increased grazing or trampling effects to the plants (Heidel 2005).

**Stressor:** • Oil and Gas Leasing

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Oil and gas leasing occurs at the west end of the Bear – Mountain – Junk Hill – Ferris blowout penstemon population. This development includes pumps, pumping stations, and a pipeline corridor (Heidel 2012).

**Stressor:** • Off-Highway Vehicle Use

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Off-highway vehicle (OHV) use has been observed within a blowout penstemon population in Nebraska, and many plants were damaged (USFWS 1992). Hill climbing and associated OHV recreation activities may ensure continued disturbance and erosion of the sand hills and dunes, but driving over and crushing plants may cause severe negative impacts to the plants (USFWS 1992).

**Stressor:** • Changes in Habitat Quality

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Historically, fires removed the protective cover from the soil in the Nebraska Sandhills region resulting in shifting sand dunes and blowouts. Control of prairie fires followed the area's settlement period. Virtual elimination of fire from the Sandhills ecosystem allowed the vegetation to advance into the majority of the eroded areas and to stabilize the sand, resulting in a decline in suitable habitat for the species (USFWS 1992). However, continual summer grazing by cattle during the first half of this century caused enough disturbances to maintain many blowouts. More recently however, the increased use of planned grazing systems (rotational grazing) during the past 30 years has greatly reduced disturbance and has been responsible for decreasing wind erosion. Other advanced range management practices in Nebraska, including techniques to more evenly distribute livestock on rangeland, have been responsible for decreasing blowout penstemon habitat, as well as the numbers of populations, and the numbers of individual plants (USFWS 1992).

**Stressor:** • Livestock Trampling and Grazing

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Sheep previously grazed the allotments occupied by blowout penstemon in Wyoming. Cattle and horses are now commonly found on the rangelands of both Nebraska and Wyoming. The influence of horses on blowout penstemon has not been documented. Cattle, however, have frequently been observed near blowout penstemon plants. Many individual plants have been inspected during and after cattle grazing periods. When adequate other forage is available, cattle occasionally graze a portion of a plant but seldom does this cause major damage to the plant (BLM 2012, USFWS 1992). Under these normal range conditions, the use of high livestock stocking rates as a disturbance factor to maintain habitat for the blowout penstemon is considered beneficial (USFWS 1992). Advanced grazing methods, referred to as "holistic resource management", may further decrease blowout penstemon habitat by reducing active erosion. Techniques which more evenly distribute livestock on rangelands such as "planned grazing systems" or "management intensive grazing" may have been responsible for decreasing blowout penstemon habitat, numbers of populations, and numbers of individual plants in Nebraska (USFWS 1992). The occasional removal of a terminal portion of a shoot of a blowout penstemon plant by a grazing herbivore may be desirable because growth of other shoots is stimulated (USFWS 1992). However, during years of low precipitation, livestock forage may be limited and blowout penstemon plants may be more intensively grazed during those times. In Nebraska during times of limited forage availability, cattle have been observed to closely graze nearly every available blowout penstemon plant. One occurrence of close grazing by cattle may or may not impact blowout penstemon plants, but repeated years of close grazing will severely weaken plants and may be the direct cause of plant death (USFWS 1992) or reduce population numbers. o Cattle trampling of established plants has not been observed to be a problem. Infrequently, cattle will break a blowout penstemon shoot, which poses no threat to the plant (USFWS 1992). Livestock trampling damage is typically not significant to blowout penstemon plants because the plants are sparsely distributed in shifting substrate areas which cattle do not normally frequent. For Wyoming populations, it has been hypothesized that wildlife are the

primary source of blowout penstemon herbivory. Wild ungulates, such as deer and elk, may have a larger grazing impact on blowout penstemon plants than cattle in Wyoming. Fertig (2001) observed stem damage from deer and elk trampling on 10 percent of the population at Bear Mountain and on 60 to 80 percent of the stems at Bradley Peak. The tracks of elk and pronghorn antelope were repeatedly observed near browsed plants during survey efforts in Wyoming (Heidel 2005).

**Stressor:** • Over-collection

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The blowout penstemon is attractive and has been cultivated. Horticultural collecting is a potential threat for this species (USFWS 1987). To date, private and commercial collectors have had little impact on blowout penstemon. It would be an attractive and desirable landscape plant, but most of the plants are in locations which are too remote or inaccessible (USFWS 1992).

**Stressor:** • Pesticide Use

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The direct impact of herbicides on blowout penstemon is not known, although it is highly probable that broadleaf weed killers would negatively influence this plant (USFWS 1992). Herbicide use is thought to be minimally used on sand hills/dune regions due to the sparse cover of its habitat. It is doubtful that ranchers would even inadvertently apply herbicide to blowout penstemon, because most ranchers try to encourage the growth of all vegetation in blowouts. Use of insecticides could negatively impact the pollinators of blowout penstemon. Numerous types of insects may be responsible for pollination; however, it is unlikely that localized insecticide use would completely eliminate insect pollination (Heidel 2005).

**Stressor:** • Encroachment by other plants

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Non-native species in or adjoining blowout penstemon habitat in Wyoming included cheatgrass (*Bromus tectorum*) and Russian knapweed (*Centaurea repens*). Russian knapweed (*C. repens*) recently got introduced at the base of the Bradley Peak population site and could become a major infestation, possibly entering blowout penstemon habitat. Cheatgrass (*B. tectorum*) is one of the more common non-native species in the Pathfinder population and has been observed to be spreading in some of the Bear Mountain subpopulations (Heidel 2012). Weeds pose may pose threats as competitors. Any herbicides used to control the noxious weeds may pose a threat to the blowout penstemon.

**Stressor:** • Construction Activities

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The area between the Ferris and Seminoe Mountains is an area of particularly high mean turbulent kinetic energy, responsible for sand deposition on steep slip-face slopes

hundreds of feet high. In recent years, there have been wind energy permit applications that encompass blowout penstemon populations. Any alteration of on-site or upwind flow patterns, or related access development and construction, could affect the species and its habitat. There are four separate dead-end roads to occupied habitat, and if there were any road developments between them, it would provide more access to occupied habitat.

**Stressor:** • Vulnerability Based on Small Population Size

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** At the time of listing in 1987, the species was known to exist in only six population centers in four counties of the Nebraska Sandhills. Approximately 7000 plants occurred on less than 10 hectares (25 acres). The small populations known at the time were thought to make the species vulnerable to localized environmental changes. In addition, the species occupies a successional niche in the development and eventual revegetation of blowout habitats. As the vegetation in these areas increases, blowout penstemon undergoes local extirpation. At the time of listing, the species was not only rare, but did not appear vigorous at the known localities in Nebraska, possibly because these blowouts had reached a stage of revegetation that exceeded the optimum habitat conditions for the species. Furthermore, the number of new blowouts was decreasing (USFWS 1987). In Wyoming, 3 populations (in addition to 6 subpopulations). The isolation of these populations from each other, as well as the isolation of these populations from other blowout penstemon populations in Nebraska, makes the Wyoming populations similarly vulnerable to the threat of random stochastic events (such as prolonged drought, introduction of invasive species) that could lead to reduction or loss of these populations.

**Stressor:** • Natural Threats

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Damaging insects and periods of drought may be the greatest natural threats to the survival of this species (USFWS 1992). Prior to the drought of the 1930's, the blowout penstemon was listed as one of the most common species in sand blowouts. Following the drought of the 1930's which severely influenced the vegetation of the Great Plains, the blowout penstemon was thought extinct until it was rediscovered in Nebraska in 1959. At one time, it was thought that a localized drought of a few years duration could eliminate most of the remaining blowout penstemon plants in Nebraska (USFWS 1992). o Destructive insects may be a primary cause of decline in populations (USFWS 1992). Several insects (and arachnids) have been observed feeding on blowout penstemon plants, including spider mites, grasshoppers, and an insect larvae which burrows into the inflorescence. Populations of invertebrates are generally at low levels. However, large numbers of penstemon aphids (*Aphis penstemonicola*) were observed on two individual transplanted blowout penstemon plants growing in a blowout near Alliance, Nebraska. Foliage of the infested plants appeared wilted, grayish-green, and stunted. Several seed predators have also been found active on blowout penstemon. The most serious insect threat appears to be the pyralid moth. Larvae of a pyralid moth did extensive damage to one population of blowout penstemon in 1990. Adult female pyralid moths deposit their eggs on blowout penstemon plants. After hatching, the larvae burrow into the stems and are active until reaching the pupal stage. These larvae damage or kill blowout penstemon plants by boring into the crown area below the plant's buds.

**Stressor:** • Disease

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Blowout penstemon plants are also quite susceptible to fungal root rots. Plants infected with these fungi wilt, rot, and usually die (USFWS 1992).

**Stressor:** • Encroachment by Other Plants

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The blowout penstemon is well adapted to the rigorous environment of an actively eroding blowout, but it does not grow in close association with most other plants. It generally grows as widely spaced plants in nearly bare sand indicating that these plants may not have the ability to compete with each other or plants of other species for moisture. Its associate in Nebraska, blowout grass, does not use large amounts of soil moisture. Blowout penstemon populations in Nebraska have been known to rapidly decline as members of new species, primarily sand bluestem (*Adropogon hallii*) and prairie sandreed (*Calamovilfa longifolia*) increase and begin to use significant amounts of soil moisture following stabilization of the sand habitat (USFWS 1992).

### ***Recovery***

#### **Reclassification Criteria:**

Blowout penstemon will be considered eligible for reclassification to threatened when: 1. a minimum of 10,000 individuals in at least 5 population groups is established; and 2. the 5 populations have the minimum level of protection that will ensure their continued existence.

Recovery Priority Number: 11C

#### **Delisting Criteria:**

Blowout penstemon will be considered eligible for delisting when: 1. a minimum of 15,000 individuals in at least 10 population groups, each with a minimum population of 300 plants is established; and 2. the 10 populations are demonstrated to be at minimum viable population level s.

#### **Recovery Actions:**

- 1. Protect and monitor naturally occurring, reintroduced, and introduced populations. 2. Inventory suitable habitat for naturally occurring populations and determine potential reintroduction sites. 3. Conduct research to determine life history, minimum viable population parameters, and management criteria. 4. Establish new populations of blowout penstemon. 5. Establish and implement management plans for each population.

### ***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: x Consider revising the recovery plan so that it considers and incorporates the latest information on the species. x Clarify uncertainties regarding the species' taxonomy in Wyoming (USFWS, 2022).

## SPECIES ACCOUNT: *Penstemon penlandii* (Penland beardtongue (aka Kremmling beardtongue))

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 08/14/1989; Mountain-Prairie Region (R6)

### **Physical Description**

A short plant with linear leaves and several clumped, pubescent stems up to 25 centimeters (10.0 inches) tall. There are 5-15 bright bicolored flowers with blue lobes and a violet throat, 1.2-1.5 centimeters (0.5-0.6 inches) long, per inflorescence; the fruits are small brown capsules. (USFWS, 1992)

### **Taxonomy**

*Penstemon penlandii* was independently discovered in July 1986 by David Johnson of Western Resource Development Company and John Anderson, then a botanist — with the U.S. Fish and Wildlife Service (Service), on visits to the Osterhout milkvetch site along Troublesome Creek near Sulphur Springs. It was described the same year by Dr. William Weber of the University of Colorado (Weber 1986). A member of the snapdragon family (Scrophulariaceae). (USFWS, 1992)

### **Historical Range**

Endemic to Middle Park near Kremmling in Grand County, Colorado (USFWS, 1992).

### **Current Range**

Near Kremmling in Grand County, Colorado .(USFWS, 1992)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Asexual: vegetative, sexual: cross-pollination, self-pollination (USFWS, 2016)

### **Lifespan**

Adult: Unknown (USFWS, 2016)

### **Breeding Season**

Adult: June - July (USFWS, 2016)

### **Key Resources Needed for Breeding**

Adult: Bee pollinators, especially *Osmia* spp. (USFWS, 2016)

### **Reproduction Narrative**

Adult: Blooms in June and July. Kremmeling beardtongue has rhizomes and vegetative growth. It is not known how long-lived *Penstemon penlandii* individuals are. The plant exhibits a mixed mating system: it can produce seed with pollen from the same plant but is significantly more successful with pollen from another plant. Pollen must be moved from plant to plant with the assistance of pollinators. The primary pollinators are native solitary bees, especially those in the genus *Osmia* (USFWS, 2016).

**Habitat Type**

Adult: Terrestrial (USFWS, 2016)

**Habitat Vegetation or Surface Water Classification**

Adult: Troublesome Formation shale (USFWS, 2016); sagebrush (USFWS, 1992)

**Geographic or Habitat Restraints or Barriers**

Adult: ~7,500 ft. elevation (USFWS, 1992)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2016)

**Habitat Narrative**

Adult: The Kremmeling beardtongue is only known to occur on white to tan barren shale soil exposures. The plant is locally abundant but highly restricted to sparsely vegetated shales of the Troublesome Formation that are high in selenium. The plant community is dominated by grasses and mixed shrubs (especially sagebrush, rabbitbrush, and bitterbrush) (USFWS, 2016). It inhabits a high elevation sagebrush park at 7,500 feet. Penland beardtongue is only known Pierre Shales and of late Tertiary (Miocene Troublesome Formation) siltstone sediments (USFWS, 1992). It occurs on alkaline clays containing selenium, which is toxic to most plants. Optimum habitat for *P. penlandii* appears to be in runoff channels, shaded by the deeply cut banks (NatureServe, 2015).

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends*****Population Trends:**

Not available

**Species Trends:**

Stable (NatureServe, 2015)

**Number of Populations:**

1 (USFWS, 2016)

**Population Size:**

~1.4 million (NatureServe, 2015)

**Population Narrative:**

There is only one population of the Kremmling beardtongue. It is estimated the species occupies less than 1500 acres (USFWS, 2016). Estimates from Ecotone 2010 surveys are approximately 1.4 million individuals. In 2008, DBG staff set up one temporary macroplot and conducted a point in time count estimate. When compared to visual estimates from the same site in 2005, the population appears stable or increasing (Neale et al. 2008) (NatureServe, 2015).

**Threats and Stressors**

**Stressor:** Off-road vehicles (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The badlands on which *Penstemon penlandii* occurs are currently vulnerable to degradation from off-road vehicle use because of their fragile soils, steep topography, and arid environment. There are dirt roads running through the badlands which provide easy access for off-road vehicle use. Off-road vehicle damage and mineral exploration have occurred on the area. The resulting modification of the habitat could result in a reduction of the range for *Penland beardtongue* (USFWS, 1992).

**Stressor:** Collection (NatureServe, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** CNHP considers all *Penstemon* species locations as sensitive information because of the risk of collectors targeting populations for use in gardens (NatureServe, 2015).

**Recovery****Reclassification Criteria:**

The following criteria should ensure the continued existence of the species and the maintenance of its habitat:

1. Land management designations are established and habitat management programs are developed and implemented for all known populations of *Penstemon penlandii* (USFWS, 1992).
2. The species is protected from detrimental environmental impacts through fulfillment of informal and formal consultation responsibilities under Section 7 and protection regulations under Section 9 of the Endangered Species Act (USFWS, 1992).
3. Factors required to establish and maintain minimum viable populations of the species are identified and minimum viable populations are documented as being maintained (USFWS, 1992).

**Delisting Criteria:**

Removal from the list of endangered and threatened species (recovery) is not considered feasible because of small natural populations, limited habitat, and persistent nature of potential

threats (USFWS, 1992).

**Recovery Actions:**

- Inventory any remaining potential habitat: Identifying and surveying potential habitat is important for both species, but especially so for *Penstemon penlandii* due to its very limited known distribution. The best way to ensure this species long-term viability would be to discover more populations and ensure their protection and management. Most populations of *Penstemon oenlandii* occur on private lands. The discovery of additional populations of this species on public lands would decrease the species vulnerability and help ensure its long-term viability. Surveys for this species on public lands are a high priority need. (USFWS, 1992)
- Protect existing habitat: Because of the limited amount of habitat, it is important that known habitats be impacted as little as possible. Various strategies are needed for the different threats and landownerships. (USFWS, 1992)
- Protect pollinators Successful reproduction and maintenance of genetic diversity requires sufficient numbers and types of pollinators. (USFWS, 1992)
- Conduct life history/ecology studies In order to understand how to establish and maintain minimum viable populations of each species, additional population biology and ecology studies are necessary. (USFWS, 1992)
- Future actions: The necessity of these actions will be determined by the results of the studies described above. These may include: Management of surface disturbance; Management of plant communities; and Restoration of disturbed habitats. (USFWS, 1992)
- CLARIFIED RECOVERY CRITERIA Population Based Recovery Criteria P-1. Overall population trends for Osterhout milkvetch and Penland beardtongue must be stable or increasing across the current range of each species ( as described above) according to the following measures and not reduced from the baseline (see description of baseline above): a) Range-wide populations trends (measured using density (plants/m<sup>2</sup>JJ must be stable or increasing over a 10-year period as determined by the Bureau of Land Management's monitoring methodology (BLM 2017); and b) Range-wide population trends (measured using density (plants/m<sup>2</sup>JJ must maintain at least 90 percent confidence that Osterhout milkvetch and Penland beardtongue density estimates are within 10 percent of their estimated true value (BLM 2017). Data collected in years preceding this clarification can be used to measure this criterion. Threats and Management Based Criteria T-1. Land protection covering the habitat of all populations for Osterhout milkvetch and Penland beardtongue and/or statutory and regulatory protections for plants are such that the protections of the Act are no longer needed to compensate for regulatory inadequacies. Current Federal land protection through resource management plans, conservation agreements, recreation management plans, and/or travel management plans must be maintained for all Osterhout milkvetch and Penland beardtongue populations that occur on Federal lands. (USFWS, 2020)

## SPECIES ACCOUNT: *Pentachaeta bellidiflora* (White-rayed pentachaeta)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

The white-rayed pentachaeta is a small annual plant in the aster family (Asteraceae) found only in San Mateo County. The plants are 6 to 17 cm (2.3 to 6.6 in) tall and the flower heads consist of 7 to 16 white, strap-shaped petals surrounding 16 to 38 yellow ray flowers. The plants bloom from March to May. The white-rayed pentachaeta is found on serpentine grassland and co-occurs with dwarf plantain (*Plantago erecta*), purple needlegrass (*Nasella pulchra*), and coastal tidytips (*Layia platyglossa*) (Service 2010, p. 3) (USFWS, 2021)

### **Taxonomy**

*Pentachueta bellidiflora* (white-rayed pentachaeta) was first collected in 1853 to 1854 near Corte Madera by John Milton Bigelow, surgeon and botanist for a railway route exploration (Van Horn 1973). The plant was described as *Pentachaeta bellidiflora* (Greene 1884). Keck (1958) transferred the entire genus to *Chaetopappa*. Van Horn (1973) studied *Chaetopappa* and *Pentachaeta* and concluded that the two genera are not closely related. Based on differences in floral and vegetative morphology and chromosome number, Van Horn (1973) reinstated the genus *Pentachaeta* (USFWS, 1998).

### **Historical Range**

See current range/distribution.

### **Current Range**

At the time of listing, *Pentachaeta bellidiflora* was known from a single large occurrence in the Triangle area which extended east of I-280 into Eastwood Regional Park. Historically, the species was more widespread and was known from at least nine locations in Marin, San Mateo, and Santa Cruz Counties. Most of the occurrences were lost due to urbanization or disturbance from off-road vehicles (CNDDDB 2010). The Triangle remains the only known verified occurrence of *P. bellidiflora* (CNDDDB 2010); however, since the time of listing, a small occurrence of *P. bellidiflora* may have been found on the west side of Upper Crystal Springs Reservoir in San Mateo County (M. Vasey, San Francisco State University, in litt., May 28, 2010). Further surveys need to be done to confirm this occurrence (USFWS, 2010)

### **Critical Habitat Designated**

Yes;

### **Life History**

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Insect pollinated (USFWS, 1998)

**Breeding Season**

Adult: Pentachaeta bellidflora flowers from March to May (Van Horn 1973) and may be visited by the federally threatened bay checkerspot butterfly (Euphydryas editha bayensis) (USFWS, 1998).

**Reproduction Narrative**

Adult: Pentachaeta bellidflora flowers from March to May (Van Horn 1973) and may be visited by the federally threatened bay checkerspot butterfly (Euphydryas editha bayensis). The butterfly may incidentally pollinate the plant, but the primary pollinators of Pentachaeta bellidflora are unknown (Robison and Morey 1992b). Given that the seeds apparently do not over-winter well, the species may have a limited soil seed bank (Van Horn 1973). Detailed data on the reproductive biology of Pentachaeta bellidflora are not available (USFWS, 1998).

**Habitat Type**

Adult: Bunchgrass communities (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Serpentine soils (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits bunchgrass communities associated with serpentine soils (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the species unique habitat requirements and low number of known populations.

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends*****Population Trends:**

Not available

**Population Narrative:**

Surveys conducted prior to the listing in 1995 showed that the occurrence at the Triangle contained about 1.5 million plants in each of the two years the plant was surveyed in the early 1990's (U.S. Fish and Wildlife Service 1995). The most recent surveys reported to the CNDDDB in 2000 noted only that the species numbered in the millions of plants. This population extends to the east side of I-280 on Edgewood Park land; this portion of the population was found to contain 43 plants in 2004 (CNDDDB 2010). No abundance information is available for the possible occurrence near Crystal Springs Reservoir (USFWS, 2010).

**Threats and Stressors**

**Stressor:** Recreation (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Construction of a trail is no longer proposed on the San Francisco Water Department land within the Triangle site (S. Foree, in litt., May 19, 2010) which alleviates this source of non-native plants as a threat. The SFPUC is proposing to create the Adobe Gulch Grassland Restoration Site near the southwest edge of Crystal Springs Reservoir, immediately adjacent to the possible location of a second occurrence of *P. bellidiflora* (Winzler and Kelly 2010). The proposed actions within the Restoration Site include enhancing the coastal terrace prairie by shrub removal. Potential habitat for *P. bellidiflora* may exist within the Restoration Site; however, surveys have not been conducted to determine if the area supports additional plants. Disturbance to the Restoration Site may encourage invasive plants to become established (M. Vasey pers. comm., June 29, 2010) and compete with the *Pentachaeta bellidiflora* if it exists there (USFWS, 2010).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The Endangered Species Act is the primary Federal law that has provided protection for these species since the dates of their listing as endangered in 1985 and 1995. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent their status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2010).

**Stressor:** Non-native plants (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Invasive plant species that are present on the Triangle site are teasel, jubata grass, fennel, harding grass, hoary mustard, bull thistle, and Spanish broom; however, these plants do not directly threaten the *Pentachaeta bellidiflora* which is located on a hillside that supports fewer weedy plants (S. Foree, in litt., May 21, 2010). Weiss and Luth (2003); however, have conducted research on the effects of nitrogen deposition in a serpentine grassland in the Santa Clara Valley which has bearing on threats to *P. bellidiflora*. Weiss and Luth found that nitrogen

deposition from automobiles on Interstate 280 were responsible for higher nitrogen levels within 400 meters on the west side of the roadway. Grass cover was higher in these areas. The authors noted that the only known occurrence of *P. bellidiflora* exists east of the freeway. There is an elevated zone of nitrogen-deposition extending out approximately 100 meters on the east side of the freeway and the species may be at long-term risk from invasions of nitrogen-loving grasses and other weedy plant species. *P. bellidiflora* is restricted to the thinnest soils in that 100 meter zone; beyond 100 meters, it is one of the dominant plants in the grassland. (S. Weiss in litt, May 25, 2010). Invasions of these nitrogen loving plants into nitrogen-limited grasslands and shrublands appears to be a common response to atmospheric nitrogen deposition (USFWS, 2010).

**Stressor:** Natural catastrophes (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Extinction

**Narrative:** Because the species is found at a single site, it is threatened by natural catastrophes that could effect the entire occurrence such as fire, disease, genetic depletion, or drought. These events could increase the risk of genetic changes that decreases the ability of the species to survive (USFWS, 2010).

**Stressor:** Climate change (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Although the specific effects of climate change on *Acanthomintha obovata* ssp. *duttonii*, *Cirsium fontinale* var. *fontinale*, and *Pentachaeta bellidiflora* are unknown, the effects of increased winter flooding and drought conditions in the spring have the potential to adversely affect these species (USFWS, 2010).

## **Recovery**

### **Reclassification Criteria:**

*Pentachaeta bellidiflora* may be downlisted to threatened status when: 1. A total of five populations are secured and protected from incompatible uses. These include occupied and former known habitat at the Triangle and Edgewood Park and at the new potential occurrence if it is confirmed to be *P. bellidiflora* along with additional populations and adjacent unoccupied habitat and a 150-meter (500-foot) buffer (USFWS, 2010).

2. A management plan is approved and implemented for recovery areas and includes survival of the species as an objective for all populations and any adjacent areas identified as essential to continued survival of the species (USFWS, 2010).

3. Population monitoring in specified recovery areas shows stable or increasing numbers of plants with evidence of increasing numbers over a 20-year period that includes a normal precipitation cycle (or longer if suggested by the results of demographic monitoring) (USFWS, 2010).

4. Seeds stored in at least two Center for Plant Conservation-certified facilities; seed germination and propagation techniques understood (USFWS, 2010).

**Delisting Criteria:**

*Pentachaeta bellidiflora* may be delisted when: 1. A total of ten populations are secured and protected from incompatible uses with at least 3 populations in each of Marin, San Mateo, and Santa Cruz Counties (USFWS, 2010).

2. A management plan is approved and implemented for recovery areas and includes survival of the species as an objective for all populations and any adjacent areas identified as essential to continued survival of the species (USFWS, 2010).

3. Population monitoring in specified recovery areas shows no decline in numbers of plants after downlisting with evidence of increasing numbers over a 20-year period that includes a normal precipitation cycle (or longer if suggested by the results of demographic monitoring) (USFWS, 2010)

**Recovery Actions:**

- Reclassification criteria: This criterion has not been met. No occurrences other than the Triangle site occurrence have been verified. No introductions or reintroductions of the species have taken place. No additional information about the potential new occurrence near Crystal Springs Reservoir is available (USFWS, 2010). Delisting criteria: This criterion has not been met. No occurrences other than the single Triangle site occurrence in San Mateo County have been verified. A second occurrence near the Crystal Springs Reservoir has been reported but must be confirmed. No information is available regarding whether other occurrences which are presumed by CNDDDB to be extirpated have been revisited since the time of listing (USFWS, 2010).
- Reclassification criteria: This criterion has partially been met. As noted above in the section on *Cirsium fontinale* var. *fontinale*, the San Francisco Public Utilities Commission has developed and implemented the Peninsula Watershed Management Plan ([http://sfwater.org/detail.cfm/MC\\_ID/20/MSID/177/C\\_ID/2162](http://sfwater.org/detail.cfm/MC_ID/20/MSID/177/C_ID/2162), accessed May 25, 2010). This plan covers the Lower Crystal Springs Reservoir and the Triangle. The plan addresses rare plants (S. Foree, in litt., May 21, 2010). Policy V5 and V6 of the Plan are as follows: V5. Protect, preserve, and enhance significant botanical resources, including populations of rare, threatened, endangered, and sensitive plant species and their habitat; V6. Encourage and allow investigations of special status plants and communities on the watershed to further the SFPUC's understanding of the watershed's vegetation and its condition. This plan does not specifically identify which areas are essential to the continued survival of the species (USFWS, 2010). Delisting criteria: This criterion has not been completely met. The San Francisco Public Utilities Commission has developed and implemented Peninsula Watershed Management Plan ([http://sfwater.org/detail.cfm/MC\\_ID/20/MSID/177/C\\_ID/2162](http://sfwater.org/detail.cfm/MC_ID/20/MSID/177/C_ID/2162), accessed May 25, 2010). This plan covers the Lower Crystal Springs Reservoir and the Triangle. The plan addresses rare plants (S. Foree, in litt., May 21, 2010). Policy V5 and V6 of the Peninsula Watershed Management Plan are as follows: V5. Protect, preserve, and enhance significant botanical resources, including populations of rare, threatened, endangered, and sensitive plant species and their habitat; V6. Encourage and allow investigations of special status plants and communities on the watershed to further the SFPUC's understanding of the watershed's

- vegetation and its condition. This plan does not specifically identify which areas are essential to the continued survival of the of the species (USFWS, 2010).
- **Reclassification criteria:** This criterion has not been met. Monitoring in the late 1980's and early 1990's (CNDDDB 2010) has shown numbers of plants at the Triangle were apparently stable; however, no monitoring has been reported since 2000. The portion of the occurrence that is located in Edgewood Park has declined from 100 plants in 1989 to 43 plants in 2004 (CNDDDB 2010). No monitoring data is available at the potential Crystal Springs Reservoir site. Monitoring has not been continuous over a 20-year period. Only the Triangle occurrence is known to occur. No introductions or reintroductions have taken place (USFWS, 2010). **Delisting criteria:** This criterion has not been met. The downlisting criterion has not been met. Only one verified occurrence is known to exist. Monitoring in the late 1980's and early 1990's (CNDDDB 2010) has shown numbers of plants were apparently stable; however, no monitoring has been reported since 2000. The portion of the occurrence that is located in Edgewood Park declined from 100 plants in 1989 to 43 plants in 2004 (CNDDDB 2010). Monitoring has not been continuous over a 20-year period (USFWS, 2010).
  - **Reclassification criteria:** This criterion has been partially met. Approximately 15,000 seeds were collected from the Triangle occurrence in 2010 by staff from San Francisco Public Utilities Commission and UC Berkeley Botanical Garden. Seed will be sent to U.S.D.A. National Center for Genetic Resource Preservation in Fort Collins, Colorado for germination testing (USFWS, 2010).
  - Conduct surveys at occurrences of all three species which have not been visited for five years to determine if habitat remains and whether these areas would be suitable reintroduction sites if the species is no longer present (USFWS, 2010).
  - Collect information on habitat preferences for all species in order to facilitate the search for suitable habitat for outplanting. Data to be collected should include associated plant communities, soil types, soil nutrients, pollinators, and hydrology of the currently occupied habitat as well as the historically occupied sites. Conditions at currently occupied sites may not represent the habitat that supported the species at historic locations, particularly for *Pentachaeta bellidiflora* which had a far greater range historically and likely more variability between sites (USFWS, 2010).
  - Conduct research on propagation methods for the *Cirsium fontinale* var. *fontinale* and *Pentachaeta bellidiflora* for future outplantings and habitat restoration (USFWS, 2010).
  - Conduct research on the relationship between *Cirsium fontinale* var. *fontinale* and *Deschampsia caespitosa* ssp. *holciformis* (tufted hairgrass). Determine if *D. caespitosa* ssp. *holciformis* is critical to outplantings and restoration of *C. fontinale* var. *fontinale* occurrences (USFWS, 2010).
  - Determine identity and importance of pollinators for *Acanthomintha obovata* ssp. *duttonii* and *Pentachaeta bellidiflora*. (This information has already been collected for *Cirsium fontinale* var. *fontinale*). Determine habitat needs of the pollinators and ways to incorporate this information into management and restoration/outplanting plans for the species (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS:** Here we propose several habitat conservation and ecological research recommendations that will aid in the recovery and conservation of the white-rayed pentachaeta. Some of these recommendations have already been discussed in our previous status review (Service 2010, p. 28): 1. Conduct surveys at known occurrences at least every five

years to determine population trends and habitat changes. 2. Collect information on habitat preferences in order to facilitate the search for suitable habitat for outplanting. Data to be collected should include associated plant communities, soil types, soil nutrients, pollinators, and hydrology of the currently occupied habitat as well as the historically occupied sites. Conditions at currently occupied sites may not represent the habitat that supported the species at historic locations, particularly for white-rayed pentachaeta, which had a far greater range historically and likely more variability between sites. 3. Conduct surveys for potential locations in which to establish new populations. The surveys should also confirm that there is only a single population stretching across both the Triangle and Edgewood Park properties, rather than two or more populations separated by a quarter mile or more. 4. Work with partners and landowners to establish new populations. 5. Work with partners to produce and implement management plans specific to white-rayed pentachaeta conservation at each population site. (USFWS, 2021)

## SPECIES ACCOUNT: *Pentachaeta lyonii* (Lyon's pentachaeta)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 02/28/1997; Pacific Southwest (R8)

#### **Physical Description**

An annual herb, 6-48 cm tall, with yellow flower heads that bloom in the spring. Each plant may produce 30 or more flower heads. (NatureServe, 2015)

#### **Taxonomy**

*Pentachaeta lyonii* was described by Asa Gray (1886) based on a plant collected by William S. Lyon "near Palos Verdes Mountain" in Los Angeles County. David D. Keck (1958) combined *Pentachaeta* with *Chaetopappa* and published the combination *Chaetopappa lyonii*. This was recognized by Munz and Keck (1959) and Munz (1974). Van Horn (1973) conducted a taxonomic status of *Pentachaeta* and *Chaetopappa* and demonstrated that the two genera were distinct in morphological, anatomical features, and breeding systems. This treatment has been followed in current floristic treatments (Raven et al. 1986, Lane 1993) (USFWS, 1999).

#### **Historical Range**

See current range/distribution.

#### **Current Range**

Endemic to coastal southern California, where currently known only from eastern Ventura and western Los Angeles Counties, in the Santa Monica Mountains and western Simi Hills (CNDDB 2008 cited in USFWS 2008). Formerly also known from the Palos Verdes Peninsula and Santa Catalina Island, but now believed historical/extirpated from these areas (CNDDB 2008 cited in USFWS 2008). (NatureServe, 2015)

#### **Critical Habitat Designated**

Yes; 12/14/2006.

#### **Legal Description**

On November 14, 2006, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective 12/14/2006) for *Pentachaeta lyonii* (Lyon's pentachaeta) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes seven critical habitat units (CHUs), in California (71 FR 66374-66423).

#### **Critical Habitat Designation**

The critical habitat designation for *Pentachaeta lyonii* includes six CHUs in Ventura, and Los Angeles Counties, California. Approximately 3,396 ac (1,372 ha) fall within the boundaries of the critical habitat designation. The critical habitat units are located in Ventura and Los Angeles Counties, California. Brief descriptions are presented below; detailed coordinates and maps are included in the Final Rule. (USFWS, 2006).

**Unit 1: Simi Valley Unit:** This unit is located east of Moorpark and west of Simi Valley in Ventura County and consists of 390 ac (157 ha) of private land. This unit is divided into four subunits (subunits 1a, 1b, 1c, and 1d) and mapped from occurrences known at the time of listing. The

subunits are in the same geographic area; they are all within 2.5 mi (4000 m) of each other.

**Unit 2: Montclef Ridge Unit:** This unit is located along Montclef Ridge, northwest of Newbury Park in Ventura County. It consists of 892 ac (361 ha) of local agency land (Lynmere, Wildwood Park, and Mount Clef Ridge) owned and managed by COSCA and Conejo Recreation and Parks District, and 265 ac (107 ha) of private land. This unit is divided into three subunits (subunits 2a, 2b, and 2c) that occur within the same geographic area, and are mapped from occurrences known at the time of listing and one occurrence identified after listing.

**Unit 3: Thousand Oaks Unit:** This unit is located in Thousand Oaks near Lake Sherwood in Ventura and Los Angeles Counties. It consists of 671 ac (272 ha) of local agency land (COSCA, Las Virgenes Metropolitan Water District, and Mountain Resources Conservation Authority) and 588 ac (238 ha) of private land. This unit is divided into three subunits (Subunits 3a, 3b, 3c (eastern portion), and 3d (western portion)) mapped from occurrences known at the time of listing and two occurrence identified after listing.

**Unit 4. Triunfo Canyon Unit:** This unit is located in unincorporated Los Angeles County. It consists of 197 ac (80 ha) of local agency land owned by Mountains Recreation and Conservation Authority, and 9 ac (3 ha) of private land. It is mapped from an occurrence known at the time of listing and includes multiple patches within a large, single population complex.

**Unit 5: Mullholland Drive Unit:** This unit is located in the Santa Monica Mountains in Los Angeles County and consists of 105 ac (42 ha) of Federal land (Santa Monica Mountains National Recreation Area) and 187 ac (75 ha) of private land. It is divided into 4 subunits (Subunits 5a, 5b, 5c, and 5d) mapped from occurrences known at the time of listing and occurrences identified after listing.

**Unit 7: Malibu Lake Unit:** This unit is located in the Santa Monica Mountains in Los Angeles County and consists of 58 ac (23 ha) of State land (Malibu Creek State Park) and 34 ac (14 ha) of private land. It is mapped from an occurrence known at the time of listing.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Pentachaeta lyonii* critical habitat consists of three components (71 FR 66374-66423):

- (i) Clay soils of volcanic origin;
- (ii) Exposed soils that exhibit a microbiotic crust, which may inhibit invasion by other plant competitors; and
- (iii) A mosaic of bare ground (>10%) patches in an area with less than 60 percent cover.

#### **Special Management Considerations or Protections**

Threats that may require special management are specified in the Final Rule for each Critical Habitat Unit: Unit 1. The invasion of annual grasses and nonnative plants that could crowd out *P. lyonii*, and grazing, edge effects from urban development, road maintenance, and vehicle traffic, which could result in removal or trampling of plants. Unit 2: The invasion by annual

grasses and nonnative plants that could crowd out *P. lyonii*; recreation, including equestrian activities, foot traffic, and off-road vehicles, which could result in trampling of plants; illegal dumping, urban development, which could result in removal of plants; and edge effects from existing urban development. Unit 3: Edge effects from urban development, removal of plants for urban development or fuel management, invasion by annual grasses and nonnative plants that could crowd out *Pentachaeta lyonii*, and equestrian and foot traffic that could result in trampling of plants. Unit 4: The invasion by annual grasses and nonnative plants, which could crowd out *P. lyonii*, fuel management, which could result in removal of plants, and foot traffic, which could result in trampling of plants. Unit 5: The potential for development, which could result in removal of plants; fuel management, which could also result in removal of plants; and invasion by annual grasses and nonnative plants, which could crowd out *Pentachaeta lyonii*. Unit 7: Recreation activities such as foot traffic, which may result in trampling of plants. (USFWS, 2006)

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Insect pollinated (NatureServe, 2015, USFWS, 2006))

### **Reproduction Narrative**

Adult: *Pentachaeta lyonii* is not capable of self-pollination, but is dependent upon insect pollinators for successful seed production (Fotheringham and Keeley 1998). Pollinators of *P. lyonii* include digger bees, andrenid bees, and megachilid bees (Braken and Verhoeven 1998; Fotheringham and Keeley 1998). These pollinators are polylectic, meaning that they utilize several plant species within an area (Braken and Verhoeven 1998), and a variety of plants are necessary to sustain pollinator populations. Known pollinators of *P. lyonii* have the ability to pollinate individual plants up to 1,968 ft (600 m) from the pollen source, suggesting that genetic connectivity occurs between populations that are up to 1,968 ft (600 m) apart from each other. (USFWS, 2006). Seeds have deciduous pappus bristles, suggesting that this species is not often dispersed long distances by wind. However, seeds of species in this family (Asteraceae) are also sometimes transported by small seed-eating mammals and birds (Martin et al. 1961 cited in USFWS 2008). This species' seeds likely persist in the soil for several years during extended dry spells (Fotheringham and Keeley 1998 cited in USFWS 2008).; Predominantly outcrossing; SEXUAL; BIOTIC; Hymenoptera (NatureServe, 2015).

### **Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

### **Habitat Narrative**

Adult: Species occurs in saddles between hills, on the tops of small knolls, or in flat areas at the base of slopes. Plants are found within small open, grassy sites that intergrade with fire-adapted chaparral and coastal sage scrub; also on road and trail edges. Occupied sites tend to feature a mosaic of bare ground patches in an area with low overall vegetative cover. Tends to occur on exposed, rocky clay soils of volcanic origin that exhibit a microbiotic crust. Does not compete well with dense annual grasses or shrubs; can apparently persist without disturbance if site conditions (e.g. exposed soils with a microbiotic crust) inhibit the growth of plant competitors,

otherwise periodic disturbance to remove these competitors may be necessary. 85 - 628 m (USFWS 2008). (NatureServe, 2015)

### ***Dispersal/Migration***

#### **Dispersal**

Adult: Wind/mammals (USFWS, 2006)

#### **Dispersal/Migration Narrative**

Adult: produce on the order of 1,000 seeds. The seeds likely persist in the soil for several years during extended dry spells (Fotheringham and Keeley 1998). Plant seeds are frequently dispersed by a variety of vectors, some which result in short-distance dispersal, and others which result in long-distance dispersal (Cain et al. 2000; Nathan and MullerLandau 2000). The presence of deciduous pappus bristles on the seeds indicates that the plant does not exhibit long-distance dispersal by wind, as do many other species in this family, reducing the likelihood of colonization of new areas and contributing to the limited distribution by this method (Keeley and Baer-Keeley 1992; Fotheringham and Keeley 1998). Longdistance dispersal, however, is likely achieved by transport of seeds by wildlife. Seeds from species within the Asteraceae family are known to be transported by small seed-eating mammals, including ground squirrels (*Citellus* sp.) pocket mice (*Perognathus* sp.), kangaroo rats (*Dipodomys* sp.), and birds, including quail (*Lophortyx* sp.) (Martin et al. 1961). Small mammals facilitate seed dispersal through consumption and elimination of undigested seed and through seed caching (Cain et al. 2000; Sieg 1987) (USFWS, 2006).

### ***Population Information and Trends***

#### **Population Trends:**

Decreasing (NatureServe, 2015)

#### **Population Growth Rate:**

This species has apparently been extirpated from the southern portion of its historical range (Palos Verdes Peninsula and Santa Catalina Island) (CNDDDB 2008 cited in USFWS 2008). Decline of 50-90% (NatureServe, 2015)

#### **Number of Populations:**

21 - 80 (NatureServe, 2015)

#### **Population Size:**

65,000-70,000 plants (NatureServe, 2015)

#### **Population Narrative:**

This species has apparently been extirpated from the southern portion of its historical range (Palos Verdes Peninsula and Santa Catalina Island) (CNDDDB 2008 cited in USFWS 2008). Decline of 50-90% Approximately 65,000-70,000 plants as of most recent counts, but this species is an annual known to exhibit large year-to-year fluctuations in population size, so this particular number may not have much meaning in terms of the species' long-term persistence. Annual fluctuations are believed to occur in response to external factors such as rainfall and competition with other plant species (USFWS 2008). Approximately 32 occurrences are believed

extant, with an additional 5 considered historical. At least 3 occurrences have been extirpated. (NatureServe, 2015)

### ***Threats and Stressors***

**Stressor:** Urban Development (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** At the time of listing, the primary threats to *Pentachaeta lyonii* were destruction of habitat from urban development. An indirect threat to the species was the influence of urban development on the surrounding environment, which facilitated the introduction of competitive weeds and altered ecosystem processes. Effects of urban development include habitat fragmentation, which reduces gene flow between sites, reduces insect pollinators, and displaces *P. lyonii* as a result of changes to the structure and composition of pocket grassland communities (i.e., introduction of competitive weeds, changes in local hydrology, and increased gopher activity) (Alberts et al. 1993, Conservation Biology Institute 2000). Gophers are known to till the soil and can facilitate the growth of annual grasses. One site was extirpated in 1993 after the site was burned and non-native annual grasses and gophers became prevalent at the site (CNDDDB 2008) (USFWS, 2008).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Inadequacy of existing regulatory mechanisms was identified in the final listing document as a threat in determining endangered status for *Pentachaeta lyonii*. The species is listed as endangered under the California Endangered Species Act (CESA). Although CESA prohibits “take” of State-listed plants, this appears to be inadequate to protect against the taking of plants via habitat modification or land use change by landowners. After the California Department of Fish and Game (CDFG) notifies a landowner that a State-listed plant grows on his or her property, CDFG Code only requires that the landowner notify CDFG “at least 10 days in advance of changing the land use to allow salvage of such plant” (chapter 10 sec. 1913). Determinations by local lead agencies under the California Environmental Quality Act (CEQA) have resulted in negative impacts to *P. lyonii* (62 FR 4172). Because the intent of CEQA is to disclose project impacts, proposed mitigation measures do not necessarily guarantee protection and conservation of sustainable populations of *P. lyonii* (USFWS, 2008).

**Stressor:** Fire (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Despite efforts to suppress fires in coastal southern California, the present fire frequency of every 15 years or less, is substantially higher than it was historically, which is thought to be every 50 to 100 years (Keeley 2006). Over a period of 60 years, most of the Santa Monica Mountains burned an average of three to five times, with an average interval of every 12.4 to 20.7 years (Radtke et al. 1982). This current fire frequency may have negatively impacted *Pentachaeta lyonii* by displacing chaparral and coastal sage scrub communities with annual

invasive grasses that displace *P. lyonii*. In addition, fire prevention and suppression activities such as spraying fire retardant and discing the soil around urban development remains a threat because it facilitates the growth of annual grasses (USFWS, 2008).

**Stressor:** Human recreation (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Some light recreation is thought to be compatible and even beneficial to the species. Trails create a zone of compacted soils, and may reduce competition from annual grasses and allow *Pentachaeta lyonii* to grow. One of the largest populations, with a population of 100,000 plants reported, occurs alongside a popular trail (CNDDDB 2008). However, higher intensity uses such as equestrian or vehicle use is a threat to the species. A portion of the population on NPS land was severely reduced after an increase in equestrian use (CNDDDB 2008). The remaining portions of the population have been fenced and have shown some signs of recovery (NPS unpublished data 2007) (USFWS, 2008).

**Stressor:** Stochastic extinction (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Extinction

**Narrative:** Ten of the 30 known occurrences have greater than 10,000 plants; the remaining populations are small, with several reported at less than 1,000 plants (CNDDDB 2008; Appendix A). The small populations are vulnerable to extirpation by demographic, environmental, and genetic stochasticity, and natural catastrophes (Shaffer 1981). Demographic stochasticity is random variability in survival or reproduction among individuals within a population (Shaffer 1981), and could play a role in the extirpation of small populations of *Pentachaeta lyonii*. Environmental stochasticity refers to annual variation in birth and death rates in response to weather, disease, competition, predation, or other factors external to the population (Shaffer 1981). This could play a role in extirpations of small populations because the species exhibits large annual fluctuations in population size, probably in response to external factors such as rainfall and competition with other plant species. Genetic stochasticity results from changes in gene frequencies due to founder effect, random fixation, or inbreeding (Shaffer 1981). The low levels of genetic variation among and within populations (Arias et al. no date) could impair the species' ability to adapt to changes in the environment or contribute to inbreeding depression (i.e., loss of reproductive fitness or vigor). Natural catastrophes such as fire, landslide, or prolonged drought could result in extirpation of populations (Shaffer 1981). The entire range of *P. lyonii* occurs within a distance of 24 km (15 mi); therefore, all populations would be expected to experience similar rainfall patterns or could be affected by a single fire (USFWS, 2008).

**Stressor:** Climate change (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Hayhoe et al. 2004, Cayan et al. 2005, Intergovernmental Panel on Climate Change (IPCC) 2007). Recently, the potential impacts of climate change on the

flora of California were discussed by Loarie et al. 2008). Based on modeling, they predicted that species' distributions will shift in response to climate change, specifically that the species will "move" or disperse to higher elevations and northward, depending on the ability of each species to do so. Species diversity will also shift in response to these changes with a general trend of diversity increases shifting towards the coast and northwards with these areas becoming de facto future refugia. The Santa Monica Mountains is expected to increase in diversity becoming one of these potential future refugia (Loarie et al. 2008). These increases in species diversity in the refugia, due to climate change, have the potential to result "...in new species mixes, with consequent novel patterns of competition and other biotic interactions..." to the species present (Loarie et al. 2008) with unknown consequences to the species present. We recognize that climate change is an important issue with potential effects to listed species and their habitats. While we lack adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors such as small population size, will affect *Pentachaeta lyonii*, small ranged species, such as *Pentachaeta lyonii*, are more vulnerable to extinction due to these changing conditions (Pimm and Raven 2000, Loarie et al. 2008) (USFWS, 2008).

### **Recovery**

#### **Reclassification Criteria:**

1. When 10 populations of 10,000 or more plants, from the 30 current sites (see Table 2 of the Recovery Plan), are fully protected and self-sustaining (as demonstrated through monitoring) (USFWS, 1999)
2. When the populations from Reclassification Criterion 1 are managed to control threats such as alien plants (USFWS, 1999)
3. When the populations from Reclassification Criterion 1 are self-sustaining over a minimum of 15 years (or longer, if data suggest large population fluctuations). (USFWS, 1999)

#### **Delisting Criteria:**

1. When 20 populations of 10,000 or more plants, from the 30 current sites (see Table 2 of the Recovery Plan), are fully protected and self-sustaining (as demonstrated through monitoring) (USFWS, 1999)
2. When the populations from Delisting Criterion 1 are managed to control threats such as alien plants (USFWS, 1999)
3. When the populations from Delisting Criterion 1 are self-sustaining over a minimum of 15 years (or longer, if data suggest large population fluctuations). (USFWS, 1999)

#### **Recovery Actions:**

- Protect and secure populations and habitat on unprotected lands. Habitat for the listed plants must be protected and secured in perpetuity, from identified threats of loss. Methods for securing lands include permanent conservation easements established through land use decisions, in-fee purchase, gifts of easement, or fee interest by property owner (USFWS, 1999).

- Manage and monitor protected areas. The process of evaluating past and current management and making adjustments as needed is termed “adaptive management.” Public and private conservation lands should be adaptively managed to maximize their potential to support listed species and their habitats. (USFWS, 1999)
- Survey historic locations and other potential habitat where species may occur, Surveys of the potential albeit limited, habitat within the species range should be done. Several California Natural Diversity Database occurrence records for the listed species are represented only by observations. Information on population status, threats, and abundance is also needed for these sites. Information gathered from the additional details will be used to provide lead agencies to determine protective land use designation for the listed plant species . Data gathered will assist in determining the range of site characteristics, population vigor, and species viability to help establish minimum population standards for rare plant reserves, and consequently, for recovery. (USFWS, 1999)
- Conduct biological and ecological research to define life history strategies and population dynamics to guide recovery/conservation efforts. A better understanding of the population dynamics and identification of ecological factors that may be affecting those dynamics are needed to develop appropriate management plans to recover the plant species. (USFWS, 1999).
- Develop outreach plans to conserve the species. Outreach is an important component of implementing this recovery plan. This plan should be developed to enhance the public’s understanding of issues related to conservation and recovery of the listed species. Participation from both public and private entities should be encouraged for the establishment of conservation plans for the listed species. (USFWS, 1999)
- Recommendations for Future Actions from 2019 5-Year Review: • Increase monitoring of within and among mainland occurrences for better understanding of population trends. • Monitor the Santa Catalina Island occurrence for better understanding of population numbers, trends, and geographic extents. • Collect additional seed for banking from both mainland and Santa Catalina Island occurrences. • Augment existing occurrences when possible. • Search for additional suitable outplanting locations on protected lands and establish new occurrences. (USFWS, 2019)

## SPECIES ACCOUNT: *Peperomia wheeleri* (Wheeler's peperomia)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 1/14/1987

### **Physical Description**

An evergreen, glabrous, erect herb which may reach 1 meter in height. The stems root only at the base and may be up to 1 centimeter in diameter. The opposite leaves are entire, fleshy, elliptic to ellipticobovate, with 3 or 5 main veins ascending from the base. They may be 5 to 7 centimeters long and 2 to 3 centimeters wide with the base tapered to a 1 centimeter petiole. The lower side of the leaf is inconspicuously black punctate. Inflorescences are spikes, 10 to 16 centimeters long and 5 millimeters in diameter, which are borne solitary and opposite the leaves or at the leaf axils. Flowers are minute, approximately .5 millimeter in diameter. (USFWS, 1990)

### **Taxonomy**

During this review we have received information that *Peperomia myrtifolia* is frequently misidentified as *P. wheeleri*. *Peperomia myrtifolia* is a highly variable taxon distributed throughout the Lesser Antilles and the Virgin Islands (Axelrod 2011). Presently, some species experts agree that *P. wheeleri* is not a distinctive species from *P. myrtifolia* because the major difference between the two species is the leaf shape and leaf apex (Axelrod 2011, J. Vélez-Gavilan, UPRM, 2014, pers. comm.). Hence, some authors (e.g., Axelrod 2011) treat *P. wheeleri* as a synonym of *P. myrtifolia*. Currently, no genetic studies have been conducted to demonstrate that *P. wheeleri* is not a valid species. Thus, for the purpose of this review we are treating *P. wheeleri* as a valid species. This taxonomic issue should be appropriately assessed in the future. When the recovery plan for *P. wheeleri* was approved in 1990, no common name was recognized for the species. Presently, the name Wheeler's peperomia seems to be widely accepted. This common name has been adopted by the USDA PLANTS database, the Integrate Taxonomic Information System (ITIS) and the IUCN Red List. Therefore, the Service intends to use this common name for this federally listed plant (USFWS, 2014).

### **Historical Range**

See current range/distribution.

### **Current Range**

Known only from Culebra, a small island approximately 27 kilometers to the east of Puerto Rico. The species has not been reported from adjacent small islands or the main island of Puerto Rico (USFWS, 1990)

### **Critical Habitat Designated**

Yes;

### **Life History**

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Biotic (USFWS, 1990)

**Breeding Season**

Adult: Little is known about natural reproduction, however, individuals growing at Fairchild Tropical Garden (Garden) in Miami, Florida, flowered from June through August in 1989 (USFWS, 1990).

**Key Resources Needed for Breeding**

Adult: Flowers of Wheeler's peperomia (*Peperomia wheeleri*) are bisexual. Pollination may be carried out by insects or wind, although the pollination biology of this species has not been studied. Many individuals have been observed flowering or in fruit and numerous seedlings are scattered throughout the area (Vivaldi and Woodbury 1981, U.S. Fish and Wildlife Service 1987). Little is known about natural reproduction, however, individuals growing at Fairchild Tropical Garden (Garden) in Miami, Florida, flowered from June through August in 1989. Seed collected from this flowering began germination after 34 days; germination rate in this initial trial was less than 10 percent. Branches which have broken off and fallen to the ground in the Garden also root easily where they have fallen on humus (Lippincott pers. comm.). Cuttings root easily and many individuals are currently growing at the Garden (USFWS, 1990).

**Other Reproductive Information**

Adult: Following Hurricane Hugo's devastating attack on Culebra in 1989, 25 cuttings were collected by the Refuge Manager at Culebra National Wildlife Refuge (NWR) from the Monte Resaca area. These were planted at the Department of Sports and Recreation nursery in Vega Alta, Puerto Rico and rooted quickly. The forest of the Monte Resaca area was defoliated by the hurricane but cover returned quickly, and the *Peperomia wheeleri* population suffered limited damage (USFWS, 1990).

**Habitat Type**

Adult: Semi-evergreen forest (USFWS, 1990)

**Environmental Specificity**

Adult: Narrow/specialist (USFWS, 1990)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS, 1990)

**Site Fidelity**

Adult: High (inferred from USFWS, 1990)

**Habitat Narrative**

Adult: *Peperomia wheeleri*, a herbaceous plant, occurs on large granodiorite boulders beneath the semi-evergreen seasonal forest of the Monte Resaca area of Culebra Island (USFWS, 1990)

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Increasing (USFWS, 2020)

**Species Trends:**

Increasing (USFWS, 2020)

**Number of Populations:**

7 (USFWS, 2020)

**Population Size:**

~ 2,595 (USFWS, 2020)

**Population Narrative:**

By 2014, Wheeler's peperomia was known from approximately 2,595 individuals in 7 areas in Puerto Rico (USFWS 2014). On the mainland Puerto Rico, the current populations are located at Isabela (El Costillar; C. Pacheco, USFWS, unpubl. data 2007a), Ciales-Florida (Río Encantado Natural Reserve; R. Rodríguez pers. comm. 2013), Arecibo (El Tallonal; Monsegur and ColónMerced, USFWS, unpubl. data 2010), and Guajataca State Forest (Monsegur and Pacheco, USFWS, unpubl. data 2009; and Trejo, unpubl. data 2018). In addition, there are three populations in Culebra Island (Radio tower site, Playa Brava site, Monte Resaca South, C. Pacheco, USFWS, unpubl. data 2007a). These populations are comprised by both natural and planted individuals. Also, an undetermined number of individuals were known from U.S. Virgin Islands, and British Virgin Islands. (USFWS, 2020). When the recovery plan was approved, the Wheeler's peperomia abundance was estimated at several hundred plants on Monte Resaca and almost twenty plants at the Helipad hill, both in Culebra Island (USFWS 1990). In 1995, Santiago-Valentín and Vives-Helyger conducted a survey of the species at El Costillar in Isabela, estimating that population on 50 plants (Santiago-Valentín and Vives-Helyger, 1997). In 2007, Carlos Pacheco conducted a rapid assessment of Wheeler's peperomia in Puerto Rico, estimating its population at 2,466 plants (C. Pacheco, USFWS, unpubl. data, 2007 a,b). Since 2007, the Service has propagated the species in their greenhouses at the Cabo Rojo National Wildlife Refuge and the Culebra National Wildlife Refuge, producing over 200 plants. Presently, the species has been introduced in different localities in Puerto Rico, estimating the population of Wheeler's peperomia at 2,595 individuals in Puerto Rico and Culebra Island (Table 1). Therefore, based on our field observations, and new information available on the species, we believe that the Wheeler's peperomia population trend should be considered as increasing. (USFWS, 2020)

**Threats and Stressors**

**Stressor:** Escaped domestic fowl (USFWS, 1990)

**Exposure:**

**Response:**

**Consequence:** Loss of/Damage to plants

**Narrative:** Populations of *Peperomia wheeleri*, although protected as part of the Culebra National Wildlife Refuge, continue to face the threat of foraging by escaped domestic fowl (USFWS, 1990).

**Stressor:** Cattle grazing (USFWS, 1990)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The possibility of impacts from erosion by cattle passing through the area is listed as a threat to this species (USFWS, 1990).

**Stressor:** Over collection (USFWS, 1990).

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Collecting has not been documented as a factor in the continued decline of *Peperomia wheeleri*. However, the number of remaining plants is small enough that taking of the species for any purpose could become a threat in the future, particularly if horticultural interest in the species develops (USFWS, 1990).

**Stressor:** Deforestation (USFWS, 1990)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Forest cover is essential for healthy plants and continued reproduction. Any disturbance in this area could result in the loss of these plants (USFWS, 1990).

**Stressor:** Hurricanes (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Due to limited distribution, hurricanes are listed as a threat to this species (USFWS, 2014).

**Stressor:** Human induced fires (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Due to limited distribution, human induced fires are listed as a threat to this species (USFWS, 2014).

**Stressor:** Genetic variation (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Given the extremely limited geographic distribution of Wheeler's peperomia, it is highly likely that its genetic variability is very low. This would result in a loss of alleles by random genetic drift, which would limit the species' ability to respond to changes in the environment (Honnay and Jacquemyn, 2007). In order to safeguard the remaining genetic diversity, the protection and monitoring of known adult individuals should be considered as a high priority for the conservation of the species. Based on the above, we consider the potential lack of genetic variation as a possible threat to the species (USFWS, 2014).

**Stressor:** Climate change (USFWS, 2014)

**Exposure:**

**Response:****Consequence:** Loss of habitat

**Narrative:** Changes in climate can have a variety of direct and indirect impacts on species, and can exacerbate the effects of other threats. Rather than assessing “climate change” as a single threat in and of itself, we examine the potential consequences to species and their habitats that arise from changes in environmental conditions associated with various aspects of climate change. Vulnerability to climate change impacts is a function of sensitivity to those changes, exposure to those changes, and adaptive capacity (IPCC 2007; Glick et al. 2011). An expected effect of the climate change is the increase in intensity of hurricanes and tropical storm, followed by extended period of drought (IPCC 2012). This climate change may alter (modify) the microclimate and the surrounding vegetation around the populations of the Wheeler’s peperomia. Hurricane effects followed by extended period of drought may result in changes in soil conditions and microclimate and may allow other plants (native or non-native, herbaceous or woody) adapted to drier conditions to become established (Lugo 2000). Invasive species (e.g. *Megathyrus maximus*) may spread and colonized the Wheeler’s peperomia habitat, and it could alter fire regimen, microclimate, and nutrient cycling of the habitat that the species depend. Due to its limited distribution and number of natural populations, we consider the cumulative effects by hurricanes, genetic variation, and exotic and invasive species (plants and animals) as detrimental to the Wheeler’s peperomia as a whole. The population dynamics of the species is poorly known (e.g., depressed genetic variability and its competitive abilities), there are only few known natural populations, and there is a lack of information to determine what constitutes a viable population. Therefore, we consider the above mentioned threats as high in magnitude because the species has only few known populations; but not imminent because threats like climate change are not likely to occur in near future (USFWS, 2014).

**Recovery****Reclassification Criteria:**

The existing population is adequately protected. [Note: This includes all known occurrences at the time the plan was written.] (USFWS, 2014).

Two additional populations are established within the Culebra National Wildlife Refuge or on other protected areas on Culebra Island (USFWS, 2014).

**Delisting Criteria:**

- 1) Existing populations of *P. wheeleri* in Culebra Island (2 populations) and Puerto Rico (2 populations) exhibit a stable or increasing population trend, evidenced by natural recruitment, and multiple age classes (addresses Factors A, C, and E) (USFWS, 2019)
- 2) Establish or discover two additional populations (as defined in criterion 1) of *P. wheeleri* on lands protected via conservation mechanism on Culebra Island (Addresses Factors A and E). (USFWS, 2019)
- 3) Establish two additional populations *P. wheeleri* (as defined in criterion 1) on lands protected via a conservation mechanism on mainland Puerto Rico (Addresses Factors A and E). (USFWS, 2015)

4) Threats have been addressed and/or managed to the extent that the species will remain viable into the foreseeable future (addresses Factors C and E) (USFWS, 2019)

**Recovery Actions:**

- The first criterion has been partially met. Currently, two of the four known natural populations of Wheeler's peperomia in Puerto Rico are protected as they are located within lands set aside for conservation (Table 1). On Culebra Island, the populations at the Radio tower and Playa Brava are located within the Culebra National Wildlife Refuge (CNWR), land managed by the Service for the conservation of fish and wildlife resources (USFWS 2012). Additionally, the Comprehensive Conservation Plan (CCP) for the Culebra National Wildlife Refuge includes measures for the protection and recovery of the Wheeler's peperomia within this refuge (USFWS 2012). However, the other two natural populations (i.e., El Costillar and Monte Resaca south; Table 1) are not adequately protected because they occur in privately-owned land subjected to urban development and agricultural practices such as cattle and goat grazing. Since 2009, Wheeler's peperomia has been introduced in private and Commonwealth lands managed for conservation (Table 1). These new populations are considered adequately protected because conservation measures have been taken to avoid or minimize threats to the species at each site (USFWS, 2014).
- The second criterion has been partially met. This criterion states that two additional populations of the Wheeler's peperomia should be established within protected areas on Culebra Island. Given that the species has been found in other areas outside Culebra Island, we recommend that this criterion should be reconsidered. Since the recovery plan for this species was approved, two new populations of Wheeler's peperomia have been found in Culebra Island, and another population was discovered at an area known as El Costillar in the municipality of Isabela, in northern Puerto Rico. Additionally, the Wheeler's peperomia has been introduced in three other locations in Puerto Rico (Figure 2). In 2009, the Service and the PRDNER established two populations within the Guajataca Commonwealth Forest, located between the municipalities of Isabela and Quebradillas (Monsegur and Pacheco, USFWS, unpubl. data, 2009). At El Tallonal, a private land in the municipality of Arecibo, the Service established two populations of Wheeler's peperomia in 2010; this property is managed for conservation by the local non-government organization Ciudadanos del Karso (Monsegur and Colón-Merced, USFWS, unpubl. data, 2010). In 2013, the Service and the local Trust Para la Naturaleza planted 40 individuals of Wheeler's peperomia at the Río Encantado Natural Reserve, a private land managed for conservation located between the municipalities of Ciales and Florida (R. Rodríguez, Para la Naturaleza, unpubl. data, 2013). Thus, now there are three populations of this species in the northern karst region of Puerto Rico (USFWS, 2014).
- Conduct genetic studies to determine whether to *P. wheelier* is a synonym of *P. myrtifolia*. (USFWS, 2019)
- International coordination is needed for the implementation of protection and management actions in the other Caribbean Islands and to ensure species' viability outside of US jurisdiction (USFWS, 2019)
- Conduct genetic studies to verify if *Peperomia wheeleri* is a valid species or a synonym of *Peperomia myrtifolia* (USFWS, 2014).
- Develop measurable objective criteria for delisting the species (USFWS, 2014).
- Conduct studies on the biology and ecology of the Wheeler's peperomia (USFWS, 2014)

- Continue a propagation program for the species and establish new populations in protected areas or increase / augment existing populations (USFWS, 2014).
- Continue working with landowners to enhance existing populations or establish new ones within protected areas that ensure their long-term protection (USFWS, 2014).
- Incorporate the private landowners in habitat conservation programs (e.g., Partners for Fish and Wildlife, Coastal Program, PRDNER-Bosque Auxiliary) (USFWS, 2014).
- Evaluate the abundance and distribution of the species through surveys within traditional and non-traditional sites, using the best available plant survey methodology to determine current population numbers and number of viable populations necessary to protect and stabilize Wheeler's peperomia populations (wild, naturally-reproducing populations large enough to maintain sufficient genetic variation and evolve and respond to natural habitat changes) (USFWS, 2014).
- Appropriate government agencies should continue evaluating and implementing conservation measures to minimize possible adverse effects on natural drainages on Culebra Island (USFWS, 2014).
- Quantify predation pressure on the species and determine if predation is a limiting factor for its recovery (USFWS, 2014)

## SPECIES ACCOUNT: *Phacelia argillacea* (Clay phacelia)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 10/29/1978; Mountain-Prairie Region (R6) (USFWS, 2016)

### **Physical Description**

A winter annual, 1-4 dm tall, with deeply lobed leaves. The plants produce clusters of lavender-purple flowers in summer (NatureServe, 2015).

### **Taxonomy**

A member of the waterleaf family. Clay phacelia is very closely related to *Phacelia glandulosa* Nutt., a west slope Idaho, Wyoming, and Montana native (NatureServe, 2015).

### **Historical Range**

It was initially collected at Pleasant Valley Junction, Wasatch County, Utah, in 1883. It was collected a second time at Clear Creek, Utah County, Utah, in 1894 (USFWS, 1982).

### **Current Range**

It is only found in Utah along the Douglas Creek and Gordon Gulch members of the Green River formation in the Wasatch Mountains in Pleasant Valley (NatureServe, 2015).

### **Critical Habitat Designated**

Yes;

### **Life History**

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Sexual (NatureServe, 2015), cross-pollination (USFWS, 2013)

### **Lifespan**

Adult: 2 years (USFWS, 2013)

### **Breeding Season**

Adult: May - July (NatureServe, 2015)

### **Key Resources Needed for Breeding**

Adult: Late summer or early autumn storms, two rain events per summer, seed bank, insect pollinators (USFWS, 2013)

### **Reproduction Narrative**

Adult: Clay phacelia reproduces sexually. It is unknown whether this species is an obligate selfer, a facultative selfer, or an obligate out-crosser (Harper 1990). Seeds typically germinate in spring and fall, although they sometimes germinate in mid-summer if there is enough available moisture (England 1989). The plant blooms in late July, but non-flowering rosettes have been observed in both June and August (Matheson 1989). England (1989) verifies that advanced

plants have been observed in the spring with early flowering in late May or early June. The pollen vector is unknown; however, a 1988 Bee Biology and Systematics Lab field collection at the Tucker site "yielded the largest series of specimens recorded of a rare species of colletid bee, *HYLAEUS GRANULATUS*" (Tepedino 1989). Although the very first observed females of this rare bee were among the specimens collected, Harper (1990) surmises that this bee species is far too rare to be the primary pollinator for Clay phacelia. He further speculates that wind, or the more common ground-nesting bees in the area, could prove to be the major pollinators for Clay phacelia. Clay phacelia has the capacity of developing four mature seeds per fruit. In the summer of 1987, England (1989) estimated that as many as 8000 seeds were produced on one adult winter annual. Embryo viability of seed collected in June 1988 was tested by means of a tetrazolium (TZ) test. The TZ equaled 95% or 19 viable seeds out of the 20 tested (Matheson 1989) (NatureServe, 2015). Clay phacelia was formerly considered a winter annual but new data supports the idea that it is instead a true biennial (Meyer 2011b). Germination seems to be triggered by late summer or early autumn storms and two rain events per summer seem to be critical for survival (Meyer 2011a). The species harbors an extended seed bank, and one successful recruitment event every 10-15 years, coupled with high seed output, may be enough for the species survival through time (Meyer 2011a, 2011b). Seeds produced in one year germinate over the course of several years thus ensuring a robust seedbank that can withstand stochastic events. Clay phacelia are likely obligate outcrossers (Smith et al. 1989) that require insect pollinators. The flower is large and showy and is visited by a variety of pollinators, including native sweat and carpenter bee species (USFWS, 2013).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Juniper-pinyon and mountain brush communities (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Cool, subhumid climate (NatureServe, 2015); soil pH 7.7 - 7.9 (USFWS, 2016)

**Geographic or Habitat Restraints or Barriers**

Adult: 6,000 - 7,000 ft. elevation, vegetative cover > 10% (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Scattered (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Clay phacelia occurs on steep slopes in sparse juniper-pinyon and mountain brush communities (Welsh 1987. The general climate for all of the element occurrence sites can, however, be classified as cool and subhumid (England 1989). The majority of plants grow on slopes facing west through southeast. At each site, the plants occur on a xeric, exposed slope of the Green River Formation, somewhere between 6,000 and 7,000 feet elevation (Franklin and Tuhy 1989). The slope at the site which holds the largest number of plants was measured at 70 percent (Armstrong 1990). *P. argillacea* is dependent upon available, disturbed ground, with

little or no competition (England, 1990). Extant populations of Clay phacelia cover only three to five percent of the slope's surface area in the patches where they occur. Overall vegetative cover is about ten percent in these same areas of critical habitat (England 1989) (NatureServe, 2015). All soils where Clay phacelia occurs are basic, with pH ranging from 7.7- 7.9 for the occupied sites (Armstrong 1992) (USFWS, 2016).

### ***Dispersal/Migration***

#### **Dispersal**

Adult: Typically low (inferred from NatureServe, 2015)

#### **Dispersal/Migration Narrative**

Adult: It is surmised by England (1989) that short distant seed dispersal is achieved primarily by wind, water, and gravity. Rosettes are generally located below or in association with mature adult plants. Some long-distance dispersal may be achieved through grazing and defecation, but the plants are probably grazed prior to seed set (England 1989) (NatureServe, 2015).

### ***Population Information and Trends***

#### **Population Trends:**

Unknown (USFWS, 2013)

#### **Number of Populations:**

3 (USFWS, 2013)

#### **Population Size:**

~340 individuals range-wide (USFWS, 2019)

#### **Population Narrative:**

The number of individuals is currently unknown. There are only three known populations of the plant that are occupied. The range of clay phacelia extends along a 7.5 mile (12 kilometer) stretch of Highway 6 in Spanish Fork Canyon in Utah County, Utah. The Service does not have accurate population estimates or trends (USFWS, 2013).; The population size of the Tucker – Clear Creek population is larger now, with 237 individuals documented in 2017, and includes habitat on private and Bureau of Land Management (BLM) lands (Skopec et al. 2018). The Water Hollow – Garner Canyon population contains approximately 100 individuals based on the last partial-population estimate in 2006. At the time of our last 5-Year Review, we did not provide a range-wide total population estimate for clay phacelia (USFWS 2013); we now cautiously estimate there are 340 individuals range-wide. Surveys for the species since our last 5-year review have not documented new occurrences and pilot introduction attempts on U.S. Forest Service (USFS) lands (Tie Fork and Water Hollow – Garner Canyon) were not large enough to maintain the species' presence on Federal lands. Researchers are able to propagate the species from seed, and two propagation efforts are underway to prepare for future introduction efforts on Federal lands. (USFWS, 2019)

### ***Threats and Stressors***

**Stressor:** Small population size

**Exposure:****Response:****Consequence:**

**Narrative:** Numerous threats exist for Clay phacelia. Probably the most significant current threat is the species' inherent vulnerability due to small population size and number. In populations with less than 1000 individuals, demographic uncertainties can play a significant role in extinction probability (Shaffer 1987). This may be mitigated by a presumably large soil seed bank. However, the 1987 sheep staging episode significantly impacted the habitat, and the little soil that had accumulated in the area was partly washed away in subsequent thunderstorms. In spite of this, England still suspects a sizeable seed bank (England 1989) (NatureServe, 2015).

**Stressor:** Habitat modification (NatureServe, 2015; USFWS, 2019)

**Exposure:****Response:****Consequence:**

**Narrative:** Human land-use activities in and near the critical habitats have played the largest role in Clay phacelia's recent dramatic decline. Livestock and sheep have grazed and trampled the plants and their surrounding habitat. The Denver and Rio Grande Western (D&RGW) railroad is adjacent to the Clear Creek site. Construction activities have already modified the neighboring habitat through stabilization of cuts and fills, runoff control, and material storage (Gill et al. 1982). In addition, Highway 6 bisects the Tucker population. Highway maintenance and construction activities such as burning and shoulder stabilization may also impact both potential and existing Clay phacelia and accompanying bee (pollen vector) habitats (NatureServe, 2015).; Within the species' small range, highway construction and maintenance, and transportation and transmission line development are threats that are likely to result in continued habitat loss and fragmentation. There continues to be potential for widening of the Highway 6 corridor into occupied habitat of clay phacelia. The Highway 6 corridor in Spanish Fork Canyon is a designated national energy corridor under section 368 of the Energy Policy Act of 2005. The national energy corridor designation encourages and facilitates the installation of additional transmission lines, and two transmission lines are planned within the species' range (USFWS 2016a and 2016b). Project proponents for two planned transmission lines committed to avoiding and minimizing impacts to clay phacelia through section 7 consultation of the Act, however there are likely to be future transmission line proposals in this area (USFWS, 2019)

**Stressor:** Grazing (NatureServe, 2015; USFWS, 2019)

**Exposure:****Response:****Consequence:**

**Narrative:** Grazing from endemic ungulates and herbivory from small native herbivores has collectively impacted Clay phacelia. Specific threats include mule deer, elk, and occasional moose that frequent the area of critical habitat in the winter. The exposed south- and west-facing slopes provide a welcome winter home with food and relatively warm areas for bedding down. Rock squirrels have also been sighted nibbling on the herbage (Gill et al. 1982) (NatureServe, 2015).; Herbivory by native and domesticated ungulates is another threat to clay phacelia. Periodic herbivory, largely from mule deer, at the Tucker – Clear Creek population has repeatedly resulted in significant plant losses (Skopec et al. 2018). There are plans by The Nature Conservancy, BLM, USFS, and Weber State University to actively manage the threat of herbivory by installing fences and cages, repairing existing fences, and monitoring wildlife activity at the Tucker – Clear Creek,

Tie Fork, and Water Hollow – Garner Canyon populations. (USFWS, 2019)

**Stressor:** Competition (NatureServe, 2015; USFWS, 2019)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Long-term monitoring of exotic and native species which grow in association with Clay phacelia has not been conducted. However, this should be looked at closely, especially in the absence of grazing. Both *MARUBIUM VULGARE* and *CYNOGLOSSUM OFFICINALE* could pose significant competition to *P. ARGILLACEA* (England 1989) (NatureServe, 2015).; Weeds are another threat to clay phacelia. Weed invasion into occupied habitat by houndstongue (*Cynoglossum officinale*), horehound (*Marrubium vulgare*), and white top (*Lepidium draba*) can increase competition for soil moisture and alter the suitability of the habitat for clay phacelia (USFWS 2013). Private, state, Federal and university partners are actively managing weeds in the Tucker – Clear Creek population. We are exploring the use of alternative non-chemical weed control methods and low-residual herbicides in and near occupied habitat. (USFWS, 2019)

**Stressor:** Climate change (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The impacts of global climate change at this time are uncertain, and could either be positive or negative for this species. Overall temperatures may not be a problem, but changes in precipitation and precipitation patterns may alter survivability and retention of a viable seed bank (Meyer 2011a). Because this species is particularly dependent on multiple rains in the summer and fall to produce successful progeny for the year, changes in rainfall patterns have the potential to affect the seed bank and therefore long-term viability of the species (USFWS, 2013).

**Stressor:** Wildfire (USFWS, 2019)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Wildfire is a potential threat to clay phacelia due to the high frequency of wildfire occurrence in Spanish Fork Canyon. Wildfire has not impacted clay phacelia or its habitat to date; however, the risk and severity of wildfire in occupied habitat may increase with the spread and coverage of weeds from adjacent road and other habitat disturbances. (USFWS, 2019)

## **Recovery**

### **Reclassification Criteria:**

1. To establish a self-sustaining population of 2,000 to 3,000 individuals on 120 acres of protected habitat, and possibly establish at least one new population (USFWS, 2013).

### **Delisting Criteria:**

We are developing objective and measureable delisting recovery criteria for clay phacelia. The delisting criterion identified in the 1982 recovery plan (USFWS 1982) is not objective or measurable: I. Clay phacelia will be delisted when the U.S. Fish and Wildlife Service through collaboration with professional botanists, including the Utah Native Plant Society, is satisfied

that adequate self-sustaining populations have been established. (USFWS, 2019)

**Recovery Actions:**

- Protect individual specimens and habitat (USFWS, 1982).
- Inventory Green River Formation and surrounding areas (USFWS, 1982).
- Introduce plants into new habitat (USFWS, 1982).
- Conduct a public information program (USFWS, 1982).
- Monitor existing and new populations (USFWS, 1982).
- Continue present efforts to establish new populations on USFS lands (USFWS, 2013).
- Provide funding for ongoing and future research (USFWS, 2013).
- Maintain partnerships with TNC, the USFS, and Red Butte Gardens to continue current research and monitoring projects (USFWS, 2013).
- Protect species from further population and habitat fragmentation from development and maintenance of developed areas (USFWS, 2013).
- Continue to protect species from trampling and habitat degradation from livestock activities (USFWS, 2013).
- Develop and implement an invasive, exotic plant management control plan with appropriate stakeholders (USFWS, 2013).
- Secure remaining occupied habitat under conservation management (USFWS, 2013).
- In conjunction with the Utah Division of Wildlife Resources, develop and implement a wildlife management plan to protect the species from ungulate and lagomorph herbivory (USFWS, 2013).
- Continue to monitor population size of this species through time (USFWS, 2013).
- Monitor seed bank viability, seedling recruitment, and seedling survivorship (USFWS, 2013).
- Document and quantify herbivory pressure from free-ranging herbivores (USFWS, 2013).
- Revisit the sites, creating GPS coordinates for each plant location, and identify areas to survey where the plant may occur (USFWS, 2013).
- Monitor invasive, exotic species distribution and abundance in suitable habitat (USFWS, 2013).
- Complete a population viability analysis (PVA) for this species and reevaluate the number of individuals needed for a healthy population (USFWS, 2013).
- Continue collecting and maintaining a genetically representative ex-situ seed collection for the species (USFWS, 2013).
- Augment introduced sites to ensure genetic representation of the species on Federal lands (USFWS, 2013).
- Study the effects of climate change on this species including how altered precipitation, water volume, availability, and timing of rain events may affect the species (USFWS, 2013).
- Determine the environmental conditions and tolerances necessary for each life stage of the species (USFWS, 2013).
- Determine if and how road and railway traffic volume influences this species, and its community associates such as pollinators (USFWS, 2013).
- Determine the extent to which the plants and their pollinators are being affected by road and railroad maintenance activities (USFWS, 2013).
- Re-examine the genetic diversity of this species in the future to determine if genetic diversity has been maintained or been reduced through time, using samples from multiple years (USFWS, 2013).
- Study the plants' pollinators and the pollinators' habitats (USFWS, 2013).

- Determine the effects of erosion on the species and identify actions that may restore soil conditions (USFWS, 2013).
- Examine conditions surrounding seedling emergence, the dynamics and characteristics of the seed bank including seed dormancy and germination (USFWS, 2013).

## SPECIES ACCOUNT: *Phacelia formosula* (North Park phacelia)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 09/01/1982; Mountain-Prairie Region (R6) (USFWS, 2016). Proposed for delisting.

### **Physical Description**

A biennial herb, 1.5-2.2 dm high, with deeply divided, leaves and bearing violet-purple flowers in a coiled, scorpion tail-like cluster. The species has been observed in flower in July and August, but flowering and fruiting times may be somewhat variable depending on rainfall and other environmental conditions (NatureServe, 2015).

### **Taxonomy**

A member of the waterleaf family (NatureServe, 2015). *P. formosula* appears to be most closely related to *P. glandulosa* (USFWS, 1986).

### **Historical Range**

It was first collected near Walden, Colorado (Jackson County) in 1918 (USFWS, 1986).

### **Current Range**

Currently, North Park Phacelia occurs in 11 disjunct populations (Figure 2). Eight of the 11 populations are in Jackson County, Colorado, and three in the Laramie River valley in northwestern Larimer County, Colorado. In past assessments, based on the best scientific information available at that time, we did not consider the three Laramie River valley occurrences to be North Park Phacelia (FWS 2012, p. 7). However, recent genetic analysis concluded that the three Laramie River valley populations are indeed North Park Phacelia (Riser et al. 2020, entire, in prep). Therefore, our understanding of the current range and distribution of the species has improved since our last 5-year status review with the inclusion of the Laramie River valley populations (Figure 4). The CNHP provided the geographic information system data displayed in Figure 4. The shape of the polygons include a masking technique to hide the precise location of populations occurring on private lands. A data use agreement with CNHP prevents the FWS from displaying the exact location of occupied habitat occurring on private lands. (USFWS, 2020). North Park phacelia is a narrow endemic plant, which occurs in 12 populations in Jackson, Grand, and northwestern Larimer Counties, Colorado, currently occupying approximately 452 acres. (USFWS, 2023)

### **Critical Habitat Designated**

Yes;

### **Life History**

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Sexual: self-pollination, cross-pollination (USFWS, 2012)

### **Lifespan**

Adult: 2 years (USFWS, 2016)

**Breeding Season**

Adult: July - August (USFWS, 2016)

**Key Resources Needed for Breeding**

Adult: Bee pollinators (USFWS, 2012)

**Reproduction Narrative**

Adult: It blooms in July and August and is a biennial surviving for one year as a rosette of leaves before flowering and dying the following year (USFWS, 2016). *Phacelia formosula* plants can self-pollinate, but are typically pollinated by a variety of bees (USFWS, 2012).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Bare rock/talus/scree (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 7,840 to 8,260 ft. elevation (USFWS, 2020)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: North Park *Phacelia* occurs at elevations of approximately 7,840 to 8,260 feet above sea level (ASL) (2,420 – 2,517 meters ASL) in Jackson County and northwestern Larimer County, Colorado. In Jackson County, the species occurs on specific soil outcrops composed of barren, raw exposures of the sedimentary Coalmont formation, a coal-bearing sandstone substrate susceptible to erosion (Figure 2) (CNHP 2015, p. 1). The Laramie River valley populations occur on barren shale exposures identified as Niobrara Shale outcrops [figure 3] instead of the Coalmont formation. Both areas occupied by North Park *Phacelia* appear well drained and sparsely vegetated. (USFWS, 2020)

***Dispersal/Migration*****Dispersal**

Adult: Low (USFWS, 2012)

**Dispersal/Migration Narrative**

Adult: Seeds are poorly dispersed (Warren 1990, p. 3) (USFWS, 2012).

***Population Information and Trends*****Population Trends:**

Unknown (NatureServe, 2015)

**Species Trends:**

Stable (NatureServe, 2015)

**Resiliency:**

We describe the resiliency for each of the 11 populations in terms of the habitat, demographic, and climate factors needed by the North Park Phacelia (Service 2021, pp. 22–24). We developed a categorical model to calibrate resiliency based on a range of conditions for two habitat factors (occupied area and ecological setting) and one demographic factor (abundance measured by abundance estimates), and one climate variable (growing season water deficit) (Service 2021, pp. 23–24). We selected these factors based on their importance to resiliency and because we could evaluate them relatively consistently across all 11 populations. We then used a categorical model as a key to evaluate resiliency for each population by systematically evaluating the current condition of each factor. To calculate an overall score for resiliency, we assigned values to the resiliency categories and then calculated an average of the factor ranking (Table 8 in Service 2021, p. 24). Populations in higher resiliency categories are at less risk from potential stochastic events, such as extended drought conditions, than populations in lower resiliency categories (Service 2021, p. 25). Our SSA report provides additional detail regarding the methodology we used to evaluate resiliency for each of the 11 populations (Service 2021, pp. 22–24). (USFWS, 2021)

**Representation:**

Riser et al. (2020, entire), through genetic analysis, reported the breadth of genetic variability of the species both within and between populations of North Park Phacelia. In addition, Atwood (2010, p. 1–3) concluded that North Park Phacelia in the Laramie River valley show a number of measurable differences in growth forms of flowers, leaves, and seeds from those in North Park. Based on this information, we believe the species displays a relatively high degree of genetic diversity, which may confer some type of adaptability to environmental change. The role of pollinators is unclear since the species can self-pollinate, and we assume that some genetic exchange occurs between populations periodically. We consider ecological representation low as there is little variation in soil type and conditions at population sites. The different soil types between populations in Jackson County and those in the Laramie River valley represent what little ecological variability exists. Our SSA report provides a full account of our evaluation of resiliency, redundancy, and representation for each population, including the assessment of each habitat and demographic factor for each population. Please see the SSA report for our full analysis of current resiliency (Service 2021, pp. 23–29). (USFWS, 2021)

**Redundancy:**

Like many narrow endemic species, the redundancy of North Park Phacelia is, and has likely always been, relatively low because of its limited geographic range and habitat specificity. However, North Park Phacelia consists of 11 populations, separated by at least 1 mile. Three populations occur approximately 20 mi (30 km) from the other 8 populations, and are separated by the Medicine Bow Mountain Range, which helps spread catastrophic risk over a larger geographic area. We are not aware of any populations that have been lost to the species. Under the current circumstances, redundancy is higher with 11 known populations compared to the 2 known populations at listing (1982). There may be additional undiscovered populations within the range of the species. We believe that redundancy is likely stable under current conditions. (USFWS, 2021)

**Number of Populations:**

12 (USFWS, 2023)

**Population Size:**

~23,000 - 26,000 (USFWS, 2023)

**Population Narrative:**

The long term data population trend is unknown. Although there are no data to indicate a specific trend, the species seems to be stable within its limited available habitat (NatureServe, 2015). Roughly 16,000 individuals are known from six separate populations and the entire species is known only to an area measuring roughly 10 miles in either direction (north to south, east to west) (USFWS, 2016). Currently, North Park Phacelia occurs in 11 disjunct populations (Figure 2). Eight of the 11 populations are in Jackson County, Colorado, and three in the Laramie River valley in northwestern Larimer County, Colorado. In past assessments, based on the best scientific information available at that time, we did not consider the three Laramie River valley occurrences to be North Park Phacelia (FWS 2012, p. 7). However, recent genetic analysis concluded that the three Laramie River valley populations are indeed North Park Phacelia (Riser et al. 2020, entire, in prep). Therefore, our understanding of the current range and distribution of the species has improved since our last 5-year status review with the inclusion of the Laramie River valley populations (Figure 4). The CNHP provided the geographic information system data displayed in Figure 4. The shape of the polygons include a masking technique to hide the precise location of populations occurring on private lands. A data use agreement with CNHP prevents the FWS from displaying the exact location of occupied habitat occurring on private lands. (USFWS, 2020). there are currently 12 populations of North Park phacelia with approximately 23,000 to 26,000 plants (USFWS, 2023).

**Threats and Stressors****Stressor:** Cattle grazing (USFWS, 2013)**Exposure:****Response:****Consequence:**

**Narrative:** Grazing by cattle is ubiquitous across the range of *Phacelia formosula*. Cattle trampling and compaction of the soil and trampling of rosettes and mature plants is an ongoing threat because *P. formosula*, like most small herbaceous plants, can be severely damaged in heavily travelled areas, such as around watering areas and fences and along trails (CNAP 1996, p. 5). A few heavily impacted sites have been documented (CNHP 2010a, pp. 1, 4, 5, 9, 11, 18). Some of the adverse effects from livestock include changes in the timing and availability of pollinator food plants (Kearns and Inouye 1997, pp. 298–299); changes to insect communities (Kearns and Inouye 1997, pp. 298–299; Debano 2006, pp. 2547–2564); damage to ground-nesting pollinators and their nests (Sugden 1985, p. 309); changes in water infiltration due to soil compaction (Jones 2000, Table 1); disturbance to soil microbiotic crusts (Belnap et al. 1999, p. 167; Jones 2000, Table 1); subsequent nonnative invasive plant invasions (Parker et al. 2006, pp. 1459–1461); and soil erosion from hoof action (Jones 2000) (USFWS, 2012).

**Stressor:** Range improvements (USFWS, 2012)**Exposure:****Response:**

**Consequence:**

**Narrative:** The recovery plan cites the potential for range improvements, such as vegetation manipulation or spraying and changing water source locations, to affect the species, although no examples were available. The effects of range improvements on occurrences of *Phacelia formosula* on private lands have not been documented due to lack of access. This is considered a potential threat because future changes (such as altering water sources which forces cattle to congregate in certain areas) could impact the species (USFWS, 2012).

**Stressor:** Off-road vehicles (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** ORV tracks have been noted at five of the nine occurrences. The Airport occurrence is the most heavily impacted by ORV use. Plants still exist at this occurrence, but its viability is ranked as poor because the habitat is disturbed by ORVs and other general public uses that facilitate the introduction of nonnative invasive plants that can compete with *P. formosula* (CNHP 2010a, pp. 1-3). As on other BLM lands in western Colorado, ORV use is likely to increase (Colorado Off-Highway Vehicle Coalition 2009, p. 1-2). These activities can destroy more plants and damage habitat for *P. formosula*. Unpaved access roads on BLM and private land cause habitat fragmentation because they create abrupt transitions in vegetation; are sources of pollutants; and act as filters (allowing some species to cross but not others) and barriers (prohibiting movement) (Spellerberg 1998, pp. 317–333) (USFWS, 2012).

**Stressor:** Oil and gas development (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** BLM lands in North Park have been leased for oil, gas, and coal development since before the implementation of the ESA (USFWS 1986, p. 6). Three *Phacelia formosula* occurrences have oil and gas leases that have been issued since 2001. The leases include 144.3 ac (58.4 ha) of occupied habitat for the species. Of these occupied acres, 41.3 ac (16.7 ha) are within 500 meters of wells (Glennie 2011a, pers. comm.) (USFWS, 2012).

**Stressor:** Residential development (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Development of home sites on ranch land has been cited as a threat to *Phacelia formosula* (Kram et. al. 2008, p. 4). TNC has secured a conservation agreement for the species that allows a home to be built on a parcel that also has a protected area of plant habitat (Handwerk 2009, pers. comm.). Residential development is a potential threat of low magnitude that is likely to increase as more development occurs in North Park, depending on the economy (USFWS, 2012).

**Stressor:** Seed predation (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Seed predation by insect larvae was observed in 1980. In 1990, lepidopteran larvae were reportedly destroying half of the seed pods that were inspected. In 1993, many seed pods were destroyed by unidentified insect predation (CNAP 1994, p. 4) (USFWS, 2012).

**Stressor:** Stochastic events (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The final listing rule and the recovery plan state that any human threats to this species would exacerbate the possibility of small populations going extinct through natural population fluctuations. They also cite lack of species occurrence and environmental data and uninformed land managers, administrators, and landowners as contributing to risk factors. Given current population levels, these factors remain a concern (USFWS, 2012).

**Stressor:** Climate change (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Climate change is a potential threat to *Phacelia formosula* because the species is highly sensitive to changes in precipitation and temperature. Typical future summer monthly temperatures will be as warm as or warmer than the hottest 10% of summers that occurred between 1950 and 1999 (CWCB 2009, p. 1). *Phacelia formosula* is particularly sensitive to precipitation and temperature during germination, seedling and rosette growth, and especially while developing into flowering adults at the height of summer heat and drought (McCormick and Wu 1999, p. 5). *P. formosula* also is sensitive to extreme weather events, such as the thunderstorms that are common in North Park which can cause rill and sheet erosion and carry away the *P. formosula* plants (USFWS, 2012).

## ***Recovery***

### **Reclassification Criteria:**

Locate and secure five occurrences of approximately 500 mature flowering individuals each (USFWS, 1986).

Recovery Priority Number: 8

### **Delisting Criteria:**

Ten other areas of suitable habitat are identified and secured with 500 mature flowering individuals each (USFWS, 1986).

### **Recovery Actions:**

- Disseminate information on the known occurrences and potential occurrences of *P. formosula* habitat (USFWS, 1986).
- Implement conservation strategies for the perpetuation of the essential habitat of the species (USFWS, 1986).
- Develop strategies to assist in the perpetuation of the essential habitat and the species (USFWS, 1986).

- Initiate scientific research on known and potential habitat and the biology of the species (USFWS, 1986).
- Publicize as appropriate the value of the North Park phacelia and the recovery effort (USFWS, 1986).
- Investigate the advantages of habitat acquisition and/or conservation easements (USFWS, 1986).
- The recovery plan for *Phacelia formosula* should be revised so that it reflects the best scientific and commercial information available. The revised recovery plan should include objective, measurable criteria which, when met, will result in a determination that the species be removed from the Federal List of Endangered and Threatened Plants. Recovery criteria should address all threats impacting the species. The recovery plan also should estimate the time required and the cost to carry out those measures needed to achieve the goal for recovery and delisting. Finally, the recovery plan should evaluate and map geographic areas essential for the conservation of *P. formosula* (USFWS, 2012).
- Work with the CRPCI to develop a list of recovery priorities and implement conservation actions (USFWS, 2012).
- Develop conservation agreements and easements with partners such as land trusts, TNC, NRCS, CNAP, and Partners for Fish and Wildlife to protect *Phacelia formosula* on private lands across the entire range of the species (USFWS, 2012).
- Inventory unsurveyed suitable and potential habitat for *Phacelia formosula* on public and private lands. Report results to CNHP, BLM, and USFWS. These surveys will provide better information to guide recovery and conservation actions as well as project planning (USFWS, 2012).
- Monitor phenology of the plants and log weather patterns to inform climate change studies (USFWS, 2012).
- Develop and implement a long-term range management monitoring plan to guide grazing management for protection of *Phacelia formosula* habitat (USFWS, 2012).
- Establish and implement a range-wide trend monitoring protocol (USFWS, 2012).
- Control the location and timing of livestock movement and concentration to minimize impacts to the species (USFWS, 2012).
- Regularly monitor impacts from ORV use. If impacts from ORV use are detected, work with the land manager on reducing those effects (USFWS, 2012).
- BLM plans to expand the existing ACEC and create new ACECs to include contiguous occupied and suitable habitat for the plant and its pollinators. Oil leases have been deferred within the potential ACECs until the new RMP is final (USFWS, 2012).
- Work with the BLM Kremmling Field Office to develop and implement consistent conservation measures in the RMP revision that will avoid and minimize impacts to *Phacelia formosula* and its habitat from livestock trampling, ORV activities, and energy development (USFWS, 2012).
- Continue ongoing seed collection, germination testing, and long-term storage and preservation of seeds (USFWS, 2012).
- Undertake a study to improve understanding of dormancy characteristics in *Phacelia formosula* seed banks (USFWS, 2012).
- Conduct a study to identify pollinators and their habitat needs (USFWS, 2012).
- Perform long-term study of local changes in weather patterns and effects on plants (USFWS, 2012).
- Study livestock impacts on plants and habitat (USFWS, 2012).

- Complete the analysis of the genetic relationship between *Phacelia formosula* and *Phacelia scullyi* (the population of *Phacelia* discovered in the Laramie River Valley approximately 20 mi (~30 km) north of known *Phacelia formosula* populations) (USFWS, 2012).
- Reach out to Jackson County, the town of Walden, the State of Colorado, applicable Federal agencies, and other potential stakeholders with information about the plants, habitat requirements, and known locations in order to proactively engage partners to ensure that projects avoid impacts to *Phacelia formosula* (USFWS, 2012).
- Educate private landowners about the plant and how they can help protect the species (USFWS, 2012).

## SPECIES ACCOUNT: *Phacelia insularis* ssp. *insularis* (Island phacelia)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

An annual herb, usually about 1.5 dm tall. Small lavender to violet, bell-shaped flowers bloom in March and April. (NatureServe, 2015)

### **Taxonomy**

The summary and table of the July 31, 1997 notice in the Federal Register (in which the USFWS determines this taxon as endangered) lists the taxon as *Phacelia insularis* SSP. *insularis*; in the text the taxon is referred to as a subspecies and as a variety. The treatment the notice appears to follow is Wilken et al. (1993; in Hickman) which treats the taxon as a variety. (NatureServe, 2015)

### **Historical Range**

Endemic to the California Channel Islands and, at the time of listing in 1997, a single population on Santa Rosa Island was the only known population of the species. By the time the recovery plan was published in 2000, island phacelia was known to occur in five localities: the one on Santa Rosa Island at Carrington Point and the four on San Miguel Island (see Santa Rosa Island and San Miguel Island maps, pp. 15-16). Both islands occur on lands managed by Channel Islands National Park (Park). The Santa Rosa Island population occupies about 15 acres (6 hectares (ha)) based on its maximum observed extent in 1998. The San Miguel Island populations range from about 0.02 to 0.86 acres (0.01 to 0.35 ha). These figures are from USGS surveys made in April and May, 1998, when the largest number of plants were observed (McEachern in litt. 2007b). Surveys since 1998 have not seen such extensive numbers of plants in those same areas; however, a seed bank likely still exists (McEachern in litt. 2007b). (USFWS, 2008)

### **Current Range**

This variety occurred only in Santa Rosa and San Miguel Islands, Santa Barbara county, California. (NatureServe, 2015)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproduction Narrative**

Adult: Currently, little life history information is available for this species. This annual flower blooms from March through April (USFWS, 2000).

### **Habitat Type**

Adult: Sandy valley and foothill grassland communities, bluffs, dunes, dominated by alien grasses with some scattered native bunchgrasses, shrubs, and herbs; at or near sea level (partly

based on Calif. Nat. Diversity Database, May/1998 report). (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Sandy valley and foothill grassland communities, bluffs, dunes, dominated by alien grasses with some scattered native bunchgrasses, shrubs, and herbs; at or near sea level (partly based on Calif. Nat. Diversity Database, May/1998 report). (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Sandy valley and foothill grassland communities, bluffs, dunes, dominated by alien grasses with some scattered native bunchgrasses, shrubs, and herbs; at or near sea level (partly based on Calif. Nat. Diversity Database, May/1998 report). (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Sandy valley and foothill grassland communities, bluffs, dunes, dominated by alien grasses with some scattered native bunchgrasses, shrubs, and herbs; at or near sea level (partly based on Calif. Nat. Diversity Database, May/1998 report). (NatureServe, 2015)

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Not available

**Number of Populations:**

6 EOs (USFWS, 2021)

**Population Narrative:**

USFWS reports a population of 31 plants from Santa Rosa Island in 1994. No populations have been relocated in San Miguel Island. As of 2001, no populations exist. The California Natural Diversity Database (May/1998) reports four occurrences, none of which have been observed in the last 20 years; but USFWS (1997) reports that Sarah Chaney found one small population in 1994 in Santa Rosa Island. (NatureServe, 2015). Low redundancy, representation and resiliency are inferred based on low population numbers and low number of individuals.

***Threats and Stressors***

**Stressor:** Predation (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Some progress has been made toward eliminating non-native animals from Santa Rosa Island since the time of listing. We believe the removal of pigs by 1993, removal of cattle by 1998, and smaller populations of deer and elk since 1998 have reduced browsing pressure on island phacelia. Although habitat conditions on Santa Rosa Island and San Miguel Island show the

effects of long-term grazing, the USGS believes that at the landscape level, conditions are improving (McEachern in litt. 2007b). In fact, browsing by an animal is rarely seen, although predation does occur from mice that are known to harvest the fruits (McEachern in litt. 2007b) (USFWS, 2008).

**Stressor:** Non-native plants (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Invasion of habitats by non-native annual grasses, especially ripgut brome, continues to impact the species, particularly germination. Non-native annual grasses and the litter they produce also appear to inhibit successful establishment of phacelia seedlings in field experiments (McEachern in litt. 2007b, Levine et al. 2007) (USFWS, 2008).

**Stressor:** Small population size (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of genetic variability/extinction

**Narrative:** At the time of listing, island phacelia was threatened by the risk of stochastic extinction due to small population size and limited distribution (62 FR 40954). The conservation biology literature commonly notes the vulnerability of taxa known from one or very few locations and/or from small and highly variable populations (e.g., Shaffer 1981, 1987; Primack 2006; Groom et al. 2006). In particular, the small size of each population makes it difficult for this species to persist while sustaining the impacts of soil damage and habitat alteration from non-native species. The species remains vulnerable to extirpation due to its small population size, high inter-annual variability in plant numbers, limited distribution, and low survival rate (USFWS, 2008).

**Stressor:** Climate change (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Island phacelia may be particularly threatened by climate change because its geographic distribution is so narrow and its current range is unlikely to overlap regions that would be climatically favorable in the future (Levine et al. 2007). This is particularly acute for species on islands because they are unable to disperse to more favorable habitat as the environment changes. Because of this, Levine et al. (2007) suggest that the persistence of many rare species depends on how populations respond to climate change in their current locations (USFWS, 2008).

## **Recovery**

### **Reclassification Criteria:**

1. Discover or establish 10 populations per island (San Miguel and Santa Rosa) (USFWS, 2021)
2. Maintain stable populations for a period of 15 years that includes the normal precipitation cycle. (USFWS, 2021)

3. Seed stored in CPC cooperating facilities. (USFWS, 2021)
4. Seed germination and propagation techniques understood. (USFWS, 2021)
5. Successful outplanting techniques developed (USFWS, 2021)
6. Life history research conducted. (USFWS, 2021)
7. Weed management plan developed and implemented. (USFWS, 2021)
8. If declining, determine cause and reverse trend. (USFWS, 2021)

**Delisting Criteria:**

Discover or establish five additional populations per island (USFWS, 2008).

No decline after downlisting for 10 years (USFWS, 2008).

All potential habitat surveyed. (USFWS, 2021)

**Recovery Actions:**

- **Reclassification Criteria:** Although surveys in historical and other suitable habitat have been conducted, additional populations have not been found and no reintroduced populations have been established on Santa Rosa Island. Therefore, this criterion has not been met. We believe this criterion may be possible on San Miguel Island because, although these plants have every specific habitat requirements, there are several places on the island where suitable habitat conditions exist and the plant now occurs (McEachern, in litt. 2007a). However, this criterion is not appropriate with respect to the recovery of the species on Santa Rosa Island because suitable habitats appear to be extremely rare on the island. Suitable habitat may be available on Carrington Point; otherwise, suitable habitat on the island appears to be limited. Therefore, a more realistic goal would be to establish one additional population on Santa Rosa Island. Results of restoration field experiments over time would help establish whether or not the goal of one more population is feasible (McEachern, in litt. 2007a). **Delisting Criteria:** This criterion has not been met. We believe this criterion may be possible on San Miguel Island where three populations exist now but it is not realistic with respect to the recovery of the species on Santa Rosa Island for the same reasons described in downlisting criterion #1 above (USFWS, 2008).
- **Reclassification Criteria:** Delisting Criteria: This criterion has not been met. Although we believe the intent of this criterion is appropriate, we think it should be refined to focus on long-term trends, rather than a short-term, absolute decline, once additional information about the life history of the species and the species' response to recovery actions are better understood. Factor B is not relevant to this species. Factor D is relevant but is not addressed in the recovery criteria (USFWS, 2008).
- **Reclassification criteria:** A precipitation cycle includes periods of drought and wet years, with annual rainfall starting at 100 to 135 percent of average, dropping below 65 percent of average, and returning to at least average (Service 2000). Because the species has not been listed for a minimum of 15 years, this criterion has not been met. We believe this criterion is adequate and appropriate with respect to the recovery of the species (USFWS, 2008).

- The USGS-BRD and NPS should seek additional funding to continue field surveys and monitoring, demographic monitoring, population viability analyses, and further investigations into recovery projects (USFWS, 2008).
- The Service should work cooperatively with NPS and USGS-BRD to refine the generalized downlisting criteria to take into consideration new information. Attaining the recovery objective of securing several populations containing a minimum of 2,000 plants each is unrealistic for this species (USFWS, 2008).
- The Service should work cooperatively with NPS and USGS-BRD to refine delisting criteria to emphasize long-term population growth trends rather than short-term gains or declines (USFWS, 2008).
- The USGS-BRD and NPS should investigate the community-level factors that influence population abundance, distribution, and demographic trends (USFWS, 2008).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Continue monitoring the Santa Rosa Island occurrence of *Phacelia insularis* var. *insularis* and establish regular surveys on both Santa Rosa and San Miguel Islands. 2. Better define suitable germination and growth microhabitat for *Phacelia insularis* var. *insularis*, especially in relationship to non-native *Bromus diandrus* competition and thatch accumulation, and if needed determine how to manage *Bromus diandrus*. 3. Determine efficient methods to reduce *Bromus diandrus* thatch without harming *Phacelia insularis* var. *insularis* individuals. 4. Control non-native *Malva pueblana* in the Carrington Point area on Santa Rosa Island. 5. Improve the completeness of coverage of *Phacelia insularis* var. *insularis* in conservation seed banks, with more occurrences over more years. (USFWS, 2021)

## SPECIES ACCOUNT: *Phacelia submutica* (DeBeque phacelia)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 08/26/2011; Mountain-Prairie Region (R6) (USFWS, 2016)

### **Physical Description**

Annual plant, stems 2-8 cm long, often branched at the base, mostly prostrate, leaves hairy, oblong or egg-shaped, flowers crowded, petals 3.5-4.5 mm long, white or cream colored becoming yellowish with age, stamens not protruding beyond the petals. (NatureServe, 2015)

### **Taxonomy**

*Phacelia submutica* was first described by Howell based on specimens collected from the town of DeBeque, Mesa County, Colorado, in 1911 and 1912 (Howell 1944, pp. 370– 371 Halse (1981, pp. 121, 129, 130) reduced it to varietal status as *P. scopulina* var. *submutica*. This has been challenged as incorrect by O’Kane (1987, p. 2), who claimed Halse used inadequate collection materials, and that *P. submutica* is geographically isolated from *P. scopulina* (O’Kane 1987, p. 2; 1988, p. 462). *Phacelia submutica* is recognized at the species rank by current floristic treatments in Weber and Wittmann (1992, p. 98; 2001, p. 203) and by the Director of the Biota of North America Program (Kartesz 2008, pers. comm.). While the Integrated Taxonomic Information System (2001) database cites John Kartesz as the expert source for this species, it is not updated with his currently accepted name for the species: *Phacelia submutica* (Kartesz 2008, pers. comm.). *Phacelia* is included in the Hydrophyllaceae (waterleaf family). Recent molecular data suggest that this family should be combined in an expanded Boraginaceae (borage family). There are conflicting views on the configuration of this larger Boraginaceae and the lead author of the family treatment for the upcoming Flora of North America has chosen to retain the Hydrophyllaceae. Therefore, we will retain *Phacelia* in the Hydrophyllaceae family for this proposal (USFWS, 2010).

### **Current Range**

*Phacelia submutica* is endemic to Colorado and known only from Garfield and Mesa counties. Estimated range is 356 square kilometers, calculated in GIS by drawing a minimum convex polygon around the known occurrences.

### **Critical Habitat Designated**

Yes; 8/13/2012.

### **Legal Description**

On August 13, 2012, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Phacelia submutica* (DeBeque phacelia) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes four critical habitat units (CHUs), in Colorado (77 FR 48356-48415).

### **Critical Habitat Designation**

The critical habitat designation for *Phacelia submutica* includes nine CHUs in Garfield and Mesa Counties, Colorado. This species critical habitat encompasses approximately 25,484 acres (ac) (10,313 hectares (ha)) (77 FR 48356-48415).

Unit 1, the Sulphur Gulch Unit, consists of 1,046 ac (423 ha) of federally owned land. The Unit is located approximately 7.7 mi (12.5 km) southwest of the town of DeBeque in Mesa County, Colorado. This Unit is managed by BLM, through the Grand Junction Field Office. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent plant/vegetation cover, suitable elevational ranges of 5,480 to 6,320 ft (1,670 to 1,926 m), appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. All lands within this Unit are leased as grazing allotments, and less than 1 percent is managed as an active pipeline ROW by the BLM. While these lands currently have the physical and biological features essential to the conservation of *Phacelia submutica*, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to *Phacelia submutica* and its habitat in this Unit include energy development, recreation (especially OHV use), domestic and wild ungulate grazing and use, and nonnative invasive species, such as *Bromus tectorum*.

Unit 2, the Pyramid Rock Unit, is the largest Unit we are designating and consists of 17,321 ac (7,010 ha) of federally and privately owned lands in Mesa and Garfield Counties, Colorado. This Unit is approximately 1.6 mi (2.6 km) west of the town of DeBeque. The eastern boundary borders Roan Creek, and Dry Fork Creek runs through the northern quarter of the Unit. Eighty-nine percent is managed by BLM through the Grand Junction Field Office, and 11 percent is under private ownership. Three percent of this Unit is within the Pyramid Rock Natural Area and Pyramid Rock ACEC that was designated, in part, to protect *Phacelia submutica*, as discussed in the proposed (75 FR 35739) and final listing rules (76 FR 45054). This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent plant/vegetation cover, suitable elevational ranges of 4,960 to 6,840 ft (1,512 to 2,085 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. Ninety-four percent of this Unit is managed as a grazing allotment on BLM and private lands. Additionally, 11 percent of this Unit is managed as an active pipeline ROW. While these lands currently have the physical and biological features essential to the conservation of *Phacelia submutica*, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to *Phacelia submutica* and its habitat in this Unit include energy development, recreation (especially OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species including *Bromus tectorum* and *Halogeton glomeratus*. The Westwide Energy corridor runs through this Unit. The corridor covers almost 10 percent of this Unit (Service 2011c, p. 9).

Unit 3, the Roan Creek Unit, consists of 54 ac (22 ha) of federally and privately owned lands in Garfield County, Colorado. The Unit is located 3.3 mi (5.4 km) north of the town of DeBeque and for 1.7 mi (2.7 km) along both sides of County Road 299. Ninety-seven percent of this Unit is privately owned. Three percent of this Unit is managed by BLM through the Grand Junction Field Office. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent cover, suitable elevational ranges of 5,320 to 5,420 ft (1,622 to 1,652 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. The entire Unit is within a grazing allotment. While these lands currently have the physical and biological features essential to the conservation of *Phacelia submutica*, because of a lack of cohesive management and protections, special management

will be required to maintain these features in this Unit. Threats to *Phacelia submutica* and its habitat in this Unit include recreation (especially OHV use), livestock and wild ungulate grazing and use, nonnative invasive species including *Bromus tectorum* and *Halogeton glomeratus*, and a lack of protections on private lands.

Unit 4, the DeBeque Unit, consists of 530 ac (215 ha) of Federal and private lands in Mesa County, Colorado. This Unit is located 0.25 mi (0.4 km) north of DeBeque between Roan Creek Road and Cemetery Road. Seventy-six percent of this Unit is managed by BLM through the Grand Junction Field Office. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent plant/vegetation cover, suitable elevational ranges of 5,180 to 5,400 ft (1,579 to 1,646 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. While these lands currently have the physical and biological features essential to the conservation of *Phacelia submutica*, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to *Phacelia submutica* and its habitat in this Unit include energy development, residential development, recreation (especially OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species including *Bromus tectorum* and *Halogeton glomeratus*. Since 24 percent of the Unit is privately owned and borders the north of the town of DeBeque, this Unit is threatened by potential urban or agricultural development. The Westwide Energy corridor runs through this Unit. The corridor covers almost 66 percent of this Unit (Service 2011c, p. 9).

Unit 5, the Mount Logan Unit, consists of 277 ac (112 ha) of Federal and private lands in Garfield County, Colorado. The Unit is located 2.7 mi (4.4 km) north, northeast of the town of DeBeque, Colorado, and 0.5 mi (0.8 km) west of Interstate 70. Eighty-eight percent of this Unit is managed by BLM through the Grand Junction Field Office. The remainder of this Unit is privately owned. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent plant/vegetation cover, suitable elevational ranges of 4,960 to 5,575 ft (1,512 to 1,699 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. Eighty-eight percent of this Unit is managed as a grazing allotment by BLM, and 53 percent is managed as an active pipeline ROW. An access road runs through the Unit connecting several oil wells and associated infrastructure. While these lands currently have the physical and biological features essential to the conservation of *Phacelia submutica*, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to *Phacelia submutica* and its habitat in this Unit include energy development, recreation (especially OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species, including *Bromus tectorum* and *Halogeton glomeratus*.

Unit 6, the Ashmead Draw Unit, consists of 1,276 ac (516 ha) of Federal and private lands in Mesa County, Colorado. The Unit is located 1.5 mi (2.5 km) southeast of the town of DeBeque, Colorado, and east of 45.5 Road (DeBeque Cut-off Road). Eighty-seven percent of this Unit is managed by BLM through the Grand Junction Field Office, the remainder is private lands. This Unit is currently occupied. We slightly increased the size of this Unit from our proposed critical habitat designation in our notice of availability (77 FR 18162) to include sites that were revisited and more accurately mapped during the spring of 2011 (Service 2011e, pp. 1-3). This Unit

currently has all the physical and biological features essential to the conservation of the species including barren clay badlands with less than 20 percent plant/vegetation cover, suitable elevational ranges of 4,940 to 5,808 ft (1,506 to 1,770 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. A network of access roads runs through the Unit. Eighty-eight percent of this Unit is within a BLM grazing allotment, and 84 percent is within the Grand Junction Field Office's designated energy corridor. Thirty percent of the Unit is managed as an active pipeline ROW. While these lands currently have the physical and biological features essential to the conservation of *Phacelia submutica*, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to *Phacelia submutica* and its habitat in this Unit include energy development, recreation (especially OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species, including *Bromus tectorum* and *Halogeton glomeratus*. The Westwide Energy corridor runs through this Unit. The entire Unit is within the Westwide Energy corridor, and 88 percent is within several grazing allotments.

Unit 7, the Baugh Reservoir Unit, consists of 430 ac (174 ha) of Federal and private lands in Mesa County, Colorado. The Unit is located 6 mi (10 km) south of DeBeque, Colorado, near Kimball Mesa and Horse Canyon Road. Thirty-nine percent is managed by BLM through the Grand Junction Field Office, and the remaining 61 percent is on private lands. This Unit is currently occupied. We slightly increased the size of this Unit from our proposed critical habitat designation in our notice of availability (77 FR 18162) to include sites that were revisited and more accurately mapped during the spring of 2011 (Service 2011e, pp. 5-8). This Unit currently has all the physical and biological features essential to the conservation of the species, including barren clay badlands with less than 20 percent plant/vegetation cover, a suitable elevational range of 5,400 to 5,700 ft (1,646 to 1,737 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. An access road runs through the Unit, close to the occurrence of *Phacelia submutica*. While these lands currently have the physical and biological features essential to the conservation of *P. submutica*, because of a lack of cohesive management and protections, special management will be required to maintain these features in this Unit. Threats to *Phacelia submutica* and its habitat in this Unit include energy development, recreation, livestock and wild ungulate grazing and use, and nonnative invasive species including *Bromus tectorum* and *Halogeton glomeratus*. The Westwide Energy corridor runs through this Unit. The entire Unit is within the Westwide Energy corridor and one grazing allotment.

Unit 8, the Horsethief Mountain Unit, consists of 4,209 ac (1,703 ha) of Federal and private lands in Mesa County, Colorado. It is located approximately 3.5 mi (5.6 km) southeast of DeBeque, Colorado, and along the eastern side of Sunnyside Road (V Road). Thirty-four percent is managed by BLM through the Grand Junction Field Office, 29 percent by the White River National Forest, 23 percent by the Grand Mesa Uncompahgre National Forest, and 14 percent is on private lands. This Unit is currently occupied. This Unit currently has all the physical and biological features essential to the conservation of the species, including barren clay badlands with less than 20 percent plant/vegetation cover, a suitable elevational range of 5,320 to 6,720 ft (1,622 to 2,048 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. While these lands currently have the physical and biological features essential to the conservation of *Phacelia submutica*, because of a lack of cohesive management and protections, special management will be required to

maintain these features in this Unit. A portion of the site on USFS lands is within a proposed Research Natural Area. Threats to *Phacelia submutica* and its habitat in this Unit include energy development, recreation (especially OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species, including *Bromus tectorum* and *Halogeton glomeratus*.

Unit 9, the Anderson Gulch Unit, consists of 341 ac (138 ha) of State and private lands in Mesa County, Colorado. It is located 11 mi (17 km) southeast of DeBeque, Colorado, and 3.5 mi (5.5 km) north of the town of Molina, Colorado. Within the Unit, 56 percent of the lands are managed by CDOW, within the Plateau Creek State Wildlife Area, and 44 percent is private. This Unit is currently occupied. We slightly increased the size of this Unit from our proposed critical habitat designation in our notice of availability (77 FR 18162) to include sites that were revisited and more accurately mapped during the spring of 2011 (CNHP 2012b, spatial data). This Unit currently has all the physical and biological features essential to the conservation of the species, including barren clay badlands with less than 20 percent plant/vegetation cover, a suitable elevational range of 5,860 to 6,040 ft (1,786 to 1,841 m), the appropriate topography, and shrink-swell alkaline clay soils within the Atwell Gulch and Shire members of the Wasatch Formation. Forty-two percent of the Unit is a pending pipeline ROW. While these lands currently have the physical and biological features essential to the conservation of *Phacelia submutica*, special management may be required to maintain these features in this Unit. Threats to *Phacelia submutica* and its habitat in this Unit include energy development, recreation (especially from OHV use), livestock and wild ungulate grazing and use, and nonnative invasive species, including *Bromus tectorum* and *Halogeton glomeratus*.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Phacelia submutica* critical habitat consists of five components (77 FR 48356-48415):

(i) Suitable soils and geology. (A) Atwell Gulch and Shire members of the Wasatch formation. (B) Within these larger formations, small areas (from 10 to 1,000 ft<sup>2</sup> (1 to 100 m<sup>2</sup>)) on colorful exposures of chocolate to purplish brown, light to dark charcoal gray, and tan clay soils. These small areas are slightly different in texture and color than the similar surrounding soils. Occupied sites are characterized by alkaline (pH range from 7 to 8.9) soils with higher clay content than similar nearby unoccupied soils. (C) Clay soils that shrink and swell dramatically upon drying and wetting and are likely important in the maintenance of the seed bank.

(ii) Topography. Moderately steep slopes, benches, and ridge tops adjacent to valley floors. Occupied slopes range from 2 to 42 degrees with an average of 14 degrees.

(iii) Elevation and climate. (A) Elevations from 4,600 ft (1,400 m) to 7,450 ft (2,275 m). (B) Climatic conditions similar to those around DeBeque, Colorado, including suitable precipitation and temperatures. Annual fluctuations in moisture (and probably temperature) greatly influences the number of *Phacelia submutica* individuals that grow in a given year and are thus able to set seed and replenish the seed bank.

(iv) Plant community. (A) Small (from 10 to 1,000 ft<sup>2</sup> (1 to 100 m<sup>2</sup>)) barren areas with less than 20 percent plant cover in the actual barren areas. (B) Presence of appropriate associated species that can include (but are not limited to) the natives *Grindelia fastigiata*, *Eriogonum*

*gordonii*, *Monolepis nuttalliana*, and *Oenothera caespitosa*. Some presence, or even domination by, invasive nonnative species, such as *Bromus tectorum*, may occur, as *Phacelia submutica* may still be found there. (C) Appropriate plant communities within the greater pinyon-juniper woodlands that include: (1) Clay badlands within the mixed salt desert scrub; or (2) Clay badlands within big sagebrush shrublands.

(v) Maintenance of the seed bank and appropriate disturbance levels. (A) Within suitable soil and geologies (see paragraph (2)(i) of this entry), undisturbed areas where seed banks are left undamaged. (B) Areas with light disturbance when dry and no disturbance when wet.

### Special Management Considerations or Protections

The features essential to the conservation of this species (plant community and competitive ability, elevation, topography, soils, climate, reproduction and seed bank, and disturbance regime) may require special management considerations or protection to reduce threats. Specifically, the clay soils on which *Phacelia submutica* are found are relatively stable when dry but are extremely vulnerable to disturbances when wet. The current range of *P. submutica* is subject to human-caused modifications from natural gas exploration and production with associated expansion of pipelines, roads, and utilities; development within the Westwide Energy Corridor; increased access to the habitat by OHVs; soil and seed disturbance by livestock and other human-caused disturbances; nonnative invasive species including *Bromus tectorum* and *Halogeton glomeratus* (halogeton); and inadequacy of existing regulatory mechanisms (76 FR 45054). Special management considerations or protections are required within critical habitat areas to address these threats. Management activities that could ameliorate these threats include (but are not limited to): Development of regulations and agreements to balance conservation with energy development and minimize its effects in areas where the species resides; the establishment of additional protection areas that provide greater protections for the species; minimization of OHV use; placement of roads and utility lines away from the species and its habitat; minimization of livestock use or other human-caused disturbances that disturb the soil or seeds; and the minimization of habitat fragmentation. These management activities would protect the PCEs for the species by preventing the loss of habitat and individuals, protecting the plant's habitat and soils, and managing for appropriate levels of disturbance.

**Criteria Used To Identify Critical Habitat** As required by section 4(b)(2) of the Act, we used the best scientific data available to designate critical habitat. We reviewed available information pertaining to the habitat requirements of this species. In accordance with the Act and its implementing regulation at 50 CFR 424.12(e), we considered whether designating additional areas-- outside those currently occupied as well as those occupied at the time of listing--are necessary to ensure the conservation of the species. We are designating critical habitat in areas within the geographical area occupied by *Ipomopsis polyantha*, *Penstemon debilis*, and *Phacelia submutica* at the time of listing in 2011. We also are designating specific areas outside the geographical area occupied by *I. polyantha* and *P. debilis* at the time of listing because we have determined that such areas are essential for the conservation of the species. All units are designated based on sufficient elements of physical and biological features being present to support *Ipomopsis polyantha*, *Penstemon debilis*, and *Phacelia submutica* life-history processes. Small populations and plant species with limited distributions, like those of *Ipomopsis polyantha* and *Penstemon debilis*, are vulnerable to relatively minor environmental disturbances (Given 1994, pp. 66-76; Frankham 2005, pp. 135-136), and are subject to the loss of genetic diversity from genetic drift, the random loss of genes, and inbreeding (Ellstrand and Elam 1993, pp. 217-237; Leimu et al. 2006, pp. 942-952). Plant populations with lowered genetic diversity are more

prone to local extinction (Barrett and Kohn 1991, pp. 4, 28). Smaller plant populations generally have lower genetic diversity, and lower genetic diversity may in turn lead to even smaller populations by decreasing the species' ability to adapt, thereby increasing the probability of population extinction (Newman and Pilson 1997, p. 360; Palstra and Ruzzante 2008, pp. 3428-3447). Because of the dangers associated with small populations or limited distributions, the recovery of many rare plant species includes the creation of new sites or reintroductions to ameliorate these effects. Genetic analysis of *Ipomopsis polyantha* has not been conducted; therefore, we do not understand the genetic diversity of this species. Given the species' limited extent and presence in only two populations, we expect the species may be suffering from low genetic diversity, or could in the future. Genetic research on *Penstemon debilis*, based on neutral genetic markers, has found that there is more genetic diversity in larger populations than smaller populations, that the northeastern populations are more closely related to one another than to the southwestern populations, that inbreeding is common within each population, and that genetic diversity for the species is low when compared with other species of plants with similar life-history traits (Wolfe 2010, p. 1). The plant is partially clonal, which likely explains the lowered genetic diversity and further reduces the actual population size. Small population sizes with few individuals are a problem for this species, as supported by this research. When designating critical habitat for a species, we consider future recovery efforts and conservation of the species. Realizing that the current occupied habitat is not enough for the conservation and recovery of *Ipomopsis polyantha* and *Penstemon debilis*, we worked with species' experts to identify unoccupied habitat essential for the conservation of these two species. The justification for why unoccupied habitat is essential to the conservation of these species and methodology used to identify the best unoccupied areas for consideration for inclusion is described below. Habitat fragmentation can have negative effects on biological populations, especially rare plants, and affect survival and recovery (Aguilar et al. 2006, pp. 968-980; Aguilar et al. 2008, pp. 5177-5188; Potts et al. 2010, pp. 345-352). Fragments are often not of sufficient size to support the natural diversity prevalent in an area, and thus exhibit a decline in biodiversity (Fahrig 2003, pp. 487-515). Fragmentation effects are especially prevalent in systems where multiple generations have elapsed since the fragmentation occurred (Aguilar et al. 2008, p. 5177). Habitat fragmentation has been shown to disrupt plant-pollinator interactions and predator-prey interactions (Steffan-Dewenter and Tscharnkte 1999, p. 432-440; Aguilar et al. 2006, pp. 968-980; Eckert et al. 2010, pp. 35-43), alter seed germination percentages (Menges 1991, pp. 158-164), affect recruitment (Santos and Telleria 1997, pp. 181-187; Quesada et al. 2003, pp. 400-406), and result in lowered fruit set (Burd 1994, pp. 83-139; Cunningham 2000, pp. 1149-1152; Eckert et al. 2010, p. 38). In general, habitat fragmentation causes habitat loss, habitat degradation, habitat isolation, changes in species composition, changes in species interactions, increased edge effects, and reduced habitat connectivity (Fahrig 2003, pp. 487-515; Fisher and Lindenmayer 2007, pp. 265-280). These effects are more prevalent in arid ecosystems with low native vegetation cover (Fisher and Lindenmayer 2007, p. 272). Habitat fragments are often functionally smaller than they appear because edge effects (such as increased nonnative invasive species or wind speeds) impact the available habitat within the fragment (Lienert and Fischer 2003, p. 597). Shaffer and Stein (2000) identify a methodology for conserving imperiled species known as the three Rs: Representation, resiliency, and redundancy. Representation, or preserving some of everything, means conserving not just a species but its associated plant communities, pollinators, and pollinator habitats. Resiliency and redundancy ensure there is enough of a species so it can survive into the future. Resiliency means ensuring that the habitat is adequate for a species and its representative components. Redundancy ensures an adequate number of sites and individuals. This methodology has been

widely accepted as a reasonable conservation strategy (Tear et al. 2005, p. 841). We have addressed representation through our PCEs for each species (as discussed above) and by providing habitat for pollinators of *Ipomopsis polyantha* and *Penstemon debilis* (as discussed further under "*Ipomopsis polyantha*" below). For *Phacelia submutica*, we believe that the occupied habitat provides for both resiliency and redundancy and that with conservation of these areas, the species should be conserved and sustained into the future. For *I. polyantha*, there are only two known populations, both with few or no protections in place (low resiliency). For adequate resiliency, we believe it is necessary for the conservation and recovery of *I. polyantha* that additional populations with further protections be established. Therefore, we have identified two unoccupied areas as designated CHUs for *I. polyantha*. For *P. debilis*, there are only approximately 4,000 known individuals (low redundancy), all within 2 concentrated areas (low resiliency). For adequate redundancy and resiliency, we believe it is necessary for conservation and recovery that additional populations of *P. debilis* be established. Therefore, we have identified two unoccupied areas as designated CHUs for *P. debilis*.

***Life History*****Food/Nutrient Resources****Reproductive Strategy**

Adult: Insect pollinated/Asexual (USFWS, 2013)

**Lifespan**

Adult: One year (USFWS, 2013)

**Breeding Season**

Adult: DeBeque phacelia plants flower between late April and late June and set seed from midMay through late June (USFWS, 2013).

**Reproduction Narrative**

Adult: DeBeque phacelia plants flower between late April and late June and set seed from midMay through late June. Preliminary evidence on the pollination biology of the species indicates that insect pollinators are not necessary for reproduction (Langton and Schupp 2012a). Yearly germination is variable depending on precipitation patterns and can fluctuate widely (Burt and Spackman 1995). For example, DeBeque phacelia numbers at Horsethief Mountain fluctuated from 1,700 plants in 1986, to 50 in 1992, up to 1,070 in 2003, and down to only a few from 2006 to 2008 (Colorado Natural Heritage Program (CNHP) 2010) (Figure 1). This strategy of maintaining seed dormancy through unfavorable conditions is common among annual plant species of arid environments (Anderson et al. 2012; Baskin and Baskin 1998). Maintenance of a large seed bank is also vital to the persistence of these species through unpredictable and long periods of drought (Anderson et al. 2012). No information is currently available on the density and longevity of the species' seed bank, nor the environmental conditions required to break seed dormancy, but studies are under way (Langton and Schupp 2012b) (USFWS, 2013).

**Habitat Type**

Adult: Ridge tops (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Xeric ridge tops (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

**Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Species occurs on steep slopes and ridge-tops on xeric sites in chocolate-brown or gray clay adobe badlands of Western Colorado which often have high shrink-swell potential (large cracks in the soil). The species is adapted to grow only in very early pioneer habitats with sparse vegetation cover (Scheck 1994). The species occurs on Atwell Gulch and Shire Members of Wasatch Formation (O'Kane 1987). Associated species are *Grindelia fastigiata*, *Sarcobatus vermiculatus*, *Atriplex confertifolia*, *Eriogonum gordonii*, *Monolepis nuttalliana*, *Oenothera caespitosa*, *Astragalus flavus*, *Helianthus* sp., *Lepidium* sp., *Chenopodium* sp., *Rumex* sp., *Cymopterus planus*, *Sitanion hystrix*, *Ceratocephala testiculata*, *Lactuca serriola*, *Euphorbia fendleri*, *Asclepias cryptoceras*, *Mentzelia* sp., *Thelypodopsis* sp., *Oryzopsis hymenoides*, *Bromus tectorum*, *Sphaeralcea coccinea*, *Gutierrezia sarothrae* (O'Kane 1987). Other rare species occurring in the area are *Sclerocactus glaucus* and *Astragalus debequaeus* (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are based on the species specific habitat requirements as well as its restricted geographic range.

***Dispersal/Migration*****Dispersal**

Adult: Low (USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: Numbers of flowering plants fluctuate, but they do not disperse seeds beyond the existing patches of unique soil that are separated from one another by a few yards or several miles (Ewing 2008b, map) (USFWS, 2010).

***Population Information and Trends*****Population Trends:**

Unknown (NatureServe, 2015)

**Number of Populations:**

25 (USFWS, 2022)

**Population Size:**

10,000 - 100,000 individuals (NatureServe, 2015)

**Population Narrative:**

Vulnerable to changes in habitat conditions, especially surface disturbances such as trampling of soil. An annual species whose population size varies widely from year to year. Because *Phacelia submutica* is adapted to a very specific geologic substrate and habitat type, a range extension is unlikely. Approximately 35,000-40,000 individuals have been documented within 21 of the 22 occurrences. However, this species is a seed-banking annual with numbers of visible plants varying drastically from year to year. There are 22 principal occurrences documented in the Colorado Natural Heritage Program database. Six of the occurrences have not been observed in over 20 years (as of 2012). The USFS Conservation Assessment documents 40 occurrences (Ladyman 2003). It is likely that this discrepancy in the total number of occurrences is because some of the sites reported by Ladyman are represented in the Heritage database as portions of other occurrences and not reported separately (NatureServe, 2015). Low resilience, representation and redundancy are based on the low number of known populations, the relatively narrow geographic area this species inhabits and the variability in numbers from year to year. Across its limited range DeBeque phacelia currently has multiple individuals occurring in 25 separate EOs spread across five AUs (Service 2022, pp. 4–5). Redundancy for narrow endemic species is inherently limited; however, DeBeque phacelia plants are distributed broadly across the range of the species in the five defined AUs, providing redundancy throughout its small geographic range, especially given that the only plausible catastrophic event is prolonged extreme drought (Service 2022, p. 33). DeBeque phacelia's broad distribution and multiple moderately resilient AUs contribute to its ability to withstand catastrophic events. Additionally, BLM's ACECs reduce the influence of the stressors of OHV use and oil and gas development in 63 percent of the species' currently occupied range; approximately 359 acres of occupied DeBeque phacelia habitat and nine of the 25 DeBeque phacelia EOs occur within BLM ACECs. A BLM ACEC is a designation that highlights an area where special management attention is needed to protect important historical, cultural, and scenic values, protect fish and wildlife, or protect other natural resources. One of the eight EOs in the South Shale Ridge AU is located in the Pyramid Rock ACEC, which is intended specifically for the preservation of habitat for plant species, including DeBeque phacelia. This area is fenced and closed to livestock use; motorized, mechanized, and equestrian use; and hiking (BLM 2015, p. 31). It is unlikely that any of the ACEC designations will be withdrawn in the foreseeable future (USFWS, 2022).

**Threats and Stressors**

**Stressor:** Oil and gas development (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Increasing oil and gas development in the Piceance Basin is a significant concern in the recovery of the species. About 95 percent of occupied habitat is on BLM lands leased for energy extraction (Service 2012). Ongoing energy development activities include well pad and road construction, installation of pipelines, and construction of associated buildings, holding tanks, and other facilities. Oil and gas pipelines and well pads are present within thirteen EOs (Service 2012). Several pipelines and pipeline right-of-ways already exist within 20 ft (6 m) of DeBeque phacelia EOs (Lincoln 2008, pers. comm.; Service 2012). Roads used for energy extraction bisect

and cross the edges of eleven EOs (Service 2012) (USFWS, 2013).

**Stressor:** Utility and Energy Corridors: (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Utility and energy corridors provide pathways for future pipelines and electrical transmission lines. A portion of the designated Westwide Energy Corridor crosses 22,404 ac (9,066.6 ha) of BLM land within the range of DeBeque phacelia (see Figure 3) (Service 2012). Eight of the 20 EOs and 13 percent of critical habitat are within the Westwide Energy Corridor (Service 2012). Continued development of pipeline and transmission lines within the energy corridor is likely to affect DeBeque phacelia and its habitat (USFWS, 2013).

**Stressor:** Livestock Use and Trampling (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Potential threats related to livestock, deer, and elk use include the direct effects from trampling, and the indirect effects of habitat degradation. Ninety percent of DeBeque phacelia EOs are under management by the BLM as a grazing allotment (Service 2011a). Livestock trampling has occurred or is a threat at 14 EOs (CNHP 2010). Livestock can easily trespass from BLM or private grazing allotments onto USFS property where grazing is not allowed. This has been documented at two occurrences, one obtaining frequent disturbance from its proximity to a pond (Langton 2012). No research or monitoring has been conducted to evaluate the effects of livestock, deer, or elk use on DeBeque phacelia. However, the deleterious effects of livestock on western arid ecosystems are well documented (Milchunas et al. 1992; Jones 2000). Some of the adverse effects from livestock include changes in water infiltration due to soil compaction (Jones 2000, Table 1); changes to the physical and structural properties of soils (Kinlock and Friedel 2002); disturbance to soil microbiotic crusts (Evans and Belnap 1999; Jones 2000); subsequent nonnative invasive plant invasions (Parker et al. 2006); and soil erosion from hoof action (Jones 2000). Effects from livestock grazing to DeBeque phacelia and its habitat are occurring will likely continue (USFWS, 2013)

**Stressor:** Off-Highway Vehicle Use (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Off-highway-vehicle (OHV) use occurs on lands throughout the range of DeBeque phacelia. OHV recreation has damaged plants and habitat at seven EOs (CNHP 2012). On Federal lands, vehicles stray from designated roads to climb clay barrens for recreational purposes (Johnston 2012; Mayo 2008d). OHV trespass has even been documented within the Pyramid Rock Natural Area and BLM Area of Critical Environmental Concern (ACEC). The ACEC is fenced with post and cable, and an information sign is posted near an access point. The visible effects of OHV recreation within DeBeque phacelia habitat has been seen to persist for several years (Johnston 2012). Surface disturbances from OHV recreation cause accelerated erosion, fugitive dust production, soil compaction, sedimentation, and potentially irreversible changes to soil physical properties and chemistry (Iverson et al. 1981; Pagliali et al. 2003). Additionally, these changes in the soil environment can affect ecosystem function (DeFalco 2009. OHV use is

expected to increase in the region with the construction of additional roadways for energy development and the increasing popularity of OHV recreation. With OHV recreation within the range of the species, direct losses of plants and the seed bank, as well as indirect affects to the species and its habitat will continue to occur (USFWS, 2013).

**Stressor:** Invasive Nonnative Plants (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The threat from invasive nonnative plant species (weeds) is a growing concern in the recovery of DeBeque phacelia. Weeds have been documented at 15 EOs (CNHP 2012a). Disturbances such as roads, grading, and livestock grazing generally introduce and spread exotic species (Gelbard and Belnap 2003). Weeds invade and alter all types of plant communities, sometimes resulting in nonnative plant monocultures that support little wildlife or native plants (D'Antonio and Vitousek 1992; Olson 1999; Mooney and Cleland 2001). Many experts believe that, following habitat destruction, nonnative invasive plants are the next greatest threat to biodiversity (Randall 1996). Nonnative invasive plants alter different ecosystem attributes including geomorphology, fire regime, hydrology, microclimate, nutrient cycling, and productivity (Dukes and Mooney 2004). Species known to occur within DeBeque phacelia habitat include cheatgrass (*Bromus tectorum*), bur buttercup (*Ranunculus testiculatus*), and annual wheatgrass (*Eremopyrum triticeum*). These weeds are prevalent on public and private lands within the range of the DeBeque phacelia. Recent data suggest that weed cover in DeBeque phacelia sites is related to distance from roads, while the number of flowers was found to be higher at distances away from roads (BioLogic 2011). The control of weeds on public lands, especially around well pads, utility corridors, and roads, may also pose a danger to DeBeque phacelia. For example, herbicide drift from well pad spraying has led to the mortality of Colorado hookless cacti near DeBeque (Perkins 2012, pers. comm.) (USFWS, 2013).

**Stressor:** Water Reservoirs (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Two water reservoir projects known as Roan Creek and Sulphur Gulch were proposed within potential and occupied habitat of DeBeque phacelia (Bray and Drager 2008, pers. comm.; Grand River Consulting Corporation 2009). The proposals were withdrawn and are not imminent. However, the sites have been identified as potential reservoir locations that could be developed within 20 years if warranted by increased demands for water. Increased demands are likely, depending on the oil shale market, urban development in Colorado, and less (or altered) precipitation due to climate change. If developed, construction and inundation of these reservoirs would permanently destroy DeBeque phacelia plants and habitat within the project areas (USFWS, 2013).

**Stressor:** The Inadequacy of Existing Regulatory Mechanisms (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Removal, damage, or destruction of plants on private lands is not prohibited under the Endangered Species Act (Act). We are not aware of any state, county, city, or local laws,

ordinances or zoning that provide for the protection or conservation of DeBeque phacelia or its habitat. Though no state regulations protect rare plants in Colorado, the Colorado Natural Areas Program manages a State Natural Area on BLM land protecting 510.9 ac (206.7 ha) of the species' habitat within the Pyramid Rock population. This agreement between Colorado Natural Areas Program and the BLM can; however, be terminated with a 90-day written notice by either party. Additional habitat on state land includes 7.5 ac (3 ha) of the Anderson Gulch population. This population contains the only "A"-ranked Elemental Occurrence (CNHP 2012a) meaning it has excellent estimated viability/ecological integrity. The majority of this population (90 percent) is within the Piceance Creek State Wildlife Area and is managed by Colorado Parks and Wildlife (USFWS, 2013).

**Stressor:** Climate Change and Drought (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** According to the Intergovernmental Panel on Climate Change (IPCC), "Warming of the climate system in recent decades is unequivocal, as is now evident from observations of increases in global average air and ocean temperatures, widespread melting of snow and ice, and rising global sea level" (IPCC 2007). Research indicates that warming is occurring more rapidly in the southwest region of the United States than elsewhere in the country with an increase of 1.5°F (0.8°C) since 1979 (Karl et al. 2009). Additionally in the west, the onset of spring has been advancing since the 1970's (Cayan et al. 2001). Annual temperature is predicted to increase approximately 2.2°C (4°F) in the southwest by 2050, with summers warming more than winters (Ray et al. 2008). Effects of climate change include persistent or prolonged drought conditions, changes in the vegetative community including increased invasions by weeds (Everard et al. 2010). Climate change is likely to affect many rare plant species because seed germination, seed dormancy, and persistence of the seed bank are all directly dependent on precipitation and temperature patterns (Levine et al. 2008). However, we do not understand how these changes may affect the long-term persistence of DeBeque phacelia because no information is available on the ecology of the species. Improved localized projections and precipitation models are also needed to better understand the threat of climate change to the species. The potential impacts of climate change will be significant at a global scale and we expect the predicted increased drought conditions to affect the recovery of DeBeque phacelia (USFWS, 2013).

## **Recovery**

### **Reclassification Criteria:**

The preliminary plan lists three basic steps for recovery: 1: Protect and maintain all extant populations (USFWS, 2013).

2. Prevent or minimize habitat disturbing threats (USFWS, 2013).

Develop and implement rangewide monitoring (USFWS, 2013).

Recovery Priority Number: 14C

### **Recovery Actions:**

- Protection of Extant Populations and Habitat: Establish and implement protective measures for all known populations (USFWS, 2013).
- Threats Abatement: Implement protective measures such as fencing, controlled management of livestock use, nonnative species control and additional measures to avoid or minimize impacts to the species and its habitat (USFWS, 2013).
- Threats Abatement: Coordinate with land managers, project proponents, and other partners early in the planning process to limit direct and indirect effects of oil and gas development, grazing, OHV recreation, weeds, and additional threats that arise (USFWS, 2013).
- Threats Abatement: Work with land management agencies and other partners to formally establish land management designations to provide for long-term protection of populations and habitat (USFWS, 2013).
- Threats Abatement: Ensure that additional oil and gas leases avoid or take into consideration occupied and suitable habitat (USFWS, 2013).
- Threats Abatement: Consider installing livestock exclosures for both protection and monitoring purposes (USFWS, 2013).
- Surveys and Monitoring: Complete a comprehensive survey throughout the species' range, including areas designated as "potential habitat". Survey results should provide an accurate population estimate and allow us to identify core population areas so we can more effectively protect the species (USFWS, 2013).
- Surveys and Monitoring: Establish a survey protocol to identify areas of suitable habitat during years in which few above-ground plants are found. This protocol must take into account an evaluation of habitat components that support DeBeque phacelia (USFWS, 2013).
- Surveys and Monitoring: Establish a long-term monitoring plan to document rangewide population demographics and trends, and quantify the affects from threats. An adaptive management approach that uses feedback from implemented, site-specific recovery tasks should be integrated into the plan to inform recovery activities (USFWS, 2013).
- Surveys and Monitoring: Gain permission from landowners to survey for DeBeque phacelia on private lands with potential habitat (USFWS, 2013).
- Research: Continue research into DeBeque phacelia life history and ecology, including pollination biology, seed bank density, seed bank longevity, seed germination ecology, and habitat and soil requirements (USFWS, 2013).
- Research: Study population genetics and demographics (USFWS, 2013).
- Research: Conduct a population viability analysis (USFWS, 2013).
- Research: Conduct investigations that project DeBeque phacelia vulnerability and response to climate change (USFWS, 2013).
- Research: Improve our understanding of livestock and native ungulate grazing impacts (USFWS, 2013).
- Research: Monitor changes in invasive species prevalence and conduct research on impacts to DeBeque phacelia (USFWS, 2013).
- Research: Continue to refine a survey protocol for delineating suitable habitat (USFWS, 2013).
- Research: Continue to analyze the effects of dispersed oil and gas development and roads (USFWS, 2013).
- Seed Banking: Store genetic material in the form of seed in an appropriate repository to provide a back-up supply of genetic stock that represents as much of the available genetic diversity within the species as possible (USFWS, 2013).

## SPECIES ACCOUNT: *Phlox hirsuta* (Yreka phlox)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

Cespitose perennial subshrub from a stout, woody base. Stems stout, to 1.5dm tall. Herbage copiously hirsute with long, jointed hairs. Leaves crowded. Blooms April-June. (NatureServe, 2015)

### **Taxonomy**

Elias Nelson (1899) described *P. hirsuta* based on a collection made by Edward L. Greene in 1876. A complete nomenclatural history can be found in Appendix 1 of the Recovery Plan for *Phlox hirsuta* (Yreka Phlox) (U.S. Fish and Wildlife Service 2006). No changes in taxonomy have occurred since the time of listing (USFWS, 2007).

### **Historical Range**

*Phlox hirsuta* is known to occur at five locations, which are referred to as the "China Hill," "Soap Creek Ridge," "Cracker Gulch," "Greenhorn Creek," and "Jackson Street" occurrences. In addition, the locality information from a single 1930 collection indicates a possible historical location in the vicinity of Etna or in the vicinity of Echo Mill, near Soap Creek Ridge (California Department of Fish and Game 1986; J. Molter in litt. 2001; Appendix 1, prepared by F. Lang in U.S. Fish and Wildlife Service 2006). A *P. hirsuta* location or occurrence is defined as a group of at least 200 individual plants that is separated from any other *P. hirsuta* locality by at least 0.40 kilometer (0.25 mile). (USFWS, 2007)

### **Current Range**

In and near the towns of Yreka and Etna in Siskiyou County, northern California (USFWS 1995). Range extent is approximately 34 sq mi. (NatureServe, 2015)

### **Critical Habitat Designated**

No;

### ***Life History***

### ***Population Information and Trends***

### ***Threats and Stressors***

### ***Recovery***

#### **Reclassification Criteria:**

Recovery Priority Number: 2C

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS:** Future actions will focus on securing and permanently protecting four (up to six) Yreka phlox occurrences and ameliorating ongoing threats of invasive weeds. Work has been initiated on each of the actions listed below. • Funding is needed to purchase, or establish conservation easements on, Cracker Gulch, the northern portion of Soap Creek Ridge, and Greenhorn Creek Occurrence properties from willing sellers who have indicated their strong interest in conserving Yreka phlox habitat in perpetuity. • Complete the cooperative agreement with the Siskiyou Land Trust to approach Greenhorn Creek property owners who might wish to establish conservation agreements or easements on several additional scattered properties where Yreka phlox occurs. • Continue to cooperate with the City of Yreka and the County to protect populations from off-road vehicle trespass and invasive non-native weed infestation. • Collect and accession seeds from each Yreka phlox occurrence at the Rae Selling Berry Seed Bank and California Botanic Garden. • Consult, through section 7 of the Endangered Species Act, with the Klamath National Forest on the effects to Yreka phlox of the 2022 McKinney Fire suppression actions, especially with respect to the introduction of non-native invasive weeds on contingency fire lines (USFWS, 2024).

## SPECIES ACCOUNT: *Phlox nivalis* ssp. *texensis* (Texas trailing phlox)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 09/30/1991; Southwest Region (Region 2) (USFWS, 2016)

### **Physical Description**

The Texas trailing phlox is an evergreen perennial that forms clumps (but seldom mats). The plants are herbaceous or subshrubby. Stems tend to spread along the ground surface, and are erect only for the terminal 2—15 centimeters (0.8-5.9 in). Leaves are needlelike to lanceolate, densely packed on the stem (producing an appearance somewhat like a juniper seedling), usually less than 1.5 cm (0.6 inch) long, and more or less glandular pubescent. Older stems have smaller and darker green leaves, and typically lie directly on the ground surface. Young stems produce the flowers, are more or less erect, and have longer, slightly wider, and lighter—green leaves. Inflorescences are 3-12 flowered cymes, terminal on (typically) the tallest stems. The calyx is tubular with five sepals, which are fused for most of their length. The corolla is rotate, with a tube approximately 1.5 centimeters (0.6 inch) long. The five petals, each about 1 centimeter (0.4 inch) long, are pink to magenta in color, and darker near the throat. Petals are reported to be white in some individuals. Pistils have three styles, and the ovule is usually single. Fruits are achene—like, and apparently indehiscent (this character description of the fruit differs from previously published summaries). Flowering occurs from March to May. (USFWS, 1994)

### **Taxonomy**

Texas trailing phlox belongs to the family Polemoniaceae, which includes such plants as sweet William, Jacob's ladder, Texas plume, and phlox. Texas trailing phlox is one of two subspecies recognized in *P. nivalis*. The nominal subspecies (ssp. *nivalis*) occurs in pine/oak barrens or scrub on the Coastal Plain or Piedmont, from Alabama to Florida and north to Virginia. Flowers of this subspecies are typically white or pale pink, with plants of forma *roseiflora* having deep rose or magenta flowers (Fernald 1970). According to Wherry (1955), the major difference between the two subspecies is the presence of minute glandular hairs on *texensis*, and their absence on *nivalis*. Currently, the nearest known populations of ssp. *nivalis* to those of *texensis* are located more than 1000 kilometers (600 miles) eastward in northern Florida. Wherry included *Phlox nivalis* in series *Subulatae*, along with *Phlox subulata* and *Phlox oklahomensis*. Both of the latter species have gross morphological features similar to that of *P. nivalis*, but Bogler (1992) expressed the opinion that, based on Texas specimens, fl. *nivalis* is most similar to *P. oklahomensis*. Populations of *P. oklahomensis* found in Texas are disjunct from the main range of *P. oklahomensis* (located further north in Oklahoma), lying approximately equidistant between it and range of *P. nivalis* ssp. *texensis*. (USFWS, 1994)

### **Historical Range**

Although its historic range includes Hardin, Polk, and Tyler Counties of Texas, the Texas trailing phlox is presently known from only two sites in southeast Texas. (USFWS, 1994)

### **Current Range**

Endemic to the Pineywoods of the West Gulf Coastal Plain of east Texas. Texas trailing phlox is presently known from only two sites, one each in Tyler and Hardin counties, Texas. (USFWS, 1994; NatureServe, 2015)

**Critical Habitat Designated**

Yes;

***Life History*****Food/Nutrient Resources****Reproductive Strategy**

Adult: Asexual (vegetative) and sexual (outcrossing) (USFWS, 1994)

**Breeding Season**

Adult: Flowering generally occurs between late March and early April (Ajilvsgi 1979, Poole et al. 2007, U.S. National Park Service (USNPS) 2015), sometimes extending into May depending on precipitation and management (i.e. prescribed burning). (USFWS, 2018)

**Other Reproductive Information**

Adult: Flies, bees, and butterflies have been observed at flowers. Based on the plant's floral structure, butterflies are the most likely pollinators. (USFWS, 1994)

**Reproduction Narrative**

Adult: Flies, bees, and butterflies have been observed at flowers. Based on the plant's floral structure, butterflies are the most likely pollinators. Typically, no more than one seed is produced per flower and, based on limited field observation, fruit set is low. An individual plant may have 3 to 50+ flowers and primarily depending on number of flowers. Its low population numbers are likely due to a combination of anthropogenic factors and a naturally low reproductive rate. (USFWS, 1994); Little is known about the reproduction of the Texas trailing phlox. Their populations are small and consist of a few scattered, inconspicuous individuals (Mahler 1980). This could make asexual reproduction very important for recruitment (Parker and Warnock 1993) but this frequency is unknown. Texas trailing phlox is mostly an outcrossing species pollinated by moths and butterflies (Bogler 1992). However, it is not known whether flowers are obligate or facultative outcrossers (Maxey and Warnock 1996, USFWS 1995). Pollinators include carpenter bees (M. Quinn, pers. comm. 2008), Nessus sphinx moth (*Amphion floridensis*) (G. Grant, pers. comm. 2017), and Tiger swallowtail butterfly (*Papilio glaucus*) (G. Grant, pers. comm. 2014). Other bees and butterflies, as well as flies could also serve as pollinators (USFWS 1995, Maxey and Warnock 1996, TPWD 1997). Poole et al. (2000) noted that there is the potential of large terrestrial arthropods to act as pollinators. Also, seed and seedling biology (seed maturation, dormancy, seed viability) are largely unknown for the Texas trailing phlox. We lack information about seed dispersal; however, dehiscence could play a role in local dispersal. (USFWS, 2018)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest/woodland, savanna, shrubland/chaparral, woodland - hardwood (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Texas trailing phlox occurs in southeast Texas in the southern portion of the Pineywoods vegetational area. Within the range of Texas trailing phlox, annual precipitation averages 125 cm (49 in), with no pronounced summer drought. The average frost-free period is 244 days (Bogler 1992), from early March through mid-December (Larkin and Bomar 1983). Elevation ranges from 9 to 75 meters (30-240 feet), and topography is nearly level. This species prefers deep, sandy soils in fire-maintained openings in upland longleaf pine (*Pinus palustris*) savannahs or post oak-bluejack oak (*Quercus stellata*-*Q. incana*) woodlands. Field studies suggest that sandy surface soil, coupled with moisture-bearing clays or sandy-clay soils at depths of 0.5-2 meters (1.6-6.6 feet), provide the best soil structure for Texas trailing phlox. Overstory cover at sites of Texas trailing phlox occurrence typically ranges from 25-75 percent. Understory and shrub cover is less than 25 percent at most plant sites, but ranges up to nearly 100 percent at some. However, the best growth of Texas trailing phlox is seen at the lower percentages of understory and shrub cover. The degree of ground cover associated with optimum growth of Texas trailing phlox appears to be 25-75 percent. Litter depth is generally 3-5 cm (1.2-2.0 in), and coverage is usually 75-100 percent. The most common canopy trees associated with Texas trailing phlox are *Pinus palustris*, *P. elliottii*, *R. taeda*, *Quercus incana*, *Q. falcata*, and *Q. stellata* and *Carva texana*. (USFWS, 1994; NatureServe, 2015)

**Dispersal/Migration****Dispersal/Migration Narrative**

Adult: Not available.

**Population Information and Trends****Population Trends:**

Long-term trends indicate a decline of 30 to 70%, whereas short-term trends suggest a relatively stable population (NatureServe, 2015)

**Resiliency:**

Populations were considered to have high resiliency when they: contained at least 600 individuals, exhibited plant separation less than 2 kilometers (1.24 miles), contained canopy cover between 5-25 percent, limited shrub layer cover to 10-25 percent, maintained litter depths of 3-5 centimeters, and received an annual precipitation rate of 48-60 inches (121.9-152.4 centimeters). Frequent fire exposure (every 1-2 years) serves as a critical component to sustaining healthy individual plants within the longleaf pine ecosystem, as well as other native vegetation associated with the Pineywoods. Using all of these factors, seven extant populations were ranked either low or moderate in current resiliency (USFWS, 2020).

**Representation:**

We lacked genetic studies specific to Texas trailing phlox examining variability within and among its' populations. Further genetic analysis of Texas trailing phlox could determine to what extent, if any, the impact of range contraction contributes to the loss of the genetic variability. Due to an absence of genetic information informing our measure of representation, we used ecological

diversity as a surrogate for genetic diversity. We assumed no ecological or niche diversity at any of the specific sites therefore, the representation of Texas trailing phlox is extremely low (USFWS, 2020).

**Redundancy:**

For the Texas trailing phlox, we measured redundancy as an adequate number of resilient populations that provided an exchange of genetic material and foraging opportunities for pollinators. Due to the low or moderate resilience rankings of most populations, the few number of extant populations, and that these populations are distributed throughout a restricted range, we estimated that both connectivity for pollinating species and exchange of genetic material is limited. Therefore, we rank the overall redundancy of Texas trailing phlox as low (USFWS, 2020)

**Number of Populations:**

7 (USFWS, 2018)

**Population Size:**

<750 individuals (NatureServe, 2015)

**Population Narrative:**

Long-term trends indicate a decline of 30 to 70%, whereas short-term trends suggest a relatively stable population. Although its historic range includes Hardin, Polk, and Tyler Counties of Texas, the Texas trailing phlox is presently known from only two sites in southeast Texas. Although nineteen collections of Texas trailing phlox are reported in historical records, these appear to originate from only six definable population systems, however, only two are extant populations. Reintroductions are being attempted in areas where there were historic populations. (NatureServe, 2015); When the species was listed as endangered in 1995, there were only 2 known populations in southeast Texas, one in Hardin County (the type locality) and another from Tyler County. Since then, 17 populations were observed in Hardin, Polk, and Tyler counties, however, these are considered extirpated. The USFWS Recovery Plan (1995) provides a definition of a "population" and a "plant". Based on this definition, the USFWS recognizes that there are 7 known extant populations in Hardin, Polk, and Tyler counties that include: 1) Sunflower road (Element of Occurrence (EO) 17) and Big Thicket National Preserve (BTNP), Big Sandy Creek reintroduction; 2) Farm-to-Market 1276 right-of-way (EO 21); 3) Campbell Units (EO 22 and 23); 4) The Nature Conservancy, Roy E. Larsen Sandylands Sanctuary (EOs 3, 5, 13); 5) Resource Management Services (EO 9); 6) Hancock Timber (introduced); and 7) BTNP, Turkey Creek reintroduction. Land ownership includes private, public, and state lands. (USFWS, 2018). These extant EO ID's remain owned and managed by TNC Sanctuary staff. The EO ID was last surveyed for Texas trailing phlox in 2023. Prior to that, the Sanctuary staff conducted a thorough assessment of extant populations in 2019, surveying 68 sites (61 previously recorded and 7 new sites) counting 304 plants (W. Ledbetter, pers. comm. 2019). Dr. C. Edwards and Dr. G. Yatskievych conducted a thorough genetic analysis of the Texas trailing phlox (Edwards 2022, entire) which included sampling from known Sanctuary plants. More information about their research is detailed in the Conservation Measures section of this review. Edwards, Yatskievych, TNC, and the Service visited these EO ID's between March 30 and April 1, 2021, and found 300+ individual plants (S. Benedict, pers. comm. 2021) at 31 global positioning position (GPS) locations (Strong 2023, redacted site info excel sheet). A site assessment was not completed in 2022; however, in April and May of 2023, TNC staff counted 255 plants across the management

units (USFWS, 2023).

### ***Threats and Stressors***

**Stressor:** Habitat loss (USFWS, 1994)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Habitat loss has been caused by housing development; land—clearing and site preparation for pine plantations and pasture; encroachment of a closed canopy forest onto formerly open forest or savanna due to fire suppression; exposure to herbicides; and activities associated with pipeline, powerline, railroad, and highway construction. (USFWS, 1994)

**Stressor:** Human activities (USFWS, 1994; NatureServe, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Factors adversely affecting the habitat of Texas trailing phlox, combined with other potentially adverse activities such as off-road vehicle use, illegal dumping, burning of debris, and commercial take of plants, may continue to restrict the species to critically low population levels. Current threats include continued habitat loss due to canopy closure/encroachment of hardwood trees and soil disturbances associated with human activities. (USFWS, 1994; NatureServe, 2015)

**Stressor:** Clearcuts (NatureServe, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Much of this taxon's habitat had been clearcut and converted to slash-pine plantations, urbanized, and/or altered by fire suppression. (NatureServe, 2015)

### ***Recovery***

#### **Reclassification Criteria:**

1. At least 12 self-sustaining populations, distributed across the known geographic range of Hardin, Polk, and Tyler counties, Texas, are established. There should be at least three populations located in each county in order to provide adequate representation. The remaining three populations can be distributed in any fashion among the available habitat across the geographic range. A population will be considered self-sustaining if it reaches and maintains a population number of at least 600 reproductive individual plants. A population is considered a group of plants separated by a distance of at least 2 kilometers (km) (1.2 miles (mi)) from any other Texas trailing phlox plants, as to promote healthy populations of pollinators and the exchange of genetic material. A “plant” is defined as a cluster of Texas trailing phlox stems with no above-ground connection to other groups of stems, and separated by a distance of at least 5 decimeters (dm) (1.6 feet (ft)). Habitat will be of sufficient quality as defined by Maxey and Warnock (1996), that it promotes the success of Texas trailing phlox. The numbers of plants and populations must be verified through adequate monitoring. Populations can include both natural and ex-situ (introduction and reintroduction) efforts. To be considered under this criterion, the habitats of Texas trailing phlox must be managed in a manner that promotes the

continued survival of the subspecies. Management can include, but is not limited to, prescribed burning and/or restoration of longleaf pine habitat. (USFWS, 2019)

2. Sufficient, documented protection measures and management plans have been established for these 12 self-sustaining populations. Long-term, binding agreements that aim to conserve and protect the subspecies, and its habitat, are preferred. Private lands should be a priority focus for these agreements; however, protected areas can and should include lands owned by federal, state, or local government agencies. (USFWS, 2019)

Recovery Priority Number: 3

**Delisting Criteria:**

1. To secure redundancy of the subspecies into the foreseeable future, we conclude that more populations would be needed for delisting. Therefore, at least 15 populations distributed across the known geographic range of Hardin, Polk, and Tyler counties, Texas, have been established. At least four populations should be located in each of the counties in order to provide representation of the potential genetic and ecological diversity of the subspecies. The remaining three populations can be distributed in any fashion among the available habitat within the range. A population will be considered self-sustaining if it reaches and maintains a population number of at least 600 reproductive individual plants. Ex-situ efforts should be focused within the known geographic range unless habitat suitability mapping proves otherwise. Habitat will be of sufficient quality, as defined by Maxey and Warnock (1996), that it promotes the success of Texas trailing phlox. (USFWS, 2019)

2. Monitoring efforts indicate that the MVP level of 600 reproductive plants at each population has remained stable or has increased over a monitoring time period of 30 years. Monitoring must be routine in order to gauge subspecies' viability. Site-specific management plans should be aligned with landscape scale strategies to attain optimal habitat quality conditions that promotes the Texas trailing phlox. (USFWS, 2019)

**Recovery Actions:**

- Monitor, protect, and manage existing populations. (USFWS, 1994)
- Locate or establish additional populations of sufficient number to meet downlisting criteria. (USFWS, 1994)
- Obtain biological data necessary to refine downlisting criteria. (USFWS, 1994)
- Characterize suitable habitat of plant and determine the management regime needed to preserve suitable habitat. (USFWS, 1994)
- Determine limiting factors on reproduction. (USFWS, 1994)
- Establish captive populations to protect genetic integrity. (USFWS, 1994)
- 1) Conduct Genetics Investigations: Conduct studies to determine genetic diversity of the Texas trailing phlox. Conduct studies to determine the genetic relatedness between individual plants within a population. Determine relatedness between populations across the species geographic range. Determine the relationship between Texas trailing phlox plants to *Phlox oklahomensis*, found in Texas, and to *Phlox nivalis*, found in Louisiana. Use this new genetic information to re-evaluate the criteria used in the Texas trailing phlox Recovery Plan to define a population and an individual plant. (USFWS, 2018)

- 2) Promote Landowner Stewardship and Outreach: Encourage awareness of Texas trailing phlox, its management needs within longleaf pine savanna habitat, and its habitat structure/composition. Develop outreach resources for landowners and land managers. Provide technical support for management, surveys, monitoring, and conservation efforts. Provide financial support for management and/or leverage funds for restoration and recovery efforts. (USFWS, 2018)
- 3) Monitor Extant Populations: Continue to monitor extant populations of Texas trailing phlox to assess species viability, habitat conditions, and management needs. Continue management on sites and acquire long-term conservation easements, where feasible, or conservation agreements. (USFWS, 2018)
- 4) Survey for New Populations: Develop a habitat suitability map to assist in identifying new parcels of land for surveying, restoration, and ex-situ opportunities. Outreach to new landowners and land managers. Conduct surveys of potential Texas trailing phlox habitat, with landowner permission, throughout species' known geographic range. (USFWS, 2018)
- 5) Revisit Historic Populations: Use herbarium records, field data, and expert input to determine and revisit sites presumed to be extirpated. Coordinate with landowners and land managers to access sites. Educate landowners and land managers about the Texas trailing phlox and its habitat. Conduct surveys of suitable areas with permission. Submit data to TPWD's Texas Natural Diversity Database. (USFWS, 2018)
- 6) Actively Manage Habitat: Develop management plans with landowners and land managers with the primary goal of restoring or maintaining longleaf pine savanna habitat for Texas trailing phlox. Investigate plant response to management practices (prescribed burning, mowing, thinning), conducted in various frequency and intensity schemes. (USFWS, 2018)
- 7) Develop Reintroduction Plan: Develop a Controlled Propagation and Reintroduction Plan (per USFWS policy). Limit reintroduction work to the known geographic range of the species (Hardin, Tyler, Polk counties). Coordinate with the Center for Plant Conservation Institutions' guidelines for augmentation procedures. (USFWS, 2018)
- 8) Conduct Essential Life History Studies: Investigate pollinating species of Texas trailing phlox and promote pollinator conservation. Conduct seed biology (seed maturation, fecundity, seedbank) and seedling studies (longevity of plant, mortality). Encourage collaboration, ingenuity, financial support, and technical support between partners and the USFWS to conduct these studies. (USFWS, 2018)
- Conservation measures are not available.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Future actions to aid in the recovery of the Texas trailing phlox should focus on implementation of the following recovery actions: 1.2 Provide immediate protection for existing habitat areas. Most of the extant populations outside of the TNC Sanctuary are declining in abundance and most are on private lands. Long-term mechanisms such as cooperative agreements for conserving and protecting genetically important populations is essential and should be explored with landowners and land managers. 1.3 Contact landowners and land managers of all Texas trailing phlox sites. Changes in landowner/land managers at several of the sites, many of which are privately owned, have occurred. Contact with the new owners at the Tyler County reintroduction site were made in June 2023 and a potential site visit was discussed for fall 2023. Each land steward should be made aware of the ecologic and genetic importance of the Texas trailing phlox. The Service should seek out opportunities to build and strengthen relationships with

new land stewards and continue to work with and foster existing partnerships. 1.4 Work with landowners to develop and implement compatible management for Texas trailing phlox. Assist and/or develop management plans with land stewards with the primary goal of restoring and maintaining longleaf pine savanna habitat for the species. Investigate plant response to management practices (prescribed burning, mowing, thinning), conducted in various frequency and intensity schemes. Encourage collaboration, ingenuity, and financial and technical support between partners and the Service to conduct on the ground management and track the response of these management actions. 1.4.3. Continue to seek landowner assistance with monitoring activities. Continue to actively engage with land stewards at extant sites to monitor and understand conservation needs. Verifying the status of the EO ID records considered to be unverified or historic are a priority. 1.5 Monitor Extant Populations. Continue to monitor extant populations, assessing species' viability, habitat conditions, management needs, and potential threats. 2.1 Search for new populations in suitable East Texas habitat. Develop a habitat suitability map to assist in identifying new parcels of land appropriate for surveying, restoration, and ex-situ opportunities. Using updated habitat suitability mapping and information, the Service should seek out and conduct searches for additional populations of Texas trailing phlox across its range. 3. Implement captive propagation program. Ensure collection of seed and/or plant material from populations where threats remain high, abundance is low, and/or genetic analysis suggested distinctiveness. Work with local Center for Plant Conservation partner to follow collection and storing procedures. 5. Investigate the reproductive biology of Texas trailing phlox including pollination (5.2) seed biology (5.3), and seedling studies (5.5). Conduct essential life history studies, but not limited to the abovementioned topics, should new biological needs arise for the species. Encourage collaboration between the Service, partners, and land stewards to foster ingenuity, financial and technical support to conduct such studies. 6. Investigate the response of Texas trailing phlox to various management techniques and types of disturbance. Assist in the development and implementation of studies aimed at investigating plant response to different types of management, conducted in various seasons, frequency, and intensity. Provide updates to land stewards and partners to better manage the Texas trailing phlox and its habitat throughout the range. Ensure that findings are made available to the public and other potential managers of longleaf pine savanna habitats. 8. Develop Reintroduction Plan. Develop a Controlled Propagation and Reintroduction Plan (per USFWS policy). Limit reintroduction work to the known geographic range of the species (Hardin, Tyler, Polk counties). 9. Implement public education efforts. Encourage awareness of Texas trailing phlox, its management needs within the longleaf pine savanna habitat, and its habitat structure/composition. Develop outreach resources for land stewards. Provide technical support for management, surveys, monitoring, and conservation efforts. Provide financial support for management and/or leverage funds for restoration and recovery efforts (USFWS, 2023).

Adult: Not available.

### **Habitat Type**

Adult: Terrestrial (USFWS, 2015)

### **Habitat Narrative**

Adult: *Phyllanthus saffordii* (NCN), a woody shrub in the Phyllanthaceae family, is historically known only from the southern part of Guam within the savanna ecosystem (USFWS, 2015).

### ***Dispersal/Migration***

### **Dispersal/Migration Narrative**

Adult: Not available.

### ***Population Information and Trends***

### **Population Trends:**

Decreasing (USFWS, 2015)

### **Number of Populations:**

4 (USFWS, 2015) 4 (USFWS, 2020b)

**Population Size:**

<1,400 (USFWS, 2015) 1,400 (USFWS, 2020b)

**Population Narrative:**

Populations of *P. saffordii*, a single island endemic, are thus decreasing from initial numbers observed on Guam. Currently, *P. saffordii* is known from 4 scattered occurrences on southern Guam, totaling fewer than 1,400 individuals (Gutierrez 2013, in litt.; Gawel et al. 2013, in litt.). (USFWS, 2015). *Phyllanthus saffordii* is a small woody short-lived shrub found at the edges of erosion scar and forest vegetation in savanna habitat in southern Guam. It is often found in clusters of up to 20 individuals in one site (Demeulenaere 2020 in litt.). Because there have been no surveys to date focused on distribution and abundance of *P. saffordii*, the number of populations of *P. saffordii* is unknown (Demeulenaere 2020 in litt.). There are at least several to many populations and an overall abundance of approximately several thousand individuals (Demeulenaere 2020 in litt.). The populations have no ongoing control of threats and the occupied sites are vulnerable to loss and degradation by nonnative animals (including ungulates, rodents, the brown treesnake, and invertebrates), invasive plants, fire, typhoons, and effects due to climate change. The Guam Plant Extinction Prevention Program has secured 11 *Phyllanthus saffordii* from Mount Lamlam in their nursery, 262 seeds from Mount Alifan are in storage, and experimental plantings of this species have been conducted at three locations. Six plants were outplanted, two individuals remain alive (GPEPP 2018) (USFWS, 2020)

**Threats and Stressors**

**Stressor:** Climate change (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The Service anticipates the effects of climate change will further exacerbate many of these threats in the future. (USFWS, 2015)

**Stressor:** Urban development (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Other urban development (primarily involving housing development) will further impact the ecosystems that support native species. On Guam, a housing development is proposed for the Sigua highlands, where *Phyllanthus saffordii* is known to occur (Kelman 2013, in litt.). (USFWS, 2015)

**Stressor:** Habitat disturbance via development, military training, and urbanization (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Development, military training, urbanization (Guam DAWR 2006, p. 69), and the associated destruction or degradation of habitat through loss of forest and savanna areas, disturbance of caves, and dewatering of streams, are serious threats to 13 of the 14 plants including *Phyllanthus saffordii*. (USFWS, 2015)

**Stressor:** Alien ungulates (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The presence of alien mammals is considered one of the primary factors underlying the alteration and degradation of native plant communities and habitats on the Mariana Islands. The destruction or degradation of habitat due to nonnative ungulates, including pigs, goats, cattle, water buffalo, and deer, is currently a threat to 17 of the 23 species addressed in this final rule including *Phyllanthus saffordii*. (USFWS, 2015)

**Stressor:** Wildfire (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Wildfire is a threat to nine plant species including *Phyllanthus saffordii*, because individuals of these species occur in the savanna ecosystem or the forest ecosystem adjacent to the savanna ecosystem, on southern Guam (i.e., Cetti Watershed area) and on the Rota Sabana, where fires are common (Grimm 2012, in litt.; Gutierrez 2012, in litt.; Gutierrez 2013, in litt.). (USFWS, 2015)

**Stressor:** Recreational vehicles (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The savanna areas of Guam are popular for use of recreational vehicles. Damage and destruction caused by these vehicles are a direct threat to the plants *Hedyotis megalantha* and *Phyllanthus saffordii*, listed as endangered species in this final rule. (USFWS, 2015)

## ***Recovery***

### **Reclassification Criteria:**

Not available.

### **Delisting Criteria:**

Not available.

### **Recovery Actions:**

- Not available.
- Threat and Recovery Potential: Full species with a moderate degree of threat and a high recovery potential. (USFWS, 2020b)

## ***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS** • Determine population status and current distribution—Determine the distribution and number of all individuals on each island. Identify priority sites for species conservation. Assess the status and threats to each population to inform prioritization of conservation effort. • Conduct research to clarify life history information and threats to the populations and their habitat—Conduct research to determine the best way to control the brown treesnake, rodents, and invasive invertebrates. Assess development and land

designation and zoning threats to conservation of habitat needed for recovery. • Ungulate monitoring and control—Construct and maintain fenced exclosures to protect wild and reintroduced individuals from the negative impacts of feral ungulates. • Invasive plant monitoring and control—Control ecosystem-altering nonnative invasive plant species and those that compete with *P. saffordii* at all populations. • Captive propagation for genetic storage and reintroduction—Continue to collect seeds and other propagative materials for storage and reintroduction. • Reintroduction and translocation—Augment populations and increase numbers of populations and individuals in suitable habitat to build resiliency and redundancy and reduce the impacts of predation and typhoons, and climate change. • Reduce human disturbance, such as from recreational activities mortality and reduced viability—increase population resiliency by mitigating threats from these human activities. • Fire prevention and control—Implement more effective fuel load control. • Develop regulations and policy essential to recover the species and their habitats—Encourage the development of legislation to ensure protection of the listed species under Commonwealth or Territorial law. Develop and support the implementation of biosecurity plans to prevent the influx of new pests and invasive species into the Territory and inter-island movement of pests and invasive species. • Alliance and partnership development—Continue to contribute to planning and implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2020)

- Current Management Actions: • Surveys and inventories – • The University of Guam’s Center for Island Sustainability & Guam Plant Extinction Prevention Program surveys for *Phyllanthus saffordii* in savanna habitat (Demeulenaere 2020, in litt.). • Captive propagation for genetic storage and reintroduction • *Phyllanthus saffordii* was successfully germinated through an aseptic seed germination method by GPEPP. There are 11 individuals from Mount Lamlam currently in the plant nursery, and 262 seeds from Mount Alifan are in storage (GPEPP 2018, entire). Eventually, these individuals could be outplanted in the savanna habitat. • Habitat protection – • A major biosecurity focus within the Mariana Islands is controlling the brown treesnake on Guam. Federal agencies support local capacity. The U.S. Department of Agriculture, Wildlife Services, in coordination with the National Wildlife Research Center (NWRC), U.S. DoD Environmental Security Technology Certification Program, and the Department of Interior Office of Insular Affairs (U.S. Geological Survey, USFWS), are developing methods to suppress the snake on the landscape scale (Dorr, et al. 2016, in litt.; Phillips 2014, in litt.; BTSTWG 2015, entire; (Siers, et al. 2018, in litt.). • Researchers and students at the University of Guam’s Center for Island Sustainability (CIS) conduct biological monitoring in the savanna habitat and are currently exploring optimal restoration methods to restore degraded savanna habitat. The biologists at CIS monitor the watersheds throughout the savanna focusing on sedimentation, erosion, and runoff. There are several graduate student projects focused on savanna ecology and restoration (e.g., seed balls, plant propagation and outplanting) to reduce erosion and runoff. One of these student projects includes *Phyllanthus saffordii*. These studies are currently underway. • In 2018, public outreach/awareness efforts to protect *Phyllanthus saffordii* and the savanna habitat were initiated by NOAA Fisheries Pacific Island Regional Office. As part of this effort, NOAA created outreach materials to warn the public about the impacts of erosion on reef ecosystems and to prevent any damage to native savanna species. Cards with pictures and details about *P. saffordii* and other savanna species are being given to individuals before outplanting efforts in the savanna so extant individuals can be marked and buffers put in place. Although the cards are only currently provided to volunteers as part of outplanting trees, they may be made available to hikers or off-road bikers. • In 2002, a community effort known as the “Humåtak Project” was created to revive the watershed that is affecting Fouha Bay on southern Guam. Sediment traps to control erosion are improving habitat suitability for native plants in the savanna. Swordgrass is very opportunistic and commonly the first plant to colonize an open area

possibly limiting or prohibiting recolonization by *Phyllanthus saffordii* and other endemic shrubs. • A fire management plan to reduce wildfire potential, protect and enhance natural and cultural resources, integrate applicable permit and reporting requirements and implement ecosystem management goals, sustainable training, and objectives is being drafted (JRM 2019). • Other Natural or Manmade Factors - Recreation – The Guam's Department of Agriculture, Division of Aquatic Wildlife Resources (DWAR) has the authority to enforce laws (5 GCA, Chapter 63, PL-6-85) to protect native flora and fauna. Their Conservation Land areas include Cotal with 552 acres (223 ha) and Bolanos area with 2,830 acres (1145 ha). Cotal is primarily savanna, badlands, and some secondary forests and Bolanos consists of both savanna and forest. The Bolanos Conservation area is dominated by swordgrass and efforts are being made to rehabilitate the area by enforcing public use permits. (USFWS, 2020)

## SPECIES ACCOUNT: *Phyllostegia pilosa* (No common name)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 06/27/2013; Pacific Region (R1) (USFWS, 2016)

### **Physical Description**

A vine (USFWS, 2016).

### **Taxonomy**

A member of the mint family (Lamiaceae) (USFWS, 2016). Newly recognized Hawaiian endemic species of Moloka'i and Maui, formerly treated within *Phyllostegia mollis* (e.g., Wagner et al., Hawaii, 1990, and Kartesz 1994 and 1999). Recognized as *P. haleakalae* in Wagner and Herbst's 1999 Supplement, with *P. mollis* considered endemic to O'ahu only. However, Wagner (1999, Novon 9: 274-275) has subsequently decided that *P. pilosa* is the correct name for the plants called "*P. haliakalae*", with the latter name actually applying to the species previously known as *P. imminuta* (NatureServe, 2015)

### **Historical Range**

Historically known from Molokai. (NatureServe, 2015). The individuals identified as *P. pilosa* on Molokai, at Kamoku Flats (montane wet ecosystem) and at Mooloa (lowland mesic ecosystem), have not been observed since the early 1900s (TNC 2007; HBMP 2010) (USFWS, 2016).

### **Current Range**

It occurs west of Puu o Kaka'e on east Maui (USFWS, 2016). Distribution: Maui. Likely extirpated on Molokai (USFWS, 2021)

### **Critical Habitat Designated**

Yes; 3/30/2016.

### **Legal Description**

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Phyllostegia pilosa* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes eight detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

### **Critical Habitat Designation**

The critical habitat designation for *Phyllostegia pilosa* includes eight CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Molokai—Lowland Mesic—Unit 1 (and) *Palmeria dolei*—Unit 37—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 37— Lowland Mesic This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waianui Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea lydgatei*, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime,

and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielirectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*, *Festuca molokaiensis*, *Flueggea neowawraea*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania tomentosa*, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Wet—Unit 1 (and) *Palmeria dolei*—Unit 40—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 40— Montane Wet This area consists of 1,545 ac (625 ha) of State land, and 1,851 ac (749 ha) of privately owned land, from the headwaters of Waialeia Stream and above Pelekunu Valley, eastward along the summit area to Mapulehu, in northcentral Molokai. These units are occupied by the plants *Bidens wiebkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. profuga*, *Phyllostegia hispida*, and *Pteris lidgatei*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Montane Wet—Unit 1 is not known to be occupied by *Adenophorus periens*, *Cyanea procera*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Melicope reflexa*, *Phyllostegia mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Wet—Unit 3 consists of 77 ac (31 ha) of State land, and 726 ac (294 ha) of privately owned land, above the east rim of Wailau Valley on eastern Molokai. This unit is occupied by the plant *Melicope reflexa*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Montane Wet—Unit 3 is not known to be occupied by *Adenophorus periens*, *Bidens wiebkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. procera*, *C. profuga*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Pteris lidgatei*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical

range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 4 (and) *Palmeria dolei*—Unit 13—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 13— Montane Wet This area consists of 180 ac (73 ha) of State land and 1,653 ac (669 ha) of federally owned land (Haleakala National Park), in Kaapahu Valley on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *Cyrtandra ferripilosa*, and *Huperzia mannii*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 4 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea duvalliorum*, *C. glabra*, *C. mceldowneyi*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 41—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 41— Montane Wet This area consists of 871 ac (353 ha) of State land, and 39 ac (16 ha) of privately owned land, from Honukaupu to Olokui (between Pelekunu and Wailau valleys), in north-central Molokai. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). Although Molokai— Montane Wet—Unit 2 is not known to be occupied by *Adenophorus periens*, *Bidens wiebkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. procera*, *C. profuga*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Melicope reflexa*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Pteris lidgatei*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 11—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 11— Montane Wet This area consists of 4,075 ac (1,649 ha) of State land, 9,633 ac (3,898 ha) of privately owned land, and 875 ac (354 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Puukaukanu and upper Waihoi Valley, on the

northern and northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Geranium hanaense*, *G. multiflorum*, and *Wikstroemia villosa*, and by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 2 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea glabra*, *C. maritae*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, and *Schiedea jacobii*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 3 (and) *Palmeria dolei*—Unit 12—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 12—Montane Wet This area consists of 2,228 ac (902 ha) of federally owned land (Haleakala National Park) in Kipahulu Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. maritae*, and *Melicope ovalis*, and by the forest bird, *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 3 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea duvalliorum*, *C. glabra*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest bird, the *akohekohe* (*Palmeria dolei*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 5 (and) *Palmeria dolei*—Unit 14—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 14—Montane Wet This area consists of 222 ac (90 ha) of State land, and 165 ac (67 ha) of federally owned land (Haleakala National Park), near Kaumakani on the eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units area occupied by the plant

*Bidens campylotheca* ssp. *pentamera*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 5 is not currently occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

### Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Phyllostegia pilosa* critical habitat consists of two components. Lowland mesic (Molokai) and Montane wet (east Maui and Molokai) (81 FR 17790-18110):

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: *Ferns*, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

### Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp.

lepidotum, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to

further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

***Life History*****Food/Nutrient Resources****Lifespan**

Adult: < 10 years (inferred from USFWS, 2016). Short (USFWS, 2021)

**Reproduction Narrative**

Adult: It is a short-lived perennial (USFWS, 2016).

**Habitat Type**

Adult: Terrestrial (USFWS, 2012)

**Habitat Vegetation or Surface Water Classification**

Adult: Montane wet and lowland mesic forest (USFWS, 2012; NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: < 3,300 - 6,500 ft. elevation (USFWS, 2012)

**Habitat Narrative**

Adult: It occurs in the lowland mesic ecosystem (grasslands, shrublands, and forests, generally below 3,300 ft. (1,000 m) elevation), and montane wet ecosystem (grasslands, shrublands, forests, and bogs) found at elevations between 3,300 and 6,500 ft. elevation) (USFWS, 2012). Habitat is characterized as forest (NatureServe, 2015).

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends*****Population Trends:**

Not available

**Number of Populations:**

2 (USFWS, 2016). Unknown (USFWS, 2023)

**Population Size:**

7 (USFWS, 2016). Unknown (USFWS, 2023)

**Population Narrative:**

There are two occurrences totaling seven individuals (USFWS, 2016). There are no known individuals of *Phyllostegia pilosa* remaining in the wild. A landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections was made by Fortini et al. (2013) and their analysis showed that, before the split into different species, *P. mollis* (including *P. pilosa*) is highly vulnerable to the effects of climate change. Most of the reintroduced populations are provided some protection from ungulates within exclosures. Genetic representation is complete. Collection, propagation, and reintroduction are ongoing. (USFWS, 2020)

**Threats and Stressors**

**Stressor:** Habitat destruction or modification (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Adverse impacts on habitat of this species have been identified from nonnative animals (pigs and goats), nonnative plants, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

**Stressor:** Predation and herbivory (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Predation and herbivory by nonnative animal species (pigs, goats, and slugs) is considered an ongoing threat to *Phyllostegia pilosa* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

**Stressor:** Small populations (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** *Phyllostegia pilosa* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). The seven known individuals of *Phyllostegia pilosa* are not protected from direct predation by feral pigs and goats on Maui. This species has not been observed on Molokai for over 100 years (USFWS, 2013).

**Recovery****Reclassification Criteria:**

Number of populations and individuals needed for each plant species to meet Preventing Extinction Stage target based on population and life history characteristics: Number of Populations: 3. Mature Individuals per population: 50. (USFWS, 2023) Number of populations and individuals needed for each plant species to meet the Interim Stage target based on population and life history characteristics: Number of Populations: 3. Mature Individuals per population: 300. (USFWS, 2023) Number of population and individuals needed for downlisting based on population and life history characteristics: Number of Populations: 5. Mature Individuals per population: 500. (USFWS, 2023)

Recovery Priority Number: 5

**Delisting Criteria:**

Number of populations and individuals needed for delisting based on population and life history characteristics: Number of Populations: 10. Mature Individuals per population: 500. (USFWS, 2023)

**Recovery Actions:**

- Not available - this species does not have a recovery plan.
- Not available

**Conservation Measures and Best Management Practices:**

- **RECOMMENDATIONS FOR FUTURE ACTIONS** • Surveys and inventories—Continue to search suitable habitat for individuals of *Phyllostegia pilosa* in recent and historical locations. • Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect wild and reintroduced individuals from the negative impacts of feral ungulates. • Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species and those that compete with *P. pilosa* at all populations. • Predation and herbivory by rats and slugs—Implement effective control measures for rats and slugs at all populations. • Captive propagation for genetic storage and reintroduction—Collect seeds and other propagative materials for storage and begin propagation efforts for maintenance of genetic stock. • Reintroduction and translocation—Augment populations and increase numbers of populations and individuals in suitable habitat to reduce the impacts of predation and climate change. • Population biology research—Research the effects of nonnative insects and develop and implement control methods if necessary. Research the possible causes of lack of natural recruitment. • Climate change adaptation strategy—Research suitability of habitat in the future due to the impacts of climate change. • Alliance and partnership development—Continue to contribute to planning and implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2020)
- **Current Management Actions:** • Surveys and monitoring—PEPP monitors and surveys for individuals of *Phyllostegia pilosa* on east Maui (Oppenheimer 2019, pers. comm.). • Ungulate control— o The

East Maui Watershed Partnership (EMWP) works in coordination with landowners to protect and monitor the native ecosystems of east Maui (<http://eastmauiwatershed.org/explorethe-watershed/management/>, accessed 28 JAN 2020). The partnership addresses ungulate removal and enclosure construction (over 11 kilometers (7 miles) of fencing). Most of the reintroduced populations of *P. pilosa* are fenced. o The Nature Conservancy's Waikamoi Preserve encompasses (2,117 hectares, 5,230 acres) along the northern boundary of Haleakala National Park on east Maui (TNCH 2011, p. 4). Ungulate control is the focus of the Waikamoi resource management program, utilizing a combination of fencing, hunting, and snaring (TNCH 2011, pp. 13–14). Individuals of *P. pilosa* that occur within the preserve are provided protection by these conservation activities. o The Plant Extinction Prevention Program (PEPP) constructs and maintains fencing and conducts nonnative plant control at wild and reintroduced populations of *P. pilosa* on east Maui (PEPP 2015).

- Nonnative plant control— o The EMWP has also initiated nonnative plant control planning and implementation in areas where *P. pilosa* occurs (<http://eastmauiwatershed.org/explore-the-watershed/management/>, accessed 28 JAN 2020). o The Plant Extinction Prevention Program (PEPP) constructs and maintains fencing and conducts nonnative plant control at wild and reintroduced populations of *P. pilosa* on east Maui (PEPP 2015). o The TNCH conducts nonnative plant control (prioritized target species: *Hedychium gardnerianum*, *Fraxinus uhdei* (tropical ash), *Pinus* spp. (pine), *Cortaderia jubata* (pampas grass), and *Ulex europeaus* (gorse) within Waikamoi Preserve (TNCH 2011, p. 19).
- Captive propagation for genetic storage and reintroduction— o The Lyon Arboretum Micropropagation Laboratory reports 341 explants in storage representing five individuals from the population at Makawao-Olinda (Lyon Arboretum 2019). The Lyon Arboretum Seed Conservation Laboratory reports 17,355 seeds collected from 11 individuals representing the population at Makawao-Olinda with 17,201 of those in storage (Lyon Arboretum 2019). o Haleakala National Park (HNP) reports 70 seeds in storage representing one individual at Waikamoi Preserve (HNP 2016). o The National Tropical Botanical Garden (NTBG) reports 142 seeds in storage (collected in 2013) representing at least one individual at Waikamoi (NTBG 2019). o The Olinda Rare Plant Facility (ORPF) reports four potted plants in storage representing one individual from Waikamoi, six potted plants representing one individual from Makawao-Olinda, and 38 potted plants representing two individuals from Makawao-Olinda intended for outplanting at Makawao (ORPF 2019).
- Reintroduction and translocation—PEPP has planted approximately 164 plants at four sites, most of which are in the Makawao-Olinda area (the three other sites are Waikamoi, Haipua'ena, and Honomanu); however, no natural recruitment has been observed (PEPP 2013, 2014, 2015, 2016, 2017, 2019). (USFWS, 2020)

## SPECIES ACCOUNT: *Physaria douglasii* ssp. *tuplashensis* (White Bluffs bladderpod)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 05/23/2013; Pacific Region (R1) (USFWS, 2016)

### Physical Description

White Bluffs bladderpod is a low growing, herbaceous, perennial plant with a sturdy tap root and a dense rosette of broad gray-green pubescent leaves (WDNR 2010). The subspecies produces showy yellow flowers (USFWS, 2013a).

### Taxonomy

Although specimens of this taxon were originally collected from a population in 1883, the plant material was in poor condition, no definitive identification could be made, and the plant was not recognized as a species at that time. The population was rediscovered in 1994, and was described and published as a species, *Lesquerella tuplashensis*, by Rollins et al. (1996, pp. 319–322). Based on molecular, morphological, phenological, reproductive, and ecological data, the conclusions in AlShehbaz and O’Kane (2002, p. 322) and Caplow et al. (2006, pp. 8–10) combining the genera *Lesquerella* and *Physaria* and reducing the species *Lesquerella tuplashensis* to *Physaria douglasii* subsp. *tuplashensis*, provide the most consistent and compelling information available to date (USFWS, 2013a).

### Historical Range

In 1996, White Bluffs bladderpod was only known from a single population that occurred along the upper edge of the White Bluffs of the Columbia River in Franklin County, Washington (USFWS, 2013a). It is endemic to a small band about 17 km long by about 10 meters wide (NatureServe, 2015).

### Current Range

White Bluffs bladderpod is still known only from the single population that occurs along the upper edge of the White Bluffs of the Columbia River, Franklin County, Washington (USFWS, 2013a). Extensive searches of suitable substrate elsewhere in Washington have been conducted but no other plants have been found (USFWS, 2004; NatureServe, 2015). – In the late 1990s the subspecies was described as occupying a narrow area 17 to 20-km long on the slopes and top of the White Bluffs. When the listing rule was revised, it was determined that the occupied area had likely shrunk due to threats and habitat changes in the southern part of the range (USFWS 2013b, p. 76998). The recent and current range of White Bluffs bladderpod is uncertain because there has not been a complete survey since 1997, only the northern part of the distribution is monitored. The northern part continues to be occupied but the status of the southern part is unknown. However, Refuges’ outplanting efforts from 2013 to 2015 have resulted in at least a temporary range expansion within the Monument. As of 2020, the plants in the outplanting area were still successfully reproducing. The establishment of a self-sustaining population there could be essential to the continuation of the subspecies should there be catastrophic landslides where the main population occurs. (USFWS, 2020)

### Critical Habitat Designated

Yes; 4/23/2013.

**Legal Description**

On April 23, 2013, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Physaria douglasii* ssp. *tuplashensis* (White Bluffs bladderpod) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Washington (78 FR 76995-77005; 78 FR 24008-24032).

**Critical Habitat Designation**

The critical habitat designation for *Physaria douglasii* ssp. *tuplashensis* includes one CHU in Franklin County, Washington. This species critical habitat encompasses approximately 2,033.4 acres (ac) (822.9 hectares (ha)) (78 FR 76995-77005; 78 FR 24008-24032).

White Bluffs bladderpod is only known from a single population that occurs in a narrow band approximately 10 m (33 ft) wide by 17 km (10.6 mi) long, at the upper edge of the White Bluffs of the Hanford Reach. The subspecies only occurs at the upper surface areas of a near-vertical exposure of paleosol (ancient, buried soil whose composition may reflect a climate significantly different from the climate now prevalent in an area). This surface material overlies several hundred feet of easily eroded sediments of the Ringold Geologic Formation, a sedimentary formation made up of soft Pleistocene lacustrine deposits of clay, gravel, sand, and silt (Newcomb 1958, p. 328). The upper part of the Ringold Formation is a heavily calcified and silicified cap layer that exists to a depth of at least 4.6 m (15 ft). This layer is geologically referred to as "caliche," although it lacks the nitrate constituents found in true caliche. The caliche-like layer is a resistant caprock underlying a 275–305 m (900–1,000 ft) plateau extending north and east from the White Bluffs (Newcomb 1958, p. 330). The entire population of White Bluffs bladderpod is down-slope of irrigated agricultural land, and is being impacted to differing degrees by landslides induced by water-seepage (see Factor A). The potential for landslide is greatest in the southern portion of the subspecies' distribution where irrigated lands are closer to, or directly adjacent to, the bluffs (Lindsey 1997, p. 12). In addition, field investigations have determined that *Lesquerella* (now *Physaria*) plants can be outcompeted by nonnative, weedy plant species associated with irrigation projects and other disturbance (TNC 1998, p. 5). Therefore, based on the information above, we identify the weathered cliffs at approximately 210–275 m (700–900 ft) above sea level of the White Bluffs of the Ringold Formation exposed by natural erosion as a physical and biological feature essential to the conservation for White Bluffs bladderpod. The habitat includes the adjacent cliff breaks, moderate to gentle slopes (<100 percent slope) to the toe of slope, and flat or gently sloping cliff tops with exposed alkaline paleosols. This habitat is stable with a minimal amount of landslide occurrence. This critical habitat unit was mapped using Universal Transverse Mercator, Zone 11, North American Datum 1983 (UTM NAD 83) coordinates. These coordinates establish the vertices of the unit boundaries. The map in this entry, as modified by any accompanying regulatory text, establish the boundaries of the critical habitat designation. The coordinates or plot points or both on which the map is based are available to the public at the field office internet site (<http://www.fws.gov/wafwo/HanfordPlants/FLFCH.html>), <http://www.regulations.gov> at Docket No. FWS–R1–ES–2013–0012, and at the Service's Washington Fish and Wildlife Office. You may obtain field office location information by contacting one of the Service regional offices, the addresses of which are listed at 50 CFR 2.2.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Physaria douglasii* ssp. *tuplashensis* critical habitat consists of five components (78 FR 76995-77005; 78 FR 24008-24032):

- (i) Weathered alkaline paleosols and mixed soils overlying the Ringold Formation. These soils occur within and around the exposed caliche-like cap deposits associated with the White Bluffs of the Ringold Formation, which contain a high percentage of calcium carbonate. These features occur between 210–275 m (700–900 ft) in elevation.
- (ii) Sparsely vegetated habitat (less than 10–15 percent total cover), containing low amounts of nonnative or invasive plant species (less than 1 percent cover).
- (iii) The presence of insect pollinator species.
- (iv) The presence of native shrub steppe habitat within the effective pollinator distance (300 m (approximately 980 ft)).
- (v) The presence of stable bluff formations with minimal landslide occurrence.

#### **Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and that may require special management considerations or protection. All areas designated as critical habitat as described below may require some level of management to address the current and future threats to the physical and biological features essential to the conservation of Umtanum desert buckwheat. In all of the described units, special management may be required to ensure that the habitat is able to provide for the biological needs of the species. Further studies leading to an enhancement or reintroduction plan may be necessary to increase population size and prepare for recovery postwildfire. More research is needed to determine habitats most suitable for expansion of the current population. In summary, special management considerations or protections should address activities that would be most likely to result in the loss of Umtanum desert buckwheat plants or the disturbance, compaction, or other negative impacts to the species' habitat. These activities could include, but are not limited to, recreational activities and associated infrastructure, off-road vehicle activity, dispersed recreation, wildfire, and wildfire suppression activities. Special management considerations or protection will conserve the primary constituent elements for the species. Management activities that could ameliorate these threats include, but are not limited to, the fire management plan that has been completed for the Hanford installation (DOE 2011, p. 93) and recently revised to incorporate more detailed management objectives and standards. Though not intended to specifically address Umtanum desert buckwheat, implementation of this plan will contribute to the protection of the primary constituent elements (and physical or biological features) by: (1) Using a map of "sensitive resources" on the site during implementation, including the location of Umtanum desert buckwheat habitat; (2) requiring a biologist to assist the command staff in protecting these environments during wildfire suppression efforts; and (3) restricting public access to the entire Umtanum desert buckwheat site, including the pollinator use area. Public access without security clearance is currently prohibited at the Umtanum desert buckwheat site, reducing the risk of trampling or crushing the plants by ORV use. Special management to protect the designated critical habitat areas and the

features essential to the conservation of Umtanum desert buckwheat from the effects of the current wildfire regime may include preventing or restricting the establishment of invasive, nonnative plant species, post-wildfire restoration with native plant species, and reducing the likelihood of wildfires affecting the population and nearby plant community components. These actions may be achieved by detailed fire management planning by the DOE, including rapid response and mutual support agreements between the DOE, the Monument, the U.S. Department of the Army, Bureau of Land Management, and the Washington Department of Fish and Wildlife for wildfire control. These agreements should contain sufficient detail to identify actions by all partners necessary to protect habitat for Umtanum desert buckwheat from fire escaping from other ownerships.

***Life History*****Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2013a)

**Lifespan**

Adult: 4 - 5 years (USFWS, 2013a)

**Breeding Season**

Adult: May - July (USFWS, 2013a)

**Reproduction Narrative**

Adult: In a presentation of preliminary life history studies, Dunwiddie et al. (2002, p. 7) reported that most individuals reach reproductive condition in their first or second year, most adult plants flower every year, and the lifespan of this short-lived subspecies is probably 4 to 5 years. Flowers are produced in May, June, and July (USFWS, 2013a).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Cliff, shrubland/chaparral (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 900 - 1,000 ft. elevation (USFWS, 2013a)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Found on a dry, barren, vertical exposure of caliche (a hard, highly alkaline, highly calcareous substrate) capping a bluff (Hallock 2002; Washington Natural Heritage 2002). The environmental specificity is very narrow; it is known only from one extensive rock formation (the White Bluffs of the Columbia River), where the plants occur in a highly alkaline caliche-type cemented paleosol that caps several hundred feet of easily eroded alkaline lacustrine sediments

(USFWS, 2004). Terrestrial habitat is characterized as cliff or shrubland/chaparral (NatureServe, 2015). The uppermost part of the Ringold Formation is a heavily calcified and silicified cap layer to a depth of at least 4.6 m (15 ft.). This layer is commonly called “caliche” although in this case, it lacks the nitrate constituents found in true caliche. The “caliche” layer is a resistant caprock underlying the approximately 274–304 m (900–1,000 ft.) elevation (above sea level) plateau extending north and east from the White Bluffs (Newcomb 1958, p. 330) (USFWS, 2013a).

### ***Dispersal/Migration***

#### **Dispersal/Migration Narrative**

Adult: Not available

### ***Population Information and Trends***

#### **Number of Populations:**

1 (USFWS, 2020)

#### **Population Size:**

2,529 to 58,472 (USFWS, 2020)

#### **Population Narrative:**

The White Bluffs bladderpod population continues to fluctuate greatly among years, with an overall trend of consistently going up and down over time. The monitored portion of the population has ranged from an estimated 2,529 to 58,472 flowering plants since 2013. The size of the entire White Bluffs bladderpod population is uncertain because monitoring occurs only along permanent transects in an area totaling 3.7-km long in the northern part of the subspecies' range. A population viability analysis has not been done and therefore a minimum viable population size has not been estimated. It was suggested that there should be at least 10,500 reproductive individuals in the monitored portion for the population to be considered viable (Caplow 2003, p. 3-3) but as recently as 2015 and 2016 this threshold was not met. Therefore, small population size may continue to be a threat. (USFWS, 2020)

### ***Threats and Stressors***

**Stressor:** Irrigation (NatureServe, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** About one-third of the population is located near or adjacent to irrigated land, where excess groundwater seepage has triggered mass-slope failures (landslides) in the past that obliterate the narrow blufftop soil band in which these plants are found; *Lesquerella tuplashensis* has not been found in areas disturbed by these landslides (USFWS 2004). Recent incorporation of the area into a national monument/national wildlife refuge may increase capabilities to mitigate this threat somewhat; however, irrigation-dependent farming continues in the area (NatureServe, 2015).

**Stressor:** Pesticide use (NatureServe, 2015)

**Exposure:**

**Response:****Consequence:**

**Narrative:** Pollinators may be affected by use of agricultural pesticides nearby (USFWS, 2004; NatureServe, 2015).

**Stressor:** Invasive species (NatureServe, 2015)

**Exposure:****Response:****Consequence:**

**Narrative:** Yellow star thistle (*Centaurea solstitialis*), a highly invasive exotic weed, has been documented in the vicinity (USFWS 2003 & 2004). A seed-predator insect has also been noted in recent years (USFWS, 2004), but it is not known if this is a natural phenomenon or an exotic species introduction (NatureServe, 2015). Cheatgrass is an introduced annual grass that is widely distributed in the western United States, and has been documented in the White Bluffs bladderpod population. Cheatgrass can outcompete native plants for water and nutrients in the early spring, since it is actively growing when native plants are initiating growth. It also completes its reproductive process and becomes senescent before most native plants (Pellant 1996, p. 1–2) (USFWS, 2013b).

**Stressor:** Off-road vehicles (NatureServe, 2015)

**Exposure:****Response:****Consequence:**

**Narrative:** Off-road vehicles, including mountain bikes, have increased disturbance and erosion, and destroyed individual plants (F. Caplow, pers. comm. cited in USFWS 2003 & 2004) (NatureServe, 2015).

**Stressor:** Fire (USFWS, 2013b)

**Exposure:****Response:****Consequence:**

**Narrative:** Fire is considered to be a threat to White Bluffs bladderpod, although the decline in population numbers after the 2007 fire indicated the population estimate was still within the known range of variability. Fire events tend to be large and unpredictable in the Hanford Reach (see Table 3) and can potentially affect large numbers of plants and significant areas of pollinator habitat. In addition, wildfire also impacts pollinator communities by directly causing mortality, altering habitat, and reducing native plant species diversity (USFWS, 2013b).

**Stressor:** Predation (USFWS, 2013b)

**Exposure:****Response:****Consequence:**

**Narrative:** Since 1996, some predation by larval insects on developing fruits of White Bluffs bladderpod has been observed. Larvae of a species of Cecidomyiid fly have been observed infesting and destroying flowering buds, and an unidentified insect species has been documented boring small holes into young seed capsules and feeding on developing ovules. However, the overall effect of these insect species on the plants or population is not known (TNC 1998, p. 5). Although insect predation may be a potential threat to White Bluffs bladderpod, more thorough

investigations are necessary to determine its significance to seed production (USFWS, 2013b).

**Stressor:** Utility lines (USFWS, 2020)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Since the listing rule, one highly localized and largely temporary potential threat emerged. A 115 kilovolt electrical transmission line (Benton-Othello) crosses the White Bluffs in an area where the subspecies occurs. The line, owned by Avista Utilities (hereafter, Avista), was rebuilt from 2019-2020. Direct (e.g., uprooting plants, crushing plants) and indirect (e.g., increased likelihood of fire or non-native plants) impacts to bladderpod were expected (U.S. Department of Energy 2019, p. 44). Within the subspecies' critical habitat, the estimated disturbance was 0.02 ac permanently and 2.37 ac temporarily. The actual disturbance was less than estimated. Construction techniques were altered to reduce impacts in critical habitat; for example, spoil that would normally be placed in the right-of-way was instead hauled away (U.S. Department of Energy 2019, p. 13). Avista developed a site-specific restoration plan that specifies how damage to the habitat and vegetation will be avoided, minimized, and mitigated (U.S. Department of Energy 2019, p. 16). The Service reviewed a draft of the plan. Revegetation will begin in late 2020 and continue into 2021, with weed control to occur for several years. All disturbed areas not needed for future operation and maintenance of the line will be revegetated with native species (USFWS 2018a, pp. 4-5). Avista will monitor these areas for 5 years to ensure success criteria have been met; if not met, additional restoration and monitoring will occur (U.S. Department of Energy 2019, p. 16). (USFWS, 2020)

## **Recovery**

### **Reclassification Criteria:**

Not available - this species does not have a recovery plan.

Recovery Priority Number: 6C

### **Delisting Criteria:**

- 1) Discover or establish at least one additional population of White Bluffs bladderpod within the Monument or, if possible, on nearby protected lands. These populations will be capable of adapting to changing environmental conditions and be of sufficient size and distribution to withstand stochastic events, such that extinction is highly unlikely (USFWS, 2022).
- 2) Manage and improve sufficient habitat to support populations wherever they occur (USFWS, 2022).

### **Recovery Actions:**

- 1. Monitor population status, trend, and distribution (USFWS, 2022).
- 2. Conduct scientific research to improve understanding of the subspecies' life history, autecology, and limiting factors (USFWS, 2022).
- 3. Protect, conserve, and enhance habitat (reduce or eliminate Factor A threats) (USFWS, 2022).
- 4. Determine the minimum viable population size for White Bluffs bladderpod and the number and distribution of populations needed for long-term viability (USFWS, 2022).

- 5. If needed, increase population size and distribution (reduce or eliminate Factor E threats) (USFWS, 2022).
- 6. Promote outreach and cooperation with partners and stakeholders (USFWS, 2022).

## SPECIES ACCOUNT: *Physaria filiformis* (Missouri bladderpod)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 01/08/1987; Great Lakes-Big Rivers Region (R3) (USFWS, 2015)

### **Physical Description**

The Missouri bladderpod is a winter annual, up to 2.5 dm tall, which produces yellow flowers which are especially showy against the plant's silvery stems and foliage. The plants flower, set seed, and die in early spring; the seeds germinate in autumn and overwinter as rosettes. (NatureServe, 2015)

### **Taxonomy**

Previously known as *Lesquerella filiformis* (USFWS, 2008)

### **Historical Range**

In addition to its current range, the bladderpod is believed to be extirpated in Jasper and Lawrence counties, Missouri. (USFWS, 1987)

### **Current Range**

The Missouri bladderpod currently occurs in four counties in Missouri and five counties in Arkansas and the species is distributed on limestone glades in Southwest Missouri, dolomite glades in northern Arkansas (a report for Missouri on a dolomitic glade has not been confirmed, George Yatskievych, pers. comm. Aug. 11, 2014), and shale glades in the Ouachita Mountains in central Arkansas (Witsell, 2008). (USFWS, 2015)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Sexual; self-incompatible (USFWS, 2015)

### **Lifespan**

Adult: Less than one year (USFWS, 1988)

### **Dependency on Other Individuals or Species**

Adult: Numerous insect species as pollinators (USFWS, 2015)

### **Reproduction Narrative**

Adult: The Missouri bladderpod is a winter annual, germinating in the fall and overwintering in the form of basal rosettes. Plants send up flowering stems in late April and flower, fruit and senesce by the end of June. Seeds lie dormant on the limestone glades through the summer and germinate in the fall, starting the life cycle over again. There is considerable variation in these life history details from year to year. (USFWS, 1988) This bladderpod is an obligate outcrosser,

being dependent upon several species of pollinators for pollination and fruit set. No less than 38 species of insects in four orders, visited Missouri bladderpod plants (Edens-Meier et al., 2011). (USFWS, 2015)

**Habitat Type**

Adult: Unglaciaded prairie areas (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Limestone and dolomitic glades or grazed pastures (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Limestone, dolomitic, or shale substrate (USFWS, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from USFWS, 2015)

**Environmental Specificity**

Adult: Narrow/specialist on specific soils (inferred from USFWS, 2015)

**Site Fidelity**

Adult: High (USFWS, 2015)

**Habitat Narrative**

Adult: The Missouri bladderpod is most commonly found in open limestone glades, barrens, and outcrops within unglaciaded prairie areas. It occasionally occurs in dolomitic glades, and is known from one site on a shale substrate. It is often associated with grazed pastures. Cedar invasion of glade sites is common. (NatureServe, 2015; USFWS, 2015)

***Dispersal/Migration*****Dispersal**

Adult: Low (USFWS, 1988)

**Dispersal/Migration Narrative**

Adult: Seeds are mainly dispersed by falling from dried capsules although some dispersal occurs by seeds being washed downhill by rainwater runoff. (USFWS, 1988)

***Population Information and Trends*****Population Trends:**

Increasing (USFWS, 2015). Unknown. Inferred from information (USFWS, 2020)

**Species Trends:**

Increasing (USFWS, 2015). Unknown. Inferred from information (USFWS, 2020)

**Population Growth Rate:**

Increasing, but annually variable (USFWS, 2015)

**Number of Populations:**

76 (USFWS, 2015)

**Population Size:**

10,000 to &gt;1,000,000 individuals (NatureServe, 2015)

**Adaptability:**

Somewhat compatible with residential development and grazing. (NatureServe, 2015)

**Population Narrative:**

When listed, the Missouri bladderpod was not yet known from Arkansas and there were only 11 known populations in Missouri (USFWS, 2003). As of 2015, the species is known from 66 sites in four counties in Missouri and 10 sites in five counties in Arkansas (USFWS, 2003); Rhonda Rimer, pers. comm. Mar.10, 2014, Jan. 14, 2015; Cindy Osborne, pers. comm., Aug. 13, 2014). While the total number of populations now far exceeds the number when listed, an assessment as to whether or not they are self-sustaining is problematic because populations of *Physaria filiformis* can vary widely from year to year depending on different climatic and edaphic factors and in response to various management practices. For example, Young (2013) monitored populations of *Physaria filiformis* over a 25-year period on the largest bladderpod site on the Wilson Creek National Battlefield in Missouri and demonstrated that plants fluctuated from a few thousand in 1990, to 261,000+ in 1991, to a few thousand in 1992, to zero in 1993 and 1994, and then rebounded to highs of between 30,000+ and 137,000+ in 1995, and between 42,000+ and 114,000+ in 2011. Similar results have been noted in other areas (USFWS, 2003). While some of the currently known bladderpod sites exceed one-half acre in size, many are much smaller and the distributions of some populations are limited due to the availability of suitable glade habitat. (USFWS, 2015). While populations on managed glades are stable or increasing, data suggest that populations that receive no management are declining. During 2015 and 2016 surveys, Edwards et al. (2019, p. 18) found that *P. filiformis* was absent or only represented by a single individual in 11 of 25 populations surveyed, and many of these populations showed further decline in 2017. A review of 19 glades surveyed by MDC between 2006 and 2019 demonstrated that seven glades (37%) have stable populations, four have declining populations (21%), and eight are presumed extirpated (42%) (Rhonda Rimer, MDC, Nov. 12, 2019, Dec. 18, 2019, pers. comm.). More than half of Missouri sites have not been surveyed since 2005 and their status is unknown (USFWS, 2020). We received survey data and monitoring reports from MDC and ANHC with updated information regarding the species' status and current threats in the time since we conducted the last 5-year review. Three new sites have been documented since the last review. Results of these efforts indicate that managed populations in Missouri and Arkansas are stable and that unmanaged populations may be declining rapidly. No new threats have been documented since the last 5-year review. As described above, the recovery criteria outlined in the recovery plan has not been met. Eleven of 30 self-sustaining populations occur on public land; however, four of these occur in the Ouachita Mountains and may be reclassified as a different species in the future. Fourteen populations either occur on protected land or privately owned land but are being managed by a conservation agency. The exclusion of populations in the Ouachita Mountains would reduce the number of protected populations range-wide from 14 to 10. (USFWS, 2020)

**Threats and Stressors**

**Stressor:** Human disturbance and collection (USFWS, 1987)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The low number of individual plants make the species vulnerable to collecting and other human disturbance. Two of the populations are within the Wilson's Creek National Battlefield, where a system of interpretive trails extends through the sites. These populations receive some disturbance from the more than 124,000 annual visitors to the Battlefield site, but Morgan (1983) concluded that disturbance may help maintain the *Lesquerella filiformis* populations. In addition, wildflower collectors may reduce populations in more accessible sites. As Steyermark (1963) pointed out, this plant with handsome yellow flowers makes a desirable addition to rock gardens and may be vulnerable to overcollecting. (USFWS, 1987)

**Stressor:** Lack of management research (USFWS, 1987)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Research is needed to determine proper management techniques for maintenance of the species, especially at disturbed sites. (USFWS, 1987) Consistent glade management maintains suitable habitat for *P. filiformis* and is considered vital to the survival and recovery of populations in Arkansas and Missouri. Removal of Eastern red cedar (*Juniperus virginiana*), prescribed fire, and control of exotic species allow for the persistence and expansion of populations. Many privately owned glades in Missouri are not being managed to promote the persistence of this plant species, and surveys indicate generally low numbers of *P. filiformis*. With a few exceptions, glades on private lands are over-shaded by encroaching Eastern red cedar, intensively grazed, densely covered by grasses and forbs, and not managed with fire (Christine Edwards, MOBOT, Nov. 12, 2019, pers. comm.). Although restoration efforts increase abundance of *P. filiformis*, implementation of those efforts on privately-owned glades is challenging (Rhonda Rimer, MDC, November 12, 2019, pers. comm.). Similar to Missouri, glade habitat in Arkansas has become degraded at several locations due to lack of management. (USFWS, 2020)

**Stressor:** Right-of-way maintenance (USFWS, 1987)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Three populations of *Lesquerella filiformis* occur in Dade County within Missouri highway rights-of-way. Two of these populations extend onto private land. Because of yearly right-of-way treatments, there is a threat of destruction to these populations. Cooperation with the State Department of Highways and Transportation is necessary in order to provide these sites additional protection from accidental mowing or chemical treatment. (USFWS, 1987)

**Stressor:** Seed destruction (USFWS, 1987)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Seed predation by insects and fungal infection of developing capsules have been reported by Morgan (1983). It is not known whether the ensuing loss of reproductive capacity constitutes a significant threat to the species. (USFWS, 1987)

**Stressor:** Competition from native and exotic plants (USFWS, 2003; 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Shortly after listing, the Service (1988) documented the presence of exotic plant species, such as *Bromus tectorum* (a cheat grass), in bladderpod habitat as a significant threat, and this was further supported by observations by Hickey (1988, 2000) and Thomas (1996, 1998). (USFWS, 2003) Witsell (2008) and Eulinger and Skinner (2007) noted that encroachment by Eastern red cedar onto glades causes habitat degradation and this threat will need to be continually monitored. (USFWS, 2015)

**Stressor:** Development (USFWS, 2003)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Hickey (1988, 2000) and Thomas (1996) identified development, especially land-use changes resulting from urban expansion, as a major threat to the species. (USFWS, 2003)

**Stressor:** Climate change (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Climate change may lead to increased frequency and duration of droughts (Rind et al., 1990; Seager et al., 2007; Rahel and Olden, 2008). Climate warming may increase the virulence of nonnative parasites and increased drought conditions may favor the establishment and spread of nonnative species (Rahel and Olden 2008). Extended droughts and an increase in soil and air temperatures could negatively impact seed set, germination, and overall fitness of *Physaria filiformis*. (USFWS, 2015)

## **Recovery**

### **Reclassification Criteria:**

The bladderpod has already been reclassified from endangered to threatened based on discovery of new populations and reduced threats to large existing populations. (USFWS, 2003)

### **Delisting Criteria:**

The Missouri bladderpod may be considered for delisting when there are thirty scattered, self-sustaining populations of *Lesquerella filiformis* that are maintained and protected. Fifteen of the thirty populations must be in secure ownership, occupy a minimum of one-half acre of habitat each, and show self-sustaining populations for at least seven years. (USFWS, 1988)

### **Recovery Actions:**

- Existing populations need to be protected and managed. (USFWS, 1988)
- Suitable habitat needs to be surveyed for new populations. (USFWS, 1988)
- Populations need continuing monitoring; autecological and management research is needed on the species. (USFWS, 1988)

- Management programs need to be developed and then initiated on protected sites. (USFWS, 1988)
- New populations need to be established on public land. (USFWS, 1988)
- Programs need to be developed to enhance public awareness and support for conservation of the species. (USFWS, 1988)
- The establishment of measurable recovery criteria that address threats to the species should be developed and implemented before possible delisting is recommended. (USFWS, 2015)
- A revision of the 1998 Missouri Bladderpod Recovery Plan is needed to develop measurable delisting criteria that reflect remaining threats to the species and to incorporate new information that has been obtained in the last 26 years. Development of such a plan should be done in cooperation with the appropriate experts and stakeholders in Missouri and Arkansas. (USFWS, 2015)
- Missouri bladderpod numbers and the results of ongoing conservation efforts need to be regularly monitored to assess recovery and ongoing management efforts. It may be appropriate to identify priority populations in Missouri and Arkansas for monitoring. Monitoring efforts should include populations that occur on the three different substrate types. (USFWS, 2015)
- Studies need to be initiated on the potential impacts of climate change on the Missouri bladderpod and its habitat. The species could be impacted from droughts and accompanying problems associated with climate change; further research is warranted. (USFWS, 2015)
- *Physaria filiformis* would benefit from additional genetic studies that evaluate genetic diversity across the range of the species, especially given the now known large geographic gaps between populations in southwest Missouri and scattered populations in Arkansas and the occurrence on three different soil substrates. (USFWS, 2015)
- Outreach efforts need to be made to private landowners in Missouri and Arkansas regarding best management practices that will maintain, and where necessary restore bladderpod habitat. (USFWS, 2015)
- Ongoing survey efforts should continue to search for new populations, especially in Arkansas. (USFWS, 2015)
- Viable sites should be protected and properly managed in all the outlying clusters within the species' range. (USFWS, 2015)

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS:** The Service provides the following recommendations:
  1. Revise the recovery plan to include measurable delisting criteria that appropriately reflect remaining threats to the species and new information that has been obtained in the last 31 years. The plan should define "self-sustaining" and identify how often populations should be monitored within a 7-year period to meet that definition. Development of such a plan should be done in cooperation with the appropriate experts and conservation partners in Missouri and Arkansas.
  2. Monitor populations and use results to assess efficacy to further recovery efforts. Recovery criteria cannot be met unless  $\geq 30$  populations are monitored.
  3. Assess the status of populations in Missouri that have not been surveyed since 2010. Examine what proportion of unmanaged, extant populations in Missouri are threatened by overgrazing, encroaching Eastern red cedar and invasive grass and forb species, as well as changing land use practices that may result in extirpation of populations.
  4. Implement a simple, standardized survey to count or estimate the number of plants present in Missouri and Arkansas populations.
  5. Conduct outreach efforts with private landowners

in Missouri and Arkansas regarding best management practices to maintain, and where necessary, restore habitat for Missouri bladderpod. 6. Collect data to evaluate whether or not application of herbicide spraying to populations along rights of way and roadways in Arkansas negatively affect *P. filiformis*. 7. Implement management practices such as prescribed burning and removing Eastern red cedar and non-native plant species within glades. Develop and implement additional management plans in Missouri and Arkansas to maintain habitat on private and public lands to further recovery efforts for this plant species. 8. Protect and manage more of the populations that occur on privately owned land through an appropriate combination of financial incentives, acquisition, easements, and logistical support. 9. Continue to protect and manage at least one population within each distinct genetic group and two populations from the genetically distinct group that occur in Sharp and Izard Counties, Arkansas. 10. Conduct a morphological study to determine if populations located in the Ouachita Mountain in Arkansas are a different species. (USFWS, 2020)

## SPECIES ACCOUNT: *Physaria globosa* (Short's bladderpod)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 8/1/2014

### **Physical Description**

An erect, short-lived perennial (or biennial) herb with slender, leafy stems that spread from the base and are 3-5 dm tall, giving vigorous plants a bushy appearance. Leaves are densely hairy, grayish-green. Flowers are bright yellow to yellow-orange, cross-shaped, borne in elongated clusters of up to 50 flowers. Fruits are globe-shaped (NatureServe, 2015).

### **Taxonomy**

A member of the mustard family (Brassicaceae), Short's bladderpod was first described as *Vesicaria globosa* by Desvaux (1814, p. 184). Because of several distinctive characters, Watson (1888, pp. 249-250) proposed that the American species of the genus *Vesicaria* be placed in the genus *Lesquerella*. This treatment was recognized as valid, until Al-Shehbaz and O'Kane (2002, entire) united most of the genus *Lesquerella* with the genus *Physaria*. Within the genus *Physaria*, and earlier treatments of *Lesquerella*, *P. globosa* has long been recognized as a geographically and evolutionarily distinct taxon (USFWS, 2017a).

### **Current Range**

The species has a disjunct distribution, with populations known from Posey County, Indiana; Bourbon, Clark, Fayette, Franklin, Jessamine, Madison, Mercer, Nelson, Powell, Scott and Woodford Counties, Kentucky; and Cheatham, Davidson, Dickson, Jackson, Maury, Montgomery, Smith, Trousdale, and Williamson Counties, Tennessee (USFWS, 2017a).

### **Critical Habitat Designated**

Yes; 8/26/2014.

### **Legal Description**

On August 26, 2014, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Physaria globosa* (Short's bladderpod) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 20 critical habitat units (CHUs), in Indiana, Kentucky and Tennessee (79 FR 50990-51039).

### **Critical Habitat Designation**

The critical habitat designation for *Physaria globosa* includes 20 CHUs in Posey County, Indiana; Clark, Franklin, and Woodford Counties, Kentucky; and Cheatham, Davidson, Dickson, Jackson, Montgomery, Smith, and Trousdale Counties, Tennessee. This species critical habitat encompasses approximately 925.5 acres (ac) (373 hectares (ha)) (79 FR 50990-51039).

Unit 1: Kings and Queens Bluff: Unit 1 consists of 7.6 ha (18.9 ac) of private land, but the U.S. Army Corps of Engineers (Corps of Engineers) holds flood easements on approximately 40 percent of this land. This unit is located in Montgomery County, Tennessee, on a bluff on the right descending bank of the Cumberland River within the city limits of Clarksville, approximately 0.16 km (0.10 mi) south of the intersection of State Route 12 (Ashland City Road) and Queens Bluff Way. Beginning approximately 0.28 km (0.18 mi) south of the easternmost intersection of

Ashland City Road (U.S.–41a Bypass) and Queens Bluff Road, this unit parallels the Cumberland River in a downstream direction for approximately 1.7 km (1.1 mi). The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; and shading and competition due to encroachment of native and invasive, nonnative plants.

Unit 2: Lock B Road: Unit 2 consists of 10.1 ha (25.0 ac) of privately owned land, but the Corps of Engineers holds flood easements on approximately 3 percent of this land. This unit is located in Montgomery County, Tennessee, approximately 6.9 km (4.3 mi) south of the city limits of Clarksville, on a hillside that lies to the east and west of Lock B Road North, beginning approximately 0.8 km (0.5 mi) south of its junction with Gholson Road and continuing south for approximately 0.4 km (0.25 mi), at which point Lock B Road North veers to the southwest. From this point, this unit continues south for approximately 1.0 km (0.6 mi) along the hillside that is east of Lock B Road North. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to potential right-of-way construction or maintenance using herbicides or mechanized equipment along Lock B Road North or the Illinois Central Railroad, both of which traverse portions of the unit, and shading or competition due to encroachment of native and invasive, nonnative plants.

Unit 3: Jarrel Ridge Road: Unit 3 consists of 5.2 ha (12.8 ac) of privately owned lands, but the Corps of Engineers holds flood easements on approximately 8 percent of this land. This unit is located in Montgomery County, Tennessee, approximately 10 km south of the city limit of Clarksville, on a hillside that lies west and north of the southern terminus of Jarrel Ridge Road. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; potential right-of-way construction or maintenance using herbicides or mechanized equipment along Jarrel Ridge Road at the unit boundary or the Illinois Central Railroad, which traverses the unit; and shading or competition due to encroachment of native and invasive, nonnative plants.

Unit 4: Cheatham Lake: Unit 4 consists of 27.3 ha (67.5 ac) of privately owned, local government, and Federal lands. This unit is located in Cheatham County, Tennessee, approximately 9.0 km (5.6 mi) westnorthwest of the city limits of the town of Ashland City, on a series of hillsides that begins approximately 0.8 km (0.5 mi) northeast of the junction of Beech Grove Road and Cheatham Dam Road and arcs in a southeasterly direction for approximately 2.2 km (1.4 mi). Here, the unit crosses Cheatham Dam Road, and continues for approximately 2.2 km in a southeasterly arc to its eastern boundary on the right descending bank of the Cumberland River, approximately 0.18 km (0.11 mi) south of Kimbrough Road. The land within this unit is approximately 70 percent privately owned, 12 percent owned by Ashland City, and 18 percent owned by the Corps of Engineers. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; potential right-of-way construction or maintenance using herbicides or

mechanized equipment along the Illinois Central Railroad, which traverses the unit; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 5: Harpeth River:** Unit 5 consists of 25.5 ha (63.1 ac) of privately owned and federal land in Cheatham County, Tennessee. This unit is located approximately 5 km (3.1 mi) west of the city limits of the town of Ashland City, on the west slope of a hillside and associated bluffs that begin on the point of land formed by the confluence of Cumberland and Harpeth rivers and extend upstream along the right descending bank of the Harpeth River, reaching the unit's southernmost boundary approximately 0.6 km (0.4 mi) east of SR-49, where it crosses the Harpeth River. The land within this unit is approximately 32 percent privately owned, and 68 percent is owned by the Corps of Engineers. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 6: Montgomery Bell Bridge:** Unit 6 consists of 11.2 ha (27.7 ac) of privately owned and federal land in Cheatham and Dickson Counties, Tennessee. This unit is located approximately 5.5 km (3.4 mi) west of the city limits of the town of Ashland City, on a hillside and bluffs on the left descending bank of the Harpeth River that begin approximately 0.4 km (0.27 mi) east of the Montgomery Bell Bridge, where SR-49 crosses the river and bisects the unit, and parallels the river in an upstream direction for approximately 1.8 km (1.1 mi). The land within this unit is approximately 19 percent privately owned, and 81 percent is owned by the Corps of Engineers. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 7: Nashville and Western Railroad:** Unit 7 consists of 30.5 ha (75.3 ac) of privately owned, local government, and Federal land in Cheatham County, Tennessee. This unit is located along the southwest city limit of the town of Ashland City, on hillsides and bluffs that begin approximately 0.26 km (0.16 mi) east of the confluence of Marrowbone Creek and the Cumberland River and extend upstream on the right descending bank of the Cumberland River for approximately 2.3 km (1.4 mi). Here, the unit continues in a southeasterly direction for approximately 0.9 km (0.5 mi) from the point where the river veers away from the hillside and bluffs. The land within this unit is approximately 68 percent privately owned, 27 percent owned by the Cheatham County Rail Association, and 5 percent owned by the Corps of Engineers. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; potential right-of-way construction or maintenance using herbicides or mechanized equipment along the Nashville and Western Railroad, which traverses the unit; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 8: River Trace:** Unit 8 consists of 42.8 ha (105.7 ac) of privately owned land, with the exception of the River Trace road right-of-way. The Corps of Engineers holds flood easements on approximately 13 percent of the lands within the unit. This unit is located in Davidson and Cheatham Counties, Tennessee, on hillsides and bluffs approximately 0.9 km (0.6 mi) southeast of the city limit of the town of Ashland City, beginning at the western extent of River Trace and extending along both sides of this road in a southeasterly direction for a distance of approximately 2.3 km (1.4 mi). Here, the unit leaves River Trace and continues along the hillside and bluffs on the right descending bank of the Cumberland River in an upstream direction for approximately 2.1 km (1.3 mi). The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; potential right-of-way construction or maintenance using herbicides or mechanized equipment along River Trace or the Nashville and Western Railroad, both of which traverse the unit; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 9: Old Hickory Lake:** Unit 9 consists of 4.8 ha (11.9 ac) of privately owned and Federal lands in Trousdale County, Tennessee. This unit is located approximately 3.5 km (2.2 mi) west of the southern city limits of the town of Hartsville and 0.5 km (0.3 mi) south of Oldham Road, on a hillside and bluffs on the right descending bank of the Cumberland River. Beginning approximately 0.4 km (0.25 mi) downstream of the mouth of Second Creek, this unit parallels the Cumberland River in a downstream direction for approximately 0.7 km (0.4 mi). The land within this unit is approximately 40 percent privately owned, and 60 percent is owned by the Corps of Engineers. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 10: Coleman-Winston Bridge:** Unit 10 consists of 7.4 ha (18.2 ac) of privately owned and Federal lands in Trousdale County, Tennessee. The unit is located at the southern city limit of the town of Hartsville, on a hillside and bluffs overlooking the Cumberland River. Beginning on the right descending bank approximately 0.5 km (0.3 mi) east of SR-141, which bisects the unit where it crosses the Cumberland River at the Coleman-Winston Bridge, this unit parallels the river in a downstream direction for approximately 1.1 km (0.7 mi). The land within this unit is approximately 55 percent privately owned, and 45 percent is owned by the Corps of Engineers. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; potential right-of-way construction or maintenance using herbicides or mechanized equipment along SR-141, which bisects the unit; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 11: Cordell Hull Reservoir:** Unit 11 consists of 12.3 ha (34.2 ac) of Federal lands in Smith County, Tennessee. This unit is located approximately 4.3 km (2.7 mi) north of the city limits of

the town of Carthage, on hillsides and bluffs on the right descending bank of the Cumberland River. Beginning approximately 2.0 km (1.25 mi) upstream of the Cordell Hull Dam, this unit parallels the river in an upstream direction for approximately 0.6 km (0.4 mi), where it crosses a 0.3-km (0.2-mi) expanse of open water, and then continues paralleling the river for a distance of 1.2 km (0.7 mi). All of the land within this unit is owned by the Corps of Engineers, and the open water is not included in the area of the unit reported above. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; and shading or competition due to encroachment of native and invasive, nonnative plants.

Unit 12: Funns Branch: Unit 12 consists of 20.8 ha (51.3 ac) of Federal lands in Jackson County, Tennessee. This unit is located approximately 12.1 km (7.5 mi) southwest of the city limits of the town of Gainesboro, on hillsides and bluffs on the right descending bank of the Cumberland River. Beginning approximately 0.4 km (0.2) mi upstream of the mouth of Funns Branch, this unit parallels the river in an upstream direction for approximately 1.0 km (0.65 mi) where it crosses a 0.3-km (0.2-mi) expanse of open water, and then continues paralleling the river for a distance of approximately 1.0 km (0.64 mi). All of the land within this unit is owned by the Corps of Engineers, and the open water is not included in the area of the unit reported above. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; and shading or competition due to encroachment of native and invasive, nonnative plants.

Unit 13: Wartrace Creek: Unit 13 consists of 37.5 ha (92.6 ac) of Federal lands in Jackson County, Tennessee. This unit is located approximately 7.7 km (4.8 mi) west of the city limits of the town of Gainesboro, on hillsides and bluffs on the right descending bank of the Cumberland River. Beginning at the mouth of Indian Creek, this unit parallels the river in a downstream direction for approximately 1.6 km (1.0 mi), where it crosses the mouth of Wartrace Creek, and then continues paralleling the river for a distance of 2.5 km (1.5 mi). All of the land within this unit is owned by the Corps of Engineers, and areas of open water are not included in the area of the unit reported above. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; and shading or competition due to encroachment of native and invasive, nonnative plants.

Unit 14: Camp Pleasant Branch: Unit 14 consists of 17.4 ha (42.9 ac) of privately owned lands in Franklin County, Kentucky. This unit is located approximately 8.3 km (5.8 mi) north of the city limits of Frankfort, on hillsides near Camp Pleasant Branch, a tributary to Elkhorn Creek. Beginning approximately 0.29 km (0.18 mi) west of the intersection of Indian Gap Road and Camp Pleasant Road, the unit begins in a hollow north of Indian Gap Road and extends to the east and north along hillsides above the right descending bank of Camp Pleasant Branch for approximately 0.75 km (0.5 mi) to the intersection of Camp Pleasant Road and Gregory Woods Road. Here the unit crosses Gregory Woods Road and extends north for a distance of

approximately 0.58 km (0.36 mi), encompassing the hillside to the east of the road. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; potential right-of-way construction or maintenance using herbicides or mechanized equipment along Indian Gap Road, Camp Pleasant Road, or Gregory Woods Road, which are adjacent to the unit; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 15: Kentucky River:** This unit consists of 93.1 ha (230.0 ac) of privately owned and State land in Franklin County, Kentucky. This unit begins within the northwestern city limit of Frankfort, on a hillside that parallels U.S.–421 on its east side from approximately 0.21 km (0.13 mi) southeast of its junction with Clifty Drive to approximately 0.23 km (0.15 mi) northwest of its junction with U.S.–127. Here the unit follows the topography of the hillside as it turns away from the road to the east, leaving the city limits, and then arcs to the northeast, before abruptly turning back in a westerly direction. From this point, the hillside and this unit extend in a westerly direction for approximately 0.7 km (0.4 mi) and then parallel the Kentucky River in a downstream direction in an arc approximately 5.3 km (3.3 mi) in length on its left descending bank, encompassing hillsides in two hollows that extend from the river to the west. Approximately 90 percent of the land in this unit is privately owned, and the Commonwealth of Kentucky owns approximately 10 percent, which is part of a State nature preserve. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to erosion or prolonged inundation due to water level manipulation; changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; potential right-of-way construction or maintenance using herbicides or mechanized equipment along U.S.–421, where it parallels the unit; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 16: Owenton Road:** Unit 16 consists of 2.8 ha (7.0 acres) of privately owned and City of Frankfort municipal park lands in Franklin County, Kentucky. The unit is located approximately 0.1 km (0.08 mi) north of the city limits of Frankfort on a hill that is adjacent to and west of U.S.–127 (Owenton Road), approximately 0.6 km (0.4 mi) north of the intersection of U.S.–127 and U.S.–421. The land within this unit is approximately 46 percent privately owned, and 54 percent is owned by the City of Frankfort. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; potential right-of-way construction or maintenance using herbicides or mechanized equipment on U.S.–127; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 17: Little Benson Creek:** Unit 17 consists of 9.4 ha (23.3 ac) of privately owned lands in Franklin County, Kentucky, located within the city limits of Frankfort. Beginning approximately 1.1 km (0.7 mi) south of the intersection of Mills Lane and Ninevah Road, this unit lies on a hillside on the east side of Ninevah Road and extends to the south for approximately 0.5 km (0.3 mi), where it crosses Ninevah Road and follows a hillside that parallels Ninevah Road for approximately 1.0 km (0.65 mi) on its west side. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to changes in land use, including residential or commercial construction, which

could cause removal of forest vegetation or soils or soil loss due to erosion; potential right-of-way construction or maintenance using herbicides or mechanized equipment on Ninevah Road; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 18: Boone Creek:** Unit 18 consists of 5.0 ha (12.4 ac) of privately owned lands in Clark County, Kentucky. This unit is located approximately 13.2 km (8.2 mi) southwest of the city limits of Winchester, and begins adjacent to Grimes Mill Road approximately 0.17 km north of the Fayette and Clark County line. From here, the unit extends on a hillside to the east for a distance of approximately 0.21 km (0.13 mi), where the unit and hillside then parallel a bend in Boone Creek on its left descending bank for a distance of approximately 0.68 km (0.42 mi). The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats related to changes in land use, including residential or commercial construction, which could cause removal of forest vegetation or soils or soil loss due to erosion; potential right-of-way construction or maintenance using herbicides or mechanized equipment on Grimes Road; and shading or competition due to encroachment of native and invasive, nonnative plants.

**Unit 19: Delaney Ferry Road:** Unit 19 consists of 0.6 ha (1.4 ac) of privately owned lands in Woodford County, Kentucky. This unit is located approximately 7.8 km (4.8 mi) south of the city of Versailles. Beginning approximately 2.1 km (1.3 mi) east of the intersection of Troy Pike and Delaney Ferry Road, this unit extends approximately 0.08 km (0.05 mi) northeast along Delaney Ferry Road, where the unit boundary turns to the northwest for approximately 0.08 km (0.05 mi). From this northeast corner of the unit, the boundary extends to the southwest approximately 0.05 km (0.03 mi), where it turns to the southeast, paralleling a driveway for 0.05 km (0.03 mi) before turning to the southwest for approximately 0.03 km (0.02 mi). From this point the unit boundary turns to the southeast for approximately 0.05 km (0.03 mi), returning to the starting point. The features essential to the conservation of the species in this unit may require special management considerations or protection to address threats of shading or competition due to encroachment of native and invasive, nonnative plants. The current landowner manages encroaching vegetation to prevent shading and competition where Short's bladderpod occurs within the unit.

**Unit 20: Bonebank Road:** Unit 20 consists of 1.7 ha (4.3 ac) of lands in Posey County, Indiana, which are owned by the Indiana Department of Natural Resources. This unit is located approximately 13 km (8.1 mi) southwest of the city limits of Mt. Vernon, beginning at the intersection of Graddy Road and Bonebank Road and paralleling Bonebank Road on its west side for a distance 0.73 km (0.45 mi) north of the intersection. The surface geology at this site—Quaternary glacial outwash—and soils are markedly different from other sites on calcareous geology throughout the rest of the species' range. However, this site supports an occurrence that has numbered in the hundreds to more than a thousand individuals in the past, and the PCE of forest vegetation with canopy openings (PCE 3) is present at the road edge. The feature essential to the conservation of the species in this unit may require special management considerations or protection to address threats of shading or competition due to encroachment of native and invasive, nonnative plants.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Physaria globosa* critical habitat consists of four

components (79 FR 50990-51039):

(i) Bedrock formations and outcrops of calcareous limestone, sometimes with interbedded shale or siltstone, in close proximity to the mainstem or tributaries of the Kentucky and Cumberland rivers. These outcrop sites or areas of suitable bedrock geology should be located on steeply sloped hillsides or bluffs, typically on south- to west-facing aspects.

(ii) Shallow or rocky, well-drained soils formed from the weathering of underlying calcareous bedrock formations, which are undisturbed or subjected to minimal disturbance, so as to retain habitat for ground-nesting pollinators and potential for maintenance of a soil seed bank.

(iii) Forest communities with low levels of canopy closure or openings in the canopy to provide adequate sunlight for individual and population growth. Invasive, nonnative plants must be absent or present in sufficiently low numbers not to inhibit growth or reproduction of Short's bladderpod.

### **Special Management Considerations or Protections**

The features essential to the conservation of Short's bladderpod may require special management considerations or protection to reduce the following threats: (1) Actions that would directly result in removal of soils or indirectly cause their loss due to increased rates of erosion; (2) building, paving, or grazing of livestock within or upslope of Short's bladderpod sites that alters water movement or causes soil erosion that results in sediment deposition in suitable habitat; (3) blasting or removal of hard rock and soil substrates; (4) dumping of trash and debris; (5) prolonged inundation of sites due to manipulation of regulated waters for flood control or other purposes; (6) indiscriminate maintenance of transportation rights-of-way, including grading, mowing, or herbicide application; and (8) shading and competition due to forest canopy closure and encroachment of invasive, nonnative plants. Management activities that could ameliorate these threats include, but are not limited to: (1) Avoiding areas located in or upslope of Short's bladderpod sites when planning for location of commercial or residential development; maintenance, construction, or expansion of utility and transportation infrastructure; and access for livestock; (2) removing trash and debris that are dumped onto or upslope of Short's bladderpod sites; (3) locating suitable habitat, determining presence or absence of Short's bladderpod, and protecting or restoring as many sites or complexes of sites as possible; (4) evaluating the effects of flow regulation on Short's bladderpod occurrences within the fluctuation zone of regulated river reaches and adjusting management to avoid or minimize prolonged periods of inundation; (5) reaching out to all landowners, including private, State, and Federal landowners, to raise awareness of the plant and its habitat; (5) providing technical or financial assistance to landowners to help in the design and implementation of management actions that protect the plant and its habitat; (6) managing, including reducing, canopy cover and competition from native and invasive, nonnative plants to maintain an intact native forest community with canopy openings or low levels of canopy closure.

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Self-compatibility and self-incompatibility (USFWS, 2017a).

**Breeding Season**

Adult: Typically flowers and produces seed during the months of March through June. Timing of seed germination is not currently known, but it is possible that seeds could germinate in the fall and form rosettes over winter, germinate in spring when conditions become favorable, or exhibit either phenology depending upon the dormancy status of individual seeds and variation in seasonal climatic conditions (USFWS, 2017a).

**Key Resources Needed for Breeding**

Adult: Pollinators are likely native ground nesting bees and flies (USFWS, 2017a).

**Reproduction Narrative**

Adult: This species likely is self-incompatible, and nearly 50 percent of extant occurrences are threatened with adverse effects associated with small populations including loss of genetic variation, inbreeding depression, and reduced availability of compatible mates. Short's bladderpod is a biennial or perennial that typically flowers and produces seed during the months of March through June. Based on observations of an apparent biennial life history in at least some populations, the generation length is considered to be two years – i.e., the time between seed germination and next generation recruitment into the population would be a minimum of two years. Timing of seed germination is not currently known, but it is possible that seeds could germinate in the fall and form rosettes over winter, germinate in spring when conditions become favorable, or exhibit either phenology depending upon the dormancy status of individual seeds and variation in seasonal climatic conditions. Fitness of Short's bladderpod individuals is dependent on appropriate temperature, soil moisture and nutrients, and light regimes for seed germination; growth of seedling, juveniles, and adults; and reproduction. Availability of mate-compatible genotypes and abundance of pollinators are critical factors for production of viable seed (USFWS, 2017a). For this reason, it is essential that habitat for pollinators be conserved in close proximity to known occurrences to increase the likelihood of pollen exchange among compatible mates. Where possible, habitat patches should be protected that would reduce fragmentation between multiple occurrences among which pollinator dispersal could facilitate gene flow. Two species of dipterans (flies; *Nemotelus bruesii*, *Toxomerus geminatus*) and four species of hymenopterans (bees; *Lasioglossum illinoense*, *L. versatus*, *Halictus ligatus*, *Augochlorella striata*), from the family Halictidae, were determined to be effective pollinators for Short's bladderpod. Available data indicate that four species of hymenoptera (Pickering 2009) and *T. geminatus* (Hilty 2015) are generalist foragers. Sites where the species occurs should not be subjected to activities that would remove the soil seed bank. Moderate soil disturbance, however, could promote germination from the seed bank in locations where overstory shading and competition from herbaceous and shrub species have caused population declines (USFWS, 2014, USFWS, 2017a). The majority of floral foragers observed visiting *Physaria filiformis* (Missouri bladderpod) were true bees representing five families, with greater than 50 percent from the family Halictidae. The families Apidae and Andrenidae also were common among bee pollinators of this species, the most dependable and frequent of which were ground-nesters. (USFWS, 2020a). Seed-dispersal of Short's bladderpod has not been studied, though Shea (1993, p. 21) suggested that the seeds might be dispersed by gravity and wind. The small seeds (1.0-1.8 millimeter (mm)) (~0.4 in) of Short's bladderpod (Rollins and Shaw 1973, p. 167) exhibit no morphological adaptations to facilitate widespread dispersal by wind or any other means, thus wind dispersal would only act to disperse the seeds very short distances (~1-2 m (~3.6-7.2 ft)) from the maternal plant. Limited dispersal distance

has been demonstrated for other *Physaria* species, such as *P. ludoviciana*, for which Grant et al. (2012, p. 68) found highly significant reductions in the abundance of seeds in the seedbank 1-2 m (3.6-7.2 ft) from the mother plant relative to abundance directly adjacent to the mother plant. Cabin et al. (2000, p. 296) and Elberling (2000, p. 89) observed similarly short dispersal distances for *P. fendleri* and *P. arctica*, respectively. Although individual seeds are likely only dispersed very short distances by wind, longer distance dispersal could potentially occur if an entire fruiting raceme or branch of a plant were to break off and be transported by wind before seed pods dehisced (Thacker, pers. comm., May 2015). This hypothetical tumble-weed-like means of wind dispersal may occur infrequently, if at all, but could disperse seeds upslope on rising air currents, acting to periodically counter downslope dispersal of seeds by gravity and surface flow. It also is possible that Short's bladderpod is associated with historical travel routes of ungulates, which could have provided an alternative mechanism for dispersal of seeds upslope and over longer distances via soil stuck to hooves (Littlefield, pers. comm, November 20, 2017). (USFWS, 2020a)

**Habitat Type**

Adult: Short's bladderpod typically grows on steep, rocky, wooded slopes and talus (sloping mass of rock fragments below a bluff or ledge) areas. It also occurs along tops, bases, and ledges of bluffs and infrequently on sites with little topographic relief. The species usually is found in these habitats on south- to southwest-facing steep heels or bluffs adjacent to the Cumberland River within the Highland Rim and Central Basin Sections of the Interior Low Plateaus Province. The most stable and vigorous occurrences are found in sites with relatively open overstory canopy (USFWS, 2017a).

**Habitat Vegetation or Surface Water Classification**

Adult: Populations can include vegetation associated with both xeric and mesic conditions (USFWS, 2017a).

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits dry, open limestone ledges on river bluffs, talus of lower bluff slopes, and shale at cliff bases. These are usually south- to west-facing rocky slopes, and the tops, ledges, or bases of steep cliffs, often along major waterways, such as the Cumberland River (Pyne et al. 1995). Also on thin, calcareous soils in cedar glades. The plants should be sought on dry limestone rocks or open rock ledges. The species has also colonized artificial surfaces, especially roadcuts, downhill from natural or semi-natural bluffs (NatureServe, 2015). Short's bladderpod populations are most robust in sites where light availability is high due to low levels of shading from midstory and overstory vegetation (USFWS, 2017a).

**Dispersal/Migration**

**Dispersal**

Adult: There is a lack of evident mechanisms for long-distance dispersal for Short's bladderpod but flowing water is needed for dispersal within watershed (USFWS, 2017a).

***Population Information and Trends*****Population Trends:**

Decreasing (USFWS, 2014)

**Resiliency:**

The historical and current distributions of Short's bladderpod are characterized primarily by populations of low resiliency, owing to small population sizes and presence of threats to the species, its habitat, or both. The vulnerability of small populations is borne out by the turnover in occurrences of the species between 1992 and present day, resulting in the loss of at least 8 occurrences during that time period. With regard to the species' overall resilience, these losses have been potentially offset by the discovery of additional, albeit small, populations in Tennessee since 1992 (USFWS, 2017a).

**Representation:**

We used trends in number of physiographic sections, states, and counties occupied by the species as measures of representation. The species representation has changed between 1992 and 2016 only with respect to the counties where it occurs. In both years, the species occurred in three states and four sections of physiographic provinces. The species representation has increased in terms of numbers of counties occupied, from 10 in 1992, to 13 in 2016; despite extirpation from two counties during that time span. In Kentucky, the species is no longer extant in Bourbon or Scott counties, but is now present in Madison and Woodford counties. In Tennessee, the species was discovered in Dickson and Jackson counties after 1992' (USFWS, 2017a).

**Redundancy:**

We evaluated redundancy of Short's bladderpod by examining trends in total number of occurrences and number of occurrences with  $\geq 100$  individuals per physiographic section, state, and county. The one Indiana occurrence, located in the Shawnee Hills section, has decreased in number from an estimated hundreds-to-thousands of plants in 1992 to 18 plants that were observed in 2017. As of 1992, there were 13 Short's bladderpod occurrences in Kentucky (and the Bluegrass section), with 10 of those occurrences in Franklin County alone. Only two occurrences consisting of at least 100 individuals were known from Kentucky, one each in Bourbon and Franklin counties. There are now 11 occurrences in Kentucky, with the greatest concentration still in Franklin County, albeit reduced from 10 to 7 occurrences. There are now three occurrences where recent data indicate that at least 100 individuals are present, all in Franklin. The Bourbon County occurrence, where 118 Short's bladderpod were present in 1992, and a smaller occurrence in Scott County have been extirpated. In Tennessee, there were eight occurrences located in the Highland Rim section and three in the Nashville Basin as of 1992. There was only one Tennessee County with more than three occurrences in 1992. Three occurrences in the Highland Rim section and one in the Nashville Basin consisted of at least 100 individuals. Today there are 14 occurrences located in the Highland Rim section and 5 in the Nashville Basin. Cheatham County still has the greatest number of occurrences, up to five from

the three that were known in 1992. There are four occurrences with at least 100 individuals in the Highland Rim section and one in the Nashville Basin' (USFWS, 2017a).

**Number of Populations:**

33 (USFWS, 2021)

**Population Size:**

1 - 1,000 individuals (USFWS, 2017a)

**Minimum Viable Population Size:**

Unknown (USFWS 2017a)

**Population Narrative:**

Population numbers of this seed-banking mustard vary substantially from year to year, with maintenance of seed-bank diversity dependent on significant reproduction in at least some years. Shading from overtopping trees or invasive shrubs can deplete populations as well. Many sites are on roadsides, where they are no longer within natural ecosystems (USFWS, 2004). Species has a disjunct distribution where historically it was known from 55 occurrences, and as of 2016 there were 10 extant occurrences in Kentucky, 20 in Tennessee, and 1 in Posey County, Indiana, for a total of 31 extant occurrences range-wide (INHDC 2017, KNHP 2017, TNHID 2016). One of these (Tennessee EO 22) was not found when last visited, in 2013, and flood damage was observed at the site, but it is considered extant until such time as it is declared extirpated in the TNHID. Extant occurrences in Kentucky are distributed among Clark (1), Franklin (7), Madison (1), and Woodford (1) Counties, and in Tennessee among Cheatham (5), Davidson (3), Dickson (1), Jackson (3), Montgomery (3), Smith (2), and Trousdale (2) Counties. One Tennessee occurrence straddles the county line between Cheatham and Davidson Counties. This is an increase of 5 occurrences as compared to the 26 extant occurrences reported in the proposed listing rule for the species (78 FR 47111-47113; August 2, 2013). The rediscovery of Kentucky EO 10 in 2013 also adds Madison County to the species' current range. Of these occurrences, only 8 have greater than 100 individuals (USFWS, 2017a). The remaining populations are in many cases small, isolated, and have limited potential for recolonization should they be extirpated (USFWS, 2017b). Short's bladderpod was listed as endangered in 2014, when there were 26 extant populations of the species known to exist. The most significant threats to the species at the time of listing were the present or threatened destruction, modification, or curtailment of its habitat and range (Listing Factor A) and the often adverse effects associated with small population size, including potential for reduced genetic variation, low numbers of compatible mates, increased likelihood of inbreeding depression, and reduced resilience to recover from acute demographic effects of other threats to the species and its habitat (Listing Factor E). While the number of known extant populations has increased to 33, as of 2020, habitat at 29 of these populations is adversely affected by one or more threats discussed above under Listing Factor A. Additionally, most populations are small in size, with many having declined in abundance since the species was listed. (USFWS, 2021)

**Threats and Stressors**

**Stressor:** Soil Loss (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The features essential to the conservation of Short's bladderpod may require special management considerations or protection to reduce the following threats: (1) Actions that would directly result in removal of soils or indirectly cause their loss due to increased rates of erosion (USFWS, 2014).

**Stressor:** Development/grazing (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** (2) Building, paving, or grazing of livestock within or upslope of Short's bladderpod sites that alters water movement or causes soil erosion that results in sediment deposition in suitable habitat (USFWS, 2014).

**Stressor:** hard rock mining (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** 3) Blasting or removal of hard rock and soil substrates (USFWS, 2014).

**Stressor:** Trash dumping (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Habitat degradation

**Narrative:** (4) Dumping of trash and debris (USFWS, 2014).

**Stressor:** Prolonged inundation (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/Loss of individual plants

**Narrative:** (5) Prolonged inundation of sites due to manipulation of regulated waters for flood control or other purposes (USFWS, 2014).

**Stressor:** Right-of way maintenance (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** (6) Indiscriminate maintenance of transportation rights-of-way, including grading, mowing, or herbicide application

**Stressor:** Invasive/non-native plants (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** (8) Shading and competition due to forest canopy closure and encroachment of invasive, nonnative plants (USFWS, 2014).

## ***Recovery***

**Delisting Criteria:**

Agreements have been reached with key stakeholders to conserve, restore, and manage habitat to provide ecological conditions, as described in the Species Status Assessment for Short's bladderpod (SSA), that promote growth of individuals and support resilient populations (USFWS, 2017b).

Monitoring demonstrates stable or increasing population growth rates or an average population size for at least 25 populations that is equal to or above the minimum viable size. Populations are protected by a conservation mechanism. A minimum of 6 of these populations must be located in the Kentucky River watershed and 15 populations in the Cumberland River watershed, in addition to the population in the Wabash River watershed, in order to ensure adequate regional representation and intra-regional redundancy of resilient populations (USFWS, 2017b).

In lieu of satisfying criteria 1 and 2, the species could be considered for delisting if 50 resilient occurrences (as described in the SSA) are distributed among the physiographic regions where the species occurs (USFWS, 2017b).

Estimated Cost to Delist: The cost to recover and ultimately delist Short's Bladderpod is estimated to be \$3,029,000. Some costs are not determinable at this time, and therefore the total cost of recovery may be higher than this estimate. Date of Delisting: If all actions are fully funded and implemented as outlined, including full cooperation of all partners needed to achieve recovery, we anticipate that recovery criteria for delisting could be met by 2063. (USFWS, 2020)

**Recovery Actions:**

- Work with the Corps to develop and implement a conservation strategy for Short's bladderpod on lands that the Corps owns or controls (USFWS, 2017b). Includes: develop and implement an adaptive management framework to manage populations on Corps managed lands and implement annual monitoring of populations on Corps managed lands (USFWS, 2017c). Estimated Cost. \$475,000. Priority 1. (USFWS, 2020)
- Develop and implement management agreements with departments of transportation, local highway departments, railroad authorities, and utility companies to ensure protection of populations near rights-of-way (USFWS, 2017b). Includes: determine which populations are potentially impacted by right-of-way maintenance, assess potential impacts of rights-of-way maintenance on specific Short's bladderpod occurrences, and work with right-of-way stakeholders to develop and implement management agreements (USFWS, 2017c). Estimated Cost. \$314,000. Priority 2. (USFWS, 2020)
- Work with state agencies and private landowners in Kentucky, Tennessee, and Indiana to obtain protection for populations on privately owned lands and to develop and implement adaptive management strategies for protected sites (USFWS, 2017b). Estimated Cost. \$900,000. Priority 2. (USFWS, 2020)
- Establish standardized methods for monitoring of populations and habitat conditions, and initiate regular stage-specific monitoring at occurrences range-wide (USFWS, 2017b). Includes: develop a standardized rangewide population monitoring protocol and initiate regular stage-specific monitoring at occurrences range-wide (USFWS, 2017c). Estimated Cost. \$475,000. Priority 1. (USFWS, 2020)

- Conduct research that enhances knowledge of Short's Bladderpod to facilitate the development of scientifically sound management plans and models for conducting population viability analyses (USFWS, 2017b). Includes: conduct research to identify ecological conditions needed for germination, establishment, and reproduction of Short's bladderpod; conduct research to examine life history, seed bank longevity, breeding system, pollination, and dispersal for Short's bladderpod; determine germination and propagation requirements of Short's bladderpod; determine genetic diversity within populations and the genetic structure and distance between range-wide populations; determine the tolerance of Short's bladderpod to prolonged drought and inundation; and incorporate results from monitoring and research projects into development of models for estimating minimum viable size and demographic structure of populations and for evaluating extinction risk under various management scenarios (USFWS, 2017c). Estimated Cost. \$550,000. Priority 1. (USFWS, 2020)
- Facilitate and support surveys to identify new populations (USFWS, 2017b). Includes: develop a geospatial database to determine priority areas for surveys and conduct surveys to identify additional populations of Short's bladderpod (USFWS, 2017c). Estimated Cost. \$360,000. Priority 1. (USFWS, 2020)
- Increase the representation and genetic diversity of ex situ collections of Short's bladderpod in seedbanks to ensure the breadth of species diversity is conserved (USFWS, 2017b). Estimated Cost. \$90,000. Priority 2. (USFWS, 2020)
- Augment protected populations that are unable to grow in response to habitat management due to low population size, or introduce populations into suitable, but unoccupied, managed habitat on conservation lands (USFWS, 2017b). Estimated Cost. \$30,000. Priority 2. (USFWS, 2020)
- Continue to coordinate with Federal, State, County and City agencies to promote plant recovery and find innovative ways to increase public awareness of the need to protect this species and its habitats (USFWS, 2017b). Includes: develop a Short's bladderpod working group (USFWS, 2017c). Estimated Cost. \$200,000. Priority 3. (USFWS, 2020)
- Management activities that could ameliorate these threats include, but are not limited to:
  - (1) Avoiding areas located in or upslope of Short's bladderpod sites when planning for location of commercial or residential development; maintenance, construction, or expansion of utility and transportation infrastructure; and access for livestock (USFWS, 2014). Estimated Cost. \$110,000. Priority 3. (USFWS, 2020)
  - (2) Removing trash and debris that are dumped onto or upslope of Short's bladderpod sites (USFWS, 2014).
  - (3) Locating suitable habitat, determining presence or absence of Short's bladderpod, and protecting or restoring as many sites or complexes of sites as possible (USFWS, 2014).
  - (4) Evaluating the effects of flow regulation on Short's bladderpod occurrences within the fluctuation zone of regulated river reaches and adjusting management to avoid or minimize prolonged periods of inundation (USFWS, 2014).
  - (5) Reaching out to all landowners, including private, State, and Federal landowners, to raise awareness of the plant and its habitat (USFWS, 2014).
  - (6) Providing technical or financial assistance to landowners to help in the design and implementation of management actions that protect the plant and its habitat (USFWS, 2014).
  - (7) Managing, including reducing, canopy cover and competition from native and invasive, nonnative plants to maintain an intact native forest community with canopy openings or low

levels of canopy closure (USFWS, 2014).

**Conservation Measures and Best Management Practices:**

- RECOMMENDATIONS FOR FUTURE ACTIONS 4.1 Publish final Recovery Plan and Recovery Implementation Strategy for Short's bladderpod. 4.2 Establish and hold regular meetings of a recovery working group for Short's bladderpod to disseminate information about recovery efforts and coordinate on planning and carrying out recovery actions for the species (Action 9 in Draft Recovery Plan). 4.3 In cooperation with state conservation agencies and others, engage right-of-way managers to develop cooperative agreements providing guidance and establishing commitments for managing habitats in and adjacent to transportation and utility rights-of-way to benefit Short's bladderpod (Action 2 in Draft Recovery Plan). 4.4 Coordinate with State conservation agencies and others to develop a standardized rangewide protocol for monitoring populations and habitat conditions and conduct monitoring at regular intervals (Action 4 in Draft Recovery Plan). 4.5 Work with the Corps to develop and implement a conservation strategy for Short's bladderpod on lands that the Corps owns or controls (Action 1 in Draft Recovery Plan). In addition, encourage the Corps to inform landowners of the presence of Short's bladderpod on privately owned parcels where the Corps holds flood easements and engage those landowners in participating in recovery efforts for the species. (USFWS, 2021)
- Since 1991, the number of extant Short's bladderpod populations has increased from 25 to 33. In 1992, 18 of the populations consisted of less than 100 individuals, whereas this is true for 28 of the currently extant populations. One or more threats, including right-of-way maintenance, overstory shading, invasive species, and small population size affect most populations. The historical and current distributions of Short's bladderpod are characterized primarily by populations of low resiliency, owing to small population sizes and presence of threats to the species, its habitat, or both. The vulnerability of small populations is borne out by the turnover in occurrences of the species between 1992 and present day, resulting in the loss of at least 8 occurrences during that time period. With regard to the species' overall resilience, the discovery of additional, albeit small, populations in Tennessee since 1992 have potentially offset these losses. (USFWS, 2020a)

## SPECIES ACCOUNT: *Physaria obcordata* (Dudley Bluffs twinpod)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 02/06/1990; Mountain-Prairie Region (R6) (USFWS, 2016)

### **Physical Description**

A perennial herb with flowering stems, 1.2-1.8 dm tall, arising from a tuft of silvery, erect, basal leaves. Flowers are yellow and bloom in May and June. This species is recognized by its dense, silvery covering of dish-shaped hairs which completely encrust its stems, leaves, and heart-shaped fruits. (NatureServe, 2015)

### **Current Range**

Endemic to Colorado; known from Rio Blanco County only along the Piceance and Yellow Creek drainages and at Clamity Ridge. Estimated range is 574 square kilometers, calculated in GIS by drawing a minimum convex polygon around the known occurrences.

### **Critical Habitat Designated**

No;

### *Life History*

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Insect pollinated (USFWS, 2008)

### **Breeding Season**

Adult: Flowers are yellow and bloom in May and June (NatureServe, 2015).

### **Reproduction Narrative**

Adult: Flowers are yellow and bloom in May and June (NatureServe, 2015). These species rely exclusively on insect pollination (USFWS, 2008).

### **Habitat Type**

Adult: Shale (NatureServe, 2015)

### **Spatial Arrangements of the Population**

Adult: Clumped (natureServe, 2015)

### **Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

### **Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

### **Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Species is found in white oil-shale, Parachute Creek Member of the Green River Formation. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are based on the specific habitat requirements of this species.

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: No information found.

***Population Information and Trends*****Population Trends:**

Unknown (NatureServe, 2015)

**Population Growth Rate:**

Unknown. There is insufficient data to characterize long-term trends. Unknown (NatureServe, 2015)

**Number of Populations:**

6 - 20 (NatureServe, 2015)

**Population Size:**

10,000 - 100,000 individuals (NatureServe, 2015)

**Population Narrative:**

Population trends are unknown. There is insufficient data to characterize long-term trends. Unknown Total estimated sum of individuals from the 10 documented occurrences is 34,400. There are 10 principal occurrences documented in the Colorado Natural Heritage Program database. All of the occurrences are in a restricted geographic area. Several occurrences are within approximately 1-2 km of one another, but have not been combined due to data complexity. (NatureServe, 2015). Low resiliency and moderate redundancy and representation are based on the relatively narrow geographic range this species is known to inhabit and the overall number of known populations and individuals.

***Threats and Stressors***

**Stressor:** Oil and Gas Development (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** While not discussed in the recovery plan, ongoing oil and gas development is currently the primary threat to the bladderpod and the twinpod. Natural gas production is prolific from formations located stratigraphically below the oil shale. Four of the top 35 natural gas fields in the United States are located in the southern Piceance Basin (BLM 2007). This threat also is projected to increase significantly on the lands managed by the BLM-WRFO. Numerous projects are currently being planned and implemented to expand existing development and the

associated infrastructure within the range of both plants. Along some pipeline routes, there is no room for additional pipelines without impacting occupied plant habitat (USFWS, 2008).

**Stressor:** Oil Shale Development (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The potential for oil shale development in the Piceance Basin was identified as the primary threat to both species in the 1993 recovery plan. In 2008, the threat is imminent (USFWS, 2008).

**Stressor:** Energy Corridors (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The potential designation of energy corridors is likely to impact energy development throughout the western United States, including commercial oil shale and tar sands development, because the location of energy corridors may facilitate development by removing administrative and planning barriers for potential pipelines, electric transmission lines, and associated infrastructure (BLM 2007) (USFWS, 2008).

**Stressor:** Summary of Energy Development (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Oil and gas development presents an imminent threat to the entire range of both species. BLM has managed to avoid oil and gas impacts on the species in most of the range, but further development in some areas may not be possible without disturbing suitable habitat for the species. The potential impacts from oil shale development depend on the alternative selected and the amount and distribution of leased areas. Potential impacts could be severe. New energy corridor designations may facilitate a larger volume of oil and gas activity and threats to the species, depending on the routes. As a listed species, consultation through Section 7 should minimize impacts. In the absence of the ESA's protections, we believe substantial threats would threaten both species range-wide (USFWS, 2008).

**Stressor:** Trampling (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** information on cattle and wild horse trampling of plants shows only localized damage to plants in a few occurrences. The effect on plant numbers cannot be distinguished from population fluctuations during drought years (USFWS, 2008).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Protection of habitat for both species depends on BLM management regulations. In the past year, BLM has worked with the Service to develop and apply more comprehensive conservation measures and larger avoidance buffers for oil and gas development. To date, all Section 7 consultations for the plants have resulted in findings of not likely to adversely affect. Increasing pressure on BLM to approve applications for more intensive oil and gas development is likely to result in formal consultations and more disturbance to potential if not occupied habitat. In the absence of the ESA's protections, we believe the situation would be considerably worse (USFWS, 2008).

**Stressor:** Secondary Impacts of Energy Development (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Air pollution from diesel truck exhaust and from proposed coal-fired power plants for oil shale production could be a potential impact. Development of each new gas well requires between 375 and 1,375 round trips by large trucks to deliver materials, supplies and equipment, depending on the depth and location of the well. Operating wells require 0.25 truck trips per day (Kuhn 2006). Possible effects on the plants have not been predicted. Likewise, dust from heavy use of nearby roads may impede growth of the plants; information on likely impacts is not available. Conservation measures that are being implemented by BLM include dust abatement using water on roads, instead of magnesium chloride that could damage plants. Overspray from a produced-water evaporation pond on private land has reached an adjacent BLM plant occurrence; effects on the plants have yet to be determined. Accidental release of produced water from gas wells has been observed to kill sagebrush and associated vegetation near a few well pads. These species rely exclusively on insect pollination. As described above in section 2.3.1.1, Tepedino (1996) estimates that foraging bees may fly 4.8 km (3 mi) to obtain nesting materials. Increasing ground disturbance in the vicinity of occupied plant habitat may be curtailing nesting resources for ground nesting bee pollinators. Increasing vehicle traffic may cause mortality of pollinators. Available information regarding these potential threats is not sufficient to show that larger buffer areas would benefit the pollinators (USFWS, 2008).

**Stressor:** Climate Change (USFWS, 2008)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Changes in the global climate system during the 21st century are very likely to be larger than those observed during the 20th century (IPCC 2007). For the next two decades, a warming of about 0.2°C per decade is projected (IPCC 2007). Afterwards, temperature projections increasingly depend on specific emission scenarios (IPCC 2007). Various emissions scenarios suggest that by the end of the 21st century, average global temperatures are expected to increase 0.6 to 4.0°C with the greatest warming expected over land (IPCC 2007). Localized projections suggest the southwest may experience the greatest temperature increase of any area in the lower 48 States (IPCC 2007). It is very likely that hot extremes, heat waves, and heavy precipitation will increase in frequency (IPCC 2007). There also is high confidence that many semi-arid areas like the western United States will suffer a decrease in water resources due to climate change (IPCC 2007). Milly et al. (2005) project a 10 to 30 percent decrease in precipitation in mid-latitude western North America by the year 2050 based on an ensemble of 12 climate models. Drought years result in a loss of plants. When occurrences also are impacted

by other factors during drought years, they may require several years to recover. Dislodging of plants while monitoring during drought years has been cited as a factor in population decline at two ACEC sites (BLM-WRFO 1989; BLM-WRFO 2002b). Climate change may exacerbate the frequency and intensity of droughts in this area (USFWS, 2008).

### **Recovery**

#### **Reclassification Criteria:**

Protect and/or enhance all known occurrences of *L. congesta*/*P. congesta* (bladderpod) and *P. obcordata* (twinpod) on public and private lands. Establish land management designations, and develop and implement habitat management programs (USFWS, 2008).

Protect both species from impacts via consultation under Section 7 and protection under Section 9 of the Endangered Species Act (ESA) (USFWS, 2008)

Minimum viable populations are defined and documented as being maintained for both species (USFWS, 2008).

#### **Delisting Criteria:**

1. At least seven key conservation areas for bladderpod and eleven key conservation areas for twinpod are protected (Factors A, C, D, and E). A key conservation area includes all occupied habitat within an occurrence and the surrounding area of potential impact. The area of potential impact is the area where indirect effects may impact plants. For bladderpod and twinpod, we consider this to be the area within 1,970 ft (600 m) of occupied habitat. i. Protection of these sites means that the sites are owned or managed by an individual, agency, or organization that identifies conservation of bladderpod or twinpod as a management objective of the site, and that regulatory mechanisms or other conservation plans or programs reduce or ameliorate threats associated with habitat loss and degradation. ii. Long-term habitat protections are in place to protect key conservation areas from identified threats to the species and manage for surface disturbing activities. Habitat protection can be achieved via long-term management agreements, conservation agreements, or memoranda of understanding in accordance with landowner and agency authorities (Factor D). (USFWS, 2020)

2. Habitat within key conservation areas possesses all of the following qualities (Factors A, C, and E): i. Habitat is of the quality and quantity necessary to support a stable and self-supporting occurrence of bladderpod or twinpod. In key conservation areas where both species are present, the area may be considered a key conservation area for both species, given that the habitat of the area is of the quality and quantity necessary to support stable and self-supporting occurrences of both bladderpod and twinpod. Unless a PVA or other science provides a more detailed definition of habitat quality, necessary habitat quality will be assumed if the occurrence has been stable in that habitat for ten years, as per criterion 3. ii. Adjacent habitat is available with conditions sufficient to support pollinating insects. iii. Habitat conditions at each key conservation area are stable or improving after 10 years of monitoring. (USFWS, 2020)

3. At least seven occurrences of bladderpod and eleven occurrences of twinpod within key conservation areas are stable and self-sustaining. To be deemed stable and self-sustaining, an occurrence must demonstrate a stable or increasing growth rate ( $\lambda$  equal to or greater than 1) over a consecutive 10-year period and contain at least 4,824 plants at the end of the 10-

year period. Plant abundance may fluctuate within individual sites and from year to year, but the defined occurrences should have a stable or increasing growth rate from year one to year ten. The ten-year period may start retroactively (Factors A, C, D, and E). (USFWS, 2020)

4. All populations of bladderpod and twinpod are represented in an ex-situ seed collection that is managed according to the Center for Plant Conservation guidelines (Guerrant et al. 2004). The ex-situ seed collection should contain existing levels of genetic diversity (representation) of bladderpod and twinpod across the ranges of the species and should take place over a 10-year period (Factor E). (USFWS, 2020)

5. Criteria 1 through 4 have been realized and demonstrated effective via monitoring efforts (Factors A, C, D, and E). (USFWS, 2020)

**Recovery Actions:**

- **Inventory Remaining Potential Habitat** - Additional survey work has expanded the known distribution and abundance data for these species. Since 1993, bladderpod has been documented at two new occurrences on about 180 to 187 hectares (ha) (446 to 462 acres (ac)) (CNHP 2006b). During this same period, twinpod has been documented at five new occurrences on about 16 ha (40 ac) (CNHP 2006b, 2008). Most of the potential habitat on BLM land has been surveyed. Most of the potential habitat on private lands (primarily owned by energy companies) still needs to be surveyed. **Establish Land Management Designations on Federal Land** - Four Areas of Critical Environmental Concern (ACECs) were designated to protect the plants including about 177 ha (438 ac) (CNHP 2006a; BLM-CO 2004), or about 64 percent of known occupied habitat for both species on BLM land. Estimated occupied habitat on BLM land not protected by ACECs is 101 ha (250 ac) (CNHP 2006b), or 36 percent of known occupied habitat for both species on BLM land. Permanent protective land management designations are necessary on all, or nearly all, occupied BLM land in order to fully achieve recovery. **Protect Habitat on Private and State Land** – Ownership of one bladderpod occurrence at Duck Creek was transferred from State Division of Wildlife to a private energy company. A permanent conservation management and monitoring plan Memorandum of Agreement for the plants was attached to the land exchange. Similar agreements are needed for occurrences on other private parcels. **Create Habitat Management Plans** - Habitat management plans have not been developed for either species. **Apply No Surface Occupancy Stipulations on Federal Land** - No Surface Occupancy stipulations are applied to the four ACECs and to all known and potential habitat under BLM jurisdiction for endangered, threatened, and candidate plant species. Exceptions are allowed if surveys show there would be no direct impact or effects to the plants. Under this policy, developments including pipelines, roads and well pads have been approved by BLM within all four ACECs. In some cases, ground disturbance occurs within 30 meters (m) (98 feet (ft)) of plant habitat. No monitoring results are available to measure the effects of these actions on the plants. BLM is currently working with the Service to determine appropriate buffer distances to protect the plants and their habitat from direct and indirect effects of oil and gas development activities. The Service currently recommends a 200-m (656-ft) buffer to avoid adverse effects to plants and habitat for these listed plants. Implementation of buffers is an ongoing effort for BLM and the Service. **Review Mining Claims** – The Service has not reviewed plot records to determine the extent of historic mining claims, if any. Future claims require a plan of development and environmental analysis for mining. Current land management designations close all known and potential habitat to surface mineral materials

- development. Establish Off-highway Vehicle Designations – Within the ACECs, motorized vehicle travel is limited to designated roads and trails (BLM-WRFO 1997). The maps show about 26 segments of road that remain open within the ACECs, and about 19 that are closed. Off-highway vehicles on BLM land not in ACECs are limited to existing routes in areas with potential habitat for the plants. Additional fencing, signage, enforcement and education is needed to ensure compliance with existing road closures. Transfer Privately Owned Occurrences to BLM - Exchanges of private land into BLM management as recommended in the Recovery Plan have not occurred. Shell Oil acquired land in an exchange with the Colorado Division of Wildlife (CDOW) that includes approximately 28 ha (70 ac) of occupied bladderpod habitat adjacent to the Duck Creek ACEC and Natural Area. CDOW consulted with the Service and the Colorado Natural Areas Program to develop a Memorandum of Agreement that will protect the plant habitat acquired by Shell (CDOW 2007). The Memorandum of Agreement provided the basis for concurrence by the Service that the land exchange was not likely to adversely affect the species (USFWS, 2008).
- Process Project Clearances - BLM has ongoing informal Section 7 consultations with the Service regarding multiple gas pipelines, seismic survey projects, a large oil and gas Piceance Development Plan that covers an area including two of the ACECs, and five Oil Shale Research Development and Demonstration projects. The Service also is reviewing proposed oil shale lease areas described in the Draft Oil Shale and Tar Sands Resource Management Plan (RMP) Amendments Programmatic Environmental Impact Statement (BLM 2007). CDOW has informally consulted with the Service to avoid impacts to plant habitat on several projects involving gas pipelines, processing facilities and land exchanges. While Section 7 consultations are not considered recovery actions, they are the primary tool for implementing conservation measures to avoid or minimize disturbance of the habitat for both species (USFWS, 2008).
  - Conduct Soil Analyses, Life History Analyses and Monitoring - Detailed descriptions of the Thirteenmile Creek Tongue, the Parachute Creek Member, and the Garden Gulch Member of the Green River Formation are available, but the lack of finely mapped geology is still a limiting factor in modeling suitable habitat (Decker et al. 2006). Resources have not been available to conduct life history analyses. A minimum viable population analysis has not been performed. Because the habitat is limited and imminent threats encompass the entire range of both species (see five factor analysis, section 2.3.2, below), we are assuming that most, if not, all suitable habitat and occurrences are essential to the survival of the species. BLM has conducted sporadic monitoring on the ACEC occurrences of both species from 1985 to 2007. The Colorado Natural Areas Program and BLM have been monitoring the bladderpod at two locations on the Duck Creek ACEC and Colorado Natural Area for 10 years (Rickey and Kurzel 2007). One site for each species has been monitored on the Dudley Bluffs ACEC (Kurzel 2006). Results are described below in section 2.3.1.2 (USFWS, 2008).
  - Publish a technical correction in the Federal Register noting the change in taxonomy from *Lesquerella congesta* to *Physaria congesta*, and correcting 50 CFR 17.12 (USFWS, 2008).
  - Revise the recovery plan for both species so that it reflects the best scientific and commercial information available. The revised recovery plan should include objective, measurable criteria which, when met, will result in a determination that the species be removed from the Federal List of Endangered and Threatened Plants. Recovery criteria should address all threats meaningfully impacting the species. The recovery plan should also estimate the time required and the cost to carry out those measures needed to achieve the goal for recovery and delisting (USFWS, 2008).

- Designate critical habitat for both species. "Critical habitat" is defined as: (1) specific areas within the geographical area occupied by the species at the time of listing, if they contain physical or biological features essential to conservation, and those features may require special management considerations or protection; and (2) specific areas outside the geographical area occupied by the species if the agency determines that the area itself is essential for conservation. This could be done concurrently, in a single rule, with other neighboring plant species (USFWS, 2008).
- Recommend at least a 200 m (656 ft) buffer between occupied or suitable habitat and ground disturbance or other activities that may affect the plants or their habitat (USFWS, 2008).
- Develop and implement consistent conservation measures in the WRFO RMP revision that will avoid and minimize impacts from all development, ORV, and grazing activities. Include protection for all occupied and suitable habitat in the conservation measures. Expand existing ACECs to include contiguous occupied and suitable habitat for the plants and their pollinators. Designate the Yellow Creek occurrence as an ACEC as was proposed in the recovery plan, plus contiguous occupied and suitable habitat (USFWS, 2008).
- Inventory remaining potential habitat on public and private lands. Report results to CNHP, BLM, and the Service (USFWS, 2008).
- Map all potential habitat, occupied habitat, and areas of existing and proposed leases, applications to drill, and development activities in GIS format (USFWS, 2008).
- Develop and implement permanent conservation agreements for occurrences on private lands (USFWS, 2008).
- Monitor the effects of development activities located within 200 m (656 ft) of plant occurrences on plants, pollinators, and habitat. Change buffers as determined by monitoring results (USFWS, 2008).
- Conduct annual status evaluations including estimates of mean density and population sizes at all Element Occurrences for the duration of intense energy activities within the range of both species (USFWS, 2008).
- Research the function of pollinators in the life history needs of the species, determine the habitat requirements of key pollinators, and adjust energy development best management practices accordingly (USFWS, 2008).
- 1. Protect, enhance, and maintain existing bladderpod and twinpod populations and habitat (USFWS, 2020a)
- 2. Maintain propagule bank, including long-term seed storage for bladderpod and twinpod. (USFWS, 2020a)
- 3. Conduct research to aid in the recovery of bladderpod and twinpod. (USFWS, 2020a)
- 4. Develop and implement a post-delisting monitoring plan. (USFWS, 2020a)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Publish a technical correction in the Federal Register noting the change in taxonomy from *Lesquerella congesta* to *Physaria congesta*, and correcting 50 CFR 17.12. • Inventory remaining potential habitat on public and private lands. Report results to CNHP, BLM, and the Service. • Identify key conservation areas for both species. • Develop and implement permanent conservation agreements for occurrences on private lands. • Conduct annual status evaluations including estimates of mean density and population sizes at all key conservation areas. For more information about recommended future actions, refer to the 2019 recovery plan and implementation schedule (USFWS 2019a-b). (USFWS, 2020)

## SPECIES ACCOUNT: *Pilosocereus robinii* (Key tree cactus)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 8/20/1984; Southeast Region (R4)

### **Physical Description**

The Key tree-cactus is a large, tree-like cactus with erect columnar stems, reaching 10 m in height. At maturity, the plants are either much-branched (in variation *robinii*), or remaining few-branched (in variation *deeringii*). The stems of the tree-cactus are cylindrical, green, succulent, and 2 to 4 inches thick, with nine to 15 prominent ribs. Areoles bear 15 to 30 acicular spines that are up to 0.78 inches long and are thickly pubescent when young. Flowers are solitary in the Upper areoles, nocturnal, and 2.0 to 2.3 inches long. The outer perianth segments of the flowers are green, with tips pointed (in variation *robinii*) or rounded (in variation *deeringii*). The inner perianth segments of the flowers are white. The style is slightly exserted (in variation *robinii*) or included (in variation *deeringii*). The fruit of the Key tree cactus is globose, depressed, and 1.4 to 1.6 inches in diameter. The coat of this fruit is thin, leathery, bright red, and splits open at maturity. The seeds are small, hard, shiny black, and set in a soft, white pulp (Benson 1982, Britton and Rose 1937, Small 1931). (USFWS, 1999)

### **Taxonomy**

The taxonomy of *Pilosocereus* in the Keys has been historically confusing and is not yet clearly resolved. Most recently both *P. robinii* and *P. bahamensis* have been grouped into the more widespread species *Pilosocereus polygonus* (Lem.) Byles & G.D.Rowley (Zappi 1994, Anderson 2001). Botanists who are familiar with the Key tree-cactus have not adopted this taxonomy, and *P. polygonus* is not recognized by the Integrated Taxonomic Information System (ITIS) (ITIS 2010a). The Flora of North America (1993) also states that this treatment is not supported by existing data. The ITIS accepts *Pilosocereus robinii* (Lem.) Byles & Rowley as a valid taxon. Two varieties are recognized, *P. robinii* var. *deeringii* (Small) Kartesz & Gandhi and *P. robinii* var. *robinii* (Lem.) Byles & Rowley (ITIS 2010b). The taxonomic position of *Pilosocereus* populations in Cuba is uncertain (Adams and Lima 1994). The Service will defer any decision to adopt the revised taxonomic scheme until the ongoing difficulties with classification in this group of taxa are settled. (USFWS, 2010)

### **Historical Range**

The historical range of Key tree-cactus included the entire expanse of the Florida Keys, from Key West to Key Largo (Adams and Lima 1994), encompassing an area of about 80 miles (128 kilometers [km]) east to west, and 30 miles (48 km) north to south. (USFWS, 2010)

### **Current Range**

The Florida Keys in Florida, an area 40 miles (114 km) east to west, and 15 miles (24 km) north to south. Records exist for populations on Key West, Boca Chica Key, Big Pine Key, Long Key, Lower Matecumbe Key, Upper Matecumbe Key, Windley Key, and Key Largo. (USFWS, 2010)

### **Critical Habitat Designated**

No;

### **Life History**

**Food/Nutrient Resources****Breeding Season**

Adult: The Key tree-cactus can flower year-round, but July, August, and September are peak flowering periods.

**Reproduction Narrative**

Adult: Long distance dispersal and establishment of new tree-cactus populations is dependent upon the production of seed. However, reproduction within a single population (a clump) is mostly, if not entirely, vegetative. This reproductive strategy (formation of clonal clumps from rooted wind-thrown branches) also accounts, in part, for the clumped distribution of the species (Adams and Lima 1994). Pollination agents are unknown, but may include sphingid moths (Adams and Lima 1994). Seed dispersal by birds (*Cardinalis cardinalis*, for example) is indicated for this species (Austin 1980). The effective dispersers would be those fruit-eating birds, which favor openings in the woods. The Key tree-cactus can flower year-round, but July, August, and September are peak flowering periods. Mature flowers develop in about 12-14 days, and many flowers may occur simultaneously on a single pseudocephalium (Adams and Lima 1994). Seed dispersal, based on one observation, occurs in August (Austin 1980; Avery [no date]).

**Habitat Type**

Adult: Tropical hardwood hammocks

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: The Key tree-cactus grows in a narrow range of plant associations, which include tropical hardwood hammocks and a thorn-scrub association known locally as a “cactus hammock.” The major requirements for successful growth of Key tree-cactus are an open canopy and freedom from frequent floods or frequent fires. Hardwood hammocks inhabited by the species are typically in an early stage of succession following disturbance (Avery [no date], Small 1917, 1921). Dominant tree species include *Bumelia salicifolia*, *Bursera simaruba*, *Coccoloba diversifolia*, *Ficus aurea*, *Krugiodendron ferreum*, *Metopium toxiferum*, and *Piscidia piscipula*. The Lower story of the canopy typically contains small trees of the dominant species and plants of *Amyris elemifera*, *Ateramnus lucidus*, *Bumelia celastrina*, *Capparis flexuosa*, *Eugenia foetida*, *Guapira discolor*, *Pithecellobium guadelupense*, *Randia aculeata*, and *Zanthoxylum fagara* (Austin 1980, Weiner [no date]). These hardwood hammocks are upland communities which are flooded only rarely (during major storms) and are mesic in character (Weiner [no date]). The thorn-scrub, “cactus hammock” association occurs at relatively low elevations in the Keys and is prone to more flooding. Consequently, the canopy of this vegetative community is lower and more open than hardwood hammocks. *Conocarpus erectus* and *Ximenia americana* are the most typical dominant tree species (Weiner [no date]). *Cereus gracilis*, *Cereus pentagonus*, and *Opuntia dillenii* are common associates of Key tree-cactus in these habitats. Key tree-cactus exists on high sites within cactus hammocks that are rarely flooded. These sites support the hardwood hammock species listed above, but they are rarely extensive enough to allow typical development of hardwood hammocks. The hardwood hammocks and cactus hammocks where the Key tree-cactus grows are all on coral rock. Key tree-cactus grows well on well-drained

upland sites with little or no soil development. Mineral soil is, if present at all, a very thin (less than 0.4 inches) layer of rock rubble, calcareous sands or calcareous marl (Austin 1980). A layer of leaf litter one to two cm thick is typically present (Austin 1980). Deeper accumulations of soil may be found in pockets and crevices in the rock. These soils are classified as Histosols (Soil Conservation Service 1975). They are placed in the “catch-all” Rockland groups (Jones 1948). There is no detailed work on soil types in the Keys due to their small area, agricultural insignificance, and lack of well-developed soils. Hammocks on Key West and Boca Chica Key, where Key tree-cactus grew in the past, were developed on oolitic limestone. Soil conditions at these sites were not recorded, but were probably similar to those listed above. Key tree-cactus exists in small, isolated patches or clumps. The patches may consist of a single plant, or a group of plants may cover an area of tens of square meters (Austin 1980, Small 1917). When many plants occur in a clump, most, if not all, of the separate stems likely represent vegetative offshoots of one or a few founders. Vegetative reproduction is common because of old stems being knocked to the ground.

### ***Dispersal/Migration***

### ***Population Information and Trends***

#### **Population Trends:**

Decreasing

#### **Number of Populations:**

10 8 Natural and 2 introduced (USFWS, 2019)

#### **Population Size:**

1 - 1000 individuals (NatureServe, 2015)

#### **Population Narrative:**

As of 2018, eight (8) natural and two (2) introduced populations are extant on six (6) islands of the Florida Keys. Extant wild populations are located on Big Pine Key, Long Key, Lower Matecumbe Key, and Upper Matecumbe Key (Adams and Lima 1994, FNAI 2009, Maschinski et al. 2009, Service 1999). Reintroduction efforts since 2010 have returned the species to Key Largo and Windley Key. (USFWS, 2019)

### ***Threats and Stressors***

**Stressor:** Habitat destruction or modification

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The historic decline of Key tree-cactus was directly linked to the clearing of hardwood hammocks for development (Service 1999). Habitat destruction from development continues to occur and development pressure remains high; however, habitat loss currently occurs at substantially lower rates than in earlier periods (e.g., 1970s to 1990s). Clearing of hammocks for development is currently a threat to one population which remains unprotected on private land. Six of seven Key tree-cactus populations are protected from habitat loss to development. Four are protected on public conservation lands and two are protected by covenant or easement on

private property. Development continues to fragment the remaining habitat, restricting gene flow between populations, and limiting the potential for expansion or shift in the species range in response to environmental changes. (USFWS, 2010)

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The threat of overutilization for commercial or recreational purposes was identified at the time of original listing in 1984 (49 FR 29234). Key tree-cactus is an attractive species with high horticultural value as landscape ornamentals. Cacti are regarded as one of the groups of plants that are most vulnerable to illegal collection due to their popularity with collectors worldwide (Anderson 2001). Laws prohibit the removal of cacti from State and Federal protected areas, but enforcement is difficult due to insufficient resources and the remoteness of the plants. There is recent evidence that the illegal trade in rare cacti includes Key tree-cactus. For example, a potted Key tree-cactus was sold across state lines on a well-known auction website in 2006 (Ebay 2006). The buyer subsequently surrendered this plant to Service law enforcement. Key tree-cactus is vulnerable to unlawful exploitation and collection and removal of plants from any of the protected areas for commercial or recreational reasons would be detrimental to the species. All sites with Key tree-cactus should be monitored for possible illegal collection activities

**Stressor:** Disease or predation

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** There is no data to suggest that disease is the primary cause of the recent declines in Key tree-cactus populations. Tissue samples from several dying cacti were sent for analysis on more than one occasion. Results by Tropical Research & Education Center (TREC) of University of Florida – Institute of Food & Agricultural Sciences (UF-IFAS) (Aaron Palmateer; UF-IFAS, TREC Pathology Lab, Homestead) and Tim Schubert, Florida Department of Agriculture and Consumer Services [FDACS], Pathology, Gainesville) in January and April 2005, respectively reported no primary pathogens. A second test was conducted by TREC in 2008 and again, no primary pathogens were detected (P. Hughes, unpubl. data 2006, Goodman et al. 2008). Goodman et al. 2008 reported that a single cactus showed symptoms of basal rot that included ‘black goo’ leaking from the affected area. These are typical signs of bacterial necrosis in cacti. These bacteria are known to infect other large columnar cacti such as Saguaro (*Carnegiea gigantea*). Since this symptom has only been observed in one individual Key tree-cactus, evidence is insufficient to connect this observation to the range-wide decline phenomenon. Goodman et al. (2008) observed that the surface of the soil just below the leaf litter at one site was entirely made up of frass from the introduced yellowbanded millipede (*Anadenobolus monilicornis*). While this organism is not known to be damaging to plants, they suggested that the predominance of frass could modify the soil structure or chemistry and possibly have an effect on plants. The native ant species, *Crematogaster ashmeadi* and *Solenopsis abdita* were observed removing the pulp and seeds from still-attached fruits and carrying them to ground level. In addition, the pulp and seeds of split fruits that had fallen were similarly removed by these two ant species (Adams and Lima 1994). There is no evidence suggesting seed predation by ants is a threat to Key tree-cactus. Ants may actually aid in seed dispersal. Hennessy and Habeck (1994) reported ‘feeding damage’ on plants in NKDR. Observed damage included complete girdling of

woody trunks, uprooting, and chewing of stems. Maschinski et al. (2008) documented damage to cactus trunks at NKDR in which the fleshy tissue was removed down to the woody core of the plant. Damage occurred within 1.0 m of the ground and often on the exposed side of the plant that are more easily accessible to deer. Key deer are believed to damage Key tree-cactus through herbivory and antler polishing (Maschinski et al. 2008). Damage caused by herbivory or antler polishing by Key deer may weaken plants, making them more vulnerable to other stressors. (USFWS, 2010)

**Stressor:** Inadequacy of existing regulatory mechanisms:

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Key tree-cactus is listed as endangered by the State of Florida on the Regulated Plant Index (Florida Department of Agriculture and Consumer Services Rule 5B-40). This law regulates the taking, transport, and sale of listed plants. It does not prohibit private property owners from destroying populations of listed plants on their property nor require landowners to manage habitats to maintain populations. Existing Federal and State regulations prohibit the removal or destruction of listed plant species on public lands. However, such regulations afford no protection to listed plants on private lands. The ESA only protects populations from disturbances on Federal lands or when a 'Federal nexus' is involved for other lands, meaning any action that is authorized (e.g. permitted), funded or carried out by a Federal agency. In addition, State regulations are less stringent than Federal regulations toward land management practices that may adversely affect populations of listed plants on private land. Monroe County has adopted a point system of evaluation for building permit applications. Building permit applicants are required to replace listed plants and native vegetation removed from the construction site elsewhere on the property. Monroe County requires mitigation for impacts to rare plant species, including Key tree-cactus. If Key tree-cactus is found on a property to be developed, the property owner would be required to pay a mitigation fee to the County prior to development. Clearing is limited to 10 to 30 percent in high quality habitat. A conservation easement may then be placed on the remaining native habitat. These protections are limited, and populations can be still destroyed by private landowners. As such, existing regulatory mechanisms are adequate to protect Key tree-cactus, with exception of the single remaining unprotected population on private land. (USFWS, 2010)

**Stressor:** Hurricanes

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Hurricanes have the potential to adversely affect tree-cactus populations. High winds can bring surrounding vegetation crashing down on top of individual cacti, injuring or killing them. However, hurricanes also open hammock canopies, allowing light to penetrate, thus providing conditions that may be favorable to cactus regeneration. Hurricane Georges made landfall on Big Pine Key in October 1998 and caused severe damage to the tree-cactus population on the NKDR. Maschinski et al. (2008) provides accounts by several individuals describing dramatic impacts to the lower Keys hammocks after Hurricane Georges. Many of the larger cacti were directly damaged by high winds or injured by airborne debris. A range of models suggest that due to global warming, future tropical cyclones (typhoons and hurricanes) will likely become more intense, with larger peak wind speeds and more heavy precipitation associated with

ongoing increases of tropical sea-surface temperatures (IPCC 2007). The long-term impacts of hurricanes on tree-cactus are difficult to predict, but because the number of locations where Key tree-cactus occurs has been reduced, the potential threat of hurricanes is significant. (USFWS, 2010)

**Stressor:** Storm Surges

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Hurricanes also cause storm surges, which inundate Key tree-cactus habitat with seawater. Maschinski et al. (2008) provides a local residents account which confirms that the area of NKDR where the cactus occurs was completely inundated during the storm surge produced by Hurricane Wilma in 2005. In a hammock where a Key tree-cactus population has decreased by about 90 percent, a past storm surge is evidenced by 'wrack line' of debris at that site (Maschinski et al. 2008). Storm surges during tropical storms and hurricanes have inundated areas where Key tree-cactus occurs on Big Pine and Long Keys (Maschinski et al. 2008). Storm surges can modify habitat by increasing soil salinity. Data suggest that high soil salinity may be the cause of the recent decline phenomenon in Key tree-cactus populations (Maschinski et al. 2009). The cause of the high salt levels is suspected to be salts deposited by storm surge events, from saltwater intrusion of groundwater, or both. Storm surges temporarily inundate large areas with seawater, which then drains off and percolates through the soil, leading to increased soil salinity. (USFWS, 2010)

**Stressor:** Sea Level Rise (SLR)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The projected global average sea level in 2100 will be 0.18 to 0.59 m higher than the average reported from 1980 to 1999 (IPCC 2007). SLR predictions do not take into account the full contribution of melting ice sheets, because existing data are inadequate to quantify these inputs. As a result, the predictions may underestimate SLR (IPCC 2007). SLR is the largest climate-driven challenge to refuges and other lands in the sub-tropical ecoregion of southern Florida (CCSP 2008). According to CCSP (2008), much of lowlying, coastal south Florida "will be underwater or inundated with salt water in the coming century". SLR is expected to exacerbate inundation, storm surge, erosion and other coastal hazards. Small islands, low-lying coastal areas and coastal systems such as mangroves and salt marshes are identified as areas that will be especially affected. While habitat may be only partially inundated by 2100, it is likely that under any scenario, soil salinity will continue to increase, either by pulses as with successive storm surges, or incrementally due to saltwater intrusion. The Service anticipates that these processes will act separately or synergistically to cause ongoing mortality pulses of Key tree-cactus and eventually result in the conversion of their existing coastal hammock to transitional habitats and then tidal areas dominated by mangroves. (USFWS, 2010)

## **Recovery**

### **Reclassification Criteria:**

1. When further loss, fragmentation, or degradation of suitable, occupied habitat has been prevented (USFWS, 1999)

2. When native and non-native nuisance species have been reduced by 80 percent (USFWS, 1999)
3. When all suitable, occupied habitat on priority acquisition lists is protected either through land acquisition or cooperative agreements (USFWS, 1999)
4. When potential habitat on protected lands is restored or rehabilitated for the Key tree-cactus (USFWS, 1999)
5. When stable populations of the Key tree-cactus are distributed on secure sites within its historic range (including two on Upper Matecumbe, one on Lower Matecumbe, three on Long Key and two on Big Pine Key) (USFWS, 1999)
6. When three, additional, stable populations have been established on Windley Key, Boca Chica Key, and Key West. These populations will be considered demographically stable when they exhibit sexual reproduction and have a rate of increase equal to or greater than 0.0 as a 3-year running average for 6 years. (USFWS, 1999)

**Delisting Criteria:**

The Key tree-cactus will be considered for delisting when: 1. At least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. 2. Populations (as defined in criterion 1) occur in tropical hardwood hammock habitat and are distributed across the historical range of the species. (Factor A) 3. Populations (as defined in criterion 1) must be protected via a conservation mechanism and/or managed such that enough suitable habitat is present for the species to remain viable for the foreseeable future. (Factors A, D, and E) (USFWS, 2019)

**Recovery Actions:**

- Conduct surveys to determine the distribution and status of *P. robinii*. Known *P. robinii* populations occur in coastal hammocks on Upper Matecumbe Key, Lower Matecumbe Key, Long Key, and Big Pine Key (Adams and Lima 1994), but other populations may exist. Survey historic range and determine distribution and status of *P. robinii*. Conduct surveys on private lands first since these are most likely to be vulnerable to disturbance. (USFWS, 1999)
- Protect and enhance existing populations. The remaining population sites must be protected as the first step toward recovery. These sites are currently the only ones which will offer assurance of supporting the species. Plant stocks for expansion of the population must come from the remaining specimens. (USFWS, 1999)
- Conduct research on the biology of *P. robinii*. Study the reproductive biology of *P. robinii*. Conduct genetic studies to document genetic variation within and between populations. Determine population size and viability of all populations. Study the response of *P. robinii* to habitat management treatments. Characterize the habitat and identify suitable sites for experimental outplantings. (USFWS, 1999)
- Monitor *P. robinii* populations. Annual monitoring is the primary means to determine whether management practices are effective and what changes are needed. Inventories should detect changes in health, abundance, distribution, and threats. (USFWS, 1999)
- Increase public awareness and instill stewardship. Develop informational materials and host public workshops to increase awareness about *P. robinii* and instill a sense of stewardship

- for the protection of this endangered species. Conduct outreach efforts on national wildlife refuge properties and the State Recreation Area, through the Monroe County school system, and through press releases to emphasize the importance of the plant community, the conservation ethic, and Federal and State regulations and laws, including penalties for collection and vandalism. (USFWS, 1999)
- Establish reclassification and delisting criteria. Develop measurable reclassification criteria based on the factors that would produce a stable or increasing population, including total population size, number of subpopulations, habitat condition and availability, and level of threats. Evaluate and monitor *P. robinii*'s status in relation to reclassification criteria. Refine recovery goals. It is necessary to establish a realistic recovery objective for the species based on its biological characteristics. Recovery objectives should be re-evaluated and revised as necessary. Determine additional actions necessary to achieve the recovery objective. These actions must include legal protection, research, habitat protection, and other management strategies necessary to achieve recovery. (USFWS, 1999)
  - Habitat-level Recovery Actions. Conserve existing habitats. Acquire habitat. Acquire and protect occupied habitat within historic range. Acquire the plant's suitable unoccupied sites that contain habitat associations important to *P. robinii*. Protect and manage *P. robinii* on private and public lands. Restore areas to suitable habitat. Conduct research on habitat-level ecological processes. Monitor the status of *P. robinii* habitat. Increase public awareness of *P. robinii* habitat and instill stewardship. (USFWS, 1999)
  - Continue to acquire privately owned parcels when there are willing sellers. (USFWS, 2010)
  - Experiment with plant enclosures at NKDR to prevent potential damage to the plants by Key deer. (USFWS, 2010)
  - Continue to monitor mature individuals for flowering/fruitleting and collect seed if found. (USFWS, 2010)
  - Continue and increase monitoring for signs of disease. (USFWS, 2010)
  - Attempt to increase seed set through hand pollination in selected plants to equalize representation in stock available for reintroduction projects. (USFWS, 2010)
  - Maintain an aggressive program to salvage representative samples from dying cacti. (USFWS, 2010)
  - Continue to monitor extant populations to confirm whether the rapidly declining populations have truly stabilized after 2007. (USFWS, 2010)
  - Initiate genetic assessments to determine the genetic structure of the species at a range of spatial scales (clusters, populations, and species). Include the *P. bahamensis* population on Key Largo, and *Pilosocereus* in Cuba to determine the identity of these populations and relationship to *P. robinii*. (USFWS, 2010)
  - Expand ex situ collections via cuttings from earlier collections and from seeds. Complete studies of soil to further test hypothesis that soil salinity is the main cause of the population decline. (USFWS, 2010)
  - Conduct a greenhouse experiment to determine the range of salinity tolerance of Key tree-cactus. (USFWS, 2010)
  - Determine the importance of specific elements and conditions that contribute to increased soil salinity – saltwater intrusion, storm surges, elevation, and drainage patterns. (USFWS, 2010)
  - Continue to monitor soil salinity at all sites to provide early detection of rising salinity or evidence of declining salinity. (USFWS, 2010)
  - Expand the scoring and evaluation of potential reintroduction sites. (USFWS, 2010)

- Develop an Emergency Response Plan for hurricanes and storm surges. (USFWS, 2010)
- Provide the Village of Islamorada ongoing technical support regarding cactus and site management in the newly acquired parcel. (USFWS, 2010)
- Reintroduce cactus in multiple, well dispersed sites, including those with raised elevation in the Lower Keys (e.g., NKDR; Key West Tropical Forest and Botanical Garden), and representing a range of percent canopy cover. (USFWS, 2010)

## SPECIES ACCOUNT: *Pinguicula ionantha* (Godfrey's butterwort)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 8/11/1993; Southeast Region (R4)

### **Physical Description**

*Pinguicula ionantha* has a rosette of fleshy, oblong, bright green leaves that are rounded at their tips, with only the edges rolled upward. The rosette is about 15 cm (6 in) across. The upper surfaces of the leaves are covered with short glandular hairs that capture insects. The flowers are on leafless stalks (scapes) about 10-15 cm (4-6 in) tall. When a flower is fully open, its corolla is about 2 cm (almost 1 in) across. The five corolla lobes are pale violet to white. The throat of the corolla and the corolla tube are deeper violet with dark violet veins. The corolla has a spur 4-5 mm (0.2 in) long that is yellow to olive (Godfrey and Stripling 1961, Godfrey and Wooten 1981). (USFWS, 1994)

### **Taxonomy**

*Pinguicula ionantha* Godfrey (Godfrey's butterwort or violet-flowered butterwort) is a member of the bladderwort family (Lentibulariaceae), a small family of carnivorous plants closely related to the snapdragon family (Scrophulariaceae) (USFWS, 1994). *Pinguicula* L., the second most diverse genus of the carnivorous Lentibulariaceae, is monophyletic and composed of about 85 to 100 species native to Europe, North America, Asia, and South and Central Americas (Cieslax et al. 2005, Degtjareva et al. 2006). Six species can be found in Florida, of which *P. ionantha* Godfrey is endemic (Gluch 2005). All Florida species belong to the section or subgenus *Isoloba* (Fleischmann 2021, Cieslax et al. 2005, Gluch 2005). We are not aware of any changes to the taxonomy of this entity, and it is still considered valid by the Service and the scientific community (USFWS, 2023).

### **Historical Range**

See current range/distribution.

### **Current Range**

Endemic to the central panhandle region of Florida with reported occurrences in Bay, Calhoun, Franklin, Gulf, Liberty, and Wakulla counties (USFWS, 2018).

### **Critical Habitat Designated**

Yes;

### **Life History**

### **Food/Nutrient Resources**

### **Food/Nutrient Narrative**

Adult: *Pinguicula* L., the second most diverse genus of the carnivorous Lentibulariaceae is monophyletic and composed of about 85 to 100 species native to Europe, North America, Asia, South and Central America, and southern Mexico (Cieslax et al. 2005, Degtjareva et al. 2006). Members of this genus use sticky, glandular leaves to trap and digest insects (USFWS, 2009). It is unclear what benefit the plant derives from this carnivory.

**Breeding Season**

Adult: The flowers rise from late February to April according to temperatures (USFWS, 2009).

**Reproduction Narrative**

Adult: *Pinguicola ionantha* has a rosette of fleshy, bright green-yellow leaves of up to 15 cm across that can be characterized by upward rolled leaf edged. The plants stay in rosette form all year. The flowers rise from late February to April according to temperatures. The flowers, borne on stalks of about 10 to 15 cm in height, are about two centimeters across and possess five pale violet to white petals all of same shape corolla. The throat of the corolla and the corolla tube are deeper violet with dark violet veins. A yellow to olive spur 4 to 5 mm long is present on the corolla and the palate is yellow with a purple base and covered with yellow hairs (Godfrey and Stripling 1961, Godfrey and Wooten 1981) (USFWS, 2009). SEXUAL; ABIOTIC; Wind; (NatureServe, 2015)

**Habitat Type**

Adult: Bos/long leaf pine savannas (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits open, acidic soils of seepage bogs on gentle slopes, deep quagmire bogs, ditches, and depressions in grassy pine flatwoods and grassy savannas, often occurring in shallow standing water. "*Pinguicula ionantha* occurs in herb bog habitats embedded in longleaf pine savannas. Specifically, it is found between a lower elevation habitat dominated by pond cypress (*Taxodium ascendens*) overstory and a slightly higher elevation pine flatwoods dominated by an overstory of longleaf pine (*Pinus palustris*) (USFWS 2009) (NatureServe, 2015). High ecological integrity of the community and site fidelity and low tolerance ranges are inferred based on the species specific habitat needs.

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: No information found.

***Population Information and Trends*****Population Trends:**

Unknown (USFWS, 2018)

**Species Trends:**

Unknown (USFWS, 2018)

**Population Growth Rate:**

It is estimated that between 85 and 98% of herb bog/savanna habitats have been lost (Folkerts 1982 cited by Kesler et al. 2008). Decline of >70% (NatureServe, 2015)

**Number of Populations:**

~66. (approximately 54 occurrences on public lands and an additional 12 on private lands) (USFWS, 2023).

**Population Size:**

2500 - 100,000 individuals (NatureServe, 2015)

**Additional Population-level Information:**

Previously, 83 historical sites were documented between 1956 and 2009 (FNAI 2008). Based on information provided by FNAI (2017) and FWCC (2018) and recent surveys, the number of sites has increased to 92; technically representing 66 EOs. About 10,558 plants were present at 21 of the 23 EOs revisited in 2015 (Molano-Flores et al. 2014). A total of 52 sites were visited in 2006, 2008, and 2009 surveys: 33 sites were revisited by Kesler and Trusty (2008) during April 2006, and 19 sites were visited by Negrón-Ortiz during 2008 and 2009 surveys. Plants were present at 24 (46%) of these sites. Searches did not locate plants at 22 (42%) of the previously recorded sites. Additionally, high water or a dense woody midstory prevented access to six previously recorded sites in Gulf and Franklin counties (Kesler and Trusty 2008, Negrón-Ortiz, 2008 surveys). This species appears to be increasing in number of populations on public lands. However, overall trends in both abundance of individuals within each population and the total number of populations through the species range remain unknown. (USFWS, 2018)

**Population Narrative:**

Current survey information indicates an increase in the number of populations. Survey information shows 22 (33%) of the 66 EOs appear to be extirpated due to development and/or habitat modification. However, since surveys were conducted irregularly and based on either presence/absence and/or qualitative visual estimate (Jenkins et al. 2007); with most sites visited only once; and the actual counts of plants rarely provided, a comprehensive population survey is needed in order to better assess the current status of this species. Studies have demonstrated variation among the number of plants necessary for a population to survive risks of extinction (Given 1994, Matthies et al. 2004, Menges 1990). Matthies et al. (2004) study of 379 populations of eight threatened plant species in northern Germany demonstrated that very small populations face a considerable risk of extinction, while the risk for populations with more than 1000 individuals was very small. Because most of the *P. ionantha* populations have less than 1000 individuals, any impact to existing populations (specifically sites outside the ANF) could cause extirpation of these populations. Furthermore, the relatively low level of genetic diversity associated with this species is a concern as it may impair fitness and evolutionary adaptability in a changing environment (Zaya et al. 2016). (USFWS, 2018). Godfrey's butterwort is a carnivorous plant presently located in six Florida panhandle counties. The species' populations primarily found on Apalachicola National Forest and Tate's Hell State Forest. There are approximately 54 occurrences on public lands and an additional 12 on private lands. Most of the *P. ionantha* populations have less than 1000 individuals, therefore any impact to existing populations (specifically sites outside the Apalachicola National Forest) could cause loss of these

populations (USFWS, 2023).

### ***Threats and Stressors***

**Stressor:** Logging and Pulpwood Production (USFWS, 2018)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Privately owned forests managed (clearcutting, mechanical site preparation, and bedding) for commercial timber production, is a primary threat to *P. ionantha* habitat. An active paper mill located in Panama City (Bay County) receives timber from thousands of acres of pine plantation. The commercial timber industry in North Florida became well established in the 1850's (FNAI 2005). It started in Franklin County in the 1870's and continued to be a prominent industry until the mid-1990's (Howell and Hartsell 1995). The Timberland Company had close to a million acres in timber production in the eastern region of the Panhandle and they plan to continue to commercially harvest and replant off-site pine species. The Company also owned a paper mill in Port St. Joe until it was sold and shut down in 1999. In 2013, the Timberland Company sold more than 380,000 acres of its land to AgReserves, Inc.. The land sold included timberlands in Bay, Calhoun, Franklin, Gadsden, Gulf, Jefferson, Leon, Liberty and Wakulla counties. Within Gulf County, AgReserves, Inc. has repurposed timberlands into pasture lands for cattle (A. North, FDEP, 2/6/2018, pers. comm.). (USFWS, 2018)

**Stressor:** Coastal real estate and road development (USFWS, 2018)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Urban development continues to threaten Godfrey's butterwort. The Timberland Company is one of the largest private landowners in Florida, and one of the largest real estate operating companies in the Southeast. The Company develops both residential and commercial properties along roadways and near or within business districts in the region. More than a third of Florida's land is projected to be developed by 2070 along with a grow of about 33.7 million residents—almost 15 million more people than in 2010 (University of Florida GeoPlan Center 2017). Many *P. ionantha* locations are found along U.S. and state roads. Construction activity may directly kill individual plants or convert habitat to unsuitable habitat; widening may convert native habitat to managed road side; and culvert modification may change drainage patterns, which may change seasonal hydrology. Evidence suggests past road improvements have resulted in localized extirpation of Godfrey's butterwort in ANF (Kesler and Trusty 2008). Therefore, because they contribute to habitat loss, road widening and new roads continue to pose a threat to the species. (USFWS, 2018)

**Stressor:** Fire suppression (USFWS, 2018)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Suppression of fire during the growing season continues to threaten the pineland and savanna's flora, as fire is an important factor in the maintenance of flatwoods (Abrahamson and Hartnett 1990). Fire influences community structure and composition (Abrahamson and Hartnett 1990), and with insufficient frequency in longleaf pine communities, a woody midstory quickly

develops (Glitzenstein et al. 1995), negatively affecting the understory diversity. Several studies have shown that frequent, low intensity prescribed fire regimes are important for maintenance of flatwoods diversity (Hiers et al. 2007). Therefore, frequent prescribed burnings, i.e., < 3 yr interval, are needed to maintain optimal habitat for *P. ionantha* populations (Kesler et al. 2008). At present, the Apalachicola National Forest utilizes a 3- to 5-yr interval burn rotation (2-4 yr burn rotation at the burn units with *P. ionantha*, J. Drake, USFS, 02/21/2018, pers. comm.); Box-R WMA and SJBSBP utilize 2- to 3-yr interval; and Lathrop Bayou applies prescribed fire on a 2- to 7-yr interval. Thus, fire suppression continues to threaten to *P. ionantha* habitat and population numbers. Lack of fire, and subsequent growth of shrubs (particularly encroachment of *Cyrilla racemiflora* L., commonly known as swamp titi) and saplings in the understory, in addition to shading by planted pines, inhibits this species emergence (Negrón-Ortiz, 2008, pers. observ.; FNAI 2008, Kesler et al. 2008). Declining fire frequency reduces *P. ionantha* abundance in areas where it was previously observed in large quantities (FNAI 2008). Emergence of this species is prolific within one year of the fire event (Kesler and Trusty 2008). (USFWS, 2018)

**Stressor:** Over collection (USFWS, 2018)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** This factor is a threat, but the magnitude has been reduced. Butterworts are widely cultivated, grown and sold by plant enthusiasts and nurseries. *Pinguicula ionantha* was overcollected in the 1970s (58 FR 37440). Many thousands of plants propagated by tissue culture were sold without permits, but the plant is no longer commercially available in large quantities (D'Amato, California carnivores). In order to implement conservation measures and regulations, the Service granted a permit (TE061005-1) to the International Carnivorous Plant Society (ICPS) in 2003, which allows the society to sell seeds of endangered and threatened carnivorous plants only within the USA. Some restrictions apply to this permit (see <http://www.carnivorousplants.org/conservation/policies>); in addition, an annual report is required stipulating their selling activities. Collecting guidelines for live plants and seeds were developed by the ICPS: 1) they do not recommend collecting live plants unless it is for scientific purposes such as herbaria, the species has never been introduced to cultivation, or because a variant (a taxon exhibiting slight differences in form); 2) they will not accept field collected seed of listed plants, only seeds from cultivated plants will be accepted if they are donated in accordance with all relevant laws. The Nurseries Stock Restrictions manual summarizes the entry status of regulated plant material capable of or intended for propagation (USDA 2010). (USFWS, 2018)

**Stressor:** Hurricanes (USFWS, 2018)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Saltwater inundation from storm surges caused by hurricanes represents a threat. Kesler and Trusty (2008) monitored one population in Franklin County, which was flooded during Hurricane Francis in 2004. In 2005, they observed that the plant number declined from about 100 to two individuals. (USFWS, 2018)

**Stressor:** Sea Level Rise (USFWS, 2018)

**Exposure:**

**Response:****Consequence:**

**Narrative:** Sea level rise (SLR) as a result of climate change is a growing concern for much of Florida's coastline and the endemic species that occur there because about 10% of Florida is less than 1 meter above current sea level. Being endemic to Florida, Godfrey's butterwort is threatened by climate change. Using the NOAA Sea Level Rise and Coastal Flooding Impacts Viewer (<https://coast.noaa.gov/slr/>), the projections indicated potential impacts to six known *P. ionantha* EOs (Bay Co.: 1 EO; Franklin Co.: 5 EOs) by intrusion of saltwater beginning at one foot SLR. (USFWS, 2018)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2018)

**Exposure:****Response:****Consequence:**

**Narrative:** Section 7(b)(4) and 7(b)(2) of the Endangered Species Act (Act) generally do not apply to listed plant species. However, limited protection of listed plants from take is provided to the extent that the Act prohibits the removal and reduction to possession of Federally listed threatened and endangered plants or the malicious damage of such plants on areas under Federal jurisdiction, or the destruction of endangered plants on non-Federal areas in violation of State law or regulations or in the course of any violation of a State criminal trespass law. Seeds of both threatened and endangered species found on Federal land are regulated under the Act. However, the seeds of threatened species are not regulated if they come from cultivated plants (7 CFR 319.37.2, USDA 2008). Since *P. ionantha* is a threatened species, growers can obtain and sell seeds from other growers. Several populations of *P. ionantha* occur on private timberland and ROWs. While the Act requires Federal agencies to carry out programs for the conservation of endangered and threatened species, no such programs are stipulated for private landowners. The Act does not provide for protection of plants on private lands as long as the activity is permissible under state/local laws. The State requires permission of private landowners for collecting of State-listed plants from their property. *Pinguicula ionantha* is protected under Florida State Law, chapter 581.185: Preservation of native flora of Florida, which includes preventions of take, transport, and the sale of the plants listed under the State Law. The rule Chap. 5B-40, Florida Administrative Code, contains the "Regulated Plant Index" (5B-40.0055) and lists endangered, threatened, and commercially exploited plant species for Florida; defines the categories; lists instances where permits may be issued; and describes penalties for violations (Coile and Garland 2003). Bay County Comprehensive plan, under chapter 6, provides restrictions, constraints and requirements to protect and preserve designated habitat conservation areas for rare, threatened, or endangered species, and wetlands (<http://baycountyfl.gov/276/Planning-Zoning>). Calhoun, Gulf, Franklin, and Liberty Counties do not have such regulations. Highway ROW maintenance activities are not always reviewed for threatened and endangered species impact. However, if there is an activity (e.g., construction, mowing, or maintenance projects) affecting protected species, then the Service can recommend consultation to the FDOT under section 7 of the Act. The FDOT routinely consults with the Service on all major road construction activities. (USFWS, 2018)

**Recovery****Reclassification Criteria:**

Not relevant. (USFWS, 1994)

**Delisting Criteria:**

1. When 15 populations are adequately protected and managed throughout its historic range. Existing public land (mainly the Apalachicola National Forest) does not suffice for recovery). (USFWS, 1994)

**Recovery Actions:**

- Manage ROW Continue fostering conservation practices for utility and highway Right-of-Ways with the Forest Service, FDOT, and USFWS; a ROW Best Management Practices plan should be developed and implemented. (USFWS, 2018)
- Develop a stand-alone plan for managing listed plants at the Apalachicola National Forest and THSF, and integrate it to their Management Plan. (USFWS, 2018)
- Conduct a long-term study using 15 populations distributed throughout the species' historical range for 10 years to determine whether the observed declines in abundance reflect acceptable stochasticity or if they are indicative of dangerously declining populations. This study could use the sites from Kesler and Trusty (2008) study, and will address the delisting criterion. (USFWS, 2018)
- Since habitat loss and degradation are leading causes of endangerment for *P. ionantha*, designating habitat that is critical for survival and recovery is recommended. (USFWS, 2018)
- Complete a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) throughout the present distribution including all the historical locations to determine the species' status. (USFWS, 2018)
- Conduct surveys/inventories on potentially new sites. This action can include the use of aerials and species distribution modeling methods to initially determine potential sites, with subsequent field inventory of the site using a consistent, statistically valid, repeatable inventory method. If new populations are discovered, protection should be sought, and identify sites for reintroductions such as areas that will not be affected by SLR and future development (USFWS, 2018)
- Establish (or continue) frequent growing-season fire regimes (i.e., 2-3 yr interval) on selected areas such as Apalachicola National Forest, SJBSBP, THSF, and Tyndall AFB to maintain optimal conditions of *P. ionantha* populations. Re-visit sites shortly after a burn event, and mark and count individual plants. Populations tend to be more evident after a fire event. (USFWS, 2018)
- Garden propagation and reintroduction. An ex-situ plant collection should be actively pursued and implemented with a botanical garden. (USFWS, 2018)
- Investigate if there is a soil seed bank persistence of *P. ionantha* seeds throughout the species geographic range. (USFWS, 2018)
- Conduct population biology studies at Apalachicola National Forest. Compare the demographic performance of *P. ionantha* in pinelands and road habitats. Survey for seedling recruitment and survival of tagged individuals (plant height and reproduction) for a period of 3-5 years in or near roadside populations of SR 65 and pinelands. (USFWS, 2018)
- The recovery plan should be updated to define objective measurable criteria and better address the five listing factors.(USFWS, 2018)
- 1. Manage ROW
- 2. Since habitat loss and degradation are leading causes of endangerment for *P. ionantha*, designating habitat that is critical for survival and recovery is recommended (USFWS, 2009).

- 3. Evaluate the current species status (USFWS, 2009).
- 4. Conduct surveys/inventories on potentially new sites. This action can include the use of species distribution modeling methods to initially determine potential sites, with subsequent validation or inspection of the sites (USFWS, 2009).
- 5. Establish frequent growing-season fire regimes (i.e. 2-3 yr interval) on selected areas such as Tate's Hell State Forest, St. Joseph State Buffer Preserve, and ANF to maintain optimal conditions of *P. ionantha* populations. Re-visit sites shortly after burn event and mark individual plants. Populations tend to be more evident after a fire event (USFWS, 2009).
- 6. Garden propagation and reintroduction. An ex-situ plant collection should be actively pursued and implemented with a botanical garden. Studies on the viability of dry-stored seeds, the timing of the germination, and whether a persistent seed bank is present should be addressed (USFWS, 2009).
- 7. Conduct population studies at ANF (USFWS, 2009).
- 8. Conduct systematic studies to examine the current taxonomic classification (USFWS, 2009).
- 9. Conduct pollination studies (USFWS, 2009).
- 10. The recovery plan should be updated to define objective measurable criteria and better address the five listing factors (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES 1. Address the delisting criterion, 'adequately protect and manage 15 populations distributed throughout the species' historical range for 10 years'. This study could use the sites from Kesler and Trusty (2008) established plots. a. Continue the long-term monitoring ANF, Tyndall, and LB sites, and set up plots in SJSBP and THSF. b. As sea levels rise, seawater intrusion increases in duration, frequency, and spatial extent. To assess the effect of salinity on *P. ionantha*, sites where intrusion of salt water occurs should be considered for long-term monitoring. 2. Conduct surveys/inventories on potentially new sites. a. Calhoun and Wakulla counties. Historically, *P. ionantha* was documented in Wakulla and Calhoun. Therefore, surveys are strongly recommended in these counties within the habitat types or vegetation communities associated with the species. b. This action can include the use of aerials and species distribution modeling methods to initially determine potential sites, with subsequent field inventory of the site using a consistent, statistically valid, repeatable inventory method. If new populations are discovered, protection should be sought. 3. Manage ROW Continue fostering conservation practices for utility and highway ROWs with the Forest Service, FDOT, and USFWS; a ROW Best Management Practices plan should be developed and implemented. 4. Develop a stand-alone plan for managing listed plants at the ANF and THSF, and integrate it to their Management Plan. 5. Since habitat loss and degradation are leading causes of endangerment for *P. ionantha*, designating habitat that is critical for survival and recovery is recommended. 6. Complete a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) throughout the present distribution including all the historical locations to determine the species' status. 7. Establish (or continue) frequent growing-season fire regimes (i.e., <4 yr interval) on selected areas such as ANF, SJSBP, THSF, and Tyndall to maintain optimal conditions of *P. ionantha* populations. Re-visit sites shortly after a burn event, and mark and count individual plants. Populations tend to be more evident after a fire event. 8. Garden propagation and reintroduction. An ex-situ plant collection should be actively pursued and implemented with a botanical garden. In February 2016, 238 plants were removed from the F-22 Munitions Storage Complex on Tyndall AFB prior to new bunker construction and relocated to a wet prairie at Tyndall

AFB. Post-transplanting monitoring is ongoing since 2017. 9. Investigate if there is a soil seed bank persistence of *P. ionantha* seeds throughout the species geographic range. The following studies were inconclusive; therefore, better observations are needed to clarify the type of seed bank present in this species. A few points from these studies: • The lack of a persistent seed bank was suggested by Kesler et al. (2008), as they observed a 430-day delay in the population growth response of *P. ionantha* to dormant season fires. • Molano-Flores et al. (2014) found the emergence of two *Pinguicula* seedlings from soil collections, but identification to species was not possible because seedlings did not reach the flowering stage during the study. • Molano-Flores et al. (2021) subsequent seed germination and seed bank studies on multiple populations of *P. ionantha*, *P. lutea*, and *P. planifolia* suggest: o transplanting seedlings is not recommended unless moisture and humidity are retained, and root disturbance is minimized. o sprouted seeds of *P. ionantha* with emerging cotyledon, previously soaked in gibberellic acid solution and rinsed with distilled water, were transplanted to a soilless mixture but did not survive o 6 months post-collection seeds kept in cold storage for about 5 months have high potential for germination o viability potential of seeds in the seed burial trial was at least 2 months (that was the duration of their study) 10. Conduct population biology studies at ANF Survey for seedling recruitment and survival of tagged individuals (plant height and reproduction) for a period of 3-5 years in or near roadside populations of SR 65 and pinelands (USFWS, 2023).

## SPECIES ACCOUNT: *Pityopsis ruthii* (Ruth's golden aster)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 7/18/1985

### **Physical Description**

A perennial herb, 1-3 dm tall. The stems are leafy with grass-like leaves. Bright yellow flower heads bloom in late summer and fall (NatureServe, 2015).

### **Taxonomy**

Past taxonomic treatments of Ruth's golden aster, and golden asters in general, have involved frequent shifting of species among genera. Small (1897) described the species as *Chrysopsis ruthii* but subsequently transferred it to the genus *Pityopsis* (Small 1933), a genus characterized as those golden asters with graminiform (grass-like) leaves. This concept was rejected by Fernald (1942) who described the recognition of *Pityopsis* as "hardly worthwhile" and retained the species in *Chrysopsis*. Later, Shinnars (1951) included *Chrysopsis* in his concept of the genus *Heterotheca*. His treatment generally was accepted by Harms (1969), who published the combination *Heterotheca ruthii*, and by Bowers (1972b) and Cronquist (1980). Dress (1953), in his study of the eastern *Chrysopsis*, continued to follow Small's 1933 nomenclature (except in the case of the *Pityopsis graminifolia* complex). Semple (1977), Semple et al. (1980), and Semple and Bowers (1985) reaffirmed *Heterotheca*, *Chrysopsis*, and *Pityopsis* as distinct genera. Semple's work is widely accepted, and Ruth's golden aster will be referred to here as *Pityopsis ruthii* (Small) Small. It is instructive to note that no student of the genus has questioned the validity of the species, only the proper generic designation (USFWS, 1990).

### **Historical Range**

See current range/distribution.

### **Current Range**

Known only to occur along short reaches of the Ocoee and Hiwassee River, Polk County, Tennessee (USFWS, 2018).

### **Critical Habitat Designated**

Yes;

### **Life History**

### **Food/Nutrient Resources**

### **Reproduction Narrative**

Adult: Reproduction in natural populations is attributed to stem regeneration or tillering of the subaerial root-rhizome crown (Wofford and Smith 1980). This agrees with White (1977), who stated that the chief method of reproduction is by existing rhizomes. White observed no seedlings in the field and concluded that *P. ruthii* has difficulty becoming established on the phyllite boulders. His comparison of plants from the Hiwassee River population with those grown for his greenhouse studies showed an average of 50 achenes and 58 achenes per flowering head, respectively. Typically, 18 percent of those achenes from the wild population

were filled (i.e., viable) compared to 19 percent from the greenhouse populations. Although White (1977) presented no figures on percentage germination of the filled achenes he sowed during his greenhouse study, he indicated that 62 percent of the *P. ruthii* seedlings resulting from the 960 filled achenes sown survived their first 3 weeks. It is suggested that a combination of wind and nonselective foraging by insects could account for the low percentage of filled achenes (Wofford and Smith 1980). No studies of pollinators or of pollination in *P. ruthii* have been performed. However, in the field, Bowers (1972a) noted several kinds of bees visiting the flowers of various members of the section *Pityopsis* (including *P. ruthii*), and in the greenhouse he observed occasional visits by flies to the flowers of the same species. He determined that members of the section *Pityopsis* are obligate outcrossers and that self-fertilization and apomixis seldom, if ever, occur. He also concluded that wind is of little importance in pollination. White (1977), while collecting soil samples in the field, observed numerous ant colonies sharing the same crevices with *P. ruthii*. He suggested there may be a relationship between the presence of the ants and the establishment of *P. ruthii* but made no further investigation of this potential relationship. Production of low numbers of viable seeds could easily contribute to difficulties in the establishment of new plants. Ineffective dispersal methods also could be a contributing factor. While Wofford and Smith (1980) stated that "age class determinations indicate only mature individuals are present," there was evidence that regeneration from seeds is occurring. In an ongoing study of *P. ruthii*, Collins and Gunn (1986) observed one subpopulation on the Hiwassee River comprising 1,149 individual plants. Relative to other subpopulations measured in 1986 and 1987, a greater preponderance of those plants were small and single-stemmed and were not located near enough other larger plants to have come from rhizomes. The same subpopulation was measured the next year (Collins and Gunn 1987), and 307 fewer individuals were found, perhaps the victims of stress from severe drought. Apparently many of the absent individuals were the small, single-stemmed plants recorded the prior year. It is possible that many of those plants were young seedlings, not yet vigorous enough to withstand the extreme conditions at the time. Furthermore, a great many more individuals not producing flowering heads were seen than were found by Wofford and Smith (1980). The extent and significance of predation upon *P. ruthii* are not known. White (1977) observed predation by the larvae of three moth species on plants in the greenhouse. In the field, Collins and Gunn (1986) also have observed insect larvae apparently feeding on the achenes in the maturing heads of some plants (USFWS, 1990).

**Habitat Type**

Adult: The species is restricted to outcrops of phyllite (rarely greywacke) within 5.7 km (3.5 mi) and 4.6 km (2.9 mi) reaches of the Hiwassee and Ocoee Rivers, respectively (USFWS, 2018).

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

**Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits soil-filled cracks in phyllite boulders along river banks and in rivers, within 5.7 km (3.5 mi) and 4.6 km (2.9 mi) reaches of the Hiwassee and Ocoee Rivers, respectively (USFWS, 2018). Shade intolerant but adapted to annual high water flows; requires periodic flooding and scouring to remove competing vegetation (NatureServe, 2015). High ecological integrity of the community and site fidelity along with low tolerance ranges are noted based on the species specific habitat requirements and the relatively low number of populations (NatureServe, 2015).

### ***Dispersal/Migration***

#### **Motility/Mobility**

Adult: Low (inferred from USFWS, 1990)

#### **Dispersal**

Adult: Low (inferred from USFWS, 1990)

#### **Dispersal/Migration Narrative**

Adult: No study of fruit dispersal has been made, but the pappus is disposed to dissemination by wind. According to Wofford and Smith (1980), dispersal also is achieved by water. They regarded effective dispersal as rare, based on the paucity of observations of seedlings in nature, but provided no supportive data (USFWS, 1990). Low mobility and dispersal are inferred based on rare effective dispersal of the species.

### ***Population Information and Trends***

#### **Population Trends:**

Stable to decreasing (USFWS, 2018)

#### **Species Trends:**

Decreasing (USFWS, 2018)

#### **Number of Populations:**

2 (USFWS, 2023)

#### **Population Size:**

~100,000 total individuals (USFWS, 2023)

#### **Population Narrative:**

As of 2017, the population from the Ocoee River was relatively stable from 2011 through 2017 ranging from a low of 1,140 during 2011 to a high of 1,299 individuals in 2015. As of 2017, there were 1,232 individuals, an overall increase of 82 individuals (7.2 percent) compared to the baseline census in 2011. Data collection on the Hiwassee River has occurred at a total of 57 sites, but only 27 sites have been counted annually. These 27 sites account for more than 90 percent of all plants counted in each year from 2011 through 2017, thus are representative of trends for the population on this river. Data from the Hiwassee demonstrate that a period of increase occurred from 2011 through 2014, followed by decreases through 2017. Using data from the 27 sites counted annually, as of 2017 there has been a decrease of 1,676 individuals (17.6 percent) compared to the 2011 baseline and a decrease of 4,125 individuals (34.5 percent)

since 2014, when the population peaked (USFWS, 2018). A study from 2013 showed moderate genetic diversity in three populations sampled and a study from 2018 determined that gene flow levels among populations within each river were sufficient to reduce risk of divergence due to genetic drift. The species is restricted to two populations located along short reaches of the Hiwassee and Ocoee rivers, in Polk County, Tennessee. Available data indicate that the Ocoee River population has increased by approximately 20 percent since 2011, to a total of 1,388 individuals in 2022. While it is the larger of the two populations, the species abundance in the Hiwassee River population has decreased by approximately 10 percent since 2011, to a total of 8,968 individuals in 2022 (USFWS, 2023).

### ***Threats and Stressors***

**Stressor:** Encroachment of competing vegetation (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** There are concerns about the loss of habitat in the Hiwassee drainage to encroachment of competing herbaceous and woody vegetation. A Biological Assessment prepared by TVA (2002) discussed the threat posed to the Hiwassee population by vegetation encroachment onto the phyllite boulders due to altered flows in the river below Apalachia Dam since its construction in 1943. They identified this threat as the cause for the observed decline of *P. ruthii* since monitoring began in 1986. Several lines of evidence support this conclusion, including the general declining trend in the Hiwassee population since monitoring began, the finding of Thomson and Schwarz (2006) that all Hiwassee populations suffered mean negative growth rates except for one plot from which vegetation had been removed in the past, and Cruzan's (2000) observation that vegetative cover in the Hiwassee floodplain has increased approximately 50 percent since the late 1940s (USFWS, 2012). Continued encroachment and habitat reduction contributes to decreases in *P. ruthii* in some sites. As abundance decreases, pollinator attraction could decrease, potentially creating a negative feedback loop reducing reproductive output and contributing to further declines (USFWS, 2018).

**Stressor:** Altered flow regimes (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Altered flow regimes (due to the Apalachia dam) and encroachment of competing vegetation into suitable habitat in the Hiwassee drainage remain the greatest active threats for *P. ruthii*. Because the process of vegetation encroachment has occurred over a period of several decades, riparian communities have become established on the phyllite boulders to the extent that periodic high flows alone would not be enough to remove this threat and restore *P. ruthii* habitat (USFWS, 2012). Maintenance work in 2015-2016 on the Apalachia powerhouse and switchyard caused elevated flows for 132 days in the Hiwassee River where *P. ruthii* occurs and a decline in this population was observed. Drought conditions also occurred during part of 2016, which could also account for the decline in the observed Ocoee River population (USFWS, 2018).

**Stressor:** Recreation (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:** Loss of individual plants

**Narrative:** The development of a whitewater recreation facility on the Ocoee River and hosting of whitewater events during the 1996 Olympics elevated concerns about recreation-related impacts to *P. ruthii*, both from whitewater paddlers and spectators. The USFS-CNF recommended corrective measures to reduce recreation-related impacts at two sites (Doublesuck and Tablesaw) where they were found to be greatest (Herrig and Wyrick 1996). The threat of trampling by spectators at the Tablesaw site was reduced by the extension of a guardrail on the nearby highway, eliminating parking access in close vicinity to this population. However, no billboard or kiosk has been constructed at the access point for paddlers upstream of Doublesuck, to inform paddlers of the presence of *P. ruthii* and biologically sensitive areas near particular whitewater features (USFWS, 2012). No adverse effects from whitewater recreationists or observers have been reported since 2015 (USFWS, 2018).

**Stressor:** Road construction (USFWS, 2018)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The Tennessee Department of Transportation is currently analyzing transportation alternatives for Corridor K, which passes through the Ocoee River Gorge and based on a preliminary map of targeted spot improvements, some of the road construction would occur along US HWY 64 where it parallels sites on the Ocoee River that *P. ruthii* occupies. A Section 7 consultation has not been completed and therefore the potential for adverse effects to *P. ruthii* that could result from implementing the Targeted Approach have not been analyzed (USFWS, 2018).

**Stressor:** Disease or predation (USFWS, 2018)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Five potential invertebrate herbivores have been observed on *P. ruthii* in situ and ex situ plants and can damage flower buds and developing seeds (USFWS, 2018).

**Stressor:** Hybridization (USFWS, 2018)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The potential for hybridization to occur between *Heterotheca ruthii* (= *P. ruthii*) and *H. graminifolia* (= *P. graminifolia* var. *latifolia*) was first documented by Bowers (1972), in a cross that produced only two seeds, one of which germinated and died within a week. Moore et al. (2016) report that P.A. Wadl (unpublished data) produced viable offspring from controlled crosses between these species. Recent evidence (Boggess 2013, Hatmaker et al. 2018, P. Wadl 2018, pers. comm.) indicates that wild hybrids may be formed where these two species co-occur. Hybridization could present a threat to reproductive output and genetic variation (USFWS, 2018).

**Stressor:** Climate change (USFWS, 2018)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Using NatureServe's Climate Change Vulnerability Index (CCVI) to assess *P. ruthii*'s predicted exposure to climate change, the species was ranged as highly to extremely vulnerable indicating that abundance and/or range extent or are either likely to decrease significantly (highly vulnerable), or extremely likely to substantially decrease or disappear (extremely vulnerable), by 2050 (Young et al., 2015)(USFWS, 2018). Drought experienced in 2016 and 2017 contributed to declines of this species and very likely reduced seedling establishment given that seedling emergence has been observed to occur beginning in November (USFWS, 2018).

### **Recovery**

#### **Delisting Criteria:**

The Ocoee River population, under the criteria described in or to be established by implementation of Task 7, is deemed recovered and the rate of natural succession on the phyllite boulders on the Hiwassee River is determined to not be detrimental to the survival of *P. ruthii* (USFWS, 1990).

The Hiwassee River population, under the criteria described in or to be established by implementation of Task 6, is deemed recovered and Tasks 7.2, 7.3, 7.4, and 7.6 are accomplished for the Ocoee River population.

*Pityopsis ruthii* shall be considered recovered when the full set of recovery goals (Tasks 6 and 7) for each population is fulfilled (USFWS, 1990).

#### **Recovery Actions:**

- 1. Maintain formal agreements among the appropriate concerned agencies on the preservation of *Pityopsis ruthii*.
- 2. Maintain permanent plots.
- 3. Determine what is necessary for effective and successful achene dispersal. seed germination, and seedling establishment. 3.1 Study achene dispersal. 3.2 Determine life history. seed germination, and seedling establishment requirements. 3.3 Determine the role of interspecific and intraspecific competition.
- 4. Determine what constitutes suitable habitat.
- 5. Search for *Pityopsis ruthii* on other rivers.
- 6. Determine and implement for the Hiwassee River population the management necessary for long-term reproduction, maintenance, and vigor. 6.1 Determine and compare Past and present stream flow regimes. 6.2 Determine the nature and role of natural succession on the phyllite boulders. 6.3 Determine whether or not the population is self-sustaining. 6.4 Establish *P. ruthii* on unoccupied suitable habitat. 6.5 Establish a cultivated population of plants descended from the Hiwassee River population and provide for long-term seed storage. 6.6 Determine feasibility and/or necessity of water releases and hand-clearing of phyllite boulders (USFWS, 1990).
- 7. Determine and implement for the Ocoee River population the management necessary for long-term reproduction, maintenance, and vigor. 7.1 Study the relationship of the river to *P. ruthii*. 7.2 Determine impacts of river recreational users and implement required management actions. 7.3 Ensure that highway construction will not damage or destroy plants or suitable habitat. 7.4 Determine whether the population is self-sustaining. 7.5 Establish *P. ruthii* on unoccupied suitable habitat. 7.6 Establish a cultivated population of

plants descended from the Ocoee River population and provide for long-term seed storage (USFWS, 1990).

- 8. Variability in population trends among sites in the Hiwassee River suggests that demographic monitoring of selected sites would be useful in understanding which life history stages are most affected by threats to the species and its habitat. Demographic monitoring will be necessary for evaluating effectiveness of any future efforts to reintroduce the species into suitable unoccupied habitat (USFWS, 2018).
- 9. Future restoration projects should explore effects of planting season and importance of mycorrhizal associations on establishment, survival, growth, and reproduction of introduced plants. Additionally, if restoration into suitable habitat is to be successful, multiple outplantings over time likely will be necessary at any given site (USFWS, 2018).
- 10. For each mapped location on the Hiwassee River, record data on apparent vulnerability to vegetation encroachment, including observations on substrate composition (e.g., bedrock, boulder, cobble, gravel, degree of sediment deposition), landform and aspect. Use these data to map risk of local extinction and assess whether and where management is needed to control vegetation encroachment (USFWS, 2018).
- 11. Incorporate observations on presence and relative abundance of *Pityopsis graminifolia* var. *latifolia* at monitoring sites, to document locations where potential threat of hybridization is greatest (USFWS, 2018).
- 12. Coordinate with TDOT to avoid potential adverse effects to *P. ruthii* from road construction activities on US HWY 64 (USFWS, 2018).
- The primary actions needed to move *P. ruthii* towards a status at which downlisting or delisting could be considered, include: 1. Determining effective methods for controlling vegetation encroachment and restoring degraded habitat in the Hiwassee drainage (USFWS, 2012).
- 2. Implementing a vegetation control and habitat restoration program to restore suitable habitat conditions across the occupied range in the Hiwassee drainage. For long-term prevention of repeated vegetation encroachment, altering flows to provide sufficient frequency and duration of scouring of phyllite boulders will likely be necessary (USFWS, 2012).
- 3. Analyzing and comparing contemporary flow regimes (i.e., since 1943) on the Hiwassee River to pre-impoundment flow regimes (USFWS, 2012).
- 4. Conducting future surveys of *P. ruthii* populations in the Hiwassee drainage in order to assess (1) the degree to which suitable habitat for the species declines due to vegetation encroachment and (2) whether the species' linear distribution along the Hiwassee River changes over time (USFWS, 2012).
- 5. Developing effective reintroduction methods for establishing *P. ruthii* in suitable habitat, in order to fulfill recovery tasks 6.4 and 7.5 (USFWS, 2012).
- 6. Ensuring that recommendations for controlling whitewater recreation-related threats to the Ocoee population are implemented (USFWS, 2012).
- 7. Continuing long-term monitoring effort that has been implemented by TVA, USFS-CNF, and TDEC (USFWS, 2012).
- 8. Continuing annual meetings of the RCWG to coordinate recovery efforts (USFWS, 2012).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES Recovery Activities In the absence of river flows sufficient to regulate vegetation encroachment in many sites where *Pityopsis ruthii* occurs along the Hiwassee

River, it could be necessary to develop effective approaches for mechanical or chemical control to prevent the species' displacement from some sites where this threat of encroaching vegetation is most aggressive. It would likely be infeasible to conduct such intensive management at the scale of the entire occupied reach, owing to the remoteness of the area and other environmental considerations (e.g., presence of endangered mussel species and designated critical habitat in this reach of the Hiwassee River). A management plan identifying the areas under the greatest threat and that guides incremental habitat restoration over a period of several years, however, may need to be developed in order to advance recovery of the species at a biologically meaningful scale. Additionally, flow prescriptions could be developed to regulate vegetation encroachment and enhance *P. ruthii* habitat, as discussed below.

**Monitoring and Research Activities**

The 2012 and 2018 5-year status reviews for *Pityopsis ruthii* discussed at length how a better understanding of artificially regulated river flows in the Hiwassee River and their influence on *P. ruthii* population growth could inform the development and implementation of more ecologically compatible flow prescriptions. The presumed importance of river flows that inundate occupied *P. ruthii* habitats at a frequency sufficient to regulate encroachment of competing herbaceous and woody vegetation are discussed in the species recovery plan, which calls for an analysis of contemporary and historical flow regimes to understand how flow alterations have contributed to changes in riparian vegetation conditions and availability of suitable sites for *P. ruthii*. Hydrological reference conditions for the Hiwassee River, however, are unavailable prior to the closing of Apalachia Dam. An alternative approach for understanding how flows interact with vegetation and suitable sites for *P. ruthii* would be to adapt a methodology used for assessing effects of river flows on another species in the family Asteraceae, beautiful Barbara's buttons (*Marshallia pulchra*) (Tracey and Simmerman 2021). These methods could be adapted to investigate relationships between discharge, depth and duration of inundation, and response of *P. ruthii* and the associated vegetation community to compare these dynamics for the Hiwassee River to the Ocoee River, where conditions have supported population increase for more than a decade of monitoring. With a better understanding of the relationship between river flows, habitat inundation, and *P. ruthii* population responses in both river systems, it might be possible to prescribe a flow regime that would support population growth in the Hiwassee River population. A collaborative effort leveraging the authorities and resources of multiple partners, such as the U.S. Fish and Wildlife Service, Tennessee Valley Authority (TVA), American Whitewater Association, US Forest Service, and Tennessee State Parks, could potentially take on such an investigation to advance the status of the species (USFWS, 2023).

## SPECIES ACCOUNT: *Plagiobothrys hirtus* (rough popcornflower)

---

### *Species Taxonomic and Listing Information*

**Commonly-used Acronym:** Plhi

**Listing Status:** Endangered; Pacific Region (R1) (USFWS, 2016)

### **Physical Description**

Rough popcornflower plants are between 7 centimeters (cm) (2.75 inches [in]) to 60 cm (23.6 in) tall, with narrow, simple hairy-margined bright-green leaves along hairy stems. The non-fragrant flowers consist of five fused petals, are trumpet-shaped, mostly white with yellow centers, and positioned in a hairy calyx. The flowers are helicoid in development and occur on paired coiled inflorescences. Each flower produces four tan to black-colored, one-seeded nutlets, which loosely adhere to the receptacle, until they drop. These nutlets will germinate readily (Amsberry and Meinke 2002, p. 24). However, due to fruit abortion or lack of pollination, flowers with fewer than four nutlets are often observed. As in most members of the Boraginaceae family, anthers are included and epipetalous (having stamens attached to the inner corolla surfaces). Rough popcornflower can be either an annual or a short-lived perennial. Rough popcornflower exhibits two distinct growth forms in the northern and southern portions of its range in Douglas County. In the northern part of its range near Yoncalla, the plants are more robust, slightly taller, and predominantly perennial (Figure 1). Here rough popcornflower has the ability to produce adventitious roots that easily establish in the moist soil of their wetland habitats. In the southern part of the range, 25.8 kilometers [km] (16 miles [mi]) south of the Yoncalla population, from the general area of Sutherlin to Wilbur, the population include annual plants, often in clusters, with a few sporadic perennial plants. The rough popcornflower and fragrant popcornflower (*P. figuratus*) are found in similar wetland habitat in northern Douglas County. Both are members of the subgenus *Allocarya* (Peck 1961, p. 66), and are quite similar in appearance. Rough popcornflower differs from fragrant popcornflower in that the entire plant is larger and has less fragrant flowers, hairier stems and fruits, more robust stems, and blooms several weeks later. The larger rough popcornflower plants grow with more arched stems as well. A stout, hairy (on the upper part of the stems) annual, 3-6 dm tall, with long, narrow leaves and white flowers. Blooms primarily from mid to late June. (NatureServe, 2015)

### **Taxonomy**

*Allocarya hirta* Greene was the original scientific name applied to the species in 1888. Since then, the species has undergone a number of taxonomic re-arrangements, including *Allocarya scouleri* var. *hirta*, *Allocarya calycosa*, and *Plagiobothrys scouleri* var. *hirtus*. Since the 1961 edition of *Plants of Oregon*, it has remained *Plagiobothrys hirtus* (Peck 1961, p. 661), and this classification is recognized as valid by the U.S. Department of Agriculture Plants Database (U.S. Department of Agriculture 2018, website) and the Integrated Taxonomic Information System (Integrated Taxonomic Information System 2019, website).

### **Historical Range**

Rough popcornflower is found only in northern Douglas County, Oregon, occurring at low elevations (100 and 230 meters (m) [328 to 755 feet (ft)]) within the Umpqua River basin, distributed in the Elk Creek, Umpqua River, and Lower North Umpqua River watersheds.

**Current Range**

Rough popcornflower has been documented at 23 populations historically; 18 are extant and 5 are extirpated. Five of the known populations occur on private land and lack monitoring access. Despite this, the species is estimated to have greater than 883,154 mature, reproductive individuals across its range. Of the 18 extant populations, 1 is very large (700,000 plants), 10 are relatively large (5,000-70,000 plants), 4 are medium (1,000-4,999 plants), and 3 are small (less than 1,000 plants). While smaller populations, in general, are more vulnerable to extirpation from stochastic events and genetic drift than larger populations (Szczecińska et al. 2016, p. 17; Ma et al. 2013, p. 805), the majority of rough popcornflower populations support more than 5,000 individuals and we believe are less susceptible to stochastic events and genetic issues.

**Critical Habitat Designated**

No;

**Legal Description**

NA

***Life History*****Food/Nutrient Resources****Competition**

Adult: Competes with both invasive and native plants

**Food/Nutrient Narrative**

Adult: water availability is dependent on annual weather patterns and heavy clay soils

**Reproductive Strategy**

Adult: r strategy, species relies on outcrossing but can self if necessary

**Reproduction Narrative**

Adult: Popcornflower can be a perennial, growing to 70 cm tall (27.5 inches), with dozens of flowering stems and hundreds of flowers, or can be a diminutive annual with only a few flowers (Amsberry and Meinke 2001). At Popcorn Swale Preserve, rough popcornflower generally reaches peak growth and flowering by mid-June. By July 1, many plants have dropped seed and are senescing. By July 15, rough popcornflower generally appears gray-brown and crispy although a rare flower or two may be found low to the ground in moister, shaded areas. Although most plants are dormant by mid-July, perhaps around 1% of individuals may still be green and actively growing and flowering. Rough popcornflower, like most borages, can potentially produce four nutlets per flower. In most sites, copious numbers of mature seeds were observed from mid-June through early September, but plants in a few wetter habitats delayed seed maturation until the beginning of August. The number of seeds produced by individual plants is largely controlled by the number of flowers produced, and correspondingly, large plants produce more flowers (USFWS, 2016). Pollination biology of rough popcornflower is not well documented but we are not currently considering lack of pollination or seed production a stressor, but are more concerned with connectivity and habitat quality since pollination is dependent of habitat corridors of an adequate variety of native and non-native plants (habitat quality). We know that the typical high seed set indicates that pollination is highly successful

since the flowers are visited by a diverse group of generalist pollinators, and that pollination is not currently a limiting factor for this species. Connectivity and habitat quality is essential to ensure that genetic exchange is taking place within and among populations by these pollinators (U.S. Fish and Wildlife Service 2003, p. 54). (USFWS, 2021b)

**Habitat Type**

Adult: River valley wetlands (USFWS, 2016)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from USFWS, 2016)

**Environmental Specificity**

Adult: Very narrow to narrow. (Natureserve, 2015)

**Habitat Narrative**

Adult: Rough popcornflower is a plant closely associated with seasonally wet, relatively level, open habitats in Douglas County formed from poor draining clay-loam soils, concentrated in the Sutherlin Creek basin in Oregon. These wet habitats are unique to the Sutherlin area and correspond to a particular type of soil series known as Conser silty clay-loam. The majority of rough popcornflower populations largely correspond to Conser soils, which is a poorly draining silty clay-loam series soil. To a lesser extent, the species occurs on clay or loam soils including Bashaw clay, Brand silty clay loam, Curtin clay, Dixonville silty clay loam, Nonpareil loam, Oakland clay-loam, Packard silty loam, Philomath-Dixonville complex, Sibold clay, and Waldo silty clay loam soil types. Rough popcornflower habitat corresponds to emergent wetlands within seasonally wet meadows or prairie, seasonally-ponding mudflats, and Oregon ash (*Fraxinus latifolia*) swale openings dominated by native wetland-associated herbs and graminoids in valley lowlands where the ground is moist well into the summer season. The species appears to be adapted to early seral succession habitat so it does not often occur under dense shade. Native perennial plant species commonly associated with rough popcornflower habitat include Oregon ash, dense sedge (*Carex densa*), green-sheathed sedge (*C. feta*), one-sided sedge (*C. unilateralis*), spreading rush (*Juncus patens*), pointed rush (*J. oxymeris*), common rush (*J. effusus*), tufted hairgrass (*Deschampsia cespitosa*), great white camas (*Camassia leichtlinii*), rush-leaved coyote thistle (*Eryngium petiolatum*), Willamette gumweed (*Grindelia integrifolia*), and western mannagrass (*Glyceria occidentalis*). Native annuals commonly associated with rough popcornflower include American sloughgrass (*Beckmannia syzigachne*), skullcap speedwell (*Veronica scutellata*), Cascade calicoflower (*Downingia yina*), and Douglas meadowfoam (*Limnanthes douglasii*). Common invasive plant associates in rough popcornflower habitat include trees (e.g. European pear [*Pyrus communis*]); shrubs (e.g. Armenian blackberry [*Rubus armeniacus*] and English hawthorn [*Crataegus monogyna*]); herbaceous plants (e.g. meadow knapweed [*Centaurea moncktonii*], teasel [*Dipsacus fullonum*], Canada thistle [*Cirsium arvense*], pennyroyal [*Mentha pulegium*], and curly dock [*Rumex crispus*]); and graminoids (e.g. reed canarygrass [*Phalaris arundinacea*] and tall fescue [*Schedonorus arundinaceus*]). Pennyroyal and tall fescue are nearly always present in or around rough popcornflower habitat. Rough popcornflower appears to be a species that requires early seral habitat and is not associated with habitat under dense tree or shrub canopies. Grazing helps to control invasive and native plant competitors and provides a measure of disturbance that maintains the preferable more-early seral and open habitat conditions for rough popcornflower. Flooding, fire, and native ungulate grazing, also likely

played a large role in the development and maintenance of habitat for the plant (U.S. Fish and Wildlife Service 2000, p. 3867). When such natural disturbance events are lacking, active management is necessary to control competing vegetation and maintain requisite conditions for this plant to compete with naturally occurring and non-native plant species. An increase in abundance of Oregon ash or spreading rush can result in a loss of rough popcornflower habitat without mowing, grazing, or fire to restore habitat suitability (USFWS 2021).

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Has increased from 8 populations at the time of listing to 18 populations. (USFWS 2021).

**Resiliency:**

We assessed habitat conditions for rough popcornflower in terms of habitat area, population size, habitat quality, connectivity, management, protection, reproduction, abundance of insect pollinators, and rainfall. Of the 18 total rough popcornflower populations, 11 had a higher probability of persistence, 3 had a moderate probability of persistence, and 4 had a low expected persistence over the next 30 years. (USFWS 2021)

**Representation:**

An abundance of insect pollinators and habitat connectivity leads to genetic diversity by the process of cross-pollination between patches within a population. There is a need to maintain the genetic variation between populations as their potential genetic and life history attributes may buffer the species to adapt to environmental changes over time. At this time, we do not know the degree of genetic variation among rough popcornflower populations and whether connectivity and active genetic exchange is occurring across populations and within patches or within populations. Most rough popcornflower populations are not isolated from one another by over 2.0 km (1.24 miles) and it is assumed that gene flow occurs among the majority of the population. (USFWS 2021)

**Redundancy:**

Rough popcornflower requires multiple resilient populations distributed throughout its range to provide for redundancy. The more populations, and the wider the distribution of those populations, the more redundancy the species will exhibit. Redundancy reduces the risk that a large portion of the species' range will be negatively affected by a catastrophic natural or anthropogenic event at a given point in time. (USFWS 2021)

**Population Growth Rate:**

From 7,000 individuals at the time of listing has increased to a total population estimate of over 883,154 individuals. (USFWS 2021).

**Number of Populations:**

18 are extant and 5 are extirpated. (USFWS 2021)

**Population Size:**

883,154 individuals (USFWS 2021)

**Minimum Viable Population Size:**

Although a minimum viable population hasn't been determined, based on studies by Lande (1995) and Lynch et al. (1995) we have recommended the recovery level population size for rough popcornflower as 5,000 plants per population. This figure is based on the authors' suggestion that in most cases, 5,000 individuals in a population, is necessary to maintain above normal levels of potentially adaptive genetic variability under a balance between mutation and random genetic drift. Without a Population Viability Analysis (PVA) to indicate what an optimal abundance level should be, using our best professional judgement, we consider a population with over 5,000 mature plants to be in high condition, over 1,000 plants to be in medium condition, and under 200 plants to be in low condition.

**Adaptability:**

We have no documentation of rough popcornflower's adaptability. Maintaining representation in the form of genetic or ecological diversity will provide rough popcornflower the capacity to adapt to future environmental changes.

**Population Narrative:**

Rough popcornflower has been documented at 23 populations historically; 18 are extant and 5 are extirpated. All known populations (naturally occurring and reintroductions) occur in Douglas County, OR. Five of the known populations occur on private land and lack monitoring access. Despite this, the species is estimated to have greater than 883,154 mature, reproductive individuals across its range. Of the 18 extant populations, 1 is very large (700,000 plants), 10 are relatively large (5,000-70,000 plants), 4 are medium (1,000-4,999 plants), and 3 are small (less than 1,000 plants). The majority of rough popcornflower populations support more than 5,000 individuals and we believe are less susceptible to stochastic events and genetic issues. Through extensive surveys and augmentation and introduction efforts, the 7,000 individuals within 8 populations known at the time of listing has increased to 18 populations, with a total population estimate of over 883,154 individuals. The bulk of this estimate includes a single extensive rough popcornflower population south of Sutherlin, which has not been adequately censused but may have as many as 700,000 individuals.

**Threats and Stressors**

**Stressor:** Competition (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Stressors to rough popcornflower habitat include encroachment by Oregon ash and European pear, Armenian blackberry and English hawthorn, pennyroyal, teasel, Canada thistle, curly dock, spreading rush and reed canarygrass), which compete for moisture, light, and space. Pennyroyal is nearly always present in rough popcornflower habitat and is an ever-present competitor. (USFWS, 2021, p. 17).

**Stressor:** Development (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Development was described as a serious stressor to rough popcornflower. In addition, habitat can become degraded by both channelization (e.g. ditching) and filling of wetland habitat.(USFWS,2021, p. 17)

**Stressor:** Agriculture (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The species appears to be adapted to early seral succession habitat and cannot compete with later successional vegetation such as Oregon ash, rushes, and tall fescue for light, moisture, and space. Stressors to rough popcornflower habitat include encroachment by Oregon ash and European pear, Armenian blackberry and English hawthorn, pennyroyal, teasel, Canada thistle, curly dock, spreading rush and reed canarygrass), which compete for moisture, light, and space. Pennyroyal is nearly always present in rough popcornflower habitat and is an ever-present competitor.

**Stressor:** Fire suppression (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Fire suppression resulting in encroaching native oaks and ash trees that shade popcornflower and reduced gene flow due to habitat fragmentation are considered to be other threat factors (USFWS 2010).

**Stressor:** Urban and Rural Development (USFWS, 2021b)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Urban and Rural Development. The final listing decision (U.S. Fish and Wildlife Service 2010, p. 3869) described how rough popcornflower populations had become fragmented due to draining and filling of wetlands from properties being developed, primarily in the city of Sutherlin area. For example, between 1995 and 2002, four rough popcornflower populations were either heavily impacted or lost due to urban development, mostly prior to the species' listing. Currently, we consider urban development in the general vicinity of Sutherlin (within and just beyond the Urban Growth Boundary) as a threat to four populations (Hawthorne, Southside Swale, Sutherlin East, and Stearns Lane). However, 11 of the 18 populations (151,195 of 883,154 total plants) throughout the species' range are under Federal, State, municipal, or land trust protections providing for the long-term persistence of these populations. At other privately owned populations on rural pasturelands (Horsepasture 2, Nonpareil), long-term persistence has been documented for over 30 years. Additionally, developers, State and Federal wetland regulators, and city and county governments are doing an increasingly better job of recognizing rough popcornflower habitat and avoiding and minimizing (or mitigating) development impacts. Because the majority of the population is protected and the species is benefitting from increased awareness, the threat posed by development has been significantly diminished. Nine rough popcornflower populations occur on Federal, State and Municipal owned lands, where management of the species is directed by species-specific management plans and regulations (Table 2). Rough popcornflower is distributed across properties with a mix of ownership (Table 2) and land use practices. These land use practices on privately owned land may or may not be

consistent with rough popcornflower conservation. For example, while some landowners mow rough popcornflower during its growing period, seed with non-native pasture grass, and use selective herbicides to promote hay or agricultural crops (i.e., practices that can be detrimental to the species), other landowners are interested in conserving the species, mow, and graze when competition with invasive non-native species is problematic for the species. As discussed above in the Habitat section, some forms of land use practice can be beneficial to the species. The fact that lands are held in private ownership in and of itself does not constitute a threat to the species. In fact, three of the largest rough popcornflower populations occur on private lands where the property is not specifically managed to benefit the species (Table 2). Of the 18 extant rough popcornflower populations, 4 with greater than 5,000 individuals occur partially or wholly on private lands which are grazed beneficially for the species. At the time of listing, only five populations of rough popcornflower were protected from detrimental land-use activities. Since listing, significant progress has been made in protecting and managing sites supporting rough popcornflower. Because 12 of the 18 of the populations are now considered protected or on adequately managed land, the threat from development activities is no longer as severe. (USFWS, 2021b)

**Stressor:** SMALL POPULATION SIZE (USFWS, 2021b)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The final listing rule (U.S. Fish and Wildlife Service 2000, pp. 3869-3870) described the distribution of the rough popcornflower as 17 small patches (approximating 7,000 plants) which were threatened by natural (i.e., flood) and / or anthropogenic (e.g., herbicide treatment) events. At the time, the species' small population size was considered a threat because a single natural or man-made event could have the potential to extirpate a small rough popcornflower patch. Although small populations occur that are still vulnerable to extirpation, there are now multiple, large populations of rough popcornflower occurring in patches larger than those at the time of listing, providing added resilience to the species. In addition, at the time of listing there were concerns that a small, isolated population might not be able to sustain adequate genetic variation, or that reproduction may be impaired (see Fertilization, below). There was also a concern that a lack of connectivity between isolated patches and populations would limit pollinator-mediated gene flow. Since then, these concerns have since been alleviated to a significant extent. At the time of listing, the limited number of individuals and populations was considered a threat. Today, eight of the 18 populations are dispersed over a much larger area (over 500 m<sup>2</sup> [5382 ft<sup>2</sup> ]) than in the past and are likely large enough to withstand a single random natural or anthropogenic event. However, the Hawthorne, Stearns Lane, and Ford's Pond populations are located in small discrete areas and are vulnerable. Even so, these small populations are broadly distributed and the likelihood of large-scale event affecting them collectively is unlikely. Overall, while this species' relatively small population is still of some concern, it is much less vulnerable than when it was listed. (USFWS, 2021b)

**Stressor:** HERBIVORY (USFWS, 2021b)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Herbivory by Columbian white-tailed deer (*Odocoileus virginianus leucurus*), black-tailed deer (*Odocoileus hemionus columbianus*), assorted rodents, and livestock, particularly

sheep, has occasionally been documented and could be a threat to rough popcornflower (U.S. Fish and Wildlife Service 2000, p. 3871). Densities of white-tailed and black-tailed deer are high in much of the Sutherlin Creek area and generally overlap with the distribution of rough popcornflower. Deer herbivory was evident following introduction of rough popcornflower to a wetland mitigation site (U.S. Fish and Wildlife Service 2020, p. 2) and some evidence of sheep herbivory has been documented (U.S. Fish and Wildlife Service 2000, p. 3871). Despite the densities of deer, herbivory does not appear to be causing widespread damage to most rough popcornflower populations. (USFWS, 2021b)

**Stressor:** INVASIVE PLANT ENCROACHMENT (USFWS, 2021b)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Non-native invasive plants are a primary threat to the establishment of rough popcornflower due to their encroachment of habitat and elimination of bare-ground, which popcornflower seeds require to germinate. Invasive pennyroyal is present at many rough popcornflower sites and controlling this species requires constant effort and is a management priority at the NBHMA, TNC Popcorn Swale Preserve, and Red Rock Park populations. Similarly, teasel and Canada thistle control requires constant effort at the NBHMA, Yoncalla South and the TNC Popcorn Swale Preserve populations. Reed canary grass covered over 70 percent of the Red Rock Park rough popcornflower site for several years and required three years of repeated manual weeding efforts and herbicide treatments to reduce this invasive plant to manageable levels. As discussed above, rough popcornflower is conservation reliant in that some form of active management is necessary to maintain habitat in an early-successional condition. For example, prescribed fire, mowing, manual weeding, and herbicide treatment may be required to help maintain many of the rough popcornflower populations into the future (U.S. Fish and Wildlife Service 2010, p. 27). This is exemplified by the active management practices and population response at multiple locations (see Appendices 2 and 3). Invasive plants appears to be less of a concern on private lands because livestock grazing controls invasive plant growth (citation). Strategic grazing by livestock, in terms of seasonal grazing periods and intensity, when closely monitored, can benefit rough popcornflower populations by reducing plant competition and creating open ground that facilitates seed germination and enables population expansion (U.S. Fish and Wildlife Service 2020, p. 2). Competition with invasive plants is an ongoing threat to rough popcornflower. However, investments in weed control and lessons learned in how to combat invasive species has resulted in flourishing populations. A continued commitment will be needed to maintain these populations (see Appendices 3 and 4). While invasive plants remain a threat to rough popcornflower, this threat can be successfully managed. (USFWS, 2021b)

**Stressor:** FIRE (USFWS, 2021b)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** At the time of listing, fire was considered a necessary natural event key to the formation and maintenance of rough popcornflower habitat (U.S. Fish and Wildlife Service 2000, p. 3867). In late September 2003, an accidental fire occurred at the Soggy Bottoms meadow within the BLM's NBHMA and burned across the introduced rough popcornflower population. The intensity of the fire was moderate but did not sterilize the soil's organic layers. Following the burn, staff noted that individual rough popcornflower plants were much larger, robust, and the

population increased from 1,193 plants in July 2003 to 1,869 plants in July 2004. However, by 2009 the population had been reduced to 15 individuals. The BLM and the Service attributed the rapid population decline to factors other than the burn, including changes in water flow and increased erosion due to stream channelization at the site that affected the hydrology of the site. While the effects of fire in rough popcornflower habitat restoration are still unknown (U.S. Fish and Wildlife Service 2010, p. 27), the fire at North Bank/Soggy Bottoms suggest that low to moderate intensity fire can have short-term beneficial effects to the species. (USFWS, 2021b)

**Stressor:** CLIMATE CHANGE (USFWS, 2021b)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The likely impacts of climate change on rough popcornflower's ecological processes are closely connected to availability of water. Due to their shallow and ephemeral nature, wet swales in southwestern Oregon are particularly sensitive to increases in evaporation or reductions in rainfall. Strong climate variability is likely to persist in the Pacific Northwest, owing in part to the year-to-year and decade-to-decade climate variability associated with the Pacific Ocean (May et al. 2019, p. 1039). Periods of prolonged drought are projected to intersperse with years featuring heavy rainfall driven by powerful atmospheric rivers and strong El Niño winters (May et al. 2019, p. 1039). Even modest increases in warming could result in more runoff in winter and less in spring and summer, more winter flooding, and drier summer soils, thereby altering the seasonality and duration of wetland hydration (Field et al. 2017, p. 18). Climate change is expected to lead to increased variability in precipitation and to an increased loss of soil moisture due to evaporation and transpiration (Field et al. 2017, p. 18), which may exacerbate effects due to drought. Drought-mediated decreases in water depth and inundation periods could increase the frequency at which wetlands dry before rough popcornflower has completed their flowering and fruiting stages. Climate change could also cause temperatures to exceed those suitable for growth of the species (U.S. Fish and Wildlife Service 2010, p. 28). The expected negative effects of climate change on rough popcornflower include heavier winter rains and limited spring moisture, which would result in decreased fruit production. (USFWS, 2021b)

**Stressor:** Herbicide use

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The species is likely affected by common herbicides. We have no knowledge the species is affected by Malathion or other general contaminants.

## ***Recovery***

### **Reclassification Criteria:**

Criterion 1. At least 9 reserves, containing a minimum of 5,000 plants each, are protected and managed to assure their long-term survival. A reserve may be composed of one or more patches of rough popcornflower located within 1 km (0.6 mi) of each other. Criterion 2. A minimum of 500 m<sup>2</sup> (5,382 ft<sup>2</sup>) is occupied by the rough popcornflower within each reserve. Occupied habitat should be determined by using a GPS device to delineate patches of plant, with the GPS data then uploaded into a GIS program to calculate total area. The maximum allowable location error is +/- 3 m (9.8 ft). For patches too small to be delineated accurately, a

GPS point location should be recorded along with a measurement of the occupied area. Criterion 3. A minimum of nine reserves, each meeting the requirements in Downlisting Criteria 1 and 2, are distributed with at least one reserve each in the Calapooya Creek and Yoncalla Creek recovery units, and a minimum of five reserves in the Sutherlin Creek recovery unit. The remaining two required reserves may be located within any of the natural recovery units, or elsewhere within the Lower North Umpqua River (1710030111), Calapooya Creek 6 (1710030301), and Elk Creek (1710030303) Hydrologic Unit Code 10 watersheds containing the recovery units. Criterion 4. Over a 5-year period with a minimum of 3 individual years of monitoring, demographic data indicate that at least seven of the nine reserves have average population numbers that are stable or increasing, without decreasing trends lasting more than 2 years.

Recovery Priority Number: 8C

**Delisting Criteria:**

Criterion 1. At least 9 reserves will have established management plans or conservation agreements that include requirements for periodic monitoring and habitat maintenance. Habitat maintenance must prioritize the removal of woody vegetation and non-native invasive plants. Criterion 2. Seed accessions need to be collected from all 9 reserves and submitted for long-term storage at a local seed bank repository, with a minimum of 15,000 seeds per reserve stored for use in future augmentations or to re-establish each source population should one ever be extirpated. Criterion 3. Over a 10-year period with a minimum of 7 years of monitoring, demographic data indicate that populations in at least seven of the 9 recovery reserves have average population numbers that are stable or increasing, without decreasing trends lasting more than 2 years.

**Recovery Actions:**

- **Recovery Measures for Popcornflower:** Evaluate the status of all existing populations. Conduct surveys to search for new populations. Rough popcornflower populations will have reserve status if protected and meet recovery criteria of 5,000 plants. Currently we consider 12 of 18 populations protected. Protect habitat to be included in reserves. Provide educational opportunities for landowners/managers/general public. Use of existing authorities and applicable regulations. Evaluate techniques to reduce competition. Evaluate techniques to reduce impacts of woody succession. Implement control measures: Implement appropriate management to reduce competition and control woody plant succession. Collect seeds from extant sites. Produce and establish transplants. Monitor existing populations. Identify ecologically appropriate habitat. Protect population introduction sites. Produce and establish transplants. Manage populations to promote viability. Monitor new populations to determine viability. Rank populations. Collect and bank seeds. Evaluate population genetic diversity. Evaluate pollinator availability. Provide outreach services for reserve owners and the general public. Evaluate the status of *Plagiobothrys hirtus*. Inventories for new and known populations of popcornflower were conducted throughout the species range in 2005 and 2014 by ODA (K. Amsberry, Oregon Department of Agriculture, pers. comm. 2014). Documentation of the distribution and abundance of popcornflower began in 1995 and has continued annually at most sites in most years; the exceptions are 2001 for BLM populations and 2008 to 2011 for TNC populations (USFWS, 2016).

***Conservation Measures and Best Management Practices:***

- Recommendations: • Recommend downlisting to threatened. • In cooperation with partners, continue to manage rough popcornflower, utilizing best management practices for this conservation-reliant species. • Enhance protection for, and augment, existing populations in the Calapooya Recovery Unit by ensuring protection through formal conservation agreements, management plans or publicly established reserves for the Nonpareil and other populations in this Recovery Unit. • Reintroduce rough popcornflower into suitable habitat, particularly in locations that will contribute to meeting recovery criteria. • Continue to pursue protected/reserve status of wetland and wet-swale habitat conditions benefitting rough popcornflower. (USFWS, 2021a)
- Vegetation Control Mowing is a management tool utilized in rough popcornflower habitat to control competing native plant species and invasive species as well as to prepare for outplanting efforts. The Red Rock Park, Wilbur Mitigation Site, the Southside Swale, and the ODOT Yoncalla South populations are regularly mowed and rough popcornflower populations have expanded. A late summer and fall mowing at Red Rock Park was instrumental in combatting pennyroyal growth throughout much of the site and resulted in the largest ever plant count at this location (U.S. Fish and Wildlife Service 2020, p. 2) (Table 2). The Service funds mowing at the Southside Swale and the TNC Popcorn Swale Preserve to control native graminoids, non-native grass, and pennyroyal. In the last 15 years, the Service funded various non-native invasive plant and native vegetation management at four rough popcornflower populations (Southside Swale, Red Rock Park, TNC Popcorn Swale Preserve, and Orenco Ponds). The initial results were promising for the four sites, which saw increased population numbers. Non-native and native tree thinning conducted in 2004, at the TNC Popcorn Swale Preserve resulted in the highest number of rough popcornflower plants recorded for the preserve (three years post-treatment). Unfortunately, over time and without further vegetation management, the native and non-native plants (spreading rush and pennyroyal) responded more aggressively than rough popcornflower and encroached on much of the habitat formerly occupied by the plant, leading to an overall population decline. The population is slowly rebounding and TNC has plans to mow the property annually, with the expectation that plants will spread into previously occupied habitat. There is no planning to utilize grazing or prescribed burns for vegetation control at this time. Fencing Fencing can protect populations from anthropogenic disturbance. The Sutherlin Red Rock Park rough popcornflower population was regularly affected by horse trampling and used horse bedding was tossed into the wetland area supporting rough popcornflower. The plants were often smothered while competing with aggressive grass and pennyroyal. Since the area was enclosed with fencing and signed with information about rough popcornflower, the plants are no longer subject to trampling and no longer smothered with the bedding and thus are able to grow in denser patches, compete better with the grass and pennyroyal, and occupy more space than prior to fencing. Introductions and Augmentation In 1998, before the species was listed, rough popcornflower plants were introduced to three locations on BLM managed lands. Two of the populations were successful and are still extant. Rough popcornflower was also introduced to the Orenco Ponds mitigation site in 2011 on a parcel owned by Douglas County and at a privately held mitigation site in 2001 (ODOT Wilbur Mitigation Site). Rough popcornflower was also successfully augmented at the Douglas SWCD property, the ODOT Wilbur Mitigation Site, and a second ODOT mitigation site (Del Rio Mitigation Site). In 2016, a new population was introduced to the NBHMA (Soggy Bottoms Sister) and is a recovery level population (i.e., greater than 5,000 plants) (J. Brown, pers. comm. 2020). Stakeholder workshops Five stakeholder meetings occurred between 2004 and 2016, at which population and species needs, recovery targets, and habitat conservation were discussed. At the most recent meeting, the agencies and landowners indicated that the species was making significant progress in recovery. Conservation Agreements Collaboration among stakeholders plays an important role in species management. For example, a Management

Plan between the Service, City of Sutherlin, ODA, and Douglas SWCD was finalized to protect and maintain the populations on Sutherlin and Douglas SWCD properties in 2007. For information specific to each reserve and other populations of rough popcornflower, see Appendices 2 and 3.

## **SPECIES ACCOUNT: *Plagiobothrys strictus* (Calistoga allocarya)**

---

### ***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

#### **Physical Description**

An annual herb, 1-4 dm tall. White flowers appear March-April in a slender, curved inflorescence. (NatureServe, 2015)

#### **Historical Range**

Historically, three populations of *Plagiobothrys strictus* were documented within a 3-kilometer (2-mile) radius of Calistoga, Napa County, California. Prior to listing one population had been extirpated due to urbanization and agricultural land conversion (California Native Plant Society 2008a). (USFWS, 2010)

#### **Current Range**

The range extent covers a small area in Napa County, near Calistoga. The total range is only about 14 sq mi. (NatureServe, 2015)

#### **Critical Habitat Designated**

No;

#### ***Life History***

#### **Food/Nutrient Resources**

#### **Reproduction Narrative**

Adult: *Plagiobothrys strictus* is an annual herb in the Boraginaceae (borage family) (USFWS, 2010).

#### **Habitat Type**

Adult: Vernal pools (NatureServe, 2015)

#### **Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

#### **Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

#### **Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

#### **Site Fidelity**

Adult: High (NatureServe, 2015)

#### **Habitat Narrative**

Adult: Species inhabits geyser- and hot spring-fed vernal pools and swales in meadows at 90-160 m elevation. Soils are clay or gravelly-clay loams. These pools contain high concentrations of boron and sulfates - substances that are toxic to most plants. Associated species include the rare Napa blue grass (*Poa napensis*). (NatureServe, 2015)

### ***Dispersal/Migration***

### ***Population Information and Trends***

#### **Population Trends:**

Decreasing (NatureServe, 2015)

#### **Population Growth Rate:**

Decline of 30-50% (NatureServe, 2015)

#### **Number of Populations:**

1 (USFWS, 2023)

#### **Population Size:**

297,963 plants (USFWS, 2023)

#### **Adaptability:**

Highly vulnerable due to annual habit and location in wetlands. (NatureServe, 2015)

#### **Population Narrative:**

Highly vulnerable due to annual habit and location in wetlands. Decline of 30-50% .Population size of this annual fluctuates from year to year. In some good years, as many as 6000 plants were reported. There are only 2 extant EO's ;there is a third, historical EO. (NatureServe, 2015). Low resiliency, representation and redundancy are based on the low number of known populations and individuals. Historically, there were only three known populations of both the *Calistoga allocarya* and the Napa bluegrass. The three populations of *Calistoga allocarya* were documented within a 3- kilometer (2-mile) radius of the city of Calistoga in Napa County, California; however, prior to listing one of the populations was extirpated due to urbanization and agricultural land conversion (Service 1997, pp. 55792, 55799). At the time of listing and our 2010 status review, there were two extant occurrences of *Calistoga allocarya*: one within a property that contains Myrtledale Hot Springs (hereafter referred to as the hot spring property) and the other on a property where the former Calistoga glider airport is located (hereafter referred to as the airport property) (Service 1997, p. 55792; Service 2010, p. 4). The combined area of the two remaining populations is less than 80 square meters (900 square feet) (CNPS 1990 as cited in Service 1997, p. 55792). The three historical occurrences of Napa bluegrass were also entirely within Napa County: two were on the hot spring property and the third was on the airport property (Service 2010, p. 4). Prior to listing, one of the Napa bluegrass populations on the hot spring property was extirpated (Department 1989, p. 2), and at the time of listing, two populations of Napa bluegrass, one at the hot spring property and one at the airport property, remained (Service 1997, p. 55799). The total area occupied by Napa bluegrass was estimated to be slightly greater than 100 square meters (1,100 square feet). In 1994, near the time of listing, the population of *Calistoga allocarya* at the airport property had approximately 5,000 plants within 180 square meters (2,000 square feet) (J. Ruygt 1996 as cited

in Service 2010, p. 5). Surveys carried out prior to the last status review in 2009 estimated the airport property population size at between 3,310 and 5,000 individual plants (Service 2010, p. 6). Since the 2010 status review, the population of *Calistoga allocarya* at the airport property has been surveyed annually from 2013–2022, except for 2020 due to Covid restrictions (WyrickBrownworth et al. 2021, p. 3) (see specific counts in Table 1, below). The number of plants counted during these annual surveys is heavily influenced by the survey methods. Surveys consisting of weekly walk-throughs of the property from early spring to early summer (January – May) are preferable as identification of individuals is difficult later in the summer when the plants have already senesced and lost their flowerheads. In 2019, the total population for *Calistoga allocarya* equated to 297,963 plants within the airport property (Wyrick-Brownworth et al. 2021, p. 6). (USFWS, 2023).

### ***Threats and Stressors***

**Stressor:** Commerical/Residential Development (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The two *Plagiobothrys strictus* and *Poa napensis* populations exist on private land and could be developed. The airport property will be required by the City of Calistoga to be evaluated under the California Environmental Quality Act for the environmental effects to these species, and the evaluation reviewed by the California Department of Fish and Game, if and when any development should ever be proposed. According to the City of Calistoga Zoning Map, one property is zoned as Rural-residential and the former airport property is zoned Commercialairport (City of Calistoga 2003). Given that both species' population sizes are very small and restricted to two locations, development of these parcels could lead to the extinction of both species. The occurrences of the two species on the second private parcel (Myrtledale Hot Springs) in the City of Calistoga had been proposed for a new hospital (USFWS, 2010).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** the California and Federal Endangered Species Acts are the primary State and Federal laws, respectively, that provide protection for this species since its listing as endangered in 1997. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2010).

**Stressor:** Human activities (USFWS, 201)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** *Poa napensis* individuals within the Myrtledale Hot Springs population could be lost to trampling should the number of hikers increase to the hot spring, the paved road is widened, or the property owner decides to alter the landscape causing the alteration of hydrology. Because the most recent observation of six *Poa napensis* individuals was in 2007 and conducted from

outside the property boundary (Occurrence #1, CNDDDB 2009b), the risk of human activities may be even greater since a more accurate count of individuals does not exist currently. The former Calistoga airport parcel could be mowed or its hydrology could be altered presenting unknown magnitude of risk to the populations of either species since neither population has been thoroughly surveyed since 1996 (*P. napensis* Occurrence #3 and *Plagiobothrys strictus* Occurrence #3, CNDDDB 2009a) (USFWS, 2010).

**Stressor:** Restricted Habitat, Range, and Few Numbers of Populations (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of genetic variability/extinction

**Narrative:** Species in natural habitats face threats both from deterministic facts such as habitat loss, overexploitation, pollution, introduced species, and stochastic events associated with small population size. Such events may be of a demographic genetic or environmental nature, including catastrophes (World Conservation Monitoring Centre 1992). The estimated population size for *Plagiobothrys strictus* was over 5,000 individuals in 1994 (Occurrence # 3, CNDDDB 2009a) and six plants in 2007 as observed from the edge of the second property boundary for *Poa napensis* (Occurrence #1, CNDDDB 2009b). Both species' populations could be susceptible to extirpation from random events due to their restricted range. Increased homozygosity resulting from genetic drift and inbreeding may lead to a loss of fitness (ability of individuals to survive and reproduce) in small populations (Menges 1991; Ellstrand and Elam 1993)

**Stressor:** Invasive plant species (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Competition from invasive plant species poses a potential threat to both species. Exotic and/or invasive, weedy plant species reduce native plant diversity and diminish the habitat suitability for native species; this is particularly the case in sensitive habitats (G. Cooley, California Department of Fish and Game, pers. comm. 2008). The consistent pattern of heavy growth of nonnative grasses when not controlled by grazing or other management can 'smother' native plants, resulting in the subsequent crowding out, outcompeting, or overshadowing of native annuals. A common consequence of such heavy annual grass growth is development of thatch, which adds to the strong smothering effect by inhibiting annuals' germination and growth (Weiss et al. 2007) (USFWS, 2010).

**Stressor:** Climate Change and Drought (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** A modeling study completed by Loarie et al. (2008) provides an evaluation of potential trends to California's floristic communities under climate change scenarios. In general, plant diversity will shift in two divergent directions: along the coast and northwards at higher elevations; and southwards at higher elevations of the Sierra Nevada. The models suggest that climate change has the potential to break up local floras, resulting in new species combinations, with new patterns of competition and biotic interactions (Loarie et al. 2008). Based on these modeling results, *Plagiobothrys strictus* and *Poa napensis* plants could be unable to shift their range because of their isolated, small populations, whose growth depend upon particular

hydrological regimes, and the limited available, suitable habitat surrounding the two private parcels (USFWS, 2010).

### ***Recovery***

#### **Reclassification Criteria:**

Recovery Priority Number: 5C

#### **Recovery Actions:**

- No final recovery plan has been completed for these species (USFWS, 2010).
- Work with the landowners, the California Department of Fish and Game, the City of Calistoga, and California Native Plant Society to ensure the protection of all known populations of *Plagiobothrys strictus* and *Poa napensis* (USFWS, 2010).
- Work with the landowners, the California Department of Fish and Game, the City of Calistoga, and California Native Plant Society to ameliorate or eliminate any threats to *Plagiobothrys strictus* and *Poa napensis* from hydrological changes and from competition from nonnative plants (USFWS, 2010).
- Collect seeds from both species from both parcel sites and store them in Center for Plant Conservation certified botanic gardens to guard against extirpation of populations from chance catastrophic events (USFWS, 2010).
- Follow conservation measures and policies as stated in the 2007 Napa County General Plan Update (USFWS, 2010).
- Follow conservation measures and policies as stated in the 2003 City of Calistoga General Plan for sensitive plant species (USFWS, 2010).
- Conduct a population assessment for each species and continue monitoring over the next 5 years (USFWS, 2010).

#### ***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of *Calistoga allocarya* and Napa bluegrass. Some of these recommendations were discussed in the last status review (Service 2010, p. 16) and remain valid. 1. Partner with private landowners, the California Department of Fish and Wildlife, the City of Calistoga, and the California Native Plant Society to ensure protection of all known populations of *Calistoga allocarya* and Napa bluegrass. 2. Work with the California Department of Fish and Wildlife, the City of Calistoga, and the California Native Plant Society to ameliorate or eliminate any threats to *Calistoga allocarya* and Napa bluegrass from hydrological changes and competition from invasive plants. 3. Collect seeds from both populations of both species and store them in Center for Plant Conservation certified botanic gardens to guard against extirpation from chance catastrophic events. 4. Follow policy CON-17 and associated conservation measures as stated in the Napa County General Plan to “Preserve and protect native grasslands, serpentine grasslands, mixed serpentine chaparral, and other sensitive biotic communities and habitats of limited distribution” (Napa County Department of Conservation, Development, and Planning 2009, p. CON-28). 5. Follow policies P1.1-3 and P1.1-4 and associated actions as stated in the Open Space and Conservation Element (Updated 2012) of the City of Calistoga General Plan to continue “efforts to identify and map biological resources on the gliderport property [airport property], which provides an important and unique habitat area within the city limits” and “explore the possibility of designating parcels as Natural Resource Preservation

Areas in areas of the city known to contain sensitive and unique species, in order to protect these resources” (City of Calistoga 2012, p. OSC-23). 6. Conduct a population assessment for each species and continue monitoring annually (USFWS, 2023)

## SPECIES ACCOUNT: *Pleodendron macranthum* (Chupacallos)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 11/25/1994

### **Physical Description**

A small to medium size aromatic evergreen tree reaching 10 meters (33 feet) in height, 20 centimeters (8 inches) in diameter with brownish twigs that are slender and hairless. Leaves are alternate, simple, leathery, entire, measuring 8.5 - 12.5 centimeters (3.5 - 5.0 inches) long and 4.5 - 5.0 centimeters (1.7 - 2 inches) wide. The blades are elliptic with the upper surface dark shiny green and the mid-vein sunken. The lower surface is pale green with a prominent mid-vein and with fine, parallel side veins. The leafstalks are about 7 millimeters (.25 inches) long and canal-shaped (Vivaldi et al. 1981). The solitary flowers, whitish in color and bisexual, are axillary and are subtended by a long flower stalk 2.5 centimeters (1 inch) long. The flowers are 2 centimeters (.8 inches) wide with 3 sepals, 12 petals and many united stamens. The cup-shaped calyx is persistent in the fruit. The aromatic purplish black fruit measures 2 centimeters (.8 inches) in diameter and contains many rounded, shiny brownish black seeds. The wood is described as nearly white, hard, and heavy (Little et al. 1974) (USFWS, 1998).

### **Taxonomy**

There are no recent taxonomic or nomenclatural changes for *P. macranthum*, which was originally described as *Cinnamodendron macranthum*. Its closest relative, *P. ekmanii*, is a very rare tree from Haiti (Little et al., 1974) whose present status is unknown. The other member of the Canellaceae family in Puerto Rico is *Canella winterana*, a dry forest species (USFWS, 2014).

### **Historical Range**

See current range/distribution.

### **Current Range**

Known from the Caribbean National Forest and the Rio Abajo Commonwealth Forest, which are administered by the USDA Forest Service and the Department of Natural and Environmental Resources (USFWS, 1998). The populations at El Yunque National Forest (EYNF) consisted of nine trees at the Jimenez Ward and two separated trees at Mameyes II Ward in Rio Grande. However, none of these populations were located during the latest surveys conducted by University of Puerto Rico at Mayagüez personnel in March 2011. (USFWS, 2019).

### **Critical Habitat Designated**

Yes;

### ***Life History***

### **Food/Nutrient Resources**

### **Breeding Season**

Adult: *Plethodendron macranthum* has been collected with flowers in February, April-June, and with fruits in June-August (Little et al. 1974) (USFWS, 1998).

**Reproduction Narrative**

Adult: Very little is known about the reproductive biology of *Plethodendron macranthum* and *Eugenia haematocarpa* due to their extremely low population numbers and isolated locations. *Plethodendron macranthum* has been collected with flowers in February, April-June, and with fruits in June-August (Little et al. 1974). This species is known to reproduce successfully on the forest; specimens with fruit have been encountered in July (USDA Forest Service 1993) (USFWS, 1998).

**Habitat Type**

Adult: Forest (USFWS, 1998)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from USFWS, 1998)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS, 1998)

**Site Fidelity**

Adult: High (inferred from USFWS, 1998)

**Habitat Narrative**

Adult: *Plethodendron macranthum* is known to exist in the subtropical wet (tabonuco forest type) and the subtropical lower montane wet (palo colorado forest type) forest life zones (USFWS, 1998). High ecological integrity of the population and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the low number of known populations.

***Dispersal/Migration******Population Information and Trends*****Number of Populations:**

6 natural populations (USFWS, 2022)

**Population Size:**

~24 natural individuals 55 outplanted (USFWS, 2022)

**Population Narrative:**

Overall, the majority of the known individuals of Chupacallos are planted trees. There are 97 known individuals in the wild, and 70 percent have been planted (Table 1). Of the 21 naturally occurring individuals, none have been observed during the last decade. The 97 individuals occur in 10 populations, 6 of which are experimental populations consisting of planted individuals (USFWS, 2014). Low representation, resiliency and redundancy are inferred based on the low number of populations and individuals as well as the specific habitat needs of the species. In the 2014 5-year status review, we reported 30 individuals of chupacallos planted by PRDNER at Guavate in the Carite Commonwealth Forest (CCF), but there is no updated information about their current status. Therefore, based on the best available information, the current estimated number of plants of chupacallos is 24 individuals in 6 natural localities, and 55 planted

individuals distributed in 6 locations (USFWS, 2022)

### ***Threats and Stressors***

**Stressor:** Deforestation (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** At the time of listing, forest management practices such as the establishment and maintenance of plantations, selective cutting, trails maintenance, and shelter construction were identified as threats to both Chupacallos and Uvillo. Based on the available information, the core of the known populations of Chupacallos and Uvillo occurs within the boundaries of Federal, State, or other protected areas. Within these areas, there is no direct evidence of populations or individuals being affected by forest management practices. Therefore, USFWS no longer considers forest management practices a threat to Chupacallos or Uvillo. However, the largest known population of Uvillo lies within Las Robledas along a ridge that marks the boundary of several private properties and some clusters of individuals lie within neighboring properties that are not managed by the PRCT. Boundary management practices (clearing and fencing) may affect individuals along these areas. Similarly, land clearing for agricultural purposes and urban development may affect the small populations of Uvillo within private properties at the Sierra de Cayey, including the private properties adjacent to Las Robledas. Undetected populations of Chupacallos and Uvillo might be affected by deforestation for urban development on the periphery of El Yunque National Forest. In the northern Karst 13 region, suitable habitat for these species may be affected by rock quarries, particularly in the Quebradillas and Isabela area. The present or threatened destruction, modification, or curtailment of the species habitat or range remains a threat to Chupacallos and Uvillo. However, since the majority of the known populations lie within properties managed for conservation and there is no direct evidence of populations being affected by habitat destruction or modification, we consider this threat to be low in magnitude and non-imminent (USFWS, 2014).

**Stressor:** Storms (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Hurricanes and landslides are listed as a threat to this species (USFWS, 2014).

**Stressor:** Climate change (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Climate change is predicted to increase the frequency and strength of tropical storms and can cause severe droughts (Hopkinson et al. 2008). Vulnerability to climate change impacts is a function of sensitivity to those changes, exposure to those changes, and the adaptive capacity of the species (Glick et al. 2011). Shifts of vegetation communities are expected as temperatures and moisture regimes are altered by climate change. Under this scenario populations of Chupacallos and Uvillo may be displaced or outcompeted by native or exotic species with wider environmental plasticity. Climate change may also compromise natural recruitment by affecting the survival of seedlings. Despite the low number of populations and individuals (particularly for

Chupacallos), at this time the USFWS considers hurricanes, landslides and climate change a moderate and non-imminent threat to both species. Climate change is occurring gradually and the frequency of severe hurricanes is low (USFWS, 2014).

**Stressor:** Decreased genetic variation (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Lack of genetic variability

**Narrative:** Along with a decreasing population size, negative impacts of habitat fragmentation may result in erosion of genetic variation through the loss of alleles by random genetic drift (Honney and Jacquemyn 2007), and may also limit the ability of a species to respond to a changing environment (Booy et al. 2000). Given the extremely small population size and low number of known natural populations of Chupacallos, it is likely that their genetic variability is low. As previously indicated, all reported populations consist of less than 10 individuals, and in some cases they are represented by a single individual. Despite the reports of new populations of Uvillo, this species may be affected by genetic depression due to the low number of individuals in some populations, as it is evident that the species was severely affected by former habitat fragmentation due primarily to extensive deforestation for agriculture. However, the wide distribution and geographical isolation of the species, from the eastern to the northwestern side of the Island (i.e., El Yunque National Forest, Sierra de Cayey, and Guajataca Commonwealth Forest), with different environmental conditions, suggests that the species may show high interpopulation genetic variability. In order to safeguard the remaining genetic diversity, the origin and survival of reintroduced individuals needs to be monitored as well as their development into mature individuals. The protection and monitoring of known adult individuals should be considered a high priority for the conservation of Chupacallos and Uvillo. Based on the above, we consider the lack of genetic variation is a high and imminent threat to Chupacallos, and a low and non-imminent threat for Uvillo (USFWS, 2014).

**Stressor:** Lack of natural recruitment (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of genetic variability

**Narrative:** Without natural recruitment or successful augmentation from captive propagated individuals, populations (natural and reintroduced) of Chupacallos are likely to become extirpated as older individuals naturally die. Despite future efforts to enhance natural populations by planting seedlings and saplings, it is unknown if planted individuals will develop into mature plants capable of reproducing. Therefore, we consider the lack of natural recruitment a high and imminent threat to Chupacallos (USFWS, 2014).

## **Recovery**

### **Reclassification Criteria:**

The two species will be considered for down listing when the following criteria are met: 1. An agreement between the USFWS and the USFS concerning the protection of Chupacallos and Uvillo within the Caribbean National Forest property has been prepared and implemented (USFWS, 2014).

2. An agreement between the USFWS and the PRDNER concerning the protection of these two species in Commonwealth Forests, specifically Río Abajo, for Chupacallos, has been prepared and implemented (USFWS, 2014).

3. New populations (the number of which will be determined by appropriate scientific studies) capable of self-perpetuation have been established within protected areas (USFWS, 2014).

Recovery Priority Number: 8

**Delisting Criteria:**

1. Three (3) natural populations of uvillo and two (2) populations of chupacallos exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes, and populations extending onto private lands are protected through a conservation mechanism (addresses Factors A and E). (USFWS, 2019).

2. Establish or discover two (2) new populations of uvillo and seven (7) new populations of chupacallos within the historic range of the species that exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes, and populations extending onto private lands are protected through a conservation mechanism (addresses Factors A and E). (USFWS, 2019).

3. Threat reduction and management activities (e.g., trail maintenance) have been implemented to a degree that the species will remain viable into the foreseeable future (addresses Factor A). (USFWS, 2019).

**Recovery Actions:**

- Criterion 1 has been partially initiated. There is no formal agreement between the USFS and USFWS for the implementation of a management plan to protect Chupacallos and Uvillo. Nonetheless, under Section 7 of the Endangered Species Act (ESA), Federal agencies are mandated to carry out programs for the conservation of endangered species. Under the ESA, it must be ensured that any action authorized, funded, or carried out by a Federal agency is not likely to jeopardize the continued existence of an endangered species. The USFS and USFWS have developed a good communication relationship, and USFS always consults with USFWS to avoid and minimize impacts to listed species and their habitat at El Yunque National Forest. Further coordination is needed for the long term monitoring of natural populations and propagation of Chupacallos and Uvillo (USFWS, 2014)
- Criterion 2 has been partially met. The Río Abajo Commonwealth Forest has an approved management plan that recognizes the presence of Chupacallos within the forest. Furthermore, PRDNER has listed Chupacallos as endangered, and as part of their list of critical elements. Species on the list of critical elements receive special consideration when evaluating development actions within suitable habitat. However, there is no formal agreement in place between USFWS and the PRDNER to protect Chupacallos populations within the Río Abajo Commonwealth Forest. Further coordination is needed for the long term monitoring of natural populations and the propagation of Chupacallos. Because the species is not monitored on the forest, adverse impacts to the populations could be occurring due to forest management practices (e.g., opening of new trails and research projects) (USFWS, 2014).

- Criterion 3 has been initiated. Several natural populations of Uvillo have been reported since the species was listed in 1994. The Puerto Rico Conservation Trust (PRCT) has conducted an exhaustive evaluation of two recently discovered population in the municipality of Cayey in two properties known as Las Robledas, and Sotomayor del Toro and have consulted with the USFWS about adequate management practices for these populations. USFWS biologists visited the population at Las Robledas and it seems to be healthy and may set the standards to establish further viable populations within these areas (Las Robledas and Sotomayor del Toro) and other Commonwealth protected areas. Furthermore, a germination experiment with Uvillo is being conducted by the PRCT in their greenhouse at Río Piedras, which is expected to improve our knowledge on the propagation of this species (USFWS, 2014). Despite the lack of available information about the natural populations of Chupacallos, this species was successfully propagated by Dr. Eugenio Santiago (professor at UPRRP). The material produced in this effort has been used to establish a new experimental population of Chupacallos in an area adjacent to the aviary of the Puerto Rican parrot at El Yunque National Forest. However, more information on the reproductive biology and ecology of this species is needed in order to establish what constitute a viable population. Thus, further research and monitoring of planted individuals of Chupacallos is needed (USFWS, 2014).
- Refined recovery action for 2019: Monitoring should be conducted on both species' phenology and reproductive biology to address other limiting factors affecting these species (e.g., natural recruitment, lack of pollinators or seed dispersers). This recovery action should be coordinated with Puerto Rico Department of Natural and Environmental Resources and United States Forest Service and be included within Task 121,212,323, 324: Monitor all known populations, Assess periodicity of flower production and pollination activity, Assess seed viability and Evaluate seedling establishment and growth of the approved recovery plan. (USFWS, 2019).
- 1. Studies should be conducted on both species' phenology and reproductive biology to address other limiting factors affecting these species (e.g., lack of pollinators or seed dispersers) (USFWS, 2014).
- 2. All known populations should be marked and monitored on a regular basis, and additional visits should be made after hurricanes or other major disturbances to determine any possible adverse effects on the populations (USFWS, 2014).
- 3. The previous ex situ conservation efforts (individuals reintroduced to the wild) should be monitored and further similar efforts should be undertaken to enhance the status of both species (USFWS, 2014).
- 4. The USFS and USFWS should develop a comprehensive survey program to inventory areas with potential habitat. This program should include training to field biologists of both agencies so these personnel is able to recognize listed species on the field (USFWS, 2014).
- 5. The populations that are actively producing seeds need to be identified and monitored to collect seed material for recovery purposes. A protocol to collect seed material should be developed and implemented to avoid altering the natural recruitment of the species. Enhancement of natural populations should be considered particularly for Chupacallos. The development of adequate propagation techniques is essential for the recovery of these species (USFWS, 2014).
- 6. The recovery plan should be revised to establish measurable down listing and delisting criteria, including how many individuals constitute a self-sustainable population and how many populations would be needed to delist these species (USFWS, 2014),

- 7. Studies should be conducted to determine the patterns of genetic variation within and among populations in order to develop a plan to preserve the species genetic variability (USFWS, 2014).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES 1. Studies should be conducted on both species' phenology and reproductive biology to address other limiting factors affecting these species (e.g., pollinators and seed dispersers). 2. Previous and ongoing planting efforts (individuals reintroduced into the wild) should be monitored, and further similar efforts should be undertaken to enhance the status of both species. 3. The U.S. Forest Service and the Service should develop a comprehensive survey and monitoring program to inventory known localities and potential habitat. This effort should provide continuity to the surveys and methodology implemented by PRDNER (2016). Populations should be monitored on a regular basis, and additional visits should be made after hurricanes or other major disturbances to determine adverse effects on the populations. 4. A propagation plan that considers the species populations genetics (geographic distribution) and habitat, should be developed for both species. A protocol to collect seed material should be developed and implemented to avoid altering the natural recruitment of the species. Enhancement of natural populations should be considered, particularly for chupacallos. 5. Studies should be conducted to determine the patterns of genetic variation within and among populations to develop a plan to preserve the species genetic variability (USFWS, 2022).

## SPECIES ACCOUNT: *Pogogyne abramsii* (San Diego mesa-mint)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

An aromatic annual herb, 1-3 dm tall, covered dense, curved hairs. Flowers (April-June) are lavender, 11-14 mm long. (NatureServe, 2015)

### **Taxonomy**

There has been some debate whether *Pogogyne abramsii* is taxonomically distinct from *Pogogyne nudiuscula*. Abrams (1951) recognized this species but considered it possibly not distinct from *Pogogyne nudiuscula*. Current work (Jokerst 1993; McMillan unpublished data 1995) supports taxonomic distinction. Not only do the two species differ in the calyx pubescence (hairiness) and bract morphology, but also in the number of flowers per stem node. All of the current *Pogogyne* populations north of Mission Valley and south of Del Mar Mesa are still considered to be *Pogogyne abramsii*. The populations from the central (San Diego) mesas were probably *Pogogyne abramsii*, but with such limited herbaria records, this question will probably never be fully resolved (USFWS, 1998).

### **Historical Range**

Historically, outside of *Pogogyne abramsii*'s current range, it is thought to have occurred around Linda Vista, the vicinity of Balboa Park, Normal Heights, and the area surrounding San Diego State University (USFWS 1998a, p. 12; Zedler et al. 1979), however some confusion has existed regarding *P. abramsii*'s historical range due to misidentified herbarium specimens (identified as *Pogogyne nudiuscula*) and vague references regarding collection sites. (USFWS, 2010)

### **Current Range**

California endemic. San Diego Co., mesas from San Diego to Miramar. (NatureServe, 2015)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Insect pollinated (NatureServe, 2015)

### **Breeding Season**

Adult: May and June (USFWS, 2010)

### **Reproduction Narrative**

Adult: The family is primarily bee pollinated (Proctor & Yeo, 1973, p. 219).; (NatureServe, 2015). *Pogogyne abramsii* usually blooms in May and June when water is absent from the vernal pool (Munz 1974, p. 531). The plants produce fruit, dry out, and senesce in the hot, dry summer

months. Pollination of *P. abramsii* was described by Schiller et al. (2000, p. 392) by monitoring insect visitors to individual plants on Del Mar Mesa. They found the Eurasian honey bee (*Apis mellifera*) and two anthophorid bees (*Exomalopsis nitens* and *E. torticornis*) to be the most common and likely pollinators of *P. abramsii*. They also documented that *P. abramsii* is self-fertile but has greater seed set when cross-pollinated (Schiller et al. 2000, p. 393) (USFWS, 2010).

**Habitat Type**

Adult: Vernal pool (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits vernal pools on coastal terraces (mesas) at 100-200 m elevation. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the low number of known populations

***Dispersal/Migration*****Dispersal**

Adult: Moderate (USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: Zedler and Black (1992, p. 4) found that *Pogogyne abramsii* seeds germinated and grew from pellets of brush rabbits and Audubon's cottontail rabbits (*Sylvilagus bachmani* and *S. auduboni*), which were collected from vernal pools on Del Mar Mesa and Miramar Mesa. They postulated that rabbit movement may be a potential mechanism for dispersal and genetic mixing of vernal pool obligate species. In addition *P. abramsii* seeds float, which may result in limited dispersal opportunities when pools interconnect or lakes fill their basins in years of greater than average precipitation (Scheidlinger 1981, p. 54) (USFWS, 2010).

***Population Information and Trends*****Population Trends:**

Decreasing (USFWS, 2010)

**Number of Populations:**

43 extant/presumed extant (USFWS, 2023)

**Population Narrative:**

About 36 populations believed extant (NatureServe, 2015). USFWS (2010) indicates that the species population levels are decreasing. Low resiliency, representation and redundancy are inferred based on the low number of known populations and decreasing population trends. Based on current updates from 2010, there are 43 distinct *Pogogyne abramsii* locations still potentially occupied (Figure 1, Table 1), of which 36 are extant and 7 are presumed extant. There are 25 *Pogogyne abramsii* locations that are considered extirpated or possibly extirpated, of which 22 are extirpated and 3 are possibly extirpated. A total of 22 locations have been extirpated since listing (3 occurrences that were historically occupied were considered extirpated prior to listing) and several past occurrences from the 2010 5-year review have been split into new, more specific occurrences. Vernal pool restoration sites MV-22 and Del Mar Mesa – Zamudio represent new occurrences for the species that did not exist during the 2010 5-year review. It is also possible that *P. abramsii* occurs at other locations that have not been surveyed or detected. We have new information about the status of *Pogogyne abramsii* locations from local monitoring efforts, which occur annually at several sites. The City of San Diego monitors several vernal pool complexes including Carroll Canyon (D5-8), Del Mar Mesa (H1-10, 13-15, 18-26), Greystone Torrey Highlands (H39), Lopez Ridge (B7-8), and Montgomery Field (N5-6) as described in the VPHCP and associated the Vernal Pool Monitoring and Management Plan. Biologists record occupancy at occurrences, percent cover, and provide notes at multiple locations (City of San Diego 2021, pp. 1-3). The occurrence table (Table 1) has been updated to reflect the current status of *P. abramsii* locations resulting from these monitoring efforts. In summary, the species is extant or presumed extant at 43 locations and a total of 25 locations are considered extirpated or possibly extirpated. Overall, the species distribution remains restricted to southern San Diego County as described in our 2010 5-year status review, and this information does not alter our understanding of the distribution of *Pogogyne abramsii* (USFWS, 2023).

### ***Threats and Stressors***

**Stressor:** Road widening (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Since listing, road projects have continued to impact *Pogogyne abramsii* occurrences. Though future work on Highway 163, Highway 52, Interstate 15, or Miramar Road could impact *P. abramsii* habitat, we don't currently consider road widening projects a direct threat. Camino Del Sur is being extended through vernal pool habitat in Del Mar Mesa (EO 38, H18-23) and while no direct impacts from the road are expected to impact *P. abramsii*, indirect impacts such as edge effects are possible (S. Wynn, 2010, pers. obs.). Edge effects to *P. abramsii* are evident as a result of road widening projects, creating outer bands of habitat distant from the center but immediately proximal to a different type of habitat, thus providing a different species composition and abundance divergent from the interior of the habitat (Forman and Gordon 1986, p. 108). These edges may allow *P. abramsii* to be in closer proximity to disturbed areas, which may facilitate the incursion of invasive, nonnative plants. Edge effects degrade extant interior habitat and create an island of the protected habitat/reserve through isolation and decrease the effective size and serviceability of a conservation area (Diamond and May 1976, pp. 228–252). Characteristics of habitat islands include less resistant habitat, more disturbed habitat, areas more susceptible to invasive species, areas with native species less resistant to disturbance, and higher seed immigration (Meyers and Bazely 2003, pp. 34-50). Further development of the

roads mentioned above and surrounding areas would exacerbate these impacts (USFWS, 2010).

**Stressor:** Urban Development (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Since listing, many *Pogogyne abramsii* occurrences impacted by approved development have been restored, partially restored (may include reshaping the basin, transplantation of inoculum containing *P. abramsii* seeds), or pools have been created to mitigate unavoidable losses (Appendix 1). These mitigation efforts are designed to help offset impacts from development of vernal pool habitat and are required under the MSCP; however, the long-term viability of such efforts remains unclear (Black and Zedler 1998). While restructured and inoculated pools (which represents the most intensive of restoration treatments) present a much more “natural” appearance than disturbed pools, the degree to which these pools resembles the original pools is unknown (Black and Zedler 1998, p. 197). Black and Zedler (1998, p. 205) also state that “there is no assurance of success, and restored pools, unless restored from only minor disturbance, do not have the same historic and scientific interest as undisturbed pools.” Successful restoration must include long-term maintenance and monitoring to ensure that the *P. abramsii* and other vernal pool species persist. Development continues to threaten *Pogogyne abramsii*, and will not, in the foreseeable future, be reduced as a threat until sufficient private land supporting vernal pools has been conserved or purchased for reserves (USFWS, 2010).

**Stressor:** Off-Highway Vehicles (OHVs) (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** OHV use remains a threat to at least eight EOs including (11 vernal pool complexes), and is a predominant threat on Del Mar Mesa (Appendix 1). Installation and maintenance of fencing and signage are needed to help protect *P. abramsii* habitat from the impact of OHV users (USFWS, 2010).

**Stressor:** Military Activities (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals/loss of habitat

**Narrative:** Provisions under the Integrated Natural Resources Management Plan (INRMP) guide conservation and management of *Pogogyne abramsii* habitat on MCAS Miramar (see Factor D for further discussion). The military must maintain the flexibility to adapt the defense mission to political and technological developments (Department of Defense Instruction 4715.3 para. F.1. i(4)). For this reason, vernal pool sites on military lands are not considered fully protected, though threats to *P. abramsii* habitat are ameliorated under the INRMP. As of July 2010, no training activities or military maneuvers are planned that are expected to negatively impact *P. abramsii* in the near future (Kassebaum pers. comm. 2010); however military activities are considered a potential threat to all extant occurrences found on MCAS Miramar in the event that unforeseen circumstances necessitate changes in vernal pool management (USFWS, 2010).

**Stressor:** Alteration of Hydrology (USFWS, 2010)

**Exposure:**

**Response:****Consequence:** Loss of habitat

**Narrative:** Although altered hydrology continues to impact this species at six EOs (six vernal pool complexes), the Service has been successful in ensuring implementation of measures to reduce this threat through section 7 consultations. For example, the use of best management practices reduces the amount of runoff entering vernal pool watersheds, and restoration projects are designed to minimize water draining off impervious surfaces into vernal pool watersheds. However, the specific impact runoff has on *Pogogyne abramsii* is unknown because site specific monitoring has not been conducted. Preserved pools should be monitored for these runoff impacts to identify remediation where feasible and prevent further damage to vernal pool systems (USFWS, 2010).

**Stressor:** Illegal Dumping (USFWS, 2010)**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** Illegal dumping was identified as a threat at listing and continues to impact *Pogogyne abramsii* habitat at Carroll Canyon (EO 27), Del Mar Mesa - Deer Canyon (EO 38, 41; H 17), and Rose Canyon (EO 1) (Appendix 1). Additionally, pool complexes in Murphy Canyon (EO 3) have served as dump sites for domestic refuse in the past (Black and Zedler 1998, p. 203). Trash and other materials can decrease the amount of space available to vernal pool species, disturb the soils, and release toxic substances and pollutants which may make vernal pools inhospitable to *P. abramsii*. Fencing and monitoring may decrease the impact of this threat on protected lands, however illegal dumping and deterrence on private lands are difficult to control making this a continuing threat to *P. abramsii* (USFWS, 2010).

**Stressor:** Nonnative Plants (USFWS, 2010)**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** Development and other threats that disturb vernal pool habitat allow certain invasive nonnative plants, such as those discussed above, to invade and replace *Pogogyne abramsii*. Invasive nonnatives pose the biggest threat to *P. abramsii* and other vernal pool obligates on MCAS Miramar (Kassebaum pers. comm. 2010), specifically, invasive grasses and bromes (e.g. *Agrostis* spp. and *Bromus* spp.) which outcompete *P. abramsii* at the drier edges of vernal pools. Therefore, we consider invasive nonnative plants to be a continuing threat to *P. abramsii* (USFWS, 2011).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2010)**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** In summary, the Act provides the greatest regulatory protection to *Pogogyne abramsii*. Habitat conservation plans, and the related conservation actions arising from the Act have contributed to short and long term conservation of *P. abramsii*. The INRMP at MCAS Miramar has created policy mechanisms and partnerships that have restored and conserved vernal pool habitat. Additional potential protection provided by other Federal, State, and local laws and ordinances is discretionary, incomplete, subject to funding availability and changing

missions, and largely dependent on the federally listed status of *P. abramsii*. As a result, regulatory mechanisms provided by other Federal, State, and local laws and ordinances do not independently or collectively provide adequate regulatory protection to *P. abramsii* (USFWS, 2010).

**Stressor:** Human Access and Disturbance (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Separation of *Pogogyne abramsii* occurrences through habitat loss and fragmentation is often accompanied by effects associated with human access or disturbance associated with adjacent development. These include trampling, OHV-activity, pedestrian introduction of nonnatives, and trash dumping. This can directly impact *P. abramsii* by crushing, shading, or releasing toxic substances that harm individual plants. Human access and disturbance has been identified as a threat to seven EOs containing nine vernal pool complexes. Trampling by pedestrians and OHVs may damage or kill plants. Pool complex C28 (EO 36) on Mira Mesa was extirpated partly as a result of human access and disturbance, more specifically OHV damage and trampling (City of San Diego 2004). Pool complex H 39 (Greystone Highlands, EO 41) on Del Mar Mesa is vulnerable to human trampling from adults and children trespassing from the nearby residential development (City of San Diego, 2006, p. 34). Protective fencing is used in many conserved occurrence areas to protect vernal pool complexes (Appendix 1). Though implementing this protective measure has lessened the impacts of human access and disturbance, such effects still threaten *Pogogyne abramsii*. Occurrences on private, non-conserved lands remain vulnerable to this threat (USFWS, 2010).

**Stressor:** Drought and Climate Change (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species (including *Pogogyne abramsii*) or sites at this time. Although we cannot predict the exact effects of climate change on *P. abramsii*, it is likely that it will exacerbate identified threats and may introduce new additional threats. A changing climate with spatial and temporal shifting of temperature and precipitation may cause this species specific adaptations to climate to work against its survival. A changing climate may also provide advantages to other native and nonnative plant species. Sharing information between scientists, land managers, and decision makers will increase our ability to address these threats. Increasing the success with which we address current threats to *P. abramsii* will increase our success of handling the uncertain effects of future climate change (USFWS, 2010).

**Stressor:** Small Population Size (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of genetic variability/extinction

**Narrative:** The restricted range and small population of *Pogogyne abramsii* pose a threat as it increases the possibility that urban development or other activities near remnant pool ecosystems could destroy a significant portion of the species' remaining population and habitat

(USFWS 1993, p. 41390). *Pogogyne abramsii* is distributed on approximately 19.2 ac (7.8 ha) of vernal pool habitat on MCAS Miramar, and approximately 0.8 ac (0.3 ha) outside the boundary of MCAS Miramar (U.S Marine Corp 2006, p. 5-4; City of San Diego 2004, p. 11). Stochastic events outside the natural range of frequency and severity, such as floods, fires, contamination, or drought, can substantially reduce or eliminate species, such as *P. abramsii* with a restricted range and small population, and increase the likelihood of extinction (Lande 1993, p. 912). Genetic effects may further influence population demography via inbreeding depression and genetic drift (Barrett and Kohn 1991, pp. 3-30; Menges 1991, pp. 58 – 61). Allee (1931, pp. 17- 50) suggested small, single populations are vulnerable to extirpation when opportunities for reproduction diminish because of reduced opportunity of individuals to reproduce (Allee effect or depensation) (Courchamp et al. 2008, pp. vi – 216). Stephens et al. (1999, pp. 185 -190), Dennis (2002, pp. 389 - 401) and Courchamp et al. (2008, pp. vi – 216) suggest that the Allee effect is a density-dependent event that is inversely related to population size. The isolated vernal pool complex on Los Pensquitos Canyon (EO 54, complex B5-8) and on Mira Mesa (EO 36, complex B11) are all that remain in both of these areas making *P. abramsii* susceptible to random events here (USFWS, 2010).

**Stressor:** Fire control (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Fire control has been identified as a potential threat to *Pogogyne abramsii* at two of the 28 extant EOs (four vernal pool complexes) listed in Appendix 1. The ecological effects of fire exclusion in the habitat of southern California has not been specifically detailed for vernal pool habitat, however the processes and structure of fire ecology is comparable to other ecosystems (Keane et al. 2002, pp. 3–11; D’Antonio and Vitousek 1992, pp. 63 - 87). Fire exclusion may affect the natural regulation of succession via selecting and regenerating plants. Species that are adapted to light fire (such as *P. abramsii* during the dry season) are replaced by species that are able to out compete for growing resources in the absence of fire (Keane et al. 2002, pp. 3 - 11). While complete fire exclusion may result in *Pogogyne abramsii* being outcompeted for space, the alternative may pose an equal threat as fires at critical times can eliminate populations of *P. abramsii* by killing individual plants, overheating soil to create hydrophobic conditions, or intense heat which kills or eliminates the seed bank (Agee 1993, pp. 1–493; Keane et al. 2002, pp. 3–11; Keeley 2001, pp. 81–94; Arno and Fiedler 2005, pp. 7-38). The severity of fires may be exacerbated by a greater fuel load provided by nonnatives (Bauder 1996, p. 3), and a higher density of established native upland species that have not been disturbed by fires in the past (MALGBC 2007, p. 7). Fire suppression has been identified as a threat at Del Mar Mesa which could act as a staging ground for fire control activities if a fire began (City of San Diego 2006, pp. 37, 42). Currently a burn study is being conducted on MCAS Miramar to determine how fire impacts vernal pool species. Initial observations show that there is no difference between species composition between burned and unburned vernal pools (Kassebaum pers. comm. 2010) (USFWS, 2010).

**Stressor:**

**Exposure:**

**Response:**

**Consequence:**

**Narrative:**

**Recovery****Reclassification Criteria:**

"Existing vernal pools and their associated watersheds...should be secured from further loss and degradation. Habitat functions and species viability... must be ensured... Maintaining habitat function and species viability (as determined by prescribed research tasks)" (USFWS, 2010)

The existing vernal pools and their associated watersheds contained within the complexes...are secured in a configuration that maintains habitat function and species viability (as determined by recommended research); (USFWS, 2010)

Secured vernal pools are enhanced or restored such that population levels of existing species are stabilized or increased; (USFWS, 2010)

Population trends must be shown to be stable or increasing for a minimum of 10 consecutive years prior to consideration for reclassification. Monitoring should continue for a period of at least 10 years following reclassification to ensure population stability" (USFWS 1998a, p. iv-vi). (USFWS, 2010)

Recovery Priority Number: 8C

**Delisting Criteria:**

In the interest of ensuring these criteria are clearly articulated, we are amending the following clarification to the existing recovery plan. This amendment does not represent a revision of the delisting criteria, it simply provides more specific terminology. Delisting for the species covered by the 1998 recovery plan may be considered when the downlisting criteria have been met and:

1. All 74 geographic areas and associated vernal pool complexes as identified in Appendices F and G of the 1998 Recovery Plan under each of the specific management areas are protected and managed to ensure long-term viability. 2. The U.S. Fish and Wildlife Service must determine that the following factors are no longer present, or continue to adversely affect, *Eryngium aristulatum* var. *parishii*, *Pogogyne abramsii*, *Pogogyne nudiuscula*, *Orcuttia californica*, and the Riverside and San Diego fairy shrimp: ( 1) the present or threatened destruction, modification, or curtailment of their habitat range; (2) over utilization for commercial, recreational, scientific, or educational purposes; (3) disease or predation; (4) the inadequacy of existing regulatory mechanisms; and ( 5) other natural and manmade factors affecting their continued existence (50 CFR 424.11). 3. Population trends for all seven taxa continue to be stable or increasing for 10 consecutive years after threats have been sufficiently ameliorated or managed ( completion of delisting criterion 2) prior to consideration for delisting. (USFWS, 2019)

**Recovery Actions:**

- "Conduct surveys and research essential to the conservation of these species; (USFWS, 2010)
- Secure the existing vernal pools and their associated watersheds; (USFWS, 2010)
- Where necessary reestablish vernal pool habitat to the historical structure; (USFWS, 2010)
- Manage and monitor habitat and listed species"(USFWS 1998a, p. vi). (USFWS, 2010)
- Support continued conservation, management and monitoring of *Pogogyne abramsii* habitat to include acquisition of occupied sites (USFWS, 2010)

- Develop a coordinated interagency invasive species prevention and eradication program for all vernal pool habitat where *Pogogyne abramsii* is extant (USFWS, 2010).
- Identify the conditions and areas necessary to support all of the necessary biotic interactions (e.g. pollination, seed dispersal, population movement) for *Pogogyne abramsii* (USFWS, 2010).
- Monitor restored/enhanced habitat to determine their suitability and impact in furtherance of recovery of *Pogogyne abramsii* (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS** The recommended actions listed below are to be initiated over the next 5 years. Successful implementation of these actions will reduce threats and provide a better understanding of *Pogogyne abramsii* population health and habitat requirements. We recognize that conservation of this taxon will require cooperation and coordination with partners to minimize impacts from current threats and aid future restoration efforts. The recommended actions listed below include actions from the previous 5-year review and new actions that are relevant to the conservation of *P. abramsii*. Work with partners to identify opportunities for conservation or preservation of *Pogogyne abramsii* occurrences on private lands. Support land acquisition to meet Habitat Conservation Plan goals. Work with local, State, and Federal partners to identify and leverage funding (i.e., section 6) to acquire *P. abramsii* habitat. 1. Adaptively manage *Pogogyne abramsii* occurrences to maintain, enhance, or restore habitat and reduce threats. a. Manage nonnative species in vernal pool habitat. b. Coordinate with partners to develop a nonnative species prevention and eradication program for all vernal pool habitat where *P. abramsii* is extant. c. Ensure the correct species pallet from a nearby source is being selected for areas during restoration projects inside and outside of the known range for *P. abramsii*. 2. Monitor occurrences (evaluate habitat quality, and threats) and assess management effectiveness. a. Conserve *Pogogyne abramsii* seed in an off-site seed bank. b. Monitor restored/enhanced habitat to determine their suitability and impact in furtherance of recovery of *Pogogyne abramsii*. c. Identify the conditions and areas necessary to support all the necessary biotic interactions (e.g., pollination, seed dispersal, population movement) for *Pogogyne abramsii*. 3. Formalize *Pogogyne abramsii* monitoring on MCAS Miramar consistent with the methodology used in the City of San Diego Vernal Pool HCP so that data can be analyzed across the range of the species. 4. Help locate funding to support nonnative plant removal activities within vulnerable vernal pool groups where *Pogogyne abramsii* occurs (i.e., MCAS Miramar) (USFWS, 2023).

## SPECIES ACCOUNT: *Pogogyne nudiuscula* (Otay mesa-mint)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

A small aromatic annual to 3 dm tall. Leaves are dark green, opposite, ovate to oblong and hairless. There are both axillary flowers and flowers at the top of the plant. The flowers are two-lipped, lavender and 11-14mm long. The fruit consists of small nutlets. Blooming is May-July. (NatureServe, 2015)

### **Taxonomy**

*Pogogyne nudiuscula* is an annual herb in the mint family (Lamiaceae). As was mentioned in the description for *Pogogyne abramsii*, Howell (1931) considered all *Pogogyne* populations on Otay Mesa to be *Pogogyne nudiuscula*. Many of the older herbarium specimens that might be from the central mesas are labeled as *Pogogyne nudiuscula*, but are likely *Pogogyne abramsii*. Howell considered *Pogogyne nudiuscula* to be diagnosable from *Pogogyne abramsii* by having a glabrous (smooth) calyx and bract with a different morphology. This distinction is supported by current work (Jokerst 1993; McMillan unpublished data 1995), and the species is also diagnosable by usually having at least six flowers per node on the stem (USFWS, 1998).

### **Historical Range**

Historically *P. nudiuscula* was found beyond Otay Mesa and occurred at 10 locations in southern San Diego County (Appendix 1). Herbarium records indicate that *P. nudiuscula* historically occurred further north near University Heights, Balboa Park, and Mission Valley (CNDDB 2010, Element Occurrence (EOs) 4, 9, and 10, respectively). Also, *P. nudiuscula* occurred in Mexico at the eastern edge of the city of Tijuana; however, it was believed to be extirpated from its Mexican locations prior to listing (Bauder and McMillan 1998, p. 65; USFWS 1993, p. 41385). Currently, *P. nudiuscula* is found at three locations on Otay Mesa: Otay Mesa West, Otay Mesa East, and Otay Mesa Northeast (Appendix 1). (USFWS, 2010)

### **Current Range**

San Diego County, California; adjacent Baja California, Mexico. The range extent covers approximately 370 sq mi. (NatureServe, 2015)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Insect pollinated (NatureServe, 2015)

### **Reproduction Narrative**

Adult: The family is primarily bee pollinated (Proctor & Yeo, 1973, p. 219).; (NatureServe, 2015). There is little documented information regarding pollination and seed dispersal mechanisms of *P. nudiusscula*. Observations in the field suggest that native syrphid flies (Syrphidae) and bee flies (Bombyliidae) are the most common pollinators (S. McMillan, EDAW pers. comm. 2010). Eurasian honeybees (Apidae) have also been seen pollinating *P. nudiusscula* (McMillan, pers. comm. 2010). Research on the similar species *Pogogyne abramsii* show that it is self-fertile but has greater seed set when cross-pollinated (Schiller et al. 2000, p. 393); further research is necessary to determine if this is the case for *P. nudiusscula* (USFWS, 2010).

**Habitat Type**

Adult: Vernal pools (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist

**Habitat Narrative**

Adult: Vernal pools (Smith & Berg, 1988). Moist flats in chaparral and coastal sage scrub (Munz, 1959). (NatureServe, 2015)

***Dispersal/Migration*****Dispersal**

Adult: Moderate (USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: Zedler and Black (1992, p. 4) found that *Pogogyne abramsii* seeds germinated and grew from pellets of brush rabbits (*Sylvilagus bachmani*) and Audubon's cottontail rabbits (*S. auduboni*) that were collected from vernal pools on Del Mar Mesa and Miramar Mesa. Zedler and Black (1992, p. 2) postulated that rabbit movement may be a potential vector for seed dispersal and genetic mixing of vernal pool obligate species including *P. abramsii*. They concluded that rabbit dispersal explains the "anomalous occurrence of vernal pool plants in newly excavated artificial pools (1992, p. 8)." Additionally, *P. abramsii* seeds float, which may result in limited dispersal opportunities when pools interconnect or lakes fill their basins in years of greater than average precipitation (Scheidlinger 1981, p. 54). It is possible that these dispersal mechanisms also apply to *P. nudiusscula*; however, data do not exist to support this assumption (USFWS, 2010).

***Population Information and Trends*****Population Trends:**

Decreasing (NatureServe, 2015)

**Number of Populations:**

17 known and 2 questionable (USFWS, 2021)

**Population Size:**

1000 - 2500 individuals (NatureServe, 2015)

**Population Narrative:**

This wetland annual endemic is highly vulnerable. The long term trend is one of very rapid decline. Decline of >90% Population numbers for this annual are mostly unknown. CNDDDB records only record a total of 1700 plants from all currently known vernal pools. This is likely wildly off from reality. Of 9 EOs, at least five may be extirpated, and all but a few are severely threatened. (NatureServe, 2015). Based on current updates, there are 24 *Pogogyne nudiuscula* locations (Figure 2, Table 1): 17 are extant, 2 are presumed extant, 3 are historically extirpated, and 2 have questionable identification. (USFWS, 2021)

**Threats and Stressors**

**Stressor:** Urban development (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Planned and ongoing development projects throughout *Pogogyne nudiuscula*'s range were described as a primary threat in the listing rule (USFWS 1993, p. 41387). Urban development may result in: (1) the loss or damage of vernal pools by filling, grading, discing, leveling, and other activities; and (2) destruction of watersheds and the hydrology that support vernal pools; (3) isolation of vernal pools; (4) fragmentation of vernal pool systems. Destruction of watersheds and disruption of hydrological systems can create further impacts by creating barriers to dispersal, such that pollination and reproductive output may be inhibited (Schiller et al. 2000, p. 395). Potential means of seed dispersal (e.g., rabbits, floating seeds) (Zedler and Black 1992, p. 2) may also be impacted. Whenever development impacts vernal pools in a complex, some degree of fragmentation occurs within and among complexes. Because *P. nudiuscula* has specific habitat requirements (e.g., soil type, water depth), habitat degradation and alteration likely result in population decline (USFWS, 2010).

**Stressor:** Road projects (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Road projects are a type of development that pose a threat to *Pogogyne nudiuscula* habitat at Otay Mesa West, Otay Mesa South, and Otay Mesa Northeast (Appendix 1). First, the listing rule identified State Route 125 construction on Otay Mesa as a project that could impact *P. nudiuscula* habitat. This project was completed and directly impacted vernal pool basins on the Otay Mesa Northeast occurrence (i.e., J29–30); however, vernal pools containing *P. nudiuscula* were avoided in one pool and seeds were collected and used to reestablish populations within their mitigation site which encompass J29–30 (Wynn, pers. obs. 2010). Second, the construction associated with Interstate 905 and Otay Mesa Road (J14) did not directly impact *P. nudiuscula*; however, indirect impacts in the future in the form of edge effects (see below) are possible. Third, State Route 11 (associated with a new U.S./Mexico border crossing) is planned southeast of State Route 125 on Otay Mesa. Though habitat is present, *P. nudiuscula* was not detected and Caltrans anticipates future potential edge effects to vernal pools if they are discovered in the area (USDOT and Caltrans 2008, p. 3.20-11–3.20-15). Edge effects to *Pogogyne nudiuscula* are evident as a result of road widening projects, creating outer bands of habitat distant from the center but immediately proximal to a different type of habitat, thus providing a different species composition and abundance divergent from the interior of the habitat (Forman and Gordon

1986, p. 108). These edges may allow *P. nudiusscula* to be in closer proximity to disturbed areas, which may facilitate the incursion of invasive, nonnative plants that can outcompete *P. nudiusscula* for space (see also Factor E discussion). Edge effects degrade extant interior habitat and create an island of the protected habitat/reserve through isolation and decrease the effective size and serviceability of a conservation area (Diamond and May 1976, pp. 228–252). Characteristics of habitat islands include less resistant habitat, more disturbed habitat, areas more susceptible to invasive species, areas with native species less resistant to disturbance, and higher seed immigration (Meyers and Bazely 2003, pp. 34-50). Further development of the roads mentioned above and surrounding areas would exacerbate these impacts (USFWS, 2010).

**Stressor:** Alteration of watershed (Hydrology) (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Although altered hydrology continues to be a threat to the species, the Service has been successful in ensuring implementation of measures to reduce this threat through section 7 consultations. For example, best management practices reduce the amount of runoff entering vernal pool watersheds, and restoration projects are designed to minimize water draining off impervious surfaces into vernal pool watersheds. However, the specific impact runoff has on *Pogogyne nudiusscula* is unknown because site specific monitoring has not been conducted. Preserved pools should be monitored for these runoff impacts to identify remediation where feasible and prevent further damage to vernal pool systems (USFWS, 2010).

**Stressor:** Compaction of erosion of soil (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Recent studies suggest that trampling associated with limited livestock grazing in the watershed may benefit some vernal pool species by increasing the inundation period of the pools through reduction of vegetation (particularly nonnative grass) in the watershed and compaction of the soil, which reduces infiltration (Marty 2005, p. 1630). Grazing may also increase the duration of vernal pool inundation by altering soil properties and modifying the rate of evapotranspiration from plants, thus counteracting the potential decrease in precipitation brought about by climate change to some degree (Pyke and Marty 2005, p. 1623). However, it is unknown if *Pogogyne nudiusscula* or vernal pool habitat in San Diego County benefit from low levels of trampling (USFWS, 2010)

**Stressor:** Off-Highway Vehicles (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Since listing, OHV continues to threaten *Pogogyne nudiusscula*, especially from recreational and Border Patrol activities (see Appendix 1). Installation and maintenance of fencing and signage are needed to help protect *P. nudiusscula* habitat from these impacts (USFWS, 2010).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2010)

**Exposure:**

**Response:****Consequence:** Loss of habitat

**Narrative:** Since listing in 1993, the Act is the primary law that provides protection for *Pogogyne nudiuscula* on Federal lands or in instances where there is a Federal nexus. Nearly all occurrences of *P. nudiuscula* are conserved under the San Diego's MSCP; however, coverage for this species and six other vernal pool species was removed from the City of San Diego Subarea Plan in April 2010. The Service accepted the City's relinquishment of coverage for vernal pool species; thus, *P. nudiuscula* is no longer a covered species under the subarea plan. However, the City of San Diego is currently working with the Service to revise and improve the management plan for *P. nudiuscula* under the MSCP. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. However, once a revised subarea plan is completed that provides coverage for *P. nudiuscula*, the Act will likely provide the most effective protection for the species (USFWS, 2010).

**Stressor:** Competition with invasive, nonnative plants (USFWS, 2010)**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** Depending upon conditions, certain invasive, nonnative plants (such as the grasses discussed above) may replace *Pogogyne nudiuscula*. Therefore, we consider invasive, nonnative plants to be a continuing rangewide threat to all extant occurrences of *P. nudiuscula* (USFWS, 2010).

**Stressor:** Human access and disturbance effects (USFWS, 2010)**Exposure:****Response:****Consequence:** Loss of individuals

**Narrative:** Protective fencing is used in several conserved areas to protect vernal pool complexes and has been successful in significantly decreasing the impact of trampling and OHV use in the J29–30 vernal pool complex at Otay Mesa Northeast and J2 N/W/S vernal pool complex at Otay Mesa West (City of San Diego 1997, p. 299, 316). Though implementing this protective measure has lessened the impacts of human access and disturbance, such effects still threaten *Pogogyne nudiuscula* occurrences. The J32 complex in the Otay Mesa West occurrence may be the most severely impacted by trampling due to foot traffic by immigrants, transients, Border Patrol, and OHV use (City of San Diego 1997, p. 236). Fencing was installed and stolen (City of San Diego 1997, p. 236) indicating that monitoring is critical in reducing the impacts of human access and disturbance (USFWS, 2010).

**Stressor:** Fire and fire suppression activity (USFWS, 2010)**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** Fire and fire suppression have been identified as a current potential threat at three of the four occurrences (vernal pool complexes J2, J2 N/W/S, J28, J14, and J29–30), with the exception of the Otay Mesa East occurrence. These areas may serve as a staging area in the event of a fire if defensible structures are developed in the vicinity (City of San Diego 1997) (USFWS, 2011).

**Stressor:** Drought and climate change (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species, including *Pogogyne nudiuscula* or sites at this time. However, it is likely that impacts from existing threats could increase and new threats may arise. Sharing information between scientists, land managers, and decision makers will increase our ability to address and manage these threats (USFWS, 2010).

**Stressor:** Small population size (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:** Lack of genetic variability/extinction

**Narrative:** Since listing, *Pogogyne nudiuscula*'s range has decreased and there have been no new occurrences of the species. Therefore, restricted range and small population size continue to threaten *P. nudiuscula* at all of its occurrences (USFWS, 2010).

## **Recovery**

### **Delisting Criteria:**

All the existing vernal pools and their watersheds identified in Appendix F and G of the Recovery Plan should be secured from further loss and degradation in a configuration that maintains habitat function and viability (as determined by prescribed research tasks) (USFWS, 2010).

Secured vernal pools must be enhanced or restored such that population levels of existing species are stabilized or increased (USFWS, 2010).

Population trends must be shown to be stable or increasing for a minimum of 10 consecutive years prior to consideration for reclassification (USFWS, 2010).

In the interest of ensuring these criteria are clearly articulated, we are amending the following clarification to the existing recovery plan. This amendment does not represent a revision of the delisting criteria, it simply provides more specific terminology. Delisting for the species covered by the 1998 recovery plan may be considered when the downlisting criteria have been met and:

1. All 74 geographic areas and associated vernal pool complexes as identified in Appendices F and G of the 1998 Recovery Plan under each of the specific management areas are protected and managed to ensure long-term viability.
2. The U.S. Fish and Wildlife Service must determine that the following factors are no longer present, or continue to adversely affect, *Eryngium aristulatum* var. *parishii*, *Pogogyne abramsii*, *Pogogyne nudiuscula*, *Orcuttia californica*, and the Riverside and San Diego fairy shrimp: ( 1) the present or threatened destruction, modification, or curtailment of their habitat range; (2) over utilization for commercial, recreational, scientific, or educational purposes; (3) disease or predation; (4) the inadequacy of existing regulatory mechanisms; and ( 5) other natural and manmade factors affecting their continued existence (50 CFR 424.11).
3. Population trends for all seven taxa continue to be stable or increasing for 10 consecutive years after threats have been sufficiently ameliorated or managed ( completion of

delisting criterion 2) prior to consideration for delisting. (USFWS, 2019)

**Recovery Actions:**

- This recovery criterion does not explicitly address any of the threat factors identified in the five factor analysis in the listing rule or in the above discussion. Moreover, achievement of this criterion as written is complicated by the fact that some pool basins within the complexes identified in Appendices F and G have been developed or preserved in accordance with provisions of regional HCPs since the completion of the Recovery Plan. However, working toward the goals in this criterion will reduce the threats discussed above under Factors A and E. Securing vernal pool complexes physically, legally, and ecologically would reduce threats posed by development (e.g., habitat loss and alterations of hydrology) and discussed under Factor A and E above. As discussed in Factor A, all of the extant occurrences of *Pogogyne nudiuscula*, are partially or completely conserved and those that are only partial conserved have been mitigated in another area of suitable habitat (Appendix 1). These protections generally extend to direct loss and not necessarily indirect loss of habitat through degradation. These lands are under conservation easements or protected in perpetuity, conserved through mitigation, or have some sort of protection from development (Appendix 1). Pools within these areas meet the criterion in the Recovery Plan as “secured legally” from further habitat loss. In the Recovery Plan, Appendix F lists the vernal pool occurrences that are necessary to stabilize the proposed and listed vernal pool species (USFWS 1998, p. F1). Appendix G of the Recovery Plan lists vernal pool occurrences identified as necessary to secure in order to reclassify the proposed and listed vernal pool species (USFWS 1998, p. G1). Appendix G broadly lists complex J (undescribed) and J–3 and J–22. *Pogogyne nudiuscula* is found throughout the J complex and portions of this complex have been conserved partially or fully and other areas have been extirpated and mitigated. Although some of these occurrences are considered secure from development, they are not all guaranteed monitoring or maintenance in perpetuity. Although it is not possible to specifically identify every complex in Appendices F and G of the Recovery Plan, development and impacts on complexes listed in Appendices F and G that contain *P. nudiuscula* should be avoided. Additionally, the Service is working towards conserving these complexes (USFWS, 2010).
- This criterion does not directly address any of the threats discussed above in the five-factor analysis. Rather, it uses a measure of stability that is not easily assessed for *Pogogyne nudiuscula*. As discussed in the abundance section of this 5-year review, the population numbers for *P. nudiuscula* are not easily measured. Because methods of measurement are not standardized and *P. nudiuscula* does not germinate every year, population abundance is not a good indicator for the species. However, restoration and management do provide a measure of protection against threats to the species. Additionally, the CFWO issues biological opinions associated with consultations under section 7 of the Act for *Pogogyne nudiuscula*. These opinions detail avoidance and minimization measures to prevent jeopardizing the species’ continued existence and can include restoration of *P. nudiuscula* habitat. Many of these opinions lead to successful restoration and protected populations of *P. nudiuscula*. Some pools are being restored and therefore meet the outlined goals of Criterion 3 in the Recovery Plan (USFWS, 2010).
- This criterion does not directly address any threats outlined in the five-factor analysis. In order to stabilize or increase the population, threats would have to be reduced. Reducing the threats discussed above in Factors A and E would help us provide the conditions needed to work toward the goal in this criterion, but vernal pool habitat has been reduced by

human-induced conversion (Bauder and McMillan 1998, p. 66). As yet, however, it is difficult to assess the abundance of *Pogogyne nudiuscula* in the absence of standardized sampling methods and population trends for vernal pool annuals are often difficult to detect. Therefore, we are unable to address this criterion (USFWS, 2010).

- Support continued conservation, management, and monitoring of vernal pool habitat that supports *Pogogyne nudiuscula*, including monitoring of restored/enhanced habitat to determine if vernal pool restoration projects continue to be viable through time (e.g., artificial clay layer remains stable and supports adequate ponding) (USFWS, 2010).
- Work with the Otay Mesa Water District to address inundation of pools in J26 from the Otay Mesa water pump. Implement measures to ensure that water does not flow over the road and into the pools (USFWS, 2010).
- Conduct research to determine life history traits most vulnerable to threats discussed in the five factor analysis (USFWS, 2010).
- Develop a dynamic, threats based, species-specific recovery plan based on analysis of current knowledge of the species (USFWS, 2010).
- Establish a seed bank for *Pogogyne nudiuscula* according to Center for Plant Conservation guidelines (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS** The recommended actions listed below were identified in the 2010 status review (USFWS 2010, p. 29). The actions were intended to reduce threats to *Pogogyne nudiuscula* and provide information to better understand the biological and physical factors limiting the population growth and distribution. We recognize that conservation of *P. nudiuscula* will require cooperation and coordination with partners to minimize impacts from current threats, aid future restoration, and maximize effectiveness of limited funding. We continue to believe the actions described in 2010 are relevant to the conservation of *P. nudiuscula*. 1. Support continued conservation and management of vernal pool habitat that supports *Pogogyne nudiuscula*, with emphasis on complexes that are not currently conserved and those within the Stockpen soil association. 2. Develop and implement a long-term monitoring program to describe population trends to better understand the resiliency of the different vernal pool complexes, including monitoring of restored and enhanced habitat to determine if vernal pool restoration projects continue to be viable through time (e.g., artificial clay layer remains stable and supports adequate ponding). 3. Identify a new conservation easement holder and land manager for the J26 complex. 4. Conduct research to determine life history traits most vulnerable to threats discussed in the five-factor analysis. 5. Develop a dynamic, threats based, species-specific recovery plan based on analysis of current knowledge of the species. (USFWS, 2021)

## SPECIES ACCOUNT: *Polygala lewtonii* (Lewton's polygala)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 5/27/1993; Southeast Region (R4) (USFWS, 2015)

### **Physical Description**

*Polygala lewtonii* is a relatively short-lived (5 to 10 year) perennial herb. Each plant produces one to several annual stems, which are spreading, upward-curving or erect, and are often branched. The leaves are small, sessile, rather succulent, broader toward the tip, and are borne upright, tending to overlap along the stem, like shingles. The normally opening flowers are in erect, loosely flowered racemes about 1.5 cm (Wunderlin et al. 1981) or 3.3 cm (Weekley 1996) long. The flowers are about 0.5 cm long and bright pink (Wunderlin et al. 1981) or purplish-red (Ward and Godfrey 1979). Two of the five sepals are enlarged and wing-like, between which the largest of the three petals forms a keel that ends in a tuft of finger-like projections (Ward and Godfrey 1979). The plant also produces two types of small, cleistogamous (non-sexual) flowers (L. Miller, Ocala NF, personal communication 1996, Weekley 1996). This species is closely related to the widespread *P. polygama*, which forms larger clumps and has a longer root, narrower leaves, and differently shaped wing sepals. It also has short branches that hug the ground, bearing inconspicuous self-pollinating flowers. (USFWS, 1999)

### **Taxonomy**

This small herb was first collected near Frostproof, Florida by F. L. Lewton in 1894, and was named by J.K. Small (1898). The status of *P. lewtonii* as a distinct species was affirmed by Blake (1924) and James (1957). There have been no other taxonomic treatments of this species. (USFWS, 1999)

### **Historical Range**

See current range.

### **Current Range**

Lewton's polygala occurs in sandhill (high pine) vegetation and Florida scrub of the Lake Wales and Mount Dora ridges in Highlands, Polk, Osceola, Orange, Lake, and Marion Counties of central Florida. (USFWS, 1999)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Insect pollination/self-fertilization

### **Lifespan**

Adult: relatively short-lived (5-10 year) (USFWS, 2019)

**Other Reproductive Information**

Adult: Lewton's polygala is amphicarpic, producing flowers and fruits above and below ground at different times (Menges and Weekley 2002). Lewton's polygala is one of only a few dozen amphicarpic angiosperms known worldwide. Amphicarpy is viewed as an adaptation for reproduction in uncertain habitats, for example, producing seeds underground where they have better chances of surviving fire (Cheplick and Quinn 1982) and are protected from herbivory (Menges and Weekley 2003). While self-fertilization occurs in Lewton's polygala, it appears to be a less-reliable mechanism for seed production than insect pollination. (USFWS, 2019)

**Reproduction Narrative**

Adult: Confusion has existed about whether *P. lewtonii* has cleistogamous flowers (James 1957, Wunderlin et al. 1981, Ward and Godfrey 1979, FWS 1996). More recently, Weekley (1996) and Miller (Ocala NF, personal communication 1996) confirmed the presence of two types of cleistogamous flowers. The first are solitary flowers in the axils of the lower leaves and the second are few-flowered racemes on underground rhizomes that are usually 5 to 15 cm long (Weekley 1996). *Polygala lewtonii* blooms from February to May with chasmogamous flowers dominating from February to April. Chasmogamous flowers have an average of four to six racemes per plant, though one extreme individual had 30 racemes (Weekley 1996). Each raceme has 20 to 25 flowers 85 to 100 percent of these set fruit. This high percentage of fruit set suggests that flowers self-pollinate when insect pollinators are not present. (USFWS, 1999).

**Habitat Type**

Adult: high pine and turkey oak barrens and transitional areas (USFWS, 1999)

**Environmental Specificity**

Adult: Narrow (USFWS, 1999)

**Habitat Narrative**

Adult: *Polygala lewtonii* is not strictly a scrub species and is found in widely scattered populations that frequently occur in transitional habitats between high pine and turkey oak barrens. *P. lewtonii* also occurs in both habitats (Wunderlin et al. 1981, Christman 1988). *P. lewtonii* depends on fire to maintain its habitat. It is found in sunny openings and often colonizes disturbed sites, such as roadsides and fire lanes. *P. lewtonii*'s preference for transitional habitats between high pine and turkey oak barrens suggests a preference for a burn frequency that is less frequent than high pine, but more frequent than turkey oak barrens. (USFWS, 1999)

***Dispersal/Migration******Population Information and Trends*****Number of Populations:**

32 known occurrences (USFWS, 2021)

**Population Narrative:**

Lewton's polygala is a perennial herb occurring in sandhill and scrub communities on the Lake Wales and Mount Dora Ridges in central Florida. Currently, there are an estimated 32 extant populations, though most are of unknown status due to lack of recent surveys, and 19 known or

possibly extirpated populations (Table 1). Of the 32 extant populations, only 1 is stable to increasing, 6 are stable, 2 are declining, and 23 have an unknown status (Table 1). Although demographic and abundance data have been collected at 6 populations for approximately 20 years (Rosner-Katz 2020; Menges et al. 2021; Noland 2021), information on natural recruitment and age distribution is lacking for almost all populations, and trends cannot be determined. (USFWS, 2021)

### ***Threats and Stressors***

**Stressor:** Habitat destruction or modification

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 million persons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** This species occurs within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

**Recovery****Reclassification Criteria:**

1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to assure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)
2. When these sites, within the historic range of *P. lewtonii*, are adequately protected from further habitat loss, degradation, and fragmentation (USFWS, 1999)
3. When these sites are managed to maintain the seral stages of high pine and xeric oak scrub to support *P. lewtonii* (USFWS, 1999)
4. When monitoring programs demonstrate that these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. (USFWS, 1999)

**Delisting Criteria:**

1. At least 40 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)
2. Populations (as defined in criterion 1) in yellow sand scrub or sand hill habitats are distributed across the known range of the species. (USFWS, 2019)
3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**

- Determine current distribution and status of *P. lewtonii*. This species' distribution is somewhat questionable since individuals are easily overlooked. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)

- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, has become isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species, more specific biological information is needed. (USFWS, 1999)
- Monitor existing populations of *P. lewtonii*. (USFWS, 1999)
- Provide public information about *P. lewtonii*. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about *P. lewtonii*. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of *P. lewtonii* and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS A detailed discussion of recovery actions and criteria are presented in the Recovery Plan and amendment (Service 1999 and 2019, respectively). During this status review new and/or targeted potential recovery activities were identified and are included below. Recovery Activities • Conduct habitat restoration efforts at possibly extirpated sites on managed lands since Lewton's polygala has a persistent soil seed bank and can reappear after fire/restoration. Lewton's polygala 5-Year Review • Work with State, Federal, and non-profit partners to ensure adequate fire management is achieved at sites that support Lewton's polygala. • Work with private landowners to acquire or conserve extant populations and restore sandhill and scrub habitat on these sites. • Strengthen ex situ conservation measures, including ensuring representation of Lewton's polygala at the National Center for Genetic Resources Preservation in Fort Collins, Colorado. Monitoring/Research Activities • Determine the condition of populations on private land whose status is currently unknown. • Expand level 3 (demographic) monitoring to more populations, such as ONF, Tiger Creek Preserve, and Bok Tower Gardens Pine Ridge Preserve, (as recommended by Menges et al. 2019) to determine trends and produce a population viability analysis. • Develop a standard methodology for monitoring Lewton's polygala on conservation lands. • Initiate large-scale level 1 (distribution) and 2 (population size/condition) monitoring of Lewton's polygala throughout the geographic range, including sites across a spectrum of time-since-fire and management regimes. • Compare germination rates of aboveground to belowground seeds and investigate the limitations to germination of aboveground seeds. • Determine the status of pollinator populations. (USFWS, 2021)

## SPECIES ACCOUNT: *Polygala smallii* (Tiny polygala)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 8/19/1985; Southeast Region (R4)

### **Physical Description**

Tiny polygala is an erect short-lived herbaceous species. Most plants germinate and die within one year. It forms a rosette and grows no more than 8 cm tall (Kennedy 1998). It has one to four, short, usually unbranched stems, and a well-developed, scented taproot. Its leaves are oblanceolate to lanceolate, from 1.5 to 5 cm long and 0.2 to 1.4 cm broad and occur in a basal rosette. The inflorescence is a cylindric raceme from 0.4 to 7 cm long and 0.5 to 1.8 cm thick and usually surpassed by the basal leaves (Kennedy 1998). The flowers have both functional stamens and pistils (perfect) and are not radially symmetrical (zygomorphic). The calyx has five sepals. The lateral pair is decurrent, large and petaloid. The corolla is a greenish-yellow color with three petals. The fruit is a thin-walled, two-celled capsule that splits down the center of the compartment. The seed is 1.2 to 1.4 mm long, with sparse rather short, stiff, appressed hairs (strigose). It also has a pair of aril-like outgrowths about half the length of the capsule (Gann and Bradley 1995, Smith and Ward 1976). (USFWS, 1999)

### **Taxonomy**

J.K. Small first described tiny polygala as *Polygala arenicola* (Small 1905; type specimen at New York Botanical Garden, Small #1276). The specific epithet was later found to be invalid due to its prior use in 1903 by Gurke in describing another species of *Polygala* from southeast Africa (Smith and Ward 1976). In 1933, Small revived the segregate genus *Pilostaxis* Raf., and renamed tiny polygala *Pilostaxis arenicola* (Small) Small. The genus *Pilostaxis* has since fallen out of use, but represents the series *Decurrentes*, a natural group of seven species of *Polygala* found only in the southeastern U.S. (Smith and Ward 1976). Long and Lakela (1971) considered tiny polygala to be conspecific with *Polygala nana* (Michx.) DC., a species widely distributed in the southeastern U.S., but in 1976, Smith and Ward defended the specific status of tiny polygala, recognizing distinct characters of the seeds, lateral sepals, flower color, and leaves, and proposed *Polygala smallii* Smith and Ward as a nomen novum. Synonyms: *Polygala arenicola* Small, non Gurke; *Pilostaxis arenicola* (Small) Small; *Polygala nana* auct., non (Michx.) DC. (USFWS, 1999)

### **Historical Range**

See Current Range. The historic distribution of tiny polygala to the north is uncertain; it possibly ranged as far north as central Brevard County, Florida. (USFWS, 1999)

### **Current Range**

This species is known to occur on the Atlantic Coastal Ridge of southeast Florida, in Miami-Dade, Palm Beach, St. Lucie, and Martin Counties. (USFWS, 2019)

### **Critical Habitat Designated**

No;

### **Life History**

**Food/Nutrient Resources****Lifespan**

Adult: ~ 180 days

**Other Reproductive Information**

Adult: Pollination in tiny polygala has not been observed in 2.5 years of monitoring (Kennedy 1998), or in 3 years of monthly life history monitoring (DERM 1994). Zomlefer (1991) reports that self-pollination may occur in species of Polygala which have a tuft of hairs on the sterile apical lobe of the stigma. These hairs catch pollen when the anthers dehisce, and, as the flower develops, these hairs may touch the receptive lobes of the stigma, transferring pollen. Tiny polygala has these hairs (Smith and Ward 1976) and may be selfpollinating. (USFWS, 1999)

**Reproduction Narrative**

Adult: Tiny polygala seedlings can be observed from late October through April, but are most typically seen from December to February (DERM 1996). Populations in Miami-Dade County appear to have two germination periods, a short one in June and a longer one between September and January (Kennedy 1998). Thus, seedlings can be germinating for 6 months out of the year, resulting in plants maturing at different times of the year, and overlapping generations within years. In populations, flowers appear throughout the year with a peak during summer. Also, seeds are produced year-round. Approximately one year following appearance of seedlings, plants show a marked reduction in condition, apparently allocating resources to flowering instead of growth or self-maintenance. By July, approximately 18 months after the first seedlings are observed, remaining plants senesce and die (DERM 1994). (USFWS, 1999)

**Habitat Type**

Adult: pine rockland, scrub, high pine, and open coastal spoil (USFWS, 1999)

**Habitat Vegetation or Surface Water Classification**

Adult: Terrestrial

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 1999)

**Habitat Narrative**

Adult: Tiny polygala occurs in four distinct habitats with similar characteristics: pine rockland, scrub, high pine, and open coastal spoil (Gann and Bradley 1995). All of these habitats are pyrogenic-extremely dry and prone to periodic natural fire. Pine rocklands historically burned every 2 to 15 years (Snyder et al. 1991). Sand pine scrub and sandhill burn less frequently, possibly every 10 to 50 years. (USFWS, 1999)

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Tiny polygala seeds have paired, fleshy outgrowths, a typical adaptation to ant dispersal. ostermeijer (1989) reports that a similar species Polygala vulgaris L. is a specialist in ant dispersal. Also, ants have been observed carrying tiny polygala seeds to their nests on several occasions in Miami-Dade County (K. Bradley, Institute for Regional Conservation, personal

communication 1996). The seeds have a bilobed aril attached to the caruncle. This bilobed aril was suggested by some to be an elaisome, a structure that contains lipids that are attractive to ants. Kennedy (1998) reports observing ants going into the flowers and removing and transporting seeds by the arils. After applying Sudan IV stain to the arils, she determined that they do not contain lipids; rather the arils appear to be hollow sacs. It is unclear why the ants are moving the seeds. (USFWS, 1999)

#### **Additional Life History Information**

Adult: *Polygala smallii* seeds are able to float in water for extended periods (over three weeks) (Kennedy 1998). The hairs on the seed coat appear to provide most of the buoyancy by trapping air. Since many of the sites where tiny *polygala* occurs are riparian or riverine and the seeds are buoyant, water may be the primary means of dispersal. After Hurricane Andrew, tiny *polygala* was found growing in areas where the soil was turned over or disturbed (ie. around uprooted fallen trees). A response to soil turnover may indicate a good seed bank. The seed banks probably occur in more habitat types than previously thought. (USFWS< 1999)

#### ***Population Information and Trends***

##### **Number of Populations:**

6 (USFWS, 2021)

##### **Population Narrative:**

*Polygala smallii* is extant on a total of nine sites in Miami-Dade, Palm Beach, St. Lucie, and Martin Counties, with the highest density of sites located in southern Miami-Dade County (Wendelberger and Frances 2004; Woodmansee et al. 2007; Maschinski, pers. comm. 2010; Florida Natural Areas Inventory [FNAI] 2010a; Lange, pers. comm. 2017; Possley, pers. comm. 2017a). Clusters of sites are separated by an average of 38 miles (61 km). Eight of nine known occurrences are on publicly owned lands, and all the sites are currently being managed for conservation of *P. smallii*. The species is known to have been extirpated from at least five historical locations, including three in Miami-Dade County and single populations in Broward and St. Lucie Counties. Five sites are known from Miami-Dade County. These include the publicly owned Zoo Miami and adjacent U.S. Coast Guard (USCG) property, both located within the 2,100-acre Richmond pinelands (Lange, pers. comm. 2017; Possley, pers. comm. 2017). Possley pers. comm. (2017a) indicates the *P. smallii* population size within Zoo Miami has fluctuated from 13 to over 1,000 individuals in the past decade. The USCG site contains the largest population, which was estimated at over 10,000 plants during a 2008 survey (Lange, pers. comm. 2017; Possley, pers. comm. 2017a); no recent estimates are available for the species at this site. The three remaining *P. smallii* sites within Miami-Dade County each retain populations of ten individuals or less (Lange, pers. comm. 2017; Possley, pers. comm. 2017a). In Palm Beach County, the *P. smallii* abundance at two known locations fluctuates dramatically from year to year (Woodmansee et al. 2007). At Jupiter Ridge Natural Area, *P. smallii* abundance has fluctuated from 86 (2005) to 8 (2017) (Buck, pers. comm. 2017). The Limestone Creek Natural Area population has ranged from 3 to 60 since being discovered in 2002, with 5 encountered during 2017 (Woodmansee et al. 2007; Shearer, pers. comm. 2017). In southern Martin County, *P. smallii* is known to occur in Jonathan Dickinson State Park (JDSP). Surveys of the site have recorded between 6 and 64 individuals (Woodmansee et al. 2007; FNAI 2010a). Woodmansee et al. (2007) indicated that while the species appears to be in decline at JDSP, it is expected that plant numbers will increase in the long run, provided fires are administered. In St.

Lucie County, a small population (14 plants) of *P. smallii* occurs at the privately owned Lynn University (Woodmansee et al. 2007). (USFWS, 2019). Tiny polygala is currently known to occur in small populations located on tracts of suitable pine rockland and scrub habitat, mostly within publicly owned lands. Its limited distribution renders tiny polygala vulnerable to random natural or human-induced effects, including fire suppression and invasive exotic species. The most recent surveys for the species indicate that plants remain on ten sites within six populations (Table 1; Woodmansee et al. 2007; FNAI 2019; Black Finch 2020; Possley 2020; Rogers 2020; Rossmanith 2020; Shearer 2020; Law 2021). The majority of known tiny polygala populations occur on publicly owned lands that are managed for conservation. The one remaining population on private lands is managed for conservation under an HCP (Coral Reef Commons in the Richmond Pineland Complex; Service 2017). (USFWS, 2021)

### ***Threats and Stressors***

**Stressor:** Habitat loss and fragmentation

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The pine rockland community of south Florida is critically imperiled globally (FNAI 2010b). In Miami-Dade County, development and agriculture have reduced pine rockland habitat by 90 percent. Continued habitat loss (Factor A) and fragmentation threaten the existence of this species, and less than 1 percent of the original acreage of pine rockland habitat remains outside of Everglades National Park (Herndon 1998). Populations on private sites remain threatened with destruction or habitat modification due to improper or lack of management (Factors A and E). (USFWS, 2019)

**Stressor:** Inadequacy of existing regulatory mechanisms

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Currently, regulatory mechanisms (Factor D) provide limited protections for this species. The Florida Department of Agriculture and Consumer Services designated these species as endangered under Chapter 5B-40, Florida Administrative Code. This law regulates the taking, transport, and sale of listed plants. This law does not prohibit private property owners from destroying listed plants, nor does it require them to manage habitats to maintain populations. The Natural Forest Communities (NFC) program was established by Miami-Dade County to encourage but not require private landowners to protect forested lands by making it necessary to apply for a permit with the County prior to working in designated NFCs (i.e., pinelands, hammocks). (USFWS, 2019)

**Stressor:** Inadequate fire management

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Fire suppression continues to affect *Amorpha crenulata* (Factor E). Historically, frequent (approximately twice per decade), lightning-induced fires were a vital component in maintaining native vegetation and ecosystem functioning within south Florida pine rocklands. A period of just 10 years without fire may result in a marked decrease in the number of herbaceous

species due to the effects of shading and litter accumulation (FNAI 2010b). The majority of extant populations of this species is affected by some degree of inadequate fire management, with the primary threat being shading by hardwoods (Bradley and Gann 1999; Bradley and Gann 2005). (USFWS, 2019)

**Stressor:** Nonnative invasive plants

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Invasion by exotic plant species continue to affect *Amorpha crenulata* (Factor E). Nonnative invasive plants compete with native plants for space, light, water, and nutrients, and make habitat conditions unsuitable for this species, which prefers open conditions (Factor E). Bradley and Gann (1999) indicated that the control of nonnative plants is one of the most important conservation actions for the pine rockland species and a critical part of habitat maintenance. Nonnative plants have significantly affected pine rocklands and negatively impacted all occurrences of this species to some degree (Bradley and Gann 1999; Bradley 2006; Bradley and Saha 2009; Bradley and van der Heiden 2013). (USFWS, 2019)

### **Recovery**

**Reclassification Criteria:**

Not developed (USFWS, 1999; USFWS, 2010)

**Delisting Criteria:**

1. Existing natural populations achieve and maintain a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factors A and E) (USFWS, 2019)
2. A network of 6 new populations are either discovered or reintroduced that exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factors A and E) (USFWS, 2019)
3. All populations (criteria 1 and 2) are protected by a conservation mechanism. (addresses Factors A, D, and E) (USFWS, 2019)
4. Threats have been reduced or eliminated to the degree that this species will remain viable for the foreseeable future. (addresses Factors A, D, and E) (USFWS, 2019)

**Recovery Actions:**

- Conduct surveys to determine distribution and status of *Polygala smallii*. Pine rocklands have been thoroughly surveyed in Miami-Dade County. Additional surveys in the historic range of this plant should be performed in the scrub, sandhill, and open coastal spoil of Broward, Palm Beach, Martin, and St. Lucie counties. Fire eliminates litter concealing species, it may kill seeds in the litter or soil surface, or it may enable seeds in the seed bank to germinate. For that reason, suitable habitats which did not contain listed species when unmanaged should be resurveyed after fire events. (USFWS, 1999)
- Protect and enhance existing populations. It is imperative for the recovery of this species that populations not be lost. (USFWS, 1999)

- Collect biological information important to species recovery. Determine population size and viability of all populations. Investigate the genetic relationship of distinct *Polygala* populations. (USFWS, 1999)
- Develop standardized monitoring. Collect existing and historical data, and place in a central location. Convene a meeting of all researchers. Monitor status and success of all populations; change management practices if so indicated. Monitor reintroduction success and modify procedures as necessary. (USFWS, 1999)
- Continue to provide public information about scrub, sandhill, and open coastal spoil habitat and its unique flora. (USFWS, 1999)
- Habitat-Level Recovery Actions: Continue to protect existing pine rockland, scrub, sandhill, and open coastal spoil plant habitats. Restore areas to suitable habitat. Research additional habitat relationships. Monitor sites with pine restoration programs to determine success. Continue implementation of the fire education program and modify as necessary, any fire management education program that has been developed. (USFWS, 1999)

#### ***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Implement, continue, or increase habitat restoration efforts (exotic species removal and prescribed fire) at all sites with tiny polygala. • Survey extirpated sites and sites with unknown status annually to monitor for potential reappearance. • Continue to monitor extant populations annually. • Examine extant populations in Palm Beach, Martin, and St. Lucie Counties to determine if they are *P. smallii* or *P. nana*. • Conduct a comparative taxonomic study of *P. smallii* and *P. nana* using a multi-data approach (e.g., morphology, genetics, geography, ecological factors, etc.). • Survey potential habitat on privately owned sites if landowners will allow access. • If additional sites with tiny polygala are discovered, pursue conservation agreements and/or acquire land. Implement appropriate management for habitat restoration, particularly on sites with former tiny polygala populations. Any opportunities for purchase of properties with tiny polygala or better management under conservation easement should be pursued. • Additional partnerships should be promoted to share information, conduct collaborative research on pine rockland and scrub habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. • Expand work on ex situ propagation and seed banks. • Conduct reintroduction feasibility studies and identify potential recipient sites. • Conduct additional demographic research including population assessments and tracking of habitat changes through time. Monitoring should assess population declines or increases and examine growth and establishment rates. • Conduct genetic studies to examine diversity among sites which may be declining due to isolation and reduced genetic drift. • Conduct research to evaluate reproductive biology. • Conduct research to examine the effects of growing season burns versus non-growing season burns on flowering, seed set, and establishment. • Conduct studies to examine the cyclic occurrence of tiny polygala and determine if select fire-return intervals can reestablish the species to historical locations. (USFWS, 2021)

## SPECIES ACCOUNT: *Polygonella basiramia* (Wireweed)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 2/20/1987; Southeast Region (R4)

#### **Physical Description**

*P. basiramia* is a short-lived, perennial herb (Hawkes, University of Pennsylvania, personal communication 1995). When vegetative, the plant consists entirely of basal, compressed stems with narrow, alternate leaves. Ocreae, the sheaths formed at stem nodes, are ciliate. Stems and leaves range in color from green to dark red; red coloration in the stems and leaves appears to be associated with individuals more exposed to sunlight and with older vegetative parts (although even seedlings are often red). As basal stems elongate, plants develop 1 to 46 slender, flowering, spike-like panicles as tall as 0.8 m (Hawkes and Menges 1995). This species is gynodioecious and plants have either only female flowers or hermaphroditic flowers. Individual flowers are small, white to slightly pink with 5 sepals (no petals), pink pistils, and black anthers. The gynoecium consists of 3 united carpels, 1-ovuled, ovary superior. Flowering occurs from the top spikelet downward on each stem. The fruit is a three-sided achene 1 to 3 mm in length. (USFWS, 1999) Wireweed *Polygonella basiramia* (= *ciliata* var. *b.*) (Small) Nesom and Bates Page 4-1149 Federal Status: Endangered (January 21, 1987) Critical Habitat: None Designated Florida Status: Endangered Figure 1. County distribution of wireweed. Recovery Plan Status: Revision (May 18, 1999) Geographic Coverage: Rangewide

#### **Taxonomy**

Originally named *Delopyrum basiramia* by Small in 1924 (Nesom and Bates 1984), this species was later thought to be a variety of *Polygonella ciliata* by Horton (1963). In 1984 Nesom and Bates recognized *P. basiramia* as a separate species. This species is commonly known as hairy or tufted wireweed. *Polygonella basiramia* is most closely related to *P. ciliata* and *P. gracilis* (Lewis and Crawford 1995). *P. basiramia* and *P. ciliata* are believed to have originated from *P. gracilis*, but whether they did so independently or from a single intermediate ancestral species is unknown. (USFWS, 1999)

#### **Historical Range**

See current range.

#### **Current Range**

Lake Wales, Winter Haven, and Bombing Range ridges in central peninsular Florida. It ranges from Lake Pierce in Polk County southward to Venus near the southern tip of the Lake Wales Ridge in Highlands County (USFWS, 1999)

#### **Critical Habitat Designated**

Yes;

#### ***Life History***

#### **Food/Nutrient Resources**

#### **Lifespan**

Adult: short-lived (average 0.31 years) (USFWS, 2019)

**Breeding Season**

Adult: September to December (USFWS, 1999)

**Other Reproductive Information**

Adult: Wireweed is an obligate seeder: no adult plants survive fire, and all post-fire recruits derive from seed. Flowering begins in September and achenes are produced in late November and early December. Because flowering is sequential, beginning at the top of each spike-like panicle and moving downwards, flowers and achenes are present at the same time mid-autumn. Achenes drop readily from the plant and most fall by mid-January. (USFWS, 2019)

**Reproduction Narrative**

Adult: *Polygonella basiramia* is gynodioecious, with individual plants producing either pistillate (female) or perfect flowers (both sexes in a single flower). The ratio of female to hermaphroditic plants is 1:1 at Archbold Biological Station (Hawkes and Menges 1995). Pollinators of *P. basiramia* include small halictid bees, *Perdita polygonellae* (a bee specific to the genus *Polygonella*), Eumenidae wasps, and potentially *Glabellula* spp. (Bombyliidae) (M. Deyrup, Archbold Biological Station, personal communication 1995). Seed production by female plants greatly exceeds that of perfect plants, with an average of 217.8 seeds per stem for females, but only 32.1 for perfect plants. *P. basiramia* is an obligate seeder which means that no adult plants survive a fire event and all new growth is from seedlings. On a population level, the number of seeds produced by *P. basiramia* in one reproductive season is more than 30 times the average plant density, sufficient to replace existing populations if only 3 percent of seeds were able to germinate and survive. (USFWS, 1999)

**Habitat Type**

Adult: scrub/scrubby flatwoods

**Environmental Specificity**

Adult: Narrow (USFWS, 1999)

**Habitat Narrative**

Adult: *Polygonella basiramia* is most commonly found in rosemary scrub, also known as rosemary phase of sand pine scrub (Abrahamson et al. 1984, Menges and Kohfeldt 1995). At Archbold Biological Station, rosemary scrubs are found only on the higher ridges and knolls at 40 to 50 m in elevation, and are largely restricted to St. Lucie and Archbold soil types (Abrahamson et al. 1984), both well drained white sands (Carter et al. 1989). Outside Archbold Biological Station, rosemary scrubs are generally found on white sands and higher elevations (Hawkes, University of Pennsylvania, personal communication 1998). The fire cycle in rosemary scrub can range from 10 to as long as 100 years (Johnson 1982, Myers 1990). *Polygonella basiramia* occupies open spaces or gaps between shrubs and can be found in abundance along sandy fire lanes, which provide similar habitat. (USFWS, 1999)

**Dispersal/Migration****Population Information and Trends**

**Population Trends:**

Declining (inferred) (USFWS, 2019)

**Population Narrative:**

The last FNAI Element Tracking Summary (FNAI 2015) reported 71 extant occurrences, 47 of which were on managed lands. This was a significant decrease (approximately 40 percent) from the 119 reported occurrences in the last 5-year status review (Service 2010d). At a larger scale, regional persistence of this species is dependent on landscape features and disturbance effects on metapopulation dynamics. Fire may expand or create the open sand gaps within a shrub matrix that support wireweed, but fire also kills established plants. Patchy fires may provide a balance, both creating suitable habitats and providing a fine-grained spatial landscape structure so wireweed can colonize those habitats. (USFWS, 2019).

**Threats and Stressors**

**Stressor:** Habitat destruction or modification

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 million persons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time

(Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range.

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** This species occurs within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

### **Recovery**

#### **Reclassification Criteria:**

1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to assure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)
2. When these sites, within the historic range of *P. basiramia*, are adequately protected from further habitat loss, degradation, and fragmentation (USFWS, 1999)
3. When these sites are managed to maintain the rosemary phase of xeric oak scrub communities to support *P. basiramia* (USFWS, 1999)
4. When monitoring programs demonstrate that populations of *P. basiramia* on these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. Individuals growing opportunistically in unnatural areas, for example fire lanes, should be excluded from consideration when determining the status of this species. (USFWS, 1999)

#### **Delisting Criteria:**

1. At least 40 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)
2. Populations (as defined in criterion 1) in rosemary scrub or scrubby flatwoods habitats are distributed across the known range of the species. (USFWS, 2019)

3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

**Recovery Actions:**

- Determine current distribution status of *Polygonella basiramia*. This species' distribution is somewhat questionable for taxonomic reasons. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics. Though much of the basic biology and ecology of this species is understood, to effectively recover this species additional biological information is needed. (USFWS, 1999)
- Monitor existing populations of *Polygonella basiramia*. (USFWS, 1999)
- Provide public information about *P. basiramia*. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

## SPECIES ACCOUNT: *Polygonella myriophylla* (Sandlace)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 5/27/1993; Southeast Region (R4)

#### **Physical Description**

*Polygonella myriophylla* is a sprawling shrub that looks somewhat like the ornamental creeping juniper (*Juniperus horizontalis*). Its many branches zigzag along the ground and root at the nodes, forming low mats. The lower parts of the creeping branches have bark that cracks and partly separates in long, flat, interlacing strips. The short lateral branches end in flowering racemes. *P. myriophylla* has the sheathing leaf stipules (ocreae and ocreolae) typical of the jointweed family. The leaves are needle-like and are from 0.3 to 10.0 mm long. The small, white or cream colored flowers have white petallike sepals up to 3.4 mm long (Kral 1983). (USFWS, 1999)

#### **Taxonomy**

Sandlace is one of 11 species of North American *Polygonella* and one of three species of *Polygonella* that occur in scrub habitat in south Florida (Lewis and Crawford 1995). The sandlace was first collected in the early 1920s and was subsequently identified and named by Small (1924) as *Dentoceras myriophylla*. Horton (1963) combined two of Small's genera with the genus *Polygonella*. *P. myriophylla* has been commonly called sandlace (Christman 1988), Small's jointweed and woody wireweed (Wunderlin 1982). (USFWS, 1999)

#### **Historical Range**

See current range/distribution.

#### **Current Range**

In the Florida Counties of Orange, Osceola, Polk (Lake Wales Ridge), and Highlands (Lake Wales Ridge). (USFWS, 1999)

#### **Critical Habitat Designated**

No;

#### ***Life History***

#### **Food/Nutrient Resources**

#### **Reproductive Strategy**

Adult: Sexual; Vegetative (USFWS, 2019)

#### **Other Reproductive Information**

Adult: Sandlace reproduces sexually and vegetatively through the rooting of prostrate branches. Sandlace is killed by fire and will recolonize burned areas by seedling recruitment or clonal growth. Most obligate seeders in Florida scrub and sandhill, including both herbs (e.g., Highlands scrub hypericum, snakeroot, Lewton's polygala) and sub-shrubs (e.g., several species in the genus *Dicerandra*), recover quickly post-fire via seedling recruitment and often show dramatic aboveground population booms. In sandlace's preferred habitats, recommended FRIs range

from 8 to 16 years for xeric scrubby flatwoods to 15 to 30 years for Florida rosemary scrub (Menges 2007). (USFWS, 2019)

**Reproduction Narrative**

Adult: Weekley and Menges (2003) confirmed that sandlace does not resprout after fire, but recolonizes burned areas from seed arriving from unburned areas, and perhaps by spreading from unburned areas. Pollinators of sandlace are genus-specific bees and likely a few varieties of wasps. Little is known about seed production and germination for this species, but seedlings do not survive in the vicinity of the mature plants, which are allelopathic, meaning they produce chemicals that inhibit the growth and survival of other nearby plants (Weidenhamer et al.1989). The major allelochemicals are gallic acid and hydroquinone (Weidenhamer and Romeo 2004).

**Habitat Type**

Adult: Scrub

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Sandlace occupies open, sandy areas within the scrub vegetation, and it appears to require fire or other disturbances that create or maintain these sandy gaps. This species is killed by fire, and reoccupies burned sites from seed (Pedro Quintana-Ascencio, University of Central Florida, pers. comm. 2004). Its abundance can easily be overestimated, because it tends to colonize disturbed areas along easily accessible road cuts and rights-of-way.

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Declining (USFWS, 2019)

**Number of Populations:**

2 extant occurrences (USFWS, 2021)

**Population Size:**

~1.5 million (USFWS, 2021)

**Population Narrative:**

The previous FNAI Element Tracking Summary (FNAI 2015) reported 72 extant occurrences, 39 of which occurred on managed land. Thirty-three of 72 extant sandlace occurrences were located on private property where they had no protection from development and were unlikely to be appropriately managed. This was a significant decrease (approximately 36 percent) from the previous 5-year status review, which reported 113 extant occurrences. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification

**Exposure:****Response:****Consequence:**

**Narrative:** This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 million persons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

**Stressor:** Lack of adequate fire management

**Exposure:****Response:****Consequence:**

**Narrative:** Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

**Stressor:** Limited geographic range

**Exposure:****Response:****Consequence:**

**Narrative:** This species occurs within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated

are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

### **Recovery**

#### **Reclassification Criteria:**

1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to assure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)
2. When these sites, within the historic range of *P. myriophylla*, are adequately protected from further habitat loss, degradation, and fragmentation (USFWS, 1999)
3. When these sites are managed to maintain the seral stage of xeric oak scrub communities to support *P. myriophylla* (USFWS, 1999)
4. When monitoring programs demonstrate that populations of *P. myriophylla* on these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. (USFWS, 1999)

#### **Delisting Criteria:**

1. At least 40 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)
2. Populations (as defined in criterion 1) in yellow sand scrub or sand hill habitats are distributed across the known range of the species. (USFWS, 2019)
3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

#### **Recovery Actions:**

- Determine current distribution of *P. myriophylla*. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics. Though much of the basic biology and ecology of this species is understood, to recover this species more specific biological information is needed. (USFWS, 1999)
- Monitor existing populations of *P. myriophylla*. (USFWS, 1999)
- Provide public information about *P. myriophylla*. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native

Plant Society, and private landowners be appropriately informed about this species. Care is needed, though, to avoid revealing specific locality information about where *P. myriophylla* is found. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of *P. myriophylla* and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)

#### **Conservation Measures and Best Management Practices:**

- **RECOMMENDATIONS FOR FUTURE ACTIONS:** Here we propose several habitat conservation and ecological research recommendations that will aid in the recovery and conservation of the white-rayed pentachaeta. Some of these recommendations have already been discussed in our previous status review (Service 2010, p. 28): 1. Conduct surveys at known occurrences at least every five years to determine population trends and habitat changes. 2. Collect information on habitat preferences in order to facilitate the search for suitable habitat for outplanting. Data to be collected should include associated plant communities, soil types, soil nutrients, pollinators, and hydrology of the currently occupied habitat as well as the historically occupied sites. Conditions at currently occupied sites may not represent the habitat that supported the species at historic locations, particularly for white-rayed pentachaeta, which had a far greater range historically and likely more variability between sites. 3. Conduct surveys for potential locations in which to establish new populations. The surveys should also confirm that there is only a single population stretching across both the Triangle and Edgewood Park properties, rather than two or more populations separated by a quarter mile or more. 4. Work with partners and landowners to establish new populations. 5. Work with partners to produce and implement management plans specific to white-rayed pentachaeta conservation at each population site. (USFWS, 2021)

## SPECIES ACCOUNT: *Polygonum hickmanii* (Scotts Valley Polygonum)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

#### **Physical Description**

a small, annual plant, 2 to 5 centimeters tall (1 to 2 inches) in the buckwheat family (Polygonaceae). The leaves are linear and pointed, and the single white flower is in the axil of bracteal leaves. (USFWS, 2009)

#### **Taxonomy**

We are not aware of any changes or proposed changes in taxonomic classification or nomenclature since listing. However, prior to listing, the following names were used in unpublished historical documents: a "draft" scientific name, *Polygonum muripes* pro. sp. (Morgan 1990a, b; Habitat Restoration Group 1992 ); and a common name, Hickman's smartweed (Denise Duffy and Associates 1997b). Hinds and Morgan (1995) used the common name Hickman's knotweed. (USFWS, 2009)

#### **Current Range**

Endemic to Santa Cruz County, California (Fish and Wildlife Service 2000). (NatureServe, 2015)

#### **Critical Habitat Designated**

Yes; 4/8/2003.

#### **Legal Description**

On April 8, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Polygonum hickmanii* (Scotts Valley Polygonum) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two critical habitat units (CHUs), in California (68 FR 16970-16990).

#### **Critical Habitat Designation**

The critical habitat designation for *Polygonum hickmanii* includes two CHUs in Santa Cruz County, California. This species critical habitat encompasses approximately 287 acres (ac) (116 hectares (ha)) (68 FR 16970-16990).

**Unit 1: Glenwood Site:** Unit 1 consists of approximately 87 ha (214 acres) to the west of Glenwood Drive and north and northwest of Casa Way, in the city of Scotts Valley. This unit includes land owned and managed by the Salvation Army and by the Scotts Valley High School District as a preserve, but excludes the rest of the High School, and land to the east of Glenwood Drive, encompassing the parcel known as the Glenwood Development. Most of the land being designated within this unit is privately owned, with a small portion (4 ha (9 ac)) owned by a local agency (High School District). This unit is essential because it supports approximately 25 to 50 percent of the known above-ground numbers of individuals of *Polygonum hickmanii*, as well as other suitable patches of wildflower field habitat that could be colonized by the species naturally, or used as introduction sites as part of a recovery effort. Much of this suitable, but unoccupied habitat, is slated to be dedicated as "open space" as part of the housing development on the Glenwood parcel; therefore, an opportunity may exist to pursue such a recovery effort. The unit

also supports intervening habitat that includes the grassland community that supports the pollinators and seed dispersers that are important to the survival and conservation of *P. hickmanii*. Additional habitat that is unsuitable for *P. hickmanii* is also included on the slopes above the wildflower field patches; this additional habitat is necessary to maintain the slope stability and therefore the hydrologic and soil conditions suitable for *P. hickmanii* and the wildflower field habitat.

Unit 2: Polo Ranch Site: The Polo Ranch site consists of approximately 30 ha (73 ac) to the east of Carbonera Creek on the east side of Highway 17 and north and northeast of Navarra Drive, in the city of Scotts Valley, in Santa Cruz County, California. All land being designated as critical habitat is privately owned. This unit is essential because it supports approximately 50 to 75 percent of the known above-ground numbers of individuals of *Polygonum hickmanii*, as well as other suitable patches of wildflower field habitat that could be colonized by the species naturally, or used as introduction sites as part of a recovery effort. The unit also supports intervening habitat that includes the grassland community necessary for pollinators and seed dispersers that are responsible for maintaining genetic variability within the species. Additional habitat that is unsuitable for the growth of *P. hickmanii* is also included on the slopes above the wildflower field patches; this additional habitat is necessary to maintain the slope stability and therefore the hydrologic and soil conditions suitable for *P. hickmanii*. Much of the unsuitable habitat will be set aside as "open space" as part of the pending housing development, because these slopes are too steep to safely support housing construction.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Polygonum hickmanii* critical habitat consists of five components (68 FR 16970-16990):

- (i) Thin soils in the Bonnydoon series that have developed over outcrops of Santa Cruz mudstone and Purisima sandstone;
- (ii) "Wildflower field" habitat that has developed on these thin-soiled sites;
- (iii) A grassland plant community that supports the "wildflower field" habitat and that supports the pollinator activity and seed dispersal mechanisms that typically occur within the grassland plant community;
- (iv) Areas around each colony to allow for recolonization to adjacent suitable microhabitat sites; and
- (v) Habitat within the subwatersheds upslope to the ridgelines to maintain the edaphic and hydrologic conditions and slope stability that provide the seasonally wet substrate for growth and reproduction of *Polygonum hickmanii*.

#### **Special Management Considerations or Protections**

Special management considerations or protections may be needed to maintain the primary constituent elements for *Polygonum hickmanii* within the units being designated as critical habitat. In some cases, protection of existing habitat and current ecologic processes may be sufficient to ensure that populations of *P. hickmanii* are maintained at those sites and have the

ability to reproduce and disperse in surrounding habitat. In other cases, however, active management may be needed to maintain the primary constituent elements for *P. hickmanii*. We have outlined below the most likely kinds of special management and protection that *P. hickmanii* may require. (1) The soils on which *Polygonum hickmanii* is found should be maintained to optimize conditions for its persistence. Physical properties of the soil, such as its chemical composition, surface crust, and drainage capabilities, would best be maintained by limiting or restricting the use or application of herbicides, fertilizers, or other soil amendments. (2) Overspray from irrigation or saturation of soils beyond the normal rainfall season should also be avoided, as this may alter the structure and composition of the grassland community or render the native species more vulnerable to pathogens found in wetter soil regimes. (3) The associated plant communities must be maintained to ensure that the habitat needs of pollinators and seed dispersal agents are maintained. The use of pesticides should be limited or restricted so that healthy populations of pollinators are present to effect pollination and, therefore, seed set in *Polygonum hickmanii*. The fragmentation of habitat through construction of roads and certain types of fencing should be limited so that dispersal agents may disperse seed of *P. hickmanii* throughout the unit. (4) Invasive, nonnative species such as brome grasses and other species may need to be actively managed within the grassland community to maintain the patches of open habitat that *Polygonum hickmanii* needs. (5) Certain areas where *Polygonum hickmanii* occurs may need to be fenced to protect it from accidental or intentional trampling by humans and livestock. While *P. hickmanii* appears to withstand light to moderate disturbance, heavy disturbance may be detrimental to its persistence. Seasonal exclusions may work in certain areas to protect *P. hickmanii* during its critical season of growth and reproduction.

### ***Life History***

#### **Food/Nutrient Resources**

#### **Breeding Season**

Adult: Plant flowers in May (USFWS, 2009)

#### **Reproduction Narrative**

Adult: Very little is known regarding the species' biology, and there is no new information since listing. Germination is in the fall or early winter in response to seasonal rains. The plants grow slowly over the next few months, remaining inconspicuous until flowering begins in May. New flowers are produced until climate or microhabitat conditions are no longer favorable. Consequently, seed production ranges from several dozen in a typical individual to several hundred in a robust individual (Morgan, pers. comm. 1998b), while depauperate plants produce few or no seeds (Morgan in California Department of Fish and Game 2003) (USFWS, 2009).

#### **Habitat Type**

Adult: Grasslands (NatureServe, 2015)

#### **Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

#### **Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

**Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Species occurs with other small annual herbs in patches within annual grasslands. These "wildflower field" patches are generally underlain by shallow, well-drained soils; this species occurs on gently sloping to nearly level shallow soils over outcrops of Santa Cruz mudstone and Purisima sandstone. It is found near the center of the patches where the soil is shallowest and often has a consolidated, crusty surface texture; other species are sparse in patch centers. Associated species include the native herbs *Chorizanthe robusta* var. *hartwegii*, *Lasthenia californica*, *Minuartia douglasii*, *Minuartia californica*, *Gilia clivorum*, *Castilleja densiflora*, *Lupinus nanus*, *Brodiaea terrestris*, *Stylocline amphibola*, *Trifolium grayii*, and *Hemizonia corymbosa*, as well as the non-natives *Filago gallica* and *Vulpia myuros*. In many cases, the habitat also supports a crust of mosses and lichens. 200 - 250 m elevation. (NatureServe, 2015)

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Declining (USFWS, 2024)

**Number of Populations:**

1 - 5 (USFWS, 2024)

**Population Size:**

139 (USFWS, 2024)

**Population Narrative:**

Restricted to 2 sites (Fish and Wildlife Service 2000). (NatureServe, 2015). Low resiliency, representation and redundancy are inferred based on the low number of known populations. Despite efforts to control invasive species through mowing, grazing, and hand removal, combined population numbers across all properties decreased from highs of approximately 2000 individuals in 1997 to a low of five in 2015. The decline in abundance has been associated with a loss of occupied habitat of approximately 85 to 90 percent since the time of listing. The relatively high number of individuals observed in 2019 (234 plants) potentially suggests that hand weeding and close monitoring at the Polo Ranch property may be having a positive effect on the few colonies that are still present (USFWS, 2020). No individuals of *Scotts Valley polygonum* have been observed at the Salvation Army or High School Preserve properties since 2011 and 2015, respectively (Service 2020, p. 5; Table 1). Polo Ranch continues to support the species at 3 of 12 historical colonies, and at four experimental locations where partners conducted reintroductions by seeding in experimental plots (Marty et al. 2023, pp. 9–10; Marty 2023, entire). The abundance of plants at the historical colonies has declined from 637 in 2020 to 139 in 2023. Weed-removal efforts have remained stable over this time despite change in management from LSA Associates, Inc. to the Wildlife Heritage Foundation. In December 2022,

under a cooperative agreement with the Service, one of our partners reintroduced seed to experimental plots that had not been occupied for a minimum of 5 years at Polo Ranch. They scattered seed over suitable habitat in areas of shallow soil and deeper soil and weeded in the same manner as the historical colonies; as of spring 2023, treatment types did not yield appreciable differences in plant growth (n=1,884 plants across all plots)(Marty 2023, entire). The continued absence of the species at the Salvation Army and High School Preserve properties suggests that reintroduction efforts may be necessary to restore the species to its historical distribution and advance recovery (USFWS, 2024)

### ***Threats and Stressors***

**Stressor:** Urban development/road construction (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/extirpation

**Narrative:** On Salvation Army land and the Scotts Valley High School Preserve, the five colonies of this population are now being substantially affected by the indirect impacts of development. These five colonies are at risk of extirpation because of the highly disturbed and fragmented nature of the ecosystem, the isolation from other colonies, the proximity to developed areas, and invasive plant species (USFWS, 2009).

**Stressor:** Recreational use (USFWS, 2009).

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Although the preserve is fenced, Lyons (2004) observed minor disturbance by students traversing to and from the high school in 2003. Gogul-Prokurat (2004) observed a number of golf balls within the preserve. Lyons (2002) previously reported residents using the preserve for golf practice (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Since listing under the Endangered Species Act, *Polygonum hickmanii* has become listed under the California Endangered Species Act. However, because none of the colonies are on Federal or State lands, the combination of all Federal and State laws has only limited ability to protect this plant species. The inadequacy of existing regulatory mechanisms remains a threat in 2009 (USFWS, 2009).

**Stressor:** Inadequate preserve design (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Lack of protection

**Narrative:** A preserve should be large enough to maintain the ecological functions upon which the target species depends, and it should have a ratio of edge to total area that minimizes edge effects and fragmentation. To increase the certainty that the target species will persist over the long term, land uses adjacent to a preserve should be compatible with maintaining the integrity

of the preserve (Service 2003). The Scotts Valley High School Preserve (3.2 hectares; 8 acres) is not large enough to maintain the ecosystem supporting *Polygonum hickmanii*, and edge effects are present because the single colony is near the preserve boundary (within approximately 18 meters; 60 feet). In addition, adjacent land uses to the immediate north (in particular, athletic fields and parking lot), and east and south of the preserve (residences) are not compatible with maintaining its integrity. Because of this, the preserve has been used for non-compatible purposes, including recreation (Lyons 2002, Gogul-Prokurat 2004), a walking short-cut to and from the school (Lyons 2004), and disposal of waste (Cheap, in litt. 2008). Prior to construction of the high school and the recycled water distribution system, the California Department of Fish and Game (in litt. 1991) recommended the two areas with *Polygonum hickmanii* be designated as one larger preserve. They stated "Our experiences with small plant preserves have demonstrated that high density residential developments next to small preserves result in significant declines in preserve quality and effectiveness from incompatible land uses if buffer areas between the preserve boundary and the rare plant habitats are too narrow. A 100- foot wide buffer between the plant populations and adjacent development is considered to be the minimum required." See Factor A for additional discussion about alteration and loss of habitat due to proximity to urban areas (USFWS, 2009).

**Stressor:** Random extinction (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Extinction

**Narrative:** Species with few populations and/or individuals are vulnerable to random extinction. In this situation, naturally occurring events can cause extinction through mechanisms operating at the genetic level (e.g., decrease in genetic variability), the population level (e.g., lack of ability to attract pollinators because of few individuals), or the landscape level (e.g., storms, drought, fire) (Service 2003). *Polygonum hickmanii* is at high risk of random extinction. The species is known from only two populations approximately 1.6 kilometers (1 mile) apart. The total occupied area comprises less than 0.4 hectare (1 acre). The most-recent surveys reported 0 individuals on the Polo Ranch in 2006 (Morgan, pers. comm. 2009), "several dozen" individuals on Salvation Army land in 2008 (Morgan, pers. comm. 2009), and 88 individuals on the Scotts Valley High School Preserve in 2003 (Lyons 2004) (USFWS, 2009).

**Stressor:** Invasive species and competitive native species (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Non-native annual grasses are now a threat to *Polygonum hickmanii* on all three properties. In particular, much of the habitat on the Scotts Valley High School Preserve and adjacent Salvation Army land is now occupied by non-native grasses, which must be mowed to reduce adverse effects to this species and *Chorizanthe robusta* var. *hartwegii*. On the Polo Ranch, competitive native species are also threatening *Polygonum hickmanii* and its habitat. See Factor A for additional discussion about invasive species and competitive native species (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Current climate change predictions for terrestrial areas in the northern hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, Intergovernmental Panel on Climate Change 2007). The potential impacts of climate change on the flora of California were discussed recently by Loarie et al. (2008). Based on modeling, they predicted that species' distributions will shift in response to climate change and that species will move to higher elevations and northward, depending on the ability of each species to do so. Increases in species diversity in higher elevations and northern locations due to climate change have the potential to result "...in new species mixes, with consequent novel patterns of competition and other biotic interactions..." with unknown consequences to the species which currently exist there (Loarie et al. 2008). While we lack adequate information to make specific and accurate predictions regarding how climate change in combination with other factors such as small population size will affect *Polygonum hickmanii*, small-ranged species are more vulnerable to extinction due to these changing conditions (Loarie et al. 2008) (USFWS, 2009).

### **Recovery**

#### **Reclassification Criteria:**

Interim recovery objective: Establishing permanent conservation easements over or acquisition of the three properties in Scotts Valley (USFWS, 2009).

Interim recovery objective: Addressing conservation measures for this species in a habitat conservation plan with the City of Scotts Valley (USFWS, 2009).

Recovery Priority Number: 5

#### **Recovery Actions:**

- Protect habitat for Santa Cruz Mountains species on private land through habitat conservation plans and landowner agreements. Little to no progress has been achieved. Because the habitat on Salvation Army land and the Scotts Valley High School Preserve is now highly degraded, the Polo Ranch is the only property where the ecosystem may be intact (USFWS, 2009).
- 2. Manage habitat for Santa Cruz Mountains species. Little progress has been achieved regarding this recommended recovery action as it pertains to *Polygonum hickmanii*. The only beneficial actions we are aware of is the mowing of invasive grasses in the vicinity of the colonies on Salvation Army land and the Scotts Valley High School Preserve, and possibly the placing of a fence around colonies on the Polo Ranch (HuffmanBroadway Group 2008) (USFWS, 2009).
- 3. Conduct research on the life history, ecology, and population dynamics of these species that will contribute to appropriate management strategies. No research has been conducted on *Polygonum hickmanii*. Monitoring has been conducted only on an irregular basis, and the data have not been used to modify management actions (USFWS, 2009).
- 4. Locate additional habitat/populations within the historic range of the species. Gogul-Prokurat (2004) reported the following. "Surveys of most remaining potentially suitable habitat throughout Scotts Valley and surrounding areas have been conducted by local botanists, and to date, no additional populations...have been discovered. Because the rock outcrop areas in which Scotts Valley polygonum occurs are also home to two other Federally-listed endangered species, the Scotts Valley spineflower...and the Ohlone tiger

beetle..., these areas have been thoroughly surveyed. Although the individual Scotts Valley polygonum plants are small and only visible during the growing season, populations should be relatively easy to locate because the rock outcrops on which they grow are...readily identifiable in the field. It is possible that some privately-owned areas of potentially suitable habitat have not been surveyed.... However, Mr. Randall Morgan, a long-time resident ecologist who is intimately familiar with the area, has thoroughly searched for suitable areas based on topographic maps and on-the-ground surveys. According to Mr. Morgan, most of the habitat likely to support Scotts Valley polygonum in this area has been developed, and it is highly unlikely that additional undeveloped areas with the potential to support the species exist.... The Department searched nine U.S. herbaria for historical records.... A literature search was also conducted. To date, no references to any...populations other than the known localities in Scotts Valley have been located." In sum, no additional habitat or populations have been located, and it now seems unlikely that any more exist (USFWS, 2009).

- 5. Develop and implement a public outreach program. A public outreach program has not been developed. The only beneficial action is Hayes and Taylor (2007) producing a fact sheet with color photos in 2006, which the Elkhorn Slough National Estuarine Research Reserve has posted on its website (USFWS, 2009).
- 6. Evaluate progress of recovery effectiveness of management and recovery actions and revise management plans. The efforts to date for *Polygonum hickmanii* have not been effective, and management plans have not been appropriately revised (USFWS, 2009).
- Polo Ranch. The Polo Ranch contains the only potentially intact ecosystem with *Polygonum hickmanii* (and *Chorizanthe robusta* var. *hartwegii*). Therefore, we recommend pursuing opportunities for acquisition of the Polo Ranch by a conservation organization to appropriately manage it as a preserve for sensitive plant species (USFWS, 2009).
- Salvation Army land. We recommend pursuing a conservation easement over the area with *Polygonum hickmanii* (and *Chorizanthe robusta* var. *hartwegii*) and that the area be appropriately managed by a conservation organization as a preserve for the plants (USFWS, 2009).
- Scotts Valley High School Preserve. We recommend the preserve and the grassland and revegetation area be protected by a conservation easement with appropriate management by a conservation organization. In addition, we recommend the Scotts Valley High School implement an education program (with assistance from the Ventura Fish and Wildlife Office) for its students and the community that includes conservation of *Polygonum hickmanii* and *Chorizanthe robusta* var. *hartwegii* (USFWS, 2009).
- Because of the high degree of threat and low potential for recovery in the wild, a botanical seed bank for *Polygonum hickmanii* should be established, with the collections stored at several institutions allied with the Center for Plant Conservation. This would provide for a genetic representation of the species in case of extinction in the wild and also a subsequent source for future re-introductions (USFWS, 2009).
- Because of the high degree of threat and low potential for recovery in the wild, living colonies of *Polygonum hickmanii* should be established at several botanical gardens allied with the Center for Plant Conservation. This would insure that living specimens of the species could be seen somewhere and also insure there is a living population through time (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS:** The following actions are recommended based on the current 5-year review: • The conservation easement at Polo Ranch should be finalized with funding to ensure adequate management by a conservation organization that has the capability to adaptively manage for long-term persistence of Scotts Valley polygonum. • Seed banking should continue annually until a sufficient amount of viable seed, from a genetic population that is as diverse as possible, has been established at multiple seed banks. This will ensure redundancy in storage in case of storage failure. Seed should be bulked to allow outplanting at all historical locations. • The most effective means of germination and propagation should be determined, first using *Polygonum parryi* as a proxy, and then with Scotts Valley polygonum. • Bulk seed should be used to establish greenhouse populations and to outplant Scotts Valley polygonum to all historical locations. The Glenwood Preserve, adjacent to both the Salvation Army property and the Scotts Valley High School Ecological Preserve, should also be considered as a novel outplanting location. The Glenwood Preserve is already managed for the presence of other federally listed plant species and has a similar suite of associated species and environmental conditions. • In order to address the inadequacy of the current preserve designs and management, the creation of a single large management unit that brings together the Salvation Army property, Scotts Valley High School Ecological Preserve, Polo Ranch property, and Glenwood Preserve should be explored. (USFWS, 2020)
- **RECOMMENDATIONS FOR FUTURE ACTIONS:** The following actions are recommended based on the current 5-year review: • Reintroduction should be expanded within Polo Ranch. • Reintroduction should be implemented at the Scotts Valley High School Ecological Preserve and Salvation Army property. • The Glenwood Preserve, adjacent to both the Salvation Army property and the Scotts Valley High School Ecological Preserve, should also be considered as a novel introduction location. The Glenwood Preserve is already managed for the presence of other federally listed plant species and has a similar suite of associated species and environmental conditions. • In order to address the inadequacy of the current preserve designs and associated management, the creation of a single large management unit that brings together the Salvation Army property, Scotts Valley High School Ecological Preserve, Polo Ranch property, and Glenwood Preserve should be explored (USFWS, 2024).

## SPECIES ACCOUNT: *Potentilla hickmanii* (Hickman's potentilla)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

A perennial herb from a woody taproot. Leaves are basal, with 4-7 pairs of deeply cleft leaflets. Stems are prostrate or decumbent, mostly 8-15 cm long. Slender flowering stems, 4-25 mm long, bearing yellow flowers arise from each stem. Blooms April-August. (NatureServe, 2015)

### **Taxonomy**

*Astragalus tener* var. *titi* (Figure 4) was first collected by Mrs. Joseph Clemens in 1904. It was first described by Alice Eastwood as *Astragalus titi* based on those specimens collected by Clemens near Moss Beach, Monterey (Eastwood 1905). Eastwood named the plant *A. titi* in honor of Dr. F. H. Titus, who also collected specimens of this plant. Jepson (1936) considered these two taxa synonymous. Howell (1938) compared type specimens of *A. tener* and *A. tener* var. *titi* and confirmed two different plants, based on the low decumbent habit and smaller flowers of *A. tener* var. *titi*. Barneby (1950) published the name *A. tener* var. *titi*, noting differences from *A. tener* var. *tener* (alkali milk-vetch) in size of various flower parts, habitat, and geographic range. *Astragalus tener* var. *tener* is native to alkaline grass flats in the Central Valley, San Francisco Bay region, and the lower Salinas Valley (Barneby 1950). Additionally, crossing studies and enzyme electrophoresis concluded that *A. tener* var. *titi* is a valid taxon (Liston 1992) (USFWS, 2004).

### **Historical Range**

*Potentilla hickmanii* was historically known from two general areas along the central coast of California: on the Monterey Peninsula in Monterey County, and in the Half Moon Bay area in San Mateo County. The type specimen was collected from the Monterey Peninsula “near the reservoir which supplies Pacific Grove” and described by Alice Eastwood in 1902. Several other collections were made from the Monterey Peninsula during the 1930s, but detail on specific locations is lacking. (USFWS, 2009)

### **Current Range**

California endemic. One extant population in Monterey County. One large population exists in San Mateo County. The total range extent consists of 3 areas and about 9 sq. mi. (NatureServe, 2015)

### **Critical Habitat Designated**

Yes;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Insect pollinated (USFWS, 2004)

**Breeding Season**

Adult: Seeds are produced late in the season (USFWS, 2004).

**Reproduction Narrative**

Adult: *Potentilla hickmanii* has protogynous flowers with a stigma that is receptive to pollen before the pollen-bearing anthers open within the same flower (Jones and Stokes Associates 1996). This mechanism can reduce self-pollination and increase the possibility of outcrossing. It is also likely that some level of interpopulational genetic diversity exists (B. Ertter in litt. 1997). Seeds are produced late in the season. Plants may produce little to no seeds in drier years, especially among early-blooming flowers (Jones and Stokes Associates 1996, B. Ertter in litt. 1997). This lack of seed set might be due to the observed absence of pollinators during blooming time of dry years. Natural population increases appear during wet years, although these population increases may not occur during dry years (Doak et al. 2000). Additionally, recent greenhouse research indicates that some plants previously counted as up to five individuals may have been one single plant with a branched caudex (V. Yadon in litt. 2002). Research was conducted during 1998 and 1999 to explore environmental factors that limit seed production and establishment, and how a limitation might vary through the plants' flowering season (Doak et al. 2000). Evidence for pollen limitation of seed set was apparent and pollen augmentation also significantly reduced the probability of reproductive failure (Doak et al. 2000). Reproductive failure may exist if both pollinator visitation and pollen dispersal is low. Doak et al. (2000) observed only one pollinator in the 2-year study (i.e., a small beetle). Additionally, this research discovered that developed, mature seed was found significantly more frequently in plants that were within at least 50 centimeters (20 inches) of each other than in isolated plants (Doak et al. 2000). *Potentilla hickmanii* will grow and bloom year-round under cultivated conditions. However, cultivated flowers that bloom later in the year tend not to set seed (V. Yadon in litt. 2002). Plants with early flowers that were grown in a hot house set seed apparently without benefit of pollinators (V. Yadon in litt. 2002) (USFWS, 2004).

**Habitat Type**

Adult: coastal scrub/forest (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits coastal bluff scrub and closed-cone pine forest (Smith & Berg 1988). Freshwater marshes, seeps and streamlets in open forested areas near the coast, 0-75 m. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the low number of known populations.

**Dispersal/Migration**

***Population Information and Trends*****Population Trends:**

Decreasing (NatureServe, 2015)

**Population Growth Rate:**

Decline of 70-90% (NatureServe, 2015)

**Number of Populations:**

2 (USFWS, 2020)

**Population Size:**

~5,000 (USFWS, 2020)

**Population Narrative:**

Hickman's potentilla occurs in very small numbers (<80) at Indian Village in Monterey County and a larger population (~5,000) occurs on land managed by the Golden Gate National Recreation Area near Montara in San Mateo County. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Development (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** current threats to the population at Pebble Beach, Monterey County, are relatively the same as at the time of listing. Because a second population has been discovered since the time of listing (Montara population in San Mateo County) and threats to the population are less than they are for the Pebble Beach, Monterey County, population, the threats to the species overall are less than they were at the time of listing. In addition, the Montara population has been transferred from private ownership to state and local agency ownership (CalTrans and Peninsula Open Space Trust ), and long-term plans are to transfer these lands to California State Parks and Golden Gate National Recreation Area, respectively. However, threats to the habitat remain at both locations, and include conversion of coastal terrace prairie habitat by native and nonnative species, alteration in hydrology, and recreation. The Pebble Beach population is threatened with extirpation from alteration and destruction of habitat because the size of coastal prairie where *Potentilla hickmanii* occurs is less than 0.25 ac (0.1 ha) and the number of individuals is so few; therefore, the remaining individuals may not be able to persist if the condition of the habitat continues to decline (USFWS, 2009).

**Stressor:** Predation (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Predation on *Potentilla hickmanii* by mule deer (*Odocoileus hemionus*) on the Pebble Beach population in Monterey County has been observed by Yadon (in litt. 1997) and others (Jones and Stokes Associates 1996). Since the time of listing, herbivory by voles (*Microtus* spp.),

snails (various species), and slugs (various species) has also been observed on both vegetative and reproductive structures (Doak et al. 2000). As recently as 2008, Staub (in litt. 2008) noted that gophers (*Thomomys* sp.) and mice (various species) are likely affecting the population. With so few individuals comprising this population (11 individuals as of 2008), predation exacerbates the threat of stochastic extinction (see Factor E). We have also become aware that the Montara population in San Mateo County is within an area being grazed by cattle (CNDDDB 2008). Cattle grazing may be either beneficial or deleterious to the species, depending on the intensity and duration. Cattle grazing may benefit the species by reducing competition from nonnative species. Too little grazing may allow nonnative species to outcompete *Potentilla hickmanii*, while too much grazing may result in predation or trampling of *Potentilla hickmanii*. We do not have specific information concerning the intensity or the overall impact of grazing that is occurring within this area (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** This species occurs within a portion of the Monterey Peninsula included in the California Coastal Zone. The Del Monte Forest Land Use Plan of 1984 was developed to comply with the Coastal Act's requirement that all counties prepare a plan for those portions of the Coastal Zone within their jurisdiction. Once the Del Monte Forest Land Use Plan was certified by the Coastal Commission, development permits within the Del Monte Forest coastal zone became the responsibility of the County of Monterey. The County of Monterey also has designated certain areas, including where *Potentilla hickmanii* grows, as Environmentally Sensitive Habitat Areas. Protection of listed species through the California Coastal Act and local land use designations is dependent upon the discretion of the lead agency involved. Although no projects have been proposed for the site where *Potentilla hickmanii* grows, these state and local regulations may not protect the species from secondary impacts that occur from such threats as changes in hydrology in adjacent areas and the spread of nonnative species (USFWS, 2009).

**Stressor:** Competition with nonnative species (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** At the Monterey Peninsula site, at least five nonnative plant species occur within *Potentilla hickmanii* habitat. These include: hairgrass, various bromes, tall fescue, and ryegrass (Ferreira 1995, Yadon pers. comm. 2008). Nonnative grasses including Harding grass (*Phalaris aquaticus*) also occur at the Montara site. Several of these nonnative taxa are known to outcompete and displace native species in general (Bossard et al. 2000). To determine the effects of competition on *Potentilla hickmanii*, Doak compared the number of inflorescences and the number of flowers on *Potentilla hickmanii* seedlings within plots where surrounding vegetation was either clipped or unclipped; *Potentilla hickmanii* seedlings in the clipped plots produced more flowers and inflorescences than those in the unclipped plots (Doak et al. 2000). At the Montara site, pampasgrass was noted as being a potential threat to one colony of *Potentilla hickmanii* (Kramer 2008) (USFWS, 2009).

**Stressor:** Reproductive failure (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Reduced number of new plants

**Narrative:** At the time of listing, we discussed that reproductive failure was a concern, primarily because the Monterey Peninsula population had a very low number of new seedlings established over a 2- year period (Morosco 1997). In addition, low seed set had been observed by several biologists (Ertter in litt. 1997, Yadon in litt. 1997). Since the time of listing, Doak et al. (2000) compared seed set in flowers that were cross-pollinated by hand with those in a control group. Based on number of ovules, each flower has the potential to produce approximately 10 seeds; the researchers found that hand-pollinated flowers achieved a higher seed set than the control group (4.8 per flower compared to 3.2) (Doak et al. 2000). The lack of pollinators observed in the field has been put forth as a potential cause for low seed set by several observers (Yadon in litt. 1997, Ertter in litt. 1997, Doak et al. 2000) (USFWS, 2009).

**Stressor:** Small numbers of individuals and populations (USFWS, 2009)

**Exposure:****Response:**

**Consequence:** Loss of genetic variability/extinction

**Narrative:** Conservation biology literature discusses that small populations are threatened by inbreeding depression (Ellstrand and Elam 1993). Small populations can have significantly lower germination rates than larger populations of the same species due to high levels of homozygosity (Menges 1991). Based on historical records, we believe that urban development and secondary impacts associated with such development has already reduced the distribution of this species in the two areas where it occurs. Indirect effects from urbanization in the watersheds include changes in hydrology, changes in vegetation, and an increase in nonnative species. The effects of competition with nonnative species is most problematic immediately adjacent to urban areas and in habitat that has been isolated or fragmented by development (Alberts et al. 1993). While any one of these factors may not be enough to threaten the survival of *Potentilla hickmanii* independently, its limited range, the cumulative and synergistic effects of all of these factors combined could be a threat to the survival and recovery of *Potentilla hickmanii* (USFWS, 2009).

**Stressor:** Alteration of fire frequency (USFWS, 2009)

**Exposure:****Response:**

**Consequence:** Loss of habitat

**Narrative:** At the time of listing, we discussed that alteration of fire frequency was a potential threat to all five taxa in the listing rule, due to fire suppression activities that increased on the Monterey Peninsula as development increased over time; we did not discuss specifically how reducing the frequency of fires in the area would affect *Potentilla hickmanii*. Although *Potentilla hickmanii* itself is associated with grassland habitats, the small meadow where it occurs is within an opening of Monterey pine forest. Without periodic fire, the pine forest would tend to expand in range over time and eventually shade out the habitat where *Potentilla hickmanii* occurs. Shading by Monterey pine was also noted as a threat to several colonies of *Potentilla hickmanii* at the Montara population (Kramer 2008). Based on current information, alteration of fire frequency may continue to be a threat to *Potentilla hickmanii* at both sites (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)

**Exposure:****Response:**

**Consequence:** Loss of habitat

**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). Recently, the potential impacts of climate change on the flora of California were discussed by Loarie et al. (2008). Based on modeling, they predicted that species' distributions will shift in response to climate change, specifically that the species will "move" or disperse to higher elevations and northward, depending on the ability of each species to do so. Species diversity will also shift in response to these changes with a general trend of diversity increases shifting towards the coast and northwards with these areas becoming de facto future refugia. However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to *Potentilla hickmanii* at this time (USFWS, 2009).

**Recovery****Reclassification Criteria:**

At least five viable populations (i.e., populations that are stable or increasing based on a minimum of 10 years monitoring) occur in suitable habitat (addresses Listing Factors A and E). This criterion is relevant and up-to-date. This criterion has not been met. In addition to the two populations known at the time of listing, one outplanting effort is underway at Point Lobos State Park (USFWS, 2009).

All five of the sites are on land that is protected from human-induced disturbance. Funds must be available for appropriate long-term management. As determined by research, protected habitat must be of adequate size (large enough to support a functioning ecosystem; e.g., species present to support seed dispersal and pollination, areas that support fluctuating distributions, areas that harbor suitable unoccupied habitat for population expansion) and configuration to ensure that ecosystem and community processes and associated species (e.g., hydrologic regime, food webs, pollinator fauna, forest meadow communities) are maintained, and that an adequate diversity of sites exist for population expansion and for colonization of new areas as microhabitat conditions change. One of these protected sites should be the Indian Village (Pebble Beach) population; another should be the Montara population in San Mateo County (addresses Listing Factors A and E). This criterion is relevant and up-to-date. This criterion has not been met (USFWS, 2009).

Surrounding vegetation has been managed for a reduction of nonnative plant species and nonnative snails and slugs. The populations should be adequately maintained, such that encroachments by nonnative plants and herbivorous predators (including deer) are not negatively affecting *Potentilla hickmanii* directly or indirectly (addresses Listing Factor C). Individuals have been caged at the Pebble Beach population, and this has reduced deer browse. However, additional management is needed to control nonnative species. This criterion is relevant and up-to-date. This criterion has been partially met for one population (USFWS, 2009).

The populations have been appropriately managed to such a degree that monitoring has determined the populations are of adequate size, density, and number that the trend for each of the populations is projected to be stable or increasing in the future (addresses Listing Factors A and E). Population censusing and demographic studies have been conducted for the Pebble Beach population, but not in a manner that is able to detect long-term trends. This criterion is relevant and up-to-date. This criterion has not been met (USFWS, 2009).

A seed bank has been established at a recognized institution certified by the Center for Plant Conservation (addresses Listing Factor E). This criterion is relevant and up-to-date. This criterion has been partially met in the following way: a portion of seed from the Pebble Beach population that was previously collected for research is being stored at the University of California, Santa Cruz (UCSC); UCSC is not a Center for Plant Conservation affiliate. A small amount of seed was collected from the Montara population in 1995 by staff from the University of California, Berkeley (Jones and Stokes 1996); its current disposition is unknown (USFWS, 2009).

**Delisting Criteria:**

Delisting Criterion 1) threats are reduced or eliminated so that protected populations are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species. The most outstanding management needs currently are: a) maintaining and restoring habitat through control of nonnative grass species, and b) control of herbivory by deer and small mammals. (USFWS, 2019).

Delisting Criterion 2) unoccupied habitat in the area has been assessed for its suitability for reintroduction efforts; the Monterey Peninsula area should be further assessed for potential sites. Two additional, new populations are established and protected where appropriate. (USFWS, 2019).

Delisting Criterion 3) all protected populations remain viable for at least 10 years to demonstrate long-term viability under a range of environmental conditions. We expect above-ground population size to fluctuate annually, based on response to amount and timing of rainfall (e.g. see Fox et al. 2006). Even though this is a perennial species, the aboveground portion is herbaceous and dies back each year, and thus responds to some extent like an annual species. Therefore, a period of 10 years should be long enough to include most of the variability in rainfall that occurs in this region (Zedler & Black 1989; NOAA 2018). (USFWS, 2019).

**Recovery Actions:**

- Work with Pebble Beach Company to evaluate current conditions and improve habitat conditions at the Pebble Beach site. Determine if additional measures can be taken to reduce threats from overwatering, invasive nonnative species, and herbivores (a portion of recovery tasks 1.4.3 and 2.3) (USFWS, 2009).
- Continue pollination ecology research initiated by Doak to determine if lack of pollinators is limiting seed set at the Pebble Beach site. Conduct research to identify pollinators at the Montara site and compare with those at Pebble Beach (a portion of recovery task 3.2.3) (USFWS, 2009).
- Seek additional sites for outplanting additional populations in Monterey and San Mateo Counties. State Park lands (aside from Point Lobos) may offer opportunities for outplanting (a portion of recovery task 4.2.3) (USFWS, 2009).

- Coordinate with Peninsula Open Space Trust to determine if management actions need to be taken to protect or enhance habitat for the species on lands they manage prior to transfer to Golden Gate National Recreation Area (GGNRA). Seek assurance from GGNRA that necessary management actions be continued (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The following actions are recommended based on the current 5-Year Review: 1. Continue management of herbivory and competing species at the Indian Village population. 2. Continue outplanting efforts at Indian Village to increase population size so that adequate natural recruitment is possible. 3. Restore associated native species to the Indian Village site to promote natural ecosystem processes. 4. Finalize and implement the National Park Service plan to manage and restore habitat and outplant Hickman's potentilla at the Montara population. 5. Resurvey and monitor the Point Lobos introduction sites. 6. Evaluate additional introduction sites in San Mateo and Monterey Counties. 7. Continue seed banking efforts until adequate seed from both populations have been stored. (USFWS, 2020)

## SPECIES ACCOUNT: *Primula maguirei* (Maguire primrose)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 08/21/1985; Mountain-Prairie Region (R6) (USFWS, 2016)

### **Physical Description**

A perennial herb with stems approximately 4-10 cm tall, each bearing 1-3 showy, conspicuous lavender-colored flowers. Blooms May-June. (NatureServe, 2015)

### **Taxonomy**

*Primula maguirei* was recently determined to be one of four varieties of *Primula cusickiana* A. Gray (Holmgren and Kelso 2001). The classification is described as *Primula cusickiana* var. *maguirei* L.O. Williams (Holmgren and Kelso 2001). The physical features of the plant are as they were when originally classified and this taxonomic reclassification does not change its limited range and geographic restrictions. *Primula maguirei* is an endemic with unique ecological and physical characteristics; however, the features that distinguish *Primula cusickiana* var. *maguirei* from other varieties within *Primula cusickiana* are not substantial enough to warrant *P. maguirei* being classified at the species level (Holmgren and Kelso 2001). We recognize the synonymy (same identity) of *P. maguirei* = *P. cusickiana* var. *maguirei* and find this taxonomic change does not affect the listing or protection of the *P. maguirei* under the ESA. We recommend that the taxonomy be amended through a technical revision to the list at 50 CFR 17.12 (see section 4). Until that time, we will continue to refer to this species as *Primula maguirei* (USFWS, 2011).

### **Current Range**

Limited area of Logan Canyon in Cache county, Utah (Tilley et al. 2011).

### **Critical Habitat Designated**

Yes;

### **Life History**

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: insect and hummingbird pollinated. Also able to reproduce asexually (USFWS, 2011)

### **Breeding Season**

Adult: Flowering mid-April to mid-May (USFWS, 2011).

### **Reproduction Narrative**

Adult: *Primula maguirei* is a perennial, herbaceous plant 50-100 millimeters (mm) (2-4 inches (in.) high, with showy reddish-lavender flowers. Leaves are oblong and 50 mm (2 in. long and 12 mm (0.5 in.) wide. *P. maguirei* has two types of flowers, the pin and thrum—this is referred to as heterostyly (Davidson and Wolf 2009). On the pin form flower, the female reproductive organs (pistil—produces ovules which become seeds) are higher than the male reproductive organs (stamen—produces pollen). The thrum form is the opposite (Davidson and Wolf 2009). The different lengths of the pin and thrum flowers are adapted for pollination by different

pollinators or different body parts of the same pollinator (Davidson 2010). These flower forms thus promote outcrossing (reproducing with non-related individuals) through sexual reproduction (Darwin 1877 in Bjerregaard and Wolf 2008). Bees, moths, and hummingbirds pollinate *Primula maguirei* flowers (Davidson 2010). *Primula maguirei* also can reproduce asexually, using underground rhizomes or horizontal plant stems to produce new shoots. Rhizomes allow storage of water in times of drought. This clonal growth pattern (genetically identical individuals growing together) allows recovery after periods of dormancy, such as during drought conditions (Kelso et al. 2009). The clonal nature of this species also makes it difficult to identify individual plants in the field (Sibul 2006). *Primula maguirei* is distributed across a linear reach (ca. 16.5 kilometers (km) (10 miles (mi)) of Logan Canyon, with occurrences aggregated in upper and lower portions of the canyon that are separated by some 9.6 km (6 mi) of unoccupied habitat (see section 2.3.1.2). The upper and lower portions of the canyon are characterized by differences in several environmental parameters likely to influence the species' life history. The average temperature over the flowering period is 5°C (9°F) warmer in the lower canyon than it is in the upper canyon (Torti 2008; Davidson and Wolf 2009; Torti and Schen 2009). The average relative humidity also is lower (15-20%) in the lower canyon than in the upper canyon (Torti 2008; Davidson and Wolf 2009; Torti and Schen 2009). Generally, flowering occurs between mid-April and early June, but due to these environmental differences, plants in the lower canyon may begin blooming 2 to 3 weeks earlier and tend to dry out faster than those in the upper canyon (Bjerregaard and Wolf 2008; Torti 2008; Davidson and Wolf 2009; Torti and Schen 2009). It is unknown if there is sufficient cross pollination between the lower and upper canyon sites (Wolf and Sinclair 1997; Bjerregaard and Wolf 2008) (see section 2.3.1.3 for genetic discussion). Some investigators have noted a period of overlap (10–17 days) where both the lower and upper canyon sites are in flower, but the number of flowering individuals is low during this period (Bjerregaard and Wolf 2008; Davidson and Wolf 2009). However, observations since 2006 have revealed little to no period of overlap, suggesting a very limited potential for gene flow between these two portions of the species' very limited geographic range (Torti 2011b) (USFWS, 2011). Flowering mid-April to mid-May. Plant associates include pink alumroot (*Huechera rubescens*), mat rockspirea (*Petrophytum caespitosum*), tadpole buttercup (*Ranunculus ranunculinus*), and narrowleaf wildparsley (*Musineon lineare*) (Tilley et al. 2011) (NatureServe, 2015).

**Habitat Type**

Adult: cliff ledge (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits damp ledges, crevices, and over-hanging rocks along canyon walls.

Almost always on north-facing, moss covered limestone cliffs at or near the canyon bottom in shallow dolomitic soils of the Laketown and Fish Haven geologic formations (Tilley et al. 2011). 1350-1700 m elevation. (NatureServe, 2015)

**Dispersal/Migration**

**Dispersal/Migration Narrative**

Adult: Seed dispersal from May to June (England 1990) (NatureServe, 2015)

***Population Information and Trends*****Population Trends:**

Unknown

**Number of Populations:**

6 - 20 (NatureServe, 2015)

**Population Size:**

250 - 2500 individuals (NatureServe, 2015); 4000 - 20000 (USFWS, 2011)

**Additional Population-level Information:**

Our evaluation of the 1990 recovery plan (USFWS 1990), and the original 1985 listing rule (50 FR 33731) indicated that we did not present how we defined a population for Maguire primrose. For this amendment and managing for Maguire primrose in the future, we use NatureServe guidelines for delimiting plant populations (NatureServe 2004) which are based on the proximity of occupied habitat areas to one another. We consider locations within 2 kilometer (km) (1.24 miles (mi)) of each other and suitable habitat in between them to be a single population. Plant locations that are greater than 2 km (1.24 mi) from each other with unsuitable habitat in between them, are considered separate populations (NatureServe 2004). Based on this criterion, there are two populations of Maguire primrose (Lower Canyon and Upper Canyon), and the number of populations has not changed since the time of our listing decision (USFWS 2019).

**Population Narrative:**

It is estimated that 3000 individuals exist across all 6 populations (Tilley et al. 2011). Past surveys have produced estimates around 1000. 6 known populations (Tilley et al. 2011). (NatureServe, 2015). Low resiliency, representation and redundancy are based on the relatively low number of populations and the relatively restricted geography this species inhabits.

***Threats and Stressors***

**Stressor:** Rock Climbing (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** The USFS has funded a number of studies to look at the interactions between rock climbing and *Primula maguirei* (Sibul 2006; Torti 2008; Torti and Schen 2009; Torti 2010, 2011a). These studies have examined climbing-related impacts at 11 of the 12 EO locations mapped for *P. maguirei* by the UNHP, and have consistently concluded that climbing-related impacts are not occurring at these sites (TABLE 2). The explanations for the apparent lack of conflict varied by site--at 3 sites, *P. maguirei* is not (and may never have been) present; of the remaining 8 sites, 1 was assessed as unsuitable for climbing; 2 have been formally closed to climbing by the USFS; another lacked any evidence of impacts despite the presence of *P. maguirei* within a few meters

of climbing routes; and at the remaining 4 sites, plants are not located along or near climbing routes (Sibul 2006; Torti 2010, 2011a, 2011b; summarized in TABLE 2 this document). Short-term monitoring (1-3 years in duration) at 5 of the 9 EOs where *P. maguirei* still occurs has indicated that plants are relatively stable, showing no significant mortality or decreased growth at any monitored location (Torti 2011a). These studies have recommended that existing climbing closures remain in effect, but have not recommended additional closures based upon the apparent lack of conflict from existing patterns and levels of climbing activity (Sibul 2006; Torti 2008; Torti and Schen 2009; Torti 2010, 2011a). Instead, these authors recommend that monitoring of both *Primula maguirei* and climbing use continue in order to gain increased confidence in apparent trends as well as to verify the assumption that climbing routes and/or pressures will not change. We believe that the threats posed by rock climbing may be less than previously assessed, based on the preliminary data and short-term monitoring that has occurred so far, and we concur with the recommendations to continue monitoring to ensure that the species is adequately protected from habitat loss from climbing-related activities. Monitoring should include an adaptive management approach that utilizes the monitoring data to determine the necessity of continued monitoring and management actions. This recommendation is reflected in section 4 (USFWS, 2011).

**Stressor:** Highway Improvements (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** At the time of listing, transportation and utility construction from the mouth of Logan Canyon to the Right Fork of Logan Canyon were considered threats to the species (50 FR 33733, August 21, 1985). Highway and utility construction had the potential to change the geomorphology of the canyon; we believed that construction could result in altered air patterns and the removal of vegetation to an extent that the microclimate habitat of the cliffs would become less suitable for *Primula maguirei*. Since the time of listing, one highway resurfacing and bridge replacement (Burnt Bridge) project has occurred near the upper canyon *Primula maguirei* sites, from the Right Fork of Logan Canyon to Garden City (Federal Highway Administration 1995). *P. maguirei* occurrences along this stretch of highway are about 40-50 feet above the highway. Conservation measures were used to protect the species, such as avoiding construction activity in *P. maguirei* habitat, limiting removal of canyon-bottom trees (preserving microhabitat conditions of the cliff face), avoiding blasting during the flowering period, and minimizing dust during the flowering period (Federal Highway Administration 1995). Highway widening projects have the potential to impact the species. However, the Utah Department of Transportation (UDOT) does not have plans to improve the highway through at least 2030 (UDOT 2007). Therefore, we do not consider highway projects to be a threat to the species in the foreseeable future (USFWS, 2011).

**Stressor:** Campground Development (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** At the time of listing, we determined that campground and trail development within Logan Canyon area may impact the species (50 FR 33733, August 21, 1985). Furthermore, we were concerned with the indirect effects of altering the microenvironment of Logan Canyon by removing canyon-bottom trees for campgrounds (50 FR 33732, August 21, 1985). Two small

campgrounds are currently within 0.25 mi of three known *Primula maguirei* locations. We are not aware of any loss of plants from campground activities. No major campground improvements have occurred since we listed *P. maguirei* and further campground development is now seen as unlikely given the limited space available in the canyon (Duncan 2010, pers. comm.). We no longer consider campground activities as a threat (USFWS, 2011).

**Stressor:** Maintenance and Improvement to Water Development (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** At the time of listing, we determined that utility construction was a threat. More specifically, the Recovery Plan stated that water development and maintenance or improvements of facilities such as reservoirs and water pipelines were threats to the species (FWS 1990). However, the only water facility in the canyon is the DeWitt Pipeline, which supplies 70% of Logan City's water (CH2MHILL 2007). We are not aware of any *Primula maguirei* occurrences within the DeWitt pipeline route (CH2MHILL 2007). The final biological assessment for the project also included best management practices and mitigation measures to reduce the likelihood negative impacts to the species would occur as a result of the project (CH2MHILL 2007). We are not aware of any additional water improvement projects planned within the vicinity of habitats occupied by *P. maguirei*. Therefore, we do not currently consider water development to be a threat (USFWS, 2011).

**Stressor:** Climate Change (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Reliable projections of climate change in the West are particularly difficult due largely to its complex topography (Smith et al. 2001). It is thus difficult to predict the long-term effects of climate change on a species such as *Primula maguirei* that occurs in a relatively small area (Wolf 2010, pers. comm.). At least one location (Right Fork, EO #007 in TABLE 2) has decreased in the number of individuals and area of coverage in apparent response to dry winter and spring conditions (Shultz 1987 in IHI 1995). Another occurrence (Lower Logan Canyon North, EO #003 in TABLE 2) was located in 1982 during a wet year, but has not been observed again since (Sibul 2006). Although rhizomes may allow *P. maguirei* to store water in times of drought (see section 2.3.1.1), extreme weather events, such as persistent or prolonged drought conditions, could ultimately exceed the drought tolerance of *P. maguirei*. In 2008, HOBO data loggers were placed at 10 sites throughout Logan Canyon and programmed to record temperature and humidity every 30 minutes (Torti 2008). Torti also established 124 permanent quadrats over the course of 2 years (2008 and 2009) to record the approximate size of clumps of *P. maguirei*, the number of stems per clump, the number of flowers per stem, the pin or thrum form of the flower, as well as the general state of the flower's phenology (Torti 2008). Follow-up surveys in 2009 and 2011 suggest that plants within permanent quadrats have been relatively stable, with no significant mortality or reductions in vegetative growth (stems) or reproduction (flowers) (Torti and Schen 2009; Torti 2011a). We recommend that this long-term monitoring effort continue in conjunction with data collection from the HOBO data loggers, so that a climate vulnerability assessment can be completed for this species (see section 4) (USFWS, 2011).

**Stressor:** Disease or predation (USFWS, 2011)

**Exposure:****Response:****Consequence:** Loss of individuals

**Narrative:** In the listing document and Recovery Plan for *Primula maguirei*, disease and predation were not considered threats to the species (50 FR 33733, August 21, 1985; FWS 1990). Herbivory from rodents is regularly encountered (Sibul 2006; Bjerregaard and Wolf 2008; Torti 2008; Davidson and Wolf 2009; Torti and Schen 2009), primarily from bushy-tailed woodrats (*Neotoma cinerea*) and similar species (Bjerregaard and Wolf 2008). Snails of the *Oreohelix* genus were observed directly on plant leaves (Davidson 2010). Insects also may damage fruits of the plants (Sibul 2006). The magnitude of herbivory of a single individual ranges from the single flower being eaten to the entire plant being devoured (Davidson 2010). Herbivory from rodents, snails and insects appears to affect plants; however, we do not have information indicating that it is occurring at unnatural or unsustainable levels. We have no evidence to indicate that this factor is a threat to this species now or for the foreseeable future (USFWS, 2011).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2011)**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** Prior to listing, *Primula maguirei* was afforded some protection because the USFS designated it as a sensitive species under the NFMA. This designation requires the USFS to analyze the effects of actions they fund, authorize, or carry out that may affect *P. maguirei*. In the event that ESA protections are removed, the USFS has expressed the intention to once again designate *P. maguirei* as a sensitive species, thereby reinstating these protections. The USFS also has designated substantial parts of Logan Canyon as a Botanical Special Interest Area, a designation which directs the agency to protect and manage (in part) for the unique botanical resources present, including *P. maguirei*. This designation also will remain in effect regardless of the ESA status of *P. maguirei*. In addition, the USFS has funded numerous research projects to better understand the status of this species and its vulnerability to threats, and has closed certain areas to climbing activity as a result of concerns stemming from the perceived threats. If these existing regulatory mechanisms continue to be adequately implemented, as they have been in recent years, we regard them as likely to be sufficient to provide for the long-term protection of the species in the event that it is de-listed (USFWS, 2011).

**Stressor:** Invasive Species (USFWS, 2011)**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** Weed infestation is a possible threat to *Primula maguirei*. Dyer's woad (*Isatis tinctoria*) is found near 8 of the 9 sites where *P. maguirei* is found (CH2MHILL 2007). Dyer's woad is primarily found in disturbed sites, such as pastures, rangeland, cropland, woodlands, and areas of disturbed soils such as housing developments (Weber County 2004). Dyer's woad also could invade lands disturbed by fire, roads, and areas associated with grazing. Because *P. maguirei* grows within the cliff face, in cracks and crevices, we do not anticipate that this infestation will directly affect *P. maguirei*. It is possible that rockslides could occur in sites occupied by *P. maguirei*, allowing Dyer's woad to gain a foothold; however, these events are rare and would not occur with great frequency. Efforts to control Dyer's woad or other invasive exotics using herbicides and/or biocontrol agents could affect *P. maguirei*; however, conservation measures

contained in the Forest Plan are adequate to avoid direct and indirect effects associated with these management activities (USDA 2003). We have no evidence to suggest that invasive exotic species are currently impacting *P. maguirei*. However, because future infestations of invasive species can be difficult to predict, this threat represents a perpetual challenge that must be periodically assessed and managed appropriately. The Forest Plan directs the USFS to manage the threat of invasive species to the sensitive botanical resources in Logan Canyon Botanical Special Interest Area (USDA 2003). At the present time, we regard this threat as foreseeable, but adequately addressed by existing regulatory mechanisms (USFWS, 2011).

**Stressor:** Small Population Risks (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Extinction

**Narrative:** Smaller numbers of plant individuals are more likely to succumb to natural catastrophes (e.g., drought, fire, and flood), environmental stochasticity (e.g., changes in weather, available pollinators, amount of predation), and demographic stochasticity (e.g., fluctuations in survival and fitness). We acknowledge that *Primula maguirei* is found in a single canyon and this limited range increases the potential for some threats to affect all known populations simultaneously. However, several factors suggest that *P. maguirei* may be less vulnerable to these risks than its limited geographic distribution otherwise suggests: • Estimates of the total number of plants in the wild have increased from 350 (at listing) to between 4,000-20,000 clumps (see section 2.3.1.2); • The number of locations known to support the species also has increased since the time of listing (also see section 2.3.1.2); • The rugged and isolated habitat (i.e., moist cliff tops, notches and boulders) in which *P. maguirei* occurs appears generally unsuitable for rock climbing routes, suggesting that although climbing occurs in Logan Canyon, this threat may have less of an effect than previously thought on the habitats in which *P. maguirei* occurs; and, • Preliminary monitoring data indicates that existing populations have been stable (low rates of mortality over the past 3 years). These increases in abundance and the number of known locations should reduce the risk of extirpation or extinction from stochastic events. However, as noted above (section 2.3.1.2), recent estimates of abundance in *Primula maguirei* populations are either imprecise (ranging from 4,000-20,000 clumps) or speculative (the presumption of additional locations in areas that have yet to be surveyed). These estimates and assumptions need verification through additional surveys before threats from small population risk can be effectively dismissed (USFWS, 2011).

## **Recovery**

### **Reclassification Criteria:**

Maintain at least two populations (Lower Canyon and Upper Canyon) at a level that demonstrates stable or increasing trend in plant abundance over a consecutive ten-year period. Plant abundance (measured by the number of ramets) may fluctuate within individual sites, but the defined populations should have a stable or increasing growth rate ( $\lambda$  equal to or greater than 1) over a consecutive ten-year period. The ten-year period may start retroactively (USFWS 2019).

Maintain an estimated range-wide total population size at or greater than 4,000 individuals for a five-year minimum period. This population estimate will be based on a measure of the number of ramets identified in criterion 1, above. The five-year period may start retroactively (USFWS

2019).

The two populations (Lower Canyon and Upper Canyon) demonstrate sexual reproduction by pollinators over a consecutive ten-year period. Sexual reproduction (recorded as the presence of mature fruits that contain viable seeds) should be documented at all eight extant sites within the two populations. This measure does not need to be recorded on an annual basis, but should be recorded every two or three years over a ten-year period. The ten-year period may start retroactively (USFWS 2019).

Long-term habitat protections are in place for the two populations (Lower Canyon and Upper Canyon) to protect Maguire primrose from rock climbing and other potential threats with the U.S. Forest Service via long-term management agreements, conservation agreements, or memoranda of understanding (MOU). Species management would include outreach and education efforts to climbing audiences that would continue to build community support for long-term protections (USFWS 2019).

The two populations (Lower Canyon and Upper Canyon) are represented in an ex-situ seed collection that is managed according to the Center for Plant Conservation guidelines (Guerrant et al. 2004). The ex-situ seed collection should contain existing levels of genetic diversity (or representation) of the two populations (USFWS 2019).

**Recovery Actions:**

- The majority of known locations of *Primula maguirei* have been mapped in databases maintained by the Utah Natural Heritage Program (UNHP), a program of the Utah Division of Wildlife Resources (UDWR). Therefore, the UNHP has historically provided the primary mechanism for managing and distributing location and trend data for rare species throughout the State, including *P. maguirei*. However, in June 2011 the UDWR reorganized, in the process eliminating its sole botanist position and, therefore, the botany data management functions formerly provided by the UNHP. At present there is no established mechanism for maintaining or distributing location data for rare plant species in the State of Utah, including *P. maguirei*. The FWS is engaged in conversations with other partners about assuming this function; however, to date no mechanism has been agreed upon. This data management challenge represents not just the mere maintenance and distribution of historical data, but rather a need to amend older data with more recent information gathered through additional survey and monitoring efforts. With respect to *Primula maguirei*, new data do exist that have yet to be incorporated into the databases of the UNHP. Specifically, in recent years, additional locations of the species have been discovered by persons not affiliated with or funded by the USFS, FWS, or UNHP; these locations have not yet been provided to these agencies nor have they been captured in the existing UNHP databases. The USFS also is funding ongoing monitoring activities at previously known locations; these activities also provide new information regarding the status of the species at known sites. Because *P. maguirei* occurs in such close (within a few meters) proximity to established and popular climbing routes, and because of the potential for climbing activities to change in the future (either in location, intensity or both), there is a continual need for periodic monitoring of *P. maguirei* populations. Therefore, the lack of an established repository to manage and distribute updated data represents a significant barrier to effective communications among relevant management interests as well as the ability of these entities to protect *P. maguirei*. This criterion has not been met (USFWS, 2011).

- The primary threat at the time of listing and writing the Recovery Plan was rock climbing and rappelling (see section 2.3.2.1). Since listing, the USFS has worked to address these threats through a combination of efforts including education, physical barricades and site-specific climbing closures (U.S. Department of Agriculture (USDA) 2003). Subsequent field observations also have revealed that *Primula maguirei* tends to occupy moist to perennially saturated habitats that are typically avoided along preferred climbing routes, suggesting that climbing activities may pose less of a threat to this species than previously assessed. Since 2006, the USFS has funded a monitoring program to assess the proximity of *P. maguirei* plants to climbing routes and apparent correlations between plant survival or growth and climbing activities (Sibul 2006; Torti 2008, Torti and Schen 2009; Torti 2010, 2011a). To date, this monitoring effort has failed to detect climbing-related impacts to the species. This primarily appears due to the degree of spatial separation between plants and climbing routes, the effectiveness of existing climbing closures at deterring entry into occupied habitats, or some combination of these factors. However, at one location, *P. maguirei* has been found to persist in close proximity (2–3 meters (m)) to well-known climbing routes within a larger area visited by thousands of climbers per year (Torti 2010). These preliminary results suggest that climbers may be avoiding the specific microsites occupied by *P. maguirei*. To the extent that this is true, this pattern of recreational use may pose even less of a threat than currently believed. However, verification of this assumption would require additional, and more detailed, data collection than is occurring at the present time. Additional protections to *Primula maguirei* and its habitat are afforded by the designation of substantial parts of Logan Canyon as a Botanical Special Interest Area (USDA 2003). This designation directs the USFS to manage the habitat of *P. maguirei* in a manner consistent with the needs of that species and other sensitive botanical resources (see section 2.3.2.4). The USFS' combined program of education, physical barriers, selective use of climbing closures and the designation of Logan Canyon Botanical Special Interest Area have collectively and substantively reduced threats to *Primula maguirei* and its habitat from rock climbing. However, as discussed below, continued monitoring is needed to verify that patterns of climbing use (location and intensity of routes) are stable, and that *P. maguirei* is persisting in areas not subject to formal site closures. In addition, additional threats unrelated to rock climbing remain in the form of accelerated climate change. The magnitude and intensity of these threats is poorly understood, and would be informed by additional analyses (e.g., climate vulnerability analyses) recommended later in this document. Therefore, this criterion has been partially met (USFWS, 2011).
- We no longer believe over-collection and commercial exploitation is a threat to the species (see section 2.3.2.3). This recovery objective is obsolete (USFWS, 2011).
- Revise the species' taxonomy in the FR to reflect the best available scientific information (USFWS, 2011).
- Federal agencies should work with partners to resurrect the UNHP and ensure the plant portion of the database is populated and maintained (USFWS, 2011).
- Continue monitoring plant survivorship, growth and reproduction in *Primula maguirei* in conjunction with assessments of climbing patterns and intensities. Iteratively assess the need for changes in climbing closures and monitoring efforts (USFWS, 2011).
- Encourage and implement standardized and quantitative reporting of population parameters (clumps, rosettes, stems) in monitoring reports, and strengthen the use of quantitative measures to assess population (or site-specific) trends (USFWS, 2011).

- Conduct additional surveys in areas of potentially suitable habitat to refine and narrow the range of available estimates of total population size (USFWS, 2011).
- Continue collecting precipitation and humidity data (using HOBO sensors or comparable field equipment) in conjunction with monitoring plant survivorship, growth, and reproduction. Use this information to prepare a climate vulnerability assessment for this species to assess its relative vulnerability to accelerated climate change (USFWS, 2011).
- Encourage the USFS to iteratively assess and manage the potential for invasive exotic species to threaten sensitive botanical resources (species and habitats) in Logan Canyon, including *P. maguirei*. These activities should specifically ensure that existing infestations of Dyer's woad (*Isatis tinctoria*) have not expanded or encroached into botanically sensitive habitats (USFWS, 2011).
- Continue and expand prior research regarding the identity and availability of pollinators (USFWS, 2011).

## SPECIES ACCOUNT: *Prunus geniculata* (Scrub plum)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 2/20/1987; Southeast Region (R4)

### **Physical Description**

The scrub plum is a heavily branched, broad-crowned shrub that can reach 2 m in height, although 0.5 m may be more typical at sites with frequent fires. It grows from gnarled, half-buried trunks and spreads by sucker shoots. Its young twigs are strongly geniculate (zig-zag shaped), while its lateral branches are either short, stubby, spur shoots bearing leaves and flowers, or are strongly tapering and spine-like. The bark of old stems is thin, gray, usually lichen-encrusted, and forms small rectangular or square plates. The bark of new shoots is lustrous reddish-brown or purplish and smooth. The scrub plum's leaves are crowded on the spur shoots (an arrangement typical of the Rosaceae family) and are widely spaced on the normal shoots. The stipules are linear-subulate, roughly 5 mm long, green, and pectinately fringed at the margins with reddish glands. The leaf blades are ovate to obovate or elliptic, 1 to 3 cm long, short-acuminate, and serrulate with gland-tipped teeth. The leaf base is rounded or broadly cuneate. The leaf stalk is a third to half as long as the blade. The scrub plum has small, fragrant flowers that are 11 to 13 mm across when open. Like the leaves, flowers found on the spur shoots are rather crowded, while those found on the regular shoots or the spine bases are spaced further apart. The pedicels extend only slightly beyond the bud scales, so the flowers give the appearance of being sessile. The flowers are radially symmetrical with a 3 mm long hypanthium (the cup-shaped structure formed by the united portions of the bases of the sepals, petals, and stamens). The 5 calyx lobes are radially symmetrical, spreading to ascending triangular with acute apices, sparsely ciliate on the margins, reddish or green, with the bottom surfaces smooth and the upper surfaces white-tomentose. The 5 petals are white, spreading, and about 5 mm long. The petal blades are ovate to obovate with rounded tips and attenuated bases ending in short, ciliate-margined claws. The stamens are numerous, roughly 0.5 mm long, and borne on the rim of the hypanthium. The fruit of the scrub plum is an ovoid or ellipsoidal drupe, 12 to 25 mm long, and dull reddish in color. It has a thin, bitter flesh and a slightly flattened seed. (USFWS, 1999)

### **Taxonomy**

*Prunus geniculata* was first described by Roland M. Harper in 1911 (Harper 1911). There has been no additional treatment of this species. The common name "scrub plum" was first used by Small (Small 1933). (USFWS, 1999)

### **Historical Range**

See current range/distribution.

### **Current Range**

In Florida, the range includes Lake County, west and southwest of Lake Apopka; the southwest and northwest corners of Orange and Osceola counties, respectively; and Polk and Highlands counties, from the City of Lake Wales south to the Highlands County/Glades County border. (USFWS, 2009)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproduction Narrative**

Adult: Scrub plum is a rare plant with a very narrow range and small, widely scattered populations. It frequently forms small colonies of several plants but may grow as solitary individuals (unpublished FNAI data). It prefers fairly open areas without a dense canopy, but older plants are able to survive in dense shade (Schultz, pers. obs.). Scrub plum's life history has not been reported in the literature. Many birds, rodents and other mammals are known to be fond of plum fruit and are probably responsible for the dissemination of the species (Van Dersal, 1938). Gopher tortoise (*Gopherus polyphemus*) could also be a vector. Kral (1983) states that *P. geniculata* respond vigorously to fire disturbance and historically was probably fire maintained due to its presence in frequently burned sandhills.; ASEXUAL; Perfect; Predominantly outcrossing; SEXUAL; BIOTIC; Birds; Mammals; BIOTIC; Hymenoptera; Insects, other; (NatureServe, 2015). From the various research efforts, we now know that scrub plum: (1) has a rare breeding system characterized by the presence of male and bisexual flowers on the same plant, (2) is partially self-incompatible and that inbreeding depression is high in self-compatible individuals, and (3) experiences high rates of fruit loss due to abortion and pre-dispersal predation. Recent research has also confirmed that scrub plum is long-lived and experiences low mortality, and populations persist for long periods in the absence of fire (Pace-Aldana et al. 2006; Menges et al. 2008; C. Weekley, Archbold Biological Station, personal communication, 2009). Current information also supports previous reports that this species is a strong postburn resprouter (Weekley et al. 2007, Weekley and Menges 2003, Menges et al. 2007) and that recruitment is low (Service 1999; Weekley and Menges 2003, 2007). Weekley and Menges (2008) are currently evaluating the effects of various land management treatments on a number scrubendemic plants, including scrub plum (USFWS, 2009).

### **Habitat Type**

Adult: Turkey oak sandhill and evergreen oak-sand pine (USFWS, 2009)

### **Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 2009)

### **Environmental Specificity**

Adult: Narrow/specialist (USFWS, 2009)

### **Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS, 2009)

### **Site Fidelity**

Adult: High (inferred from USFWS, 2009)

### **Habitat Narrative**

Adult: Species inhabits deep, yellow sands of longleaf pine-turkey oak sandhill and white, excessively leached, wind-deposited soils of evergreen scrub oak-sand pine scrub (NatureServe,

2015). High site fidelity and ecological integrity of the population as well as low tolerance range are inferred based on the specific habitat requirements of this species.

### ***Dispersal/Migration***

#### **Dispersal/Migration Narrative**

Adult: Scrub plum's life history has not been reported in the literature. Many birds, rodents and other mammals are known to be fond of plum fruit and are probably responsible for the dissemination of the species (Van Dersal, 1938). Gopher tortoise (*Gopherus polyphemus*) could also be a vector (USFWS, 2009).

### ***Population Information and Trends***

#### **Number of Populations:**

64 (USFWS, 2023)

#### **Population Size:**

2500 - 10,000 individuals (USFWS, 2009)

#### **Population Narrative:**

Responds vigorously to fire disturbance; cannot withstand soil disturbance of shade. Sometimes common, but usually only a few individuals at a site (NatureServe, 2015). FNAI updated its records for scrub plum in the 6 summer of 2008 and confirmed 83 extant populations. These 83 populations contained from 1 to 10,200 plants (A. Johnson, Florida Natural Areas Inventory, personal communication, 2009). Forty-five populations contained 10 or more plants (USFWS, 2009). *Prunus geniculata* is a long-lived, heavily branched shrub, that thrives in fire-maintained scrub habitat native to ancient ridges in central Florida. There are estimated to be 64 extant populations in 5 counties. Of these populations, 40 are found on conservation lands and 13 of those had their conditions ranked as excellent or good on when last observed. There were 51 populations that are either found on private lands or have lower ranked conditions. Additionally, only six populations on the conservation lands have an estimated size over 100 individuals (USFWS, 2023).

### ***Threats and Stressors***

**Stressor:** Fire Suppression (USFWS, 2009)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The most pervasive threat to scrub plum on public land is habitat degradation due to fire suppression. Most land managing agencies in Florida are not able to use prescribed fire at the rates, frequency, and/or intensity needed to restore and maintain most of Florida's fire-adapted ecosystems (R. Mulholland, Florida Department of Environmental Protection, personal communication, 2007; Service 2006). Consequently, the difficulties land managing agencies currently face in implementing prescribed fires probably have resulted in the degradation of scrub plum habitat in some areas (USFWS, 2009).

**Stressor:** Urban development (USFWS, 2009)

**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** Scrub plum that occur on non-conservation private lands also are vulnerable to destruction due to urban development, such as construction of roads; installation of utilities and other infrastructure; and residential, commercial, and industrial construction. Scrub plum on each private parcel is vulnerable to this threat at any time. Several populations are located in areas previously platted for residential development and these populations are at greatest risk, especially when economic conditions improve and residential construction resumes at its historic pace. One small population is imminently threatened by land clearing for commercial development. In 2006, the Service issued an incidental take permit for two fossorial skinks on about 45 acres in west-central Lake County. Several hundred scrub plum plants were also found on this parcel along with six other federally listed plants (Service 2005). The entire parcel has not yet been developed but as land clearing proceeds individual plants will be destroyed (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** On private properties, Federal or State laws provide little protection for scrub plum. Since the majority of extant scrub plum populations occur on unprotected private lands, we conclude that existing regulatory mechanisms are inadequate to protect this species (USFWS, 2009).

**Stressor:** Low seed viability (USFWS, 2009)**Exposure:****Response:****Consequence:** Loss of genetic diversity

**Narrative:** Scrub plum produce few viable seeds and recruitment is extremely low (Weekley et al. 2007; B. Pace-Aldana, TNC, personal communication, 2008). Loss of seeds due to inbreeding depression reduces the number of germinable seeds. These effects may be exacerbated by habitat fragmentation and fire exclusion (C. Weekley, Archbold Biological Station, personal communication, 2009) (USFWS, 2009).

**Recovery****Reclassification Criteria:**

Applicable to the South Florida populations: 1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations required to ensure 20 to 90 percent probability of persistence for 100 years. (USFWS, 1999)

Applicable to the South Florida populations: 2. When these populations, within the historic range of *P. geniculata* are adequately protected from further habitat loss, degradation, and fire suppression. (USFWS, 1999)

Applicable to the South Florida populations: 3. When these sites are managed to maintain the high pine and xeric oak scrub communities to support *P. geniculata*; (USFWS, 1999)

Applicable to the South Florida populations: 4. When monitoring programs demonstrate that these sites support sufficient population sizes, are distributed throughout the historic range, and are sexually or vegetatively reproducing at sufficient rates to maintain the population. (USFWS, 1999)

Applicable to the entire species range: The 1996 recovery plan lists four criteria necessary to reclassify the scrub plum from endangered to threatened status: (1) there are eight populations at four sites; (2) at least 10 years of demographic monitoring is conducted at one of these locations; (3) scrub plum is monitored at all locations; and (4) there must be protected locations in Highlands, Polk, and Lake counties. (USFWS, 1996)

Recovery Priority Number: 2

**Delisting Criteria:**

Applicable to the entire species range: To delist the scrub plum, 20 populations must be present at 5 sites and there must be 10 additional years of monitoring. (USFWS, 1996).

**Recovery Actions:**

- S1. Determine current distribution of *P. geniculata*. Conduct surveys for *P. geniculata*. Conduct surveys for *P. geniculata*. Maintain distribution of known populations and suitable habitat in GIS database. (USFWS, 1999)
- S2. Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- S3. Conduct research on life history characteristics of *P. geniculata*. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species more specific biological information is needed. (USFWS, 1999)
- S4. Monitor existing populations of *P. geniculata*. Develop monitoring protocol to assess population trends for *P. geniculata*. Develop a quantitative description of the population structure of *P. geniculata*. (USFWS, 1999)
- S5. Provide public information about *P. geniculata*. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of *P. geniculata* and other rare species requires a self sustaining, secure number of natural populations. (USFWS, 1999)
- H1. Prevent degradation of existing habitat. Extensive habitat loss, degradation, and fragmentation have already occurred throughout the range of this species. Both urbanization and fire suppression have decreased the available habitat. To date, there are six protected sites for *P. geniculata* in Polk and Highlands counties. (USFWS, 1999)

- H2. Restore areas to suitable habitat. Native habitats that have been disturbed or that have experienced a long history of fire suppression may be good candidates for future reserves. (USFWS, 1999)
- H3. Conduct habitat-level research projects. Study the response of *P. geniculata* to various land management practices, such as prescribed fire regimes, vegetative thinning, and control of exotic/invasive vegetation. (USFWS, 1999)
- H4. Monitor habitat/ecological processes. Monitor the effects of land management actions, such as prescribed fire, exotic plant control, etc., on the habitats where *P. geniculata* occurs. (USFWS, 1999)
- H5. Provide public information about scrub and its unique biota. Educational efforts, especially those conducted by Archbold Biological Station, have been successful. Without these successful efforts, the Lake Wales Ridge NWR would not have been created. Florida's system of biological preserves depends on a broad base of public understanding and support for its funding and future success. In addition to past and ongoing educational efforts by The Nature Conservancy, Bok Tower Gardens, and Archbold Biological Station, future efforts by these organizations, and the Florida Park Service, the Florida Division of Forestry, the South Florida Water Management District, the Florida Native Plant Society, and local garden clubs are crucial in increasing public appreciation of scrub and high pine communities, and their associated plant species. The Arbuckle Appreciation Day sponsored by the Florida Division of Forestry has been especially successful. (USFWS, 1999)
- Recommendation for Future Action from 2009 5-Year Review: Revise the recovery criteria to establish measurable goals for demographic monitoring, including but not limited to: the number of populations that should be monitored, the demographic parameters that should be measured, the demographic performance levels/rates that should be met, and the timeframe within which these levels/rates should be attained/maintained (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Continue demographic monitoring on the Carter Creek tract of the LWRNWR and reinitiate demographic monitoring on TNC's Tiger Creek and Longleaf Pine Preserves. Conduct Level 2 (see Menges and Gordon 1996) monitoring on multiple sites using populations in different habitats and with different management regimes (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Conduct a rangewide survey of genetic diversity in scrub plum. Such a survey could help in identifying populations that might be targeted for acquisition or included as a propagule source for creation of new populations on sites undergoing restoration (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Evaluate breeding system to identify S-locus and assay S-allele diversity within populations to assess the degree of self-incompatibility and role of inbreeding depression in seed viability (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Implement management activities on public lands that contain scrub plum, including prescribed fire at return intervals and intensities necessary to restore and/or maintain the various xeric vegetative communities that support this species (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Purchase or otherwise protect large scrub plum populations on unprotected lands. Protection should target scrub plum populations that are sufficiently large, or could be large if adequately managed, as to be self-sustaining and viable long-term (USFWS, 2009).
- Recommendation for Future Action from 2009 5-Year Review: Explore opportunities to encourage landowners to conserve and manage property known to contain this species

(USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES • Collaboration with conservation land managers to increase habitat suitability of occupied habitat by promoting beneficial management options to increase population persistence wherever additional opportunities exist when engaging with agency management personnel. • Encourage landowners whose populations occur on conservation lands to monitor occupied habitat for increased data of long-term species trends. • Initiate long-term monitoring programs for populations with highest viability potential on conservation lands to discern long-term species trends (USFWS, 2023).

## SPECIES ACCOUNT: *Pseudobahia bahiifolia* (Hartweg's golden sunburst)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

An annual herb, about 6-15 cm tall, covered throughout with white, wooly hairs. Flower heads (March or April) are bright yellow, and are borne singly at the ends of the branches. (NatureServe, 2015)

### **Historical Range**

The historical distribution of *Pseudobahia bahiifolia* is not known specifically but is thought to have spread approximately 200 miles along the eastern San Joaquin valley and foothills from Stanislaus County in the south to Yuba County in the Sacramento Valley to the north (Stebbins 1991). The distribution once extended north to Yuba County in the Sacramento Valley, based on the 1847 type collections of Karl Hartweg; however, these occurrences are now extirpated (Stebbins 1991). (USFWS 2007)

### **Current Range**

The current distribution of the majority of *P. bahiifolia* occurs in two isolated clusters, including six extant occurrences near Friant along both sides of the San Joaquin River in high pumice content soils (Fresno and Madera Counties) and six occurrences near Cooperstown in Stanislaus County. *Pseudobahia bahiifolia* grows in loam or sandy loam soil associated with Amador and Pentz series (Stanislaus County), Rocklin series (Fresno and Madera County), Amador and Hornitos soils (Merced County) (Stebbins 1991). (USFWS, 2007)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Breeding Season**

Adult: Flowering and fruiting occur in March-April (NatureServe, 2015).

### **Reproduction Narrative**

Adult: Grazing levels must be reduced during flowering and fruiting (March-April). Overgrazing during this period has been documented to be detrimental. The greatest threat to this species is destruction of habitat by ag, development and heavy grazing (NatureServe, 2015).

### **Habitat Type**

Adult: Grasslands/woodlands (NatureServe, 2015)

### **Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits non-native grasslands and occasionally grassland-blue oak woodland community ecotones in the Central Valley of California. The composition of the prehistoric grassland communities in this area is unknown; the communities have long-since become dominated by exotic grasses. *P. bahiifolia* generally occurs in areas with Mima mound topography: small mounds (30 cm to 2 m in height) interspersed with shallow basins that may form vernal pools. The plants nearly always occur on north-northeast facing mound slopes, preferentially on the upper slopes where grass cover is minimal. Plant can also occur along shady creeks or the margins of vernal pools. Plant distribution is closely correlated with certain soil types; prefers highly acidic, shallow soils derived from rhyolitic tuff. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the low number of known populations.

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Not available

**Number of Populations:**

23 presumed extant (USFWS, 2023)

**Population Size:**

10,000 to >1,000,000 individuals (USFWS, 2023)

**Population Narrative:**

About 32,000 total plants in 1990 (Stebbins 1991 Status Survey, cited in USFWS 1997). 16 Populations (USFWS 1997). (NatureServe, 2015). The current species distribution and abundance of Hartweg's golden sunburst is similar to what we described in our final listing rule and 2007 status review (Service 1997, p. 5543; Service 2007, p. 2). The known occurrences of Hartweg's golden sunburst are concentrated in the eastern San Joaquin Valley in Stanislaus, Madera, Merced, and Fresno Counties (Table 1; Service 2007, p. 6). At the time of the last 5-year review, the distribution of the majority of Hartweg's golden sunburst occurred in two isolated clusters, including six extant occurrences near the community of Friant along both sides of the San Joaquin River in high pumice content soils (Fresno and Madera Counties) and six extant

occurrences near Cooperstown in Stanislaus County (Service 2007, p. 6). The three occurrences (Diversity Database occurrence numbers 6, 7, and 17) near Cooperstown house the largest known populations of Hartweg's golden sunburst and have measured at over 10,000 individual plants (Diversity Database 2023). Currently, there are six known Diversity Database occurrences of Hartweg's golden sunburst that have had over 1,000 individuals estimated or counted during a survey (Vollmar Consulting 2010, pp. 64, 119). In addition, five Diversity Database occurrences of Hartweg's golden sunburst were discovered since the 2007 status review. Two of the new occurrences (Diversity Database occurrences 37 and 38) contained over 1,000 individuals when they were discovered; (Vollmar Consulting 2010, pp. 1, 18; Diversity Database 2023). Abundance of Hartweg's golden sunburst fluctuates greatly from year to year due to weather conditions such as rainfall. The surveys completed since the previous 5-year review do not alter our understanding of the species' current distribution or abundance and population estimates or trends have not been determined (USFWS, 2023).

### ***Threats and Stressors***

**Stressor:** Residential development (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:**

**Stressor:** Overgrazing and trampling (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:**

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2007)

**Exposure:**

**Response:****Consequence:** Loss of habitat**Narrative:****Stressor:** Non-native plants (USFWS, 2007)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:****Stressor:** Road maintenance and widening (USFWS, 2007)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:****Stressor:** Transmission line maintenance (USFWS, 2007)**Exposure:****Response:****Consequence:** Loss of individuals**Narrative:****Stressor:** Drought (USFWS, 2007)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:****Stressor:** Small population size (USFWS, 2007)**Exposure:****Response:****Consequence:** Loss of genetic variability**Narrative:****Recovery****Recovery Actions:**

- The draft recovery plan is currently under development
- Protect lands with known occurrences of either species of *Pseudobahia*, particularly those occurrences with the largest and most dense populations, through conservation easements, acquisition in title, or other methods. Manage these properties to protect and enhance growth of *P. bahiaefolia* and *P. peirsonii* (USFWS, 2007).
- Work with landowners to gain access to their property for surveying and monitoring populations of both *Pseudobahia* species (USFWS, 2007).
- Conduct coordinated surveys of all recorded occurrences of both species of *Pseudobahia*. Establish systematic periodic surveys where possible of known occurrences. Begin surveys in potentially suitable habitat of both species of *Pseudobahia* based on soil type and habitat characteristics (USFWS, 2007).

- Complete and publish the draft recovery plan and ultimately finalize the recovery plan. Much of the information contained in Stebbins' two studies (1989, 1991) is still valid and is directly applicable to a recovery plan (USFWS, 2007).
- Maintain a viable, protected seed collection for both species of *Pseudobahia*. Ensure sufficient seeds (approximately 5,000 per site, USFWS 2006a) are taken from as many sites as possible to maintain genetic heterogeneity (USFWS, 2007).
- Recovery Priority Number: 5C

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS:** Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the Hartweg's golden sunburst and San Joaquin adobe sunburst. Some of these recommendations have already been discussed in the previous 5- year review (Service 2007, pp. 17–18) and remain valid. 1. Habitat Acquisition, Management, and Restoration. Known occupied sites with Hartweg's golden sunburst and San Joaquin adobe sunburst present should be protected. Resource agencies and private partner groups should work to ensure land protection through acquisition or easement, and large unprotected areas currently occupied by the species should be given the highest priority. Large, formerly occupied sites that are unoccupied but have a high restoration potential and the sites with recent occurrences should also be considered. Protected lands must also be adequately managed or restored based on the best available science to enhance the growth of the species. 2. Work with Landowners to Gain Access and Conduct Coordinated Surveys. Gaining access to private lands where no surveying and monitoring has occurred will provide more information on the species. Coordinate surveys in these previously known occurrences and continue surveys in potentially suitable habitat based on soil type and habitat characteristics, similar to the work Vollmar Consulting conducted in 2010. 3. Develop a Recovery Plan. Hartweg's golden sunburst and San Joaquin adobe sunburst were initially included in a "Draft Recovery Plan for Fifteen Plants from the Southern Sierra Foothills, California". This plan was in development in 2007, however, the plan was never finalized. Much information contained in Stebbins' two studies (1989, 1991) is still valid and is directly applicable to a recovery plan. Additionally, the methods of establishing a new population of Hartweg's golden sunburst at Friant Ranch can be incorporated (Live Oak Associates 2015, entire). 4. Maintain a Viable, Protected Seed Collection. For both Hartweg's golden sunburst and San Joaquin adobe sunburst ensure sufficient seeds, approximately 5,000 per site (Cypher 2006, pp. 2–3), are taken from as many sites as possible to maintain genetic heterogeneity. Currently, there are 4,057 seeds of Hartweg's golden sunburst and 37,069 seeds of San Joaquin adobe sunburst stored (California Plant Rescue 2023, unpaginated) (USFWS, 2023).

## SPECIES ACCOUNT: *Pseudobahia peirsonii* (San Joaquin adobe sunburst)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

An annual herb, about 1-6 dm tall, and loosely covered with white, wooly hairs. Flower heads (March or April) have bright yellow rays and are borne singly at the ends of the branches. (NatureServe, 2015)

### **Taxonomy**

*Pseudobahia peirsonii* has had no changes in its scientific name or to its taxonomic classification since it was first described in 1949 by the California botanist Phillip A. Munz. Common names used for *P. peirsonii* include San Joaquin adobe sunburst, Tulare pseudobahia, and San Joaquin adobe sunflower (Stebbins 1991). The San Joaquin adobe sunburst is the preferred common name since it was used in the original listing notice (62 FR 5542)

### **Historical Range**

The historical distribution of *Pseudobahia peirsonii* is not known because when the species was first described in 1949, extensive areas with suitable habitat for this species in the lower San Joaquin Valley were already converted to agriculture. This extensive land conversion precluded establishing a meaningful baseline survey of *P. peirsonii* (Stebbins 1991). (USFWS, 2007)

### **Current Range**

Three major population concentrations of *P. peirsonii* now include: east of Fresno in Fresno County, west of Lake Success in Tulare County, and northeast of Bakersfield in Kern County (CNDDB 2007). (USFWS, 2007)

### **Critical Habitat Designated**

No;

### **Life History**

### **Food/Nutrient Resources**

### **Habitat Type**

Adult: Grasslands/woodlands (NatureServe, 2015)

### **Environmental Specificity**

Adult: Moderate (Inferred from NatureServe, 2015)

### **Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

### **Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits non-native grasslands and occasionally grassland-blue oak woodland community ecotones in the Central Valley of California. The composition of the prehistoric grassland communities in this area is unknown; the communities have long-since become dominated by exotic grasses. *P. peirsonii* occurs only on heavy adobe clay soils which retain moisture into the summer dry season (NatureServe, 2015).

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Not available

**Number of Populations:**

32 (USFWS, 2007)

**Population Narrative:**

The plant is found at 32 extant occurrences distributed in Fresno, Tulare and Kern Counties. Population numbers can fluctuate widely from one year to another. This fluctuation is believed to depend on annual climatic conditions, specifically the amount of seasonal rainfall, and also on competition from non-native plants (Stebbins 1989, 1991; E. Cypher, CDFG, pers. comm. 2007). Because of these annual fluctuations, population trends for these species are difficult to deduce and can not be reliably completed in a few years of surveys (Stebbins 1989). Actual plant numbers are not as useful an index of population health as is the condition of occupied habitat and general population condition (62 FR 5542) (USFWS, 2007). The current species distribution of San Joaquin adobe sunburst is similar to what we described in our final listing rule and 2007 status review, with occurrences found in Fresno, Tulare, and Kern counties (Table 2; Service 1997, p. 5543; Service 2007, p. 3). Since the 2007 status review, an additional ten new occurrences were added to the Diversity Database, although one is a historical occurrence that is possibly extirpated (Diversity Database occurrence 54; Diversity Database 2023). The known occurrences of San Joaquin adobe sunburst are in three major population concentrations east of Fresno in Fresno County, west of Lake Success in Tulare County, and northeast of Bakersfield in Kern County (Diversity Database 2023). Two new occurrences (52 and 51) expand the known range of San Joaquin adobe sunburst approximately 15 miles south (Diversity Database 2023). Typically, all occurrences report fewer than 5,000 plants and more often only a few hundred plants (Diversity Database 2023). However, occurrence 53, located at Tollhouse Ranch owned by The Nature Conservancy, observed approximately 3,000 plants in 2015 and then over 11,090 plants in 2016 (Diversity Database 2023). Abundance of San Joaquin adobe sunburst fluctuates greatly from year to year due to weather conditions such as rainfall. The surveys that have been completed since the previous 5-year review do not significantly alter our understanding of the species' current distribution or abundance and population estimates or trends have not been determined (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Residential development (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** At the time of listing, the threat to *P. peirsonii* was primarily due to the planned 462-acre combined Quail Lakes housing development and recreational lake in Fresno County that would affect the large occurrence (CNDDDB occurrence number 31) of 5,000 plants surveyed in 1990. Completion of this project included compensation for environmental impacts which involved off-site wetland construction, transplantation of *P. peirsonii* and top soil translocation to a protected area within the development site, and preservation of two high density sub-populations of *P. peirsonii* within the protected site (EIP Associates 1994). During post-construction monitoring of these sub-populations, *P. peirsonii* at this location were not seen for four years; however, large numbers were observed in a single season during the fifth year of monitoring (Halstead in litt. 2007). In the 2003 season John Stebbins did not observe any plants at this location (J. Stebbins in litt. 2007). Residential development still remains a threat to *P. peirsonii* at the following locations (two occurrences): 1. A proposed parcel split of a privately owned 65-acre parcel in Fresno County near the city of Clovis, and the proposed residential development of these sub-parcels, is located within the area described to contain *Pseudobahia peirsonii* occurrence number 36 (Halstead and Associates 2006, CNDDDB 2007). Surveys for *P. peirsonii* were performed on this property in 2004 and 2005 and no plants were found (Halstead in litt. 2007). We lack adequate information on the reproductive ecology and seed bank dynamics of this species to determine whether or not it may reappear at this site in the future. 2. The proposed Round Mountain Estates project would develop a 600-acre parcel at Round Mountain in Fresno County, an area occupied by about 40 acres of *Pseudobahia peirsonii*. Surveys in 1993 and 1996 revealed the 40 acres support an apparently stable *P. peirsonii* population and that current land use continues to be moderate cattle grazing (J. Gurule, Live Oak Associates, pers. comm. 2007). Compensation recommended for this project by the consultant is to protect in perpetuity the 40 acres that contain the *P. peirsonii* occurrence (Hartesveldt Ecological Consulting Services [now Live Oak Associates] 1996) (USFWS, 2007).

**Stressor:** Agricultural conversion (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** When federally listed in 1997, conversion of habitat to agricultural use was considered a significant but secondary threat to *Pseudobahia peirsonii*. Eight of the original recorded occurrences of *P. peirsonii* had already been extirpated from their locale due to various agricultural conversions by the time Stebbins (1991) surveyed the sites. We do not believe that agricultural conversion presents a serious threat to *P. peirsonii* at this time since occurrences are now on either public land or private land used for cattle ranching (E. Cypher pers. comm. 2007). However, *P. bahiifolia* is still threatened by agricultural development, as it was at the time of listing, because of the pressure to convert ranch lands with occurrences of *P. bahiifolia* to orchards and vineyards (E. Cypher pers. comm. 2007) (USFWS, 2007).

**Stressor:** Flooding (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Inundation of *Pseudobahia peirsonii* plants caused by the creation of Lake Success in Tulare County extirpated two of the originally recorded occurrences of *P. peirsonii* before the species was listed (Stebbins 1989, CNDDDB 2007). Three occurrences of *P. peirsonii* are now found at the Lake Success Recreation Area which is managed by the U.S. Army Corps of Engineers. Two of these occurrences are historically recorded and one occurrence is believed to be a relict of one of the original occurrences that were documented as extirpated when Lake Success was first filled (EDAW 2006a). Flooding at Lake Success continues to be a threat to the three local occurrences of *P. peirsonii* (E. Cypher in litt. 2007). Excessive rainfall during an exceptionally wet year could raise the level of Lake Success and cause inundation of at least one of the occurrences (E. Cypher in litt. 2007). In addition, two proposals for the improvement of the Lake Success dam could affect at least one other occurrence of *P. peirsonii*. The U.S. Army Corps of Engineers plans to move the dam 300 feet downstream of its current location and then increase the size of the new spillway (E. Cypher in litt. 2007). Compensation by transplanting was addressed, but is not considered a reliable option for saving the affected populations of *P. peirsonii* owing to the limited success of previous transplanting efforts (E. Cypher in litt. 2007). As a result of the creation of Lake Success, one population was subjected to the additional threat of adverse recreational activity, since that population was located on the highly impacted shoreline (Stebbins 1989, 62 FR 5542, CNDDDB 2007). The Fancher Creek flood control project, completed in the mid-1990s, impacted about 40 percent of the second largest population of *Pseudobahia peirsonii* (CNDDDB occurrence number 30, 62 FR 5542). However, *P. peirsonii* are still found at the Fancher Creek site and surveys are conducted on a regular basis (P. Bryan in litt. 2007). The possible inundation of at least part of the existing local occurrence during an exceptionally heavy rainfall season remains a threat to this occurrence because no flood control system can protect against all conceivable flood events (Stebbins 1991, Fresno Metropolitan Flood Control District 2007) (USFWS, 2007).

**Stressor:** Protected occurrences (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Two occurrences of *Pseudobahia peirsonii* are located on public, nonFederal land in Fresno County owned and managed by the Fresno Metropolitan Flood Control District (CNDDDB occurrence numbers 16 and 30). Although these occurrences are monitored by surveys and protected by fencing, flooding remains a possible threat to these occurrences. Lake Success was created when the Tule River was dammed by the earthen Success Dam, which was constructed by the U.S. Army Corps of Engineers in 1961. The property around Lake Success, owned and managed by the U.S. Army Corps of Engineers, located just east of Porterville in Tulare County, contains three occurrences of *Pseudobahia peirsonii*. Two of these occurrences were previously recorded in the CNDDDB as occurrence numbers 10 and 19; however, a new occurrence was also discovered and may be the continuation of a population that was covered by the lake when the Success Dam was first built (EDAW 2006a). The sizes of these populations were recorded as 120 individuals for occurrence 10, 30 individuals for occurrence 19, and 45 individuals for the new occurrence (EDAW 2006a). The population numbers from this recent survey appear to indicate these occurrences are somewhat stable when compared with population numbers recorded in previous surveys (1985, 1986, 1988, 2003) (EDAW 2006a; T. Beyerl, EDAW, pers.comm. 2007). These occurrences receive a certain amount of protection because they are on federally operated public land; however, flooding from this dam remains a viable threat to the local occurrences. Lewis Hill Preserve consists of 110 acres of grass-covered hills with rock outcrops

located north of Porterville in Tulare County. This preserve, owned and managed by the Sequoia Riverlands Trust, contains *Pseudobahia peirsonii* occurrence number 28, as well as the rare wildflower, *Fritillaria striata* (striped adobe lily) (Sequoia Riverlands Trust 2007). This preserve is not open to the public. Although formal surveys for the listed plant species have not been conducted since 1990, the presence of *P. peirsonii* was confirmed by preserve personnel during the 2006 flowering season (H. Destin, Sequoia Riverlands Trust, pers. comm. 2007). Currently the Lewis Hill preserve is not actively managed, but future management activities such as prescribed burns and grazing are being planned to control invasive weedy plants (H. Destin pers. comm. 2007). Before *Pseudobahia peirsonii* was listed in 1997, as compensation for impacts to the four subpopulations of occurrence number 31 by construction of the Quail Lake residential development in Fresno County (see above), two of the highest-density sub-populations were protected and a new sub-population was created by trans-locating soil from the two impacted sub-populations and seeding the soil with seeds collected earlier (completed in 1993) (62 FR 5542, EIP Associates 1994). This compensation was done in compliance with the California Endangered Species Act and California Environmental Quality Act. The area, south of Clovis in Fresno County, containing these sub-populations is protected as natural habitat in perpetuity (EIP Associates 1994). Subsequent monitoring revealed that individuals originating from seeds sewn into the trans-located soil, as well as the individual plants in the original two dense populations, were numerous, healthy, and reproducing in 1998 (J. Halstead in litt. 2007). However, *P. peirsonii* is not clearly present at Quail Lakes every year and the habitat in the area of the translocated soil appeared to be significantly degraded in 2006 (J. Halstead in litt. 2007, J. Stebbins in litt. 2007) (USFWS, 2007).

**Stressor:** Overgrazing and trampling (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of individual plants

**Narrative:** Cattle ranching was recognized as a threat to the *Pseudobahia* species in the original listing rule (62 FR 5542) because of the possibility of excessive grazing and trampling by cattle, which could destroy many individuals of the two species (Stebbins 1989). In 1997, when first listed, about 50 percent of known occurrences of *P. peirsonii* were found on private property that was used primarily for cattle grazing. Moderate grazing regimes are not believed to seriously affect either of the plant species, and may actually enhance their growth due to the removal of nonnative, aggressive, invasive grasses and forbs (Stebbins 1989, Marty 2005). Cattle do not preferentially target either of the *Pseudobahia* species while grazing (E. Cypher pers. comm. 2007). In addition, profitable cattle ranching may indirectly benefit the two *Pseudobahia* species by discouraging residential development of ranch land (E. Cypher pers. comm. 2007). Cattle grazing and trampling are no longer considered a serious threat to either species unless the grazing times are extended, leading to excessive trampling and consumption (USFWS, 2007).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** When listed in 1997, we noted that most of the occurrences of both the *Pseudobahia* species were located on private land and, thus, State and Federal laws were limited in their ability to regulate potentially detrimental human activity at these locations (62 FR 5542). No significant changes to the Federal or State laws have provided increased protection for these

species (USFWS, 2007).

**Stressor:** Non-native plants (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The final listing rule noted that the intrusive and aggressive characteristics of herbaceous weedy species appear to be detrimental to habitat quality of the two *Pseudobahia* species. Plants mentioned as being common non-native associates of *P. bahiifolia* include *Erodium cicutarium* (red-stem filaree), *E. botrys* (longbeak stork's bill), *Bromus mollis* (soft brome or soft chess), and *Bromus madritensis* ssp *rubens* (foxtail chess). Plants mentioned as being common non-native associates of *P. peirsonii* include *Avena fatua* (wild oats), *Brassica kaber* (wild mustard), *Bromus mollis* (soft brome or soft chess), *Bromus madritensis* ssp *rubens* (foxtail chess), and *Erodium cicutarium* (red-stem filaree) (62 FR 5542). Non-native grasses and forbs continue to proliferate throughout the range of the two *Pseudobahia* species and these non-native species continue to invade locations that the two species occupy. Thus, non-native plants remain a significant threat to the two *Pseudobahia* species (E. Cypher pers. comm. 2007) (USFWS, 2007).

**Stressor:** Road maintenance and widening (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Stebbins (1991) lists several road maintenance projects that would affect populations of *Pseudobahia peirsonii*. The most extensive project was the proposed widening of State Route 180 in Fresno County that may destroy plants on both sides of the road. Six other occurrences were also determined to be threatened by road maintenance activities conducted by the California Department of Transportation (CALTRANS) which include spraying herbicides, grading, scraping, slope stabilization, road widening, and road alignment. The listing rule noted that road maintenance activities were a threat to *P. peirsonii* (62 FR 5542). However, subsequent CALTRANS maintenance activities and road alignment did not appear to directly affect the occurrences of *P. peirsonii*; rather, the disturbance created from the maintenance appears to indirectly and moderately threaten both species of *Pseudobahia* by encouraging the growth of non-native weedy vegetation which competes with the two listed species of *Pseudobahia* (J. Stebbins in litt. 2007) (USFWS, 2007).

**Stressor:** Transmission line maintenance (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Two occurrences of *Pseudobahia peirsonii* (CNDDDB occurrence numbers 23 and 24) inhabit areas beneath two transmission lines supported by Southern California Edison (SCE). The properties where the transmission lines are located are considered "rights of way", and are mostly within privately owned lands. Stebbins (1991) recognized that these populations would need to be protected from the machinery and traffic (human and vehicular) that would impact the area when maintenance actions were performed on the transmission lines, and this was considered a threat when the species was listed (62 FR 5542). Routine maintenance activities include patrol road maintenance, line maintenance, and overhead canopy maintenance. Routine

maintenance actions are scheduled by SCE annually, avoid the active time periods for local listed plants, and require a minimum of off-road activities (Entrix, Inc. 1997). A more substantial threat to *P. peirsonii* is from emergency repairs to the power lines due to catastrophic failure, natural disasters, or vandalism where the need to conduct repairs expeditiously would increase the chances of incidental damage to the plants during the repair effort. Entrix, Inc. (1997) conducted a survey for *P. peirsonii* and found only one occurrence along one of the two transmission lines where the species was thought to occur. SCE maintenance personnel are provided with environmental and endangered species training to ensure they avoid impacting listed species (Entrix, Inc. 1997) (USFWS, 2007).

**Stressor:** Drought (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** At the time of listing drought was considered a threat to small and marginal populations of either *Pseudobahia* species (62 FR 5542). Natural cycles of drought are not likely to threaten the larger occurrences of either of the *Pseudobahia* species owing to the drought-adaptive nature of the plants (E. Cypher pers. comm. 2007). However, where populations persist on only marginal habitat, the addition of prolonged drought conditions is likely to result in higher rates of mortality in the short term, with the effects of low reproductive output and survivorship persisting after the drought has ceased (E. Cypher pers. comm. 2007). It is unknown how quickly the *Pseudobahia* populations may rebound after severe climatic conditions (USFWS, 2007).

**Stressor:** Small population size (USFWS, 2007)

**Exposure:**

**Response:**

**Consequence:** Loss of genetic variability

**Narrative:** The two species of *Pseudobahia* each require separate and specific soil conditions for successful germination and growth, so that the distribution of these plants is limited to the occurrences of these soil types (Stebbins 1991). The conversion to agricultural use of the geographic areas where these soil types are found began before a baseline survey of either plant could be performed, so the historic distribution can only be assumed based on a variety of factors, including soil type. The conversion to agriculture and to other land uses (discussed above) which are adverse to the proliferation of the two species have resulted in fragmented populations, many of which are of extremely limited population size (E. Cypher pers. comm. 2007). For example, about 67 percent of the *P. bahiifolia* and 62 percent of the *P. peirsonii* populations with known counts have less than 100 plants from the last surveys that were recorded (CNDDB 2007). In addition, some of the sites are questionable as to whether they are still producing any plants at all; for example, two of the presumed extant occurrences of *P. bahiifolia* are single sightings of unknown numbers of plants that have not been verified since 1937 and 1939, respectively (CNDDB 2007). At the time of listing it was recognized that such small populations may be highly susceptible to extirpation due to chance events, inbreeding depression, or additional environmental disturbance (Gilpin and Soule 1988; Goodman 1987, 62 FR 5542). The conservation biology literature commonly notes the vulnerability of species known from one or very few locations and/or from small populations (e.g., Shaffer 1981 and 1987, Primack 1998, Dunning et al. 2006). In particular, small population size makes it difficult for such species to persist while sustaining the impacts of habitat loss, competition with non-native plants, and other impacts such as prolonged drought. If an extirpation event occurs in a

population that has been fragmented, the opportunities for re-colonization will be greatly reduced due to physical isolation from other source populations. The small size of populations, along with the geographic isolation of the separate populations of both *Pseudobahia* species remains a threat (E. Cypher pers. comm. 2007) (USFWS, 2007).

### **Recovery**

#### **Reclassification Criteria:**

Recovery Priority Number: 2

#### **Recovery Actions:**

- The draft recovery plan is currently under development (USFWS, 2007).
- Protect lands with known occurrences of either species of *Pseudobahia*, particularly those occurrences with the largest and most dense populations, through conservation easements, acquisition in title, or other methods. Manage these properties to protect and enhance growth of *P. bahiaefolia* and *P. peirsonii* (USFWS, 2007).
- Work with landowners to gain access to their property for surveying and monitoring populations of both *Pseudobahia* species (USFWS, 2007).
- Conduct coordinated surveys of all recorded occurrences of both species of *Pseudobahia*. Establish systematic periodic surveys where possible of known occurrences. Begin surveys in potentially suitable habitat of both species of *Pseudobahia* based on soil type and habitat characteristics (USFWS, 2007).
- Complete and publish the draft recovery plan and ultimately finalize the recovery plan. Much of the information contained in Stebbins' two studies (1989, 1991) is still valid and is directly applicable to a recovery plan (USFWS, 2007).
- Maintain a viable, protected seed collection for both species of *Pseudobahia*. Ensure sufficient seeds (approximately 5,000 per site, USFWS 2006a) are taken from as many sites as possible to maintain genetic heterogeneity (USFWS, 2007).

#### **Conservation Measures and Best Management Practices:**

- **RECOMMENDATIONS FOR FUTURE ACTIONS:** Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the Hartweg's golden sunburst and San Joaquin adobe sunburst. Some of these recommendations have already been discussed in the previous 5- year review (Service 2007, pp. 17–18) and remain valid. 1. Habitat Acquisition, Management, and Restoration. Known occupied sites with Hartweg's golden sunburst and San Joaquin adobe sunburst present should be protected. Resource agencies and private partner groups should work to ensure land protection through acquisition or easement, and large unprotected areas currently occupied by the species should be given the highest priority. Large, formerly occupied sites that are unoccupied but have a high restoration potential and the sites with recent occurrences should also be considered. Protected lands must also be adequately managed or restored based on the best available science to enhance the growth of the species. 2. Work with Landowners to Gain Access and Conduct Coordinated Surveys. Gaining access to private lands where no surveying and monitoring has occurred will provide more information on the species. Coordinate surveys in these previously known occurrences and continue surveys in potentially suitable habitat based on soil type and habitat characteristics, similar to the work Vollmar Consulting conducted in 2010. 3. Develop a Recovery Plan. Hartweg's golden sunburst and San Joaquin adobe sunburst were initially included in a "Draft Recovery Plan for Fifteen Plants from

the Southern Sierra Foothills, California". This plan was in development in 2007, however, the plan was never finalized. Much information contained in Stebbins' two studies (1989, 1991) is still valid and is directly applicable to a recovery plan. Additionally, the methods of establishing a new population of Hartweg's golden sunburst at Friant Ranch can be incorporated (Live Oak Associates 2015, entire). 4. Maintain a Viable, Protected Seed Collection. For both Hartweg's golden sunburst and San Joaquin adobe sunburst ensure sufficient seeds, approximately 5,000 per site (Cypher 2006, pp. 2–3), are taken from as many sites as possible to maintain genetic heterogeneity. Currently, there are 4,057 seeds of Hartweg's golden sunburst and 37,069 seeds of San Joaquin adobe sunburst stored (California Plant Rescue 2023, unpaginated) (USFWS, 2023).

## SPECIES ACCOUNT: *Pseudognaphalium (=Gnaphalium) sandwicensium* var. *molokaiense* (ʻEnaʻena)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 09/30/2016; Pacific Region (R1) (USFWS, 2016a)

### Physical Description

*Pseudognaphalium sandwicensium* var. *molokaiense* (ʻenaʻena), a perennial herb in the Asteraceae (sunflower) family, is 10 to 65 cm (4 to 26 in) tall (Wagner et al. 1999, p. 321). The woolly erect to prostrate stems are 10 to 30 cm (4 to 12 in) long and olive green to white or gray in color. Leaves are spatulate to narrowly obovate, the lower ones usually 0.7 to 2 cm (0.3 to 0.8 in) wide, with only the tips of the whitish to pale yellow involucre bracts (below the flower) exposed, the remainder densely woolly (Wagner et al. 1986, pp. 115–116). Yellow flower heads are 1.5 to 7 millimeters (mm) (0.06 to 0.3 in) in diameter, arranged in terminal, corymbose (flat-topped) or sometimes nearly spherical, leafless, or nearly leafless clusters (Wagner et al. 1999, p. 321). Fruit and seeds are not described. *Pseudognaphalium sandwicensium* var. *molokaiense* is very densely woolly over the entire plant, and this is a distinguishing feature among the other varieties of this species (Wagner et al. 1986, pp. 115–116; Wagner et al. 1999, p. 321) (USFWS, 2021b).

### Taxonomy

Family: Asteraceae.

### Historical Range

Historically, this variety was found on the Hawaiian islands of Molokai and Maui, as well as on Oahu and Lanai (USFWS, 2016).

### Current Range

Distribution: Molokaʻi, Maui (extant); Oʻahu, Lānaʻi (possibly extirpated) (USFWS, 2022)

### Critical Habitat Designated

Yes;

### Life History

### Food/Nutrient Resources

### Lifespan

Adult: Short (USFWS, 2022)

### Reproduction Narrative

Adult: The pollination vectors for *Pseudognaphalium sandwicensium* var. *molokaiense* are unknown but may be insects as they have been observed visiting flowers. In general, the composite flower types of Asteraceae are attractive to bees and wasps (Lundin et al. 2018, p. 667) (USFWS, 2021b).

**Habitat Type**

Adult: The species is found in strand vegetation in dry, consolidated dunes (USFWS, 2016).

**Habitat Vegetation or Surface Water Classification**

Adult: Strand vegetation (USFWS, 2016)

**Geographic or Habitat Restraints or Barriers**

Adult: sea level to 152 meters (USFWS, 2021b)

**Environmental Specificity**

Adult: Unknown

**Habitat Narrative**

Adult: Typical habitat for this variety is strand vegetation in dry consolidated dunes, in the coastal ecosystem (Wagner et al. 1999, p. 321; TNCH 2007; HBMP 2010). Historically, this variety was known from Molokai, Oahu, Maui, and Lanai (HBMP 2010; MNTF 2010, in litt.) (USFWS, 2016). *Pseudognaphalium sandwicense* var. *molokaiense* is a perennial herb found in strand vegetation in dry consolidated dunes on the islands of Molokai and Maui, Hawaii. Historically, this variety was also found on Oahu and Lanai. This variety is known from five populations collectively totaling approximately 200 to 20,000 individuals (depending upon rainfall) in the Moomomi area on the island of Molokai, and from 2 populations of a few individuals at Waiehu dunes and at Puu Kahulianapa on west Maui (USFWS, 2014). *Pseudognaphalium sandwicense* var. *molokaiense* occurs in coastal areas at sea level to 152 meters (m) (0 to 500 feet (ft)), in predominantly arid environments in sandy soil, directly on sand dunes, and on raised limestone plains and bare clay outcrops (BISH 1022301, 1022298, 1022290, 1022303; Haase 2020, in litt.) (USFWS, 2021b).

***Dispersal/Migration******Population Information and Trends*****Number of Populations:**

5 (USFWS, 2022)

**Population Size:**

>150 (USFWS, 2022)

**Population Narrative:**

Currently, *P. sandwicense* var. *molokaiense* is known only from two locations on Molokai (as many as 20,000 individuals, depending on rainfall), and from fewer than 25 individuals on the northwest coast of Maui (Moses 2006, in litt.; Starr 2006, in litt.; Kallstrom 2008, in litt.; Oppenheimer 2015, in litt.). This variety was last observed on Lanai in 1960, and on Oahu (5 individuals) in the 1980s (HBMP 2010) (USFWS, 2016). Number of Populations: 5. Number of Individuals: >150 (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Feral goats and axis deer (USFWS, 2016b; USFWS, 2014)

**Exposure:** Habitat degradation and destruction, predation

**Response:**

**Consequence:**

**Narrative:** *Pseudognaphalium* s. var. *molokaiense* is threatened by feral goats (*Capra hircus*) and axis deer (*Axis axis*) that degrade and destroy habitat and possibly browse upon it (USFWS, 2016b; USFWS, 2014).

**Stressor:** Nonnative plants (USFWS, 2016b; USFWS, 2014).

**Exposure:** Competition

**Response:**

**Consequence:**

**Narrative:** Nonnative plants compete for light and nutrients (USFWS, 2016; USFWS, 2014).

**Stressor:** Climate change (USFWS, 2016b)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The effects of climate change are likely to further exacerbate these threats (Non-native plants and herbivory). Because of these threats, we find that this variety is endangered throughout all of its range, and, therefore, find that it is unnecessary to analyze whether it is endangered or threatened in a significant portion of its range (USFWS, 2016b).

**Stressor:** Low genetic variability (USFWS, 2016b)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** This variety experiences reduced reproductive vigor due to low levels of genetic variability, leading to diminished capacity to adapt to environmental changes, and thereby lessening the probability of long-term persistence (Barrett and Kohn 1991, p. 4; Newman and Pilson 1997, p. 361) (USFWS, 2016b).

**Stressor:** Stochastic events (USFWS, 2016b)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Rockfalls and landslides are a threat to the occurrence of this variety on a sea cliff on west Maui (HBMP 2010) (USFWS, 2016b).

**Stressor:** Climate change (USFWS, 2016b)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Fortini et al. (2013, p. 86) found that, as environmental conditions are altered by climate change, *P. sandwicense* var. *molokaiense* is unlikely to tolerate or adapt to projected changes in temperature and moisture, and is unlikely to be able to move to areas with more suitable climatic conditions (USFWS, 2016b).

## **Recovery**

**Reclassification Criteria:**

Recovery Priority Number = 3 (USFWS, 2022) Number of populations and individuals needed for each plant species to meet the preventing extinction stage based on population and life history characteristics. Number of Populations = 3. Reproducing Individuals per population = 50 (USFWS, 2022). Number of populations and individuals needed for each plant species to meet the interim stage based on population and life history characteristics. Number of Populations = 3. Reproducing Individuals per population = 300 (USFWS, 2022). Number of population and individuals of each plant species needed for downlisting based on population and life history characteristics. Number of Populations = 5. Reproducing Individuals per population = 500 (USFWS, 2022).

**Delisting Criteria:**

Number of populations and individuals of each plant species needed for delisting based on population and life history characteristics. Number of Populations = 10. Reproducing Individuals per population = 500 (USFWS, 2022).

**Recovery Actions:**

- Weed control is conducted for one population on Molokai.
- Weed control

***Conservation Measures and Best Management Practices:***

- Current Management Actions:
  - Habitat management and protection— o Mokio, a 1,769 acre parcel that was donated to the Moloka'i Land Trust (MLT) by a private landowner, contains approximately 8 kilometers (5 miles) of rugged shoreline, remnant native coastal strand and dune ecosystems, seasonal wetland, and several ancient Hawaiian sites (Haase 2020, in litt.). Molokai Land Trust primarily conducts restoration activities at the fenced Anapuka Dune Restoration Site in this area (Haase 2020, in litt.). Restoration activities include ungulate control (exclosure) and restoration of common and rare native plants. The population of *P. sandwicensium* var. *molokaiense* in this area has responded to this management with increased recruitment (Haase 2020, in litt.). o The Mo'omomi Preserve is a 921 acre site on Moloka'i managed by The Nature Conservancy (TNC) in partnership with the State of Hawai'i's Department of Natural Resources Natural Area Partnership Program. Conservation actions include ungulate control, predator control, invasive plant control, monitoring and research, rare species protection, and community outreach (TNC 2011, p. 2). o The Kalaupapa National Historical Park (NHP) populations of *P. sandwicensium* var. *molokaiense* are managed by the National Park Service (NPS). One population is located adjacent to the Kalaupapa Airport and is likely offered a layer of protection from fencing for the facility.
  - Surveys and monitoring—The Plant Extinction Prevention Program (PEPP) monitors, surveys, collects propagules, and collaborates with other conservation groups for restoration activities at Kahakuloa on Maui, and Kalaupapa and 'Īlio Point on Moloka'i (PEPP 2014, 2015). PEPP most recently surveyed for *P. sandwicensium* var. *molokaiense* at Mo'omomi and 'Īlio Point in 2020 (Bakutis 2021a, 2021b, in litt.).
  - Ungulate control— o At Mo'omomi Preserve, 175 acres were fenced in 2017; however, the deer population has been difficult to eradicate (Dunbar-Co 2021, in litt.). o TNC conducts quarterly fence checks at Mo'omomi Preserve to assess if breaches by cattle and feral ungulates have occurred (TNC 2011, p. 11). As of 2019 there were deer remaining within the exclosure (TNC 2017, p. 10; Dunbar-Co 2021, in litt.). In addition, game cameras are used at key sites to monitor and detect the presence of cats, pigs, and deer (TNC 2017, p. 11). o One population at Kalaupapa NHP is located adjacent to the airport and is likely offered a layer of protection from fencing for the facility.
  - Ecosystem-

altering invasive nonnative plant control— o The MLT works removes invasive plants at Mokio with assistance of volunteers and partner organizations such as TNC and the USDA Natural Resources Conservation Service (Haase 2020, in litt.). o TNC implements a control strategy for removal of *Prosopis pallida* adjacent to native plant communities. • Captive propagation for genetic storage and reintroduction— o Lyon Arboretum reports 10,628 seeds in storage representing pooled collections from two populations on Molokaʻi at Moʻomomi Preserve and Mokio (6,721 seeds) and one population on Maui at Kahakuloa (3,907 seeds) (Lyon Arboretum 2019). o The Maui Nui Botanical Garden (MNBG) reports propagation of 14 plants from seeds collected from Moʻomomi on Molokaʻi. Additionally, MNBG has hundreds of seeds that are in storage, representing at least 20 founders from the Kahakuloa (Puʻukāhuliʻanapa) population on Maui. These seeds were collected in collaboration with PEPP (MNBG 2019). o PEPP reported collection of seeds from 24 individuals at Kahakuloa, Maui, in 2015 (PEPP 2015). o In the 1990s, the National Tropical Botanical Garden (NTBG) reported collection and storage of 10,000 seeds from Kaiehu Point at Moʻomomi on Molokaʻi. The viability of this collection is unknown (NTBG 2019). • Population biology research—By tracking the resurgence of *P. sandwicensium* var. *molokaiense* after restoration management, MLT discovered a relationship between clearing and planting activities and the number of plants naturally recruiting. They found a delay of a year or two after clearing areas and recruitment. This is an example of the complexity of the Mokio ecosystem. Areas of Mokio need to be revegetated completely to reduce erosion while small areas should also be left open for recruitment by existing native plants like *P. sandwicensium* var. *molokaiense* (Haase 2020, in litt.) (USFWS, 2021b).

## SPECIES ACCOUNT: *Psychotria malaspinae* (Aplokating-palaoan)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 11/02/2015; Pacific Region (R1) (USFWS, 2016)

#### **Physical Description**

*Psychotria malaspinae* (aplokating palaoan), a shrub or small tree in the coffee family (Rubiaceae), is known only from Guam. (USFWS, 2015)

#### **Historical Range**

Historically, *P. malaspinae* was known from scattered occurrences on the northeast and southwest sides of Guam, in the forest ecosystem (Merrill 1914, pp. 148–149; Stone 1970, pp. 554– 555; Raulerson and Rinehart 1991, p. 83; Fosberg et al. 1993, pp. 111–112; Costion and Lorence 2012, pp. 54, 85– 86; Bishop Museum 2014—Online Database; Wagner 2012—Flora of Micronesia; WCSP 2012c—Online Database). (USFWS, 2015)

#### **Current Range**

It currently occurs on Guam (Mariana Islands) (USFWS, 2015). Distribution: Guam (USFWS, 2020b).

#### **Critical Habitat Designated**

Yes;

#### ***Life History***

#### **Food/Nutrient Resources**

#### **Reproduction Narrative**

Adult: Not available.

#### **Habitat Type**

Adult: Terrestrial (USFWS, 2015)

#### **Habitat Vegetation or Surface Water Classification**

Adult: Forests (USFWS, 2015)

#### **Habitat Narrative**

Adult: *P. malaspinae* was known from scattered occurrences on the northeast and southwest sides of Guam, in the forest ecosystem (Merrill 1914, pp. 148–149; Stone 1970, pp. 554– 555; Raulerson and Rinehart 1991, p. 83; Fosberg et al. 1993, pp. 111–112; Costion and Lorence 2012, pp. 54, 85– 86; Bishop Museum 2014—Online Database; Wagner 2012—Flora of Micronesia; WCSP 2012c—Online Database). (USFWS, 2015)

#### ***Dispersal/Migration***

#### **Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends*****Population Trends:**

Not available.

**Number of Populations:**

1 (USFWS, 2020b)

**Population Size:**

3 (USFWS, 2020b). 8-12 wild and 22 translocated (USFWS, 2020)

**Population Narrative:**

Currently, *P. malaspinae* is known from only four occurrences, three with only a single individual each (M and E Pacific, Inc. 1998, pp. 67, 79; Grimm 2012, in litt.), none of which have been observed for at least 5 years; and a fourth recently discovered occurrence with three individuals (Guam Plant Extinction Prevention Program 2015, in litt.). In summary, the species *Psychotria malaspinae*, a single island endemic, has been reduced to an estimated five individuals in the wild, and possibly fewer since several of these individuals have not been observed for several years, rendering this species vulnerable to extinction. (USFWS, 2015). Only 8 to 12 wild individuals and 22 translocated individuals of this species remain. Five of the *Psychotria malaspinae* plants are within an ungulate-fenced area (Rididian Point, Andersen Air Force Base, Guam, DoN 2018, in litt), but the remaining wild individuals have no ongoing control of any threats. Only 22 individuals have been propagated; 12 of which were outplanted by GPEPP (GPEPP 2019, in litt.).(USFWS, 2020)

***Threats and Stressors***

**Stressor:** Habitat loss from agriculture, urban development, non-native animals and plants, and typhoons (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** There are likely a few scattered individuals or small occurrences such as that recently discovered; however, these remaining individuals are at risk, due to continued habitat loss and destruction from agriculture, urban development, nonnative animals and plants, and typhoons. (USFWS, 2015)

**Stressor:** Climate change (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The Service anticipates the effects of climate change will further exacerbate many of these threats in the future. (USFWS, 2015)

**Stressor:** Herbivory (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Herbivory by pigs and deer, damage by ordnance and live-fire training, combined with the effects of low numbers of individuals, which results in loss of vigor and genetic representation, and limits its ability to compete with other species and adapt to changes in environmental conditions, contribute to the decline of *P. malaspinae*. (USFWS, 2015)

**Stressor:** Small population size (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In summary, the species *Psychotria malaspinae*, a single island endemic, has been reduced to an estimated five individuals in the wild, and possibly fewer since several of these individuals have not been observed for several years, rendering this species vulnerable to extinction. (USFWS, 2015)

**Recovery****Reclassification Criteria:**

Not available.

**Delisting Criteria:**

Not available.

**Recovery Actions:**

- Threat and Recovery Potential: Full species with a high degree of threat and a high degree of recovery potential. (USFWS, 2020b)

**Conservation Measures and Best Management Practices:**

- RECOMMENDATIONS FOR FUTURE ACTIONS • Determine population status and current distribution—Determine the distribution and number of all individuals on each island. Assess the status and threats to each population to inform prioritization of conservation effort. • Population biology and taxonomy—Research the genetic composition of populations and congeners to determine taxonomic relationships. • Conduct research to clarify life history information and threats to the populations and their habitat—Conduct research to determine the best way to control the brown treesnake, rodents, and invasive invertebrates. Assess development and land designation and zoning threats to conservation of habitat needed for recovery. • Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect wild and reintroduced individuals from the negative impacts of feral ungulates. • Invasive plant monitoring and control—Continue to control established ecosystemaltering nonnative invasive plant species and those that compete with *P. malaspinae* at all populations. Implement measures such as fire danger assessments, fire suppression responses, fuel treatments, regulations, and public outreach to prevent fire from burning native limestone forest. • Reduce human disturbance from military activities mortality and reduced viability— increase population resiliency by mitigating ordinance and wildfire threats from military activities. • Captive propagation for genetic storage and reintroduction—Continue to collect seeds and other propagative materials for storage and reintroduction. • Reintroduction and translocation—Augment population and increase numbers of populations and individuals in suitable habitat to build resiliency and redundancy and reduce the impacts of predation and typhoons, and climate change. • Develop regulations and policy essential

to recover the species and their habitats— Encourage the development of legislation to ensure protection of the listed species under Commonwealth or Territorial law. Develop and support the implementation of biosecurity plans to prevent the influx of new pests and invasive species into the Territory and inter-island movement of pests and invasive species • Alliance and partnership development—Continue to contribute to planning and implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2020)

- Current Management Actions: • Surveys and inventories – • The USFWS recommends all sites containing suitable habitat be surveyed for *Psychotria malaspinae* prior to implementation of projects entailing vegetation or soil disturbance. • Joint Region Marianas (JRM) surveyed for ESA-listed species, including *P. malaspinae*, at the Naval Munitions Site (NMS) and Naval Base Guam Telecommunication Site, Tarague Triangle, MSA Igloos, THAAD, and other projects to document locations and estimate population densities in sites that are proposed for ungulate exclusion and forest restoration (JRM 2019 and 2020). • Captive propagation for genetic storage and reintroduction • In 2012, the Guam Plant Extinction Prevention Program (GPEPP) was formed to address conservation concerns for a select group of native Mariana Islands plant species. As of May of 2019, GPEPP had propagated 22 individuals of *Psychotria malaspinae* in the GPEPP's nursery and translocated 12 of these individuals (GPEPP 2019, in litt.). • Habitat protection – • A major biosecurity focus within the Mariana Islands is preventing the spread of the brown treesnake to the CNMI from Guam. Federal agencies support local capacity both in Guam and the CNMI. Efforts include inspection of all arriving cargo from Guam to the CNMI by brown treesnake detection dogs as well as specialized trapping around all major ports of entry. The Department of Agriculture, Wildlife Services, in coordination with the National Wildlife Research Center (NWRC), U.S. DoD Environmental Security Technology Certification Program, and the Department of Interior-Office of Insular Affairs (U.S. Geological Survey, USFWS), are using aerial applications of acetaminophen to suppress BTS over forested areas in AAFB (Dorr, et al. 2016, in litt.; Phillips 2014, in litt.; BTSTWG 2015, entire). In addition, repeated and sustained applications could drastically reduce brown treesnake abundance on a landscape scale (Siers, et al. 2018, in litt.). • An island-wide Habitat Conservation Plan for Guam, that would provide a collaborative and comprehensive approach to endangered species conservation on non-federal lands, is beginning to be developed (USFWS 2020). • A 2020 Memorandum of Understanding between JRM and the USFWS outlined a mutual understanding regarding the intentions and future considerations of a Department of Defense Readiness and Environmental Protection Integration Initiative (REPI) to address conservation of upland vegetation communities (DON and USFWS 2020). • Other Natural or Manmade Factors: Limited numbers; ordnance • Range Fire Management Plan for Marine Corps Ranges on Guam. A range fire management plan to reduce range/wildfire potential, protect and enhance natural and cultural resources, integrate applicable permit and reporting requirements and implement ecosystem management goals, sustainable training, and objectives already supported on existing Marine Corps installations is being drafted (JRM 2019). (USFWS, 2020)

## SPECIES ACCOUNT: *Ptilimnium nodosum* (Harperella)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 10/28/1988; Northeast Region (Region 5) (USFWS, 2015)

### **Physical Description**

An annual herb with slender, erect stems, up to 12 dm high. The roots are shallow, diffuse-fibrous, and the plants have a faint scent of dill. Unlike those of the more common members of this genus, the leaves of *P. nodosum* are reduced to hollow, quill-like structures. Broad clusters of small white flowers bloom mostly in July and August. (NatureServe, 2015)

### **Taxonomy**

As of 2008, the U.S. FWS treatment includes *P. fluviatile* (AR, AL; river form, does not produce asexual buds), *P. viviparum* (MD, WV, VA, NC; river form, produces asexual buds), and *P. nodosum sensu stricto* (GA, SC; pond form) in *P. nodosum*, as does Kartesz (1994 and 1999); this is the treatment followed here. However, recent information suggests they may be tentatively treated as distinct entities, although not necessarily as distinct species (David Maddox pers. comm. to Alan Weakley and to Larry Morse). Specifically, a 1994 isozyme study found that there was substantial genetic differentiation among rather than within these three groups, supporting designation as distinct entities (Kress et al. 1994 cited in Douglas 2008). A 2008 DNA study (nuclear rDNA ITS sequences) found that "viviparum" accessions formed a monophyletic group, but "nodosum sensu stricto" accessions did not, with South Carolina populations forming a monophyletic group, but Georgia populations falling at the base of the clade alongside "fluviatile" accessions (Feist and Downie 2008). In summary, although there is clearly more than one distinct entity within the current broad-sense circumscription of *P. nodosum*, there is not yet a clear consensus on how to divide the material and at what taxonomic level entities should be distinguished. (NatureServe, 2015)

### **Current Range**

Currently known from scattered sites in western Maryland, eastern West Virginia, northeastern Virginia, north-central North Carolina, central South Carolina, central Georgia, northeastern Alabama, and west-central Arkansas. (NatureServe, 2015)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Asexual (vegetatively) and sexual (NatureServe, 2015)

### **Lifespan**

Adult: 1 year (USFWS, 2015)

### **Breeding Season**

Adult: July to August (USFWS, 1990)

**Reproduction Narrative**

Adult: *Ptilimnium nodosum* is an annual that reproduces both vegetatively and via seed; it is thought that established patches may persist over the long-term primarily by vegetative reproduction, while novel habitat colonization may occur primarily via seed. These multiple reproduction modes also appear to provide a survival mechanism for variable water levels; since sexual reproduction becomes more difficult within increasing water depth, the plants produce seeds and reproduce sexually in dry years, while in wet years they produce plantlets and reproduce vegetatively. It appears that both forms of reproduction contribute to overall population size in most years, with the contribution of each dependent upon hydrological patterns (Douglas 2008). Marcinko and Randall (2008) studied the mating system of *P. nodosum*, with the following findings. Flowers were self-compatible, but strong intrafloral protandry essentially prevented autonomous selfing. (NatureServe, 2015)

**Habitat Type**

Adult: Riverine, and palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Spring/spring brook, herbaceous wetland, riparian, temporary pool (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Saturated sites; flooding; water fluctuations (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Prefers saturated habitat, periodic flooding, sunny areas. Restricted to intermediate water depths (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Patches (USFWS, 1990)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (USFWS, 1990)

**Site Fidelity**

Adult: High (USFWS, 1990)

**Habitat Narrative**

Adult: *Ptilimnium nodosum* occurs in three habitat types: rocky/gravelly shoals or cracks in bedrock outcrops beneath the water surface in clear, swift-flowing streams (usually in microsites that are sheltered from rapidly moving water); edges of intermittent pineland ponds or low, wet savannah meadows on the Coastal Plain; and granite outcrop seeps. In all habitat-types, the species occurs in a narrow range of water depths; it is intolerant of deep water and of conditions that are too dry. However, the plants readily tolerate periodic, moderate flooding - something to which few potential competitors are adapted. *P. nodosum* seeds generally

germinate during short-duration spring floods and the plants have completed their life cycle by late summer or fall, just as water levels are lowest and competing species are moving in. The dominant species at *P. nodosum* sites is often *Panicum hemitimon*. Other species may include many sedges in the genera *Rhynchospora* (e.g., *B. perplexa*, *R. microcarpa*), *Carex* (e.g., *C. walteri*, *C. lupulina*), *Eleocharis* (e.g., *E. tricostrata*, *E. melanocarpa*), *Psilocarva*, *Dichromena colorata*, and *Fimbristylis*. Dicot associates include *Hypericum fasciculatum*, *H. denticulatum*, *H. myrtifolium*, *Rhexia virginica*, *R. mariana*, *B. aristosa*, *Proserpinaca pectinata*, several *Ludwigia* species, and *Sclerolepis uniflora* (Kral 1983). (USFWS, 1990; NatureServe, 2015)

### ***Dispersal/Migration***

#### **Dispersal**

Adult: Low (USFWS, 1990)

#### **Dispersal/Migration Narrative**

Adult: Seeds readily float, so dispersal probably is mediated by water flow; however, safe sites downstream are infrequently and haphazardly found. Further, seeds have no structures to facilitate aerial dispersal and drop quickly to the ground, with many seeds germinating directly under the parent plant. The natural founding of new pond populations is probably very rare because of the plant's (apparently) poor capacity for long distance dispersal and the fragmented dispersion of appropriate habitat. Thus, seed dispersal to new sites is probably a rare event. (USFWS, 1990)

### ***Population Information and Trends***

#### **Population Trends:**

Long-term trends suggest a decline of 30 to 70%, whereas short-term trends indicate a decline of >50% (NatureServe, 2015)

#### **Species Trends:**

Declining (NatureServe, 2015)

#### **Number of Populations:**

24 (NatureServe, 2015)

#### **Population Size:**

~500,000 (NatureServe, 2015)

#### **Population Narrative:**

This species may be somewhat resistant, but is sensitive to dry conditions and dependent on narrowly defined hydrologic conditions. Vulnerable to upstream development. Many sites have been lost. Approximately 25% of mapped occurrences are ranked historical or extirpated. Long-term population trends suggest a decline of 30 to 70%, whereas short-term trends indicate a decline of greater than 50%. The total number of known individuals appears to be approximately 500,000. One population (drainage/watershed) in West Virginia is estimated to contain 400,000 plants, and all populations in Arkansas are estimated to total 50,000-100,000 plants in a good year (Douglas 2008). Many of the other extant populations are small; nine of the populations (drainages/watersheds) are estimated to contain less than 400 plants (Douglas

2008). Approximately 45 occurrences are believed extant, about half of which are in Arkansas with the other states in the range having 1-5 each. Thirteen occurrences are considered historical (predominantly in Alabama and South Carolina) and 1 (in Georgia) has been extirpated. The U.S. Fish and Wildlife Service (Douglas 2008) regards 24 "populations" as extant, with "population" defined as "sites located within one drainage or watershed... each may have a number of discrete sites (element occurrences)." Under this view, there are 9 extant populations in Arkansas and 1-3 in each of the other states. (NatureServe, 2015)

### ***Threats and Stressors***

**Stressor:** Water fluctuations (USFWS, 1990)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Fluviatile tends to occupy a narrow range of water depths, manipulations of water flow upstream from populations can easily destroy suitable habitat by inundation or persistent desiccation. Dams, reservoirs, or other water impoundments or diversions would almost certainly threaten any *P. nodosum* downstream. Natural fluctuation in water flow causes significant yearly variation in subpopulation persistence. Small subpopulations are particularly susceptible to loss during normal high water events. Thus, small populations such as those in North Carolina or Maryland's Fifteen Mile Creek are at significant yearly risk. Hydrological manipulations on rivers with small populations should be strictly avoided or controlled. *Nodosum*, like *Fluviatile*, depends on intermediate water levels and is threatened by either dry conditions or total inundation. Thus, the primary threats to *Nodosum* populations are hydrological manipulation and physical destruction of their pond habitats. (USFWS, 1990)

**Stressor:** Water quality (USFWS, 1990)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** *Fluviatile* is apparently also sensitive to reductions in water quality. Siltation caused by heavy construction, residential development, and agriculture has been cited as detrimental to the plant. The negative effect of sediment on *Fluviatile* was substantiated in a greenhouse experiment: turbidity equal to that near a bridge construction site reduced *Fluviatile* growth rate by 40% (Maddox and Bartgis 1990b). (USFWS, 1990)

**Stressor:** Stream acidification (USFWS, 1990)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Another greenhouse experiment indicates that stream acidification (especially pH ~ 5.0) may cause significant plant mortality (Maddox and Bartgis 1990b). Plants growing in water with pH approximately equal to 3.4 had a 70% mortality rate; in water with pH = 4.6 plants grew at a significantly lower rate than controls. This is potentially important in Alabama, where the extant population has historically experienced low pH due to mining. At Maryland and West Virginia sites, the pH is typically 7.0. However, the acid neutralizing capacity is very low, suggesting that minor acid inputs could significantly lower pH. Other water quality variables, such as increased sewage or nitrate concentration, may also be detrimental. (USFWS, 1990)

**Stressor:** Alterations in hydrology (USFWS, 1990)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Coastal plain ponds everywhere are threatened by active drainage for conversion to pine plantations or row crops (Godfrey and Wooten 1979). Lowered water tables are probably detrimental to *Nodosum* through increased competitive and physiological stress. While hydrological manipulations directly to the pond are clearly detrimental, ditching and other manipulations of the water table from some distance away may affect coastal plain ponds, although the exact area of effect is not known (Pat Phillips, U.S. Geological Survey, pers. comm. 1989). The effective distance of such manipulations clearly is important in determining the zone around a population needed to ensure protection of the hydrological resource. (USFWS, 1990)

**Stressor:** Dredging (USFWS, 1990)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Occasionally ponds are dredged to create deep ponds for livestock; these deeper water levels probably disrupt the life cycle of *Nodosum*, a small plant. (USFWS, 1990)

### ***Recovery***

#### **Reclassification Criteria:**

1. Thirteen populations (the number of currently extant populations) have been relatively stable in population size for five years. (USFWS, 1990)
2. All thirteen populations are permanently protected. (USFWS, 1990)

#### **Delisting Criteria:**

1. Thirteen populations (the number of currently extant populations) have been relatively stable in population size for five years. (USFWS, 1990)
2. All thirteen populations are permanently protected. (USFWS, 1990)
3. There are at least 26 self-sustaining populations in existence. To reach this level, at least thirteen new populations will have to be discovered or established. This is the total number of current and historically known populations. (USFWS, 1990)
4. The populations are distributed throughout the historical range from Arkansas to Maryland. (USFWS, 1990)
5. All 26 populations are permanently protected. (USFWS, 1990)

#### **Recovery Actions:**

- Protect plants and their habitat through landowner cooperation, land protection, and regulatory authorities. (USFWS, 1990)
- Where needed, seek conservation of watersheds to protect populations. (USFWS, 1990)

- Search for additional populations. (USFWS, 1990)
- Study species and habitat characteristics. (USFWS, 1990)
- Develop a cultivated sources of plants and provide for seed storage. (USFWS, 1990)
- Implement appropriate management techniques, particularly for pond populations. (USFWS, 1990)
- Re-establish populations within the species' historical range. (USFWS, 1990)
- Inform the public about the plant's status and recovery needs. (USFWS, 1990)
- Population surveys and inventories have been performed at all current sites by State Heritage Programs or botanists from various universities. Active population monitoring occurs only in Maryland and West Virginia. (USFWS, 1990)
- Surveys for new populations have been undertaken in all states containing extant populations, except Arkansas. New populations were verified in Maryland in 1988 and Arkansas in 1990. Significant potential habitat or recent unconfirmed records remain to be investigated in Alabama, Georgia, North and South Carolina, Arkansas, southern Missouri, and eastern Oklahoma. (USFWS, 1990)
- The Nature Conservancy, Western Pennsylvania Conservancy, and Maryland Department of Natural Resources have begun a comprehensive program to protect Sideling Hill Creek, including upstream areas as buffer. To date, a number of tracts have been registered in Maryland and Pennsylvania, a tract has been acquired on the border of Maryland and Pennsylvania, and the potential purchase of the most significant tract supporting *P. nodosum* is being negotiated by the State of Maryland and The Nature Conservancy. (USFWS, 1990)
- The Nature Conservancy has acquired an easement on one Cacapon River subpopulation. Additional subpopulations in West Virginia have been added to the Conservancy's registry program. The U.S. Fish and Wildlife Service contracted with The Nature Conservancy in 1990 to expand landowner contact efforts on the Cacapon River. (USFWS, 1990)
- The Maryland Natural Heritage Program has conducted an extensive two—year investigation of the ecology and life history of *Fluviatile* (Maddox and Bartgis 1989, 1990a, 1990b). (USFWS, 1990)
- The Maryland Natural Heritage Program has collaborated with the Smithsonian Institution on a study of electrophoretically detectable genetic variation throughout the range of *P. nodosum*. This study is expected to be completed in spring of 1991. (USFWS, 1990)
- The Maryland Natural Heritage Program has produced and distributed several information brochures on the biology of *P. nodosum* and its habitat. (USFWS, 1990)
- In a 1988 survey conducted by the Center for Plant Conservation to determine the plant taxa in most imminent danger of extinction, *P. nodosum* was identified by botanists as a "B" priority taxon, i.e., one which could go extinct in the wild within the next ten years. The Center has assisted in the recovery of the plant: 7,500 seeds have been collected as part of the National Collection of Endangered Plants and are housed at the North Carolina Botanical Garden (NCBG), one of the Center's participating institutions in the region. All seeds were collected from the Tar River area in Granville County, North Carolina. Although not currently being propagated at NCBG, these seeds provide a valuable conservation resource. (USFWS, 1990)

## SPECIES ACCOUNT: *Purshia* (=Cowania) *subintegra* (Arizona Cliff-rose)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 5/29/1984; Southwest Region

### Physical Description

Arizona cliffrose is a member of the Rose Family (Rosaceae). It is a low, straggling woody perennial usually 1 - 2 meters (in) (3 - 6 feet) high and generally wider than tall. In the Cottonwood population, plants can reach a maximum of 2.4 m (8 feet) tall and 3.7 m (12 feet) in diameter. The horizontal lower branches are spreading, and the central branches are irregularly ascending (Denham and Fobes 1992b). New shoots tend to be red-brown and pubescent with a red dot below the fascicle. The older branches have light gray bark that becomes shreddy. The herbage is not viscid (sticky), although some resin glands may be present, causing slight stickiness. The shape of *Purshia subintegra* leaves is variable. The leaves are very narrow and short: averaging about 8 millimeters (mm) (0.3 inch) long (Denham and Fobes 1992b) and 3 mm (0.1 inch) wide. Leaves usually have no lobes, but occasionally have 1 or 2 rounded, shallow lobes or teeth just below the leaf tip. The margins (edges) of the leaves are curled towards the underside (revolute). The upper leaf surface is bright or dark green and usually has no punctate glands. The upper leaf surface is usually loosely arachnoidpubescent (having a few long hairs) on the upper surface, but sometimes it is hairless. The lower surface is densely white-lanate (wooly) and usually has no punctate glands. Each flower is born on a single stalk (peduncle). The end of the peduncle gradually merges with the beginning of the narrowly funnelform hypanthium, the flower part bearing the sepals, petals, and stamens. The average length of the hypanthium plus peduncle is 5.1 mm (< 0.3 inch) (Reichenbacher 1993). The hypanthium has no stipitate (stalked) glands or has few glands. The typical flower has 3 - 7 pistils and 5 white or pale yellow petals that are about 10 mm (0.4 inch) long, slightly smaller than *P. stansburiana* flowers. Occasionally, flowers have 8 - 12 petals per flower (Denham and Fobes 1992a). As the achenes (fruits) develop, the style remains attached and forms a short, white, feathery plume. (USFWS, 1995)

### Taxonomy

*Purshia subintegra* genetic variability, phenotypic plasticity, and past and recent hybridization with *P. stansburiana* have complicated taxonomic identification. Phenotypic and genetic variability among populations has been studied using morphometrics and molecular (DNA) analysis. Schaack (1987) described the San Carlos Basin (i.e., Bylas) population of *P. subintegra* as *P. pinkavae*, and designated *P. subintegra* to be of hybrid origin involving a cross between *P. stansburiana* and *P. pinkavae*. Kartesz (1994) treats *P. subintegra* as a hybrid. Reichenbacher (1994) states that although there is some character variation between the four populations of *P. subintegra*, multivariate analysis clearly indicates they exhibit a coherent syndrome of characters, and the taxonomy developed by Schaack is not supported by the analysis. The Recovery Plan concludes that *P. subintegra* is distinct from the more common *P. stansburiana*, despite sometimes overlapping plant characteristics (USFWS 1995). Travis et al. (2008) re-examined the genetic variation within *P. subintegra* and state that molecular evidence indicates a distinct classification for the Bylas population in support of the hypothesis that this population represents a separate species per Schaack (1987). However, the authors conclude that a broader taxonomic analysis of the genus is necessary to confirm such a distinction. Henrickson's unpublished description of *P. subintegra* notes considerable variation in key characteristics

within the species. Characteristics used for identification, such as occasionally lobed (or toothed) leaves, exhibit a continuum of variability between and within individuals, change seasonally (e.g., as leaves are shed during drier periods sometimes leaving only unlobed leaves), and sort out independently from other key characteristics. The demarcation between Schaack's pinkavae and *P. subintegra* is not discrete (Henrickson, pers. comm., 2013). Pending further studies, the USFWS continues to recognize that the four described populations of *P. subintegra* comprise one distinct species. Regarding nomenclature, Travis et al. (2008) present strong evidence for a hybrid origin of *P. subintegra*. Based on their molecular data and hypothesized pre-historic biogeography of the region (Anderson 1993), hybridization occurred during the late Pleistocene (11,000 to 13,000 years before the present). There has been a growing consensus for this explanation and increased use of the following nomenclature indicating a hybrid origin: *Purshia*  $\times$  *subintegra* (Kartesz 2013; Integrated Taxonomic Information System, 2013). However, such a designation for a species believed to be of hybrid origin is discretionary (International Code of Botanical Nomenclature (Article H:3.3) 2012). (USFWS, 1995))

**Historical Range**

See Current Range.

**Current Range**

In Arizona, in Graham, Maricopa, Mohave, and Yavapai counties. All known occurrences of *P. subintegra* are located in four disjunct populations, which occur along the sub-Mogollon region of central Arizona over a distance of 320 kilometers (200 miles) (Rutman 1992). (USFWS, 2013)

**Critical Habitat Designated**

No;

***Life History*****Food/Nutrient Resources****Food Source**

Adult: sunlight

**Competition**

Adult: yes, especially creasote

**Food/Nutrient Narrative**

Adult: This species acquires its energy from sunlight via photosynthesis.

**Reproductive Strategy**

Adult: Flowering plant that attracts pollinators

**Lifespan**

Adult: many years

**Dependency on Other Individuals or Species**

Adult: lepidopterans, dipterans, and bees

**Breeding Season**

Adult: late March through early May

**Reproduction Narrative**

Adult: *Purshia subintegra* generally flowers from late March through early May and is visited by a wide variety of insects, including lepidopterans, dipterans, and bees. Typically, hundreds of flowers are produced on each mature plant, which can reproduce for many years (USFWS 1995). Flower and seed production varies between years based on climatic conditions, plant vigor, browsing, and other factors. Native wild bees and introduced honeybees (*Apis mellifera*) are the most important pollinators, the latter becoming the predominant pollinator later in the flowering season (Fitts et al. 1993). Fruit dispersal occurs when summer rains dislodge seeds from plants (USFWS 1995). Experiments have shown that this species is partially self-compatible, but sets significantly more seeds and produces fruit more often when outcrossed (Fitts et al. 1993).

**Habitat Type**

Adult: desert

**Habitat Vegetation or Surface Water Classification**

Adult: limestone soils

**Geographic or Habitat Restraints or Barriers**

Adult: Restricted by competition with other plants

**Spatial Arrangements of the Population**

Adult: Clumped according to suitable resources

**Environmental Specificity**

Adult: specialist; narrow habitat requirements

**Tolerance Ranges/Thresholds**

Adult: unknown

**Site Fidelity**

Adult: high

**Habitat Narrative**

Adult: This species has narrow habitat requirements and occurs at four widely separated areas across central Arizona. These sites differ slightly in elevation and associated vegetation, but all sites have limestone soils (generally white but also reddish in color) derived from Tertiary lacustrine (lakebed) deposits. At each site *P. subintegra* is part of a locally unique vegetative community (Anderson 1993). The geographic and local distribution of *P. subintegra* appears to be limited by competition from other plant species rather than a requirement for a specific soil type. These soils are relatively infertile and have significantly lower amounts of phosphorus and organic matter compared with surrounding areas where *P. subintegra* is absent (Anderson 1986, 1993). These surrounding areas are typically dominated by creosotebush (*Larrea tridentata*), which is thought to have a competitive advantage over *P. subintegra* due to its aggressive seedling establishment (Anderson 1993). Creosotebush is unable to grow on the relatively

infertile lacustrine soils. However, it has been found growing together with *P. subintegra* in the Verde Valley, in areas with higher amounts of organic matter and phosphorus. This suggests that the distribution of *P. subintegra* within these limestone soil conditions is limited primarily by competition from creosotebush, rather than a requirement for specific soil properties (Anderson 1986, 1993, 1996).

***Dispersal/Migration*****Motility/Mobility**

Adult: not mobile

**Dispersal**

Adult: only the seeds

**Dispersal/Migration Narrative**

Adult: Fruit dispersal occurs when summer rains dislodge seeds from plants (USFWS 1995).

***Population Information and Trends*****Population Trends:**

Declining

**Species Trends:**

Declining

**Population Growth Rate:**

unknown

**Number of Populations:**

4 (USFWS, 2022)

**Population Size:**

Unknown, estimated to exceed 40,000

**Minimum Viable Population Size:**

unknown

**Resistance to Disease:**

unknown

**Population Narrative:**

The total number of plants in the four *P. subintegra* populations is not known, but has been estimated. Not all areas of potential habitat have been surveyed, and in some areas, such as Cottonwood, the presence of hybrids between *P. subintegra* and *P. stansburiana*, or introgressed forms, has complicated population estimates (USFWS 2001). Despite the potential conservation significance of hybrids, the USFWS considers these plants to be outside the definition of the species (USFWS 1995) and are not included in population estimates. In 1988, a total number for all four populations (i.e., recovery units) was estimated to exceed 40,000

plants, although a large percentage may have included hybrids (USFWS 1988). About 10,000 plants are thought to currently occur in the predominant subpopulation at Burro Creek (USFWS 2004). At the time of listing, the USFWS estimated 243 ha (600 ac) of habitat at Burro Creek, and 40 ha (100 ac) at Bylas with an estimated 700 plants (USDI 1984). The Horseshoe Lake population is estimated to include 750 plants (USFWS 1987) over an unspecified area. The Cottonwood population covers the largest area, estimated at over 405 ha (1,000 ac) (USFWS 1995), with the amount of occupied habitat recently calculated to be 78 ha (194 ac) (Goodwin 2012). Total Cottonwood population numbers were previously not known, but were conservatively estimated to include tens of thousands of plants (USFWS 2007). The most recent, intensive survey places this number considerably lower, at a total of 8,272 *P. subintegra* plants within the Cottonwood population (Goodwin 2012). Acceptance of this figure would result in a downward adjustment of the estimated total numbers of known plants in the four populations by one-half, or to about 20,000. This adjustment may be the result of a more intensive survey as opposed to a large scale decline in numbers. We have no demographic trend information from monitoring the four populations, but population viability modeling suggests that *P. subintegra* will slowly decline in the Cottonwood population under more arid scenarios (Maschinski et al. 2006). *Purshia subintegra* populations are genetically variable, exhibit phenotypic plasticity in response to environmental conditions, and hybridize with *P. stansburiana*. Gene exchange through backcrossing hybrids (introgression) of *P. subintegra* and the more common *P. stansburiana* has resulted in hybrid swarms in the Cottonwood and Horseshoe Lake populations (USFWS 1995). A hybrid swarm is a “hybrid population,” maintained by backcrossing and/or crossing with other hybrids, which may be stable or spread. The proliferation of hybrids has the potential to negatively affect long-term population dynamics of *P. subintegra* through interference competition and loss of genetic integrity (Fitts et al. 1993; Baggs and Maschinski 2001b). At the same time, hybridization may act as a mechanism to increase genetic diversity in a population, enhancing adaptation and survival, therefore potentially benefiting conservation of *P. subintegra* (Baggs and Maschinski, 2001b). Hybrid swarms illustrate the migratory and dynamic nature of evolving plant populations, and may provide the key to the future of the genus and species. For this reason, conservation of these hybrid swarms is important (USFWS 1995). A recent study by Travis et al. (2008) confirmed the presence of a hybrid swarm in the Verde Valley and emphasized its conservation significance. Because introgressed forms appear to possess potential fitness advantages under hotter, drier conditions, they may provide a viable refuge for *P. subintegra* genome in the face of climate change (Travis et al. 2008). The paper also identified three distinct genetic lineages of *P. subintegra*: the Cottonwood (Verde Valley) population, which is currently undergoing introgression; the Burro Creek and Horseshoe Lake populations, which exhibit an ancient natural hybrid origin; and the Bylas population, which is genetically distinct from the others. These findings underscore the complex genetics of this species and the importance of conserving all four populations. (USFWS, 2013). For Arizona cliffrose, the four recovery units are analogous to the four known populations of the species, which we will refer to as populations from this point forward. The four populations are Burro Creek, Cottonwood, Horseshoe Lake, and Bylas (USFWS, 2022)

### ***Threats and Stressors***

**Stressor:** Urbanization (USFWS, 1995)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Habitat loss due to urbanization is a serious threat for the Cottonwood Arizona cliffrose population. Urbanization does not appear to be a threat to the other three populations, which are either on Federal land, which precludes urbanization, or they occur where development is unlikely. A significant amount of Arizona cliffrose habitat has already been lost due to development in the Cottonwood area, but the amount of habitat loss has not been estimated. The threat of urbanization continues, because some occupied habitat remains on private lands that could be developed and a substantial amount of habitat is on State Trust land. The transfers of land from Federal ownership into private or State ownership is an indirect threat to Arizona cliffrose. These land exchanges significantly reduce the protections offered by the Endangered Species Act and may contribute to urbanization or other actions causing habitat loss or degradation. These types of transfers would be subject to section 7 consultation procedures. (USFWS, 1995)

**Stressor:** Mineral Exploration and Development (USFWS, 1995)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Mining and mining-related activities are a serious threat to the long-term survival of this species, particularly in the Burro Creek area. The soils supporting Arizona cliffrose populations are known to contain high quality bentonite (BLM 1993), a type of clay used for cosmetics and pharmaceuticals. Drilling and bulk sample procurement have reduced the number of plants and amount of available or undisturbed habitat in the Burro Creek area. (USFWS, 1995)

**Stressor:** Cattle and Feral Burro Browsing Effects (USFWS, 1995)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In 1987, the BLM- Kingman Resource Area began monitoring the effects of livestock browsing on Arizona cliffrose near Burro Creek with the objective of determining the amount of utilization. Internode distances on five branches were measured on each of 50 Arizona cliffrose plants. Cages were constructed around 25 Arizona cliffrose plants to prevent browsing by livestock, wild burros, and mule deer. Twenty-five plants were left uncaged to serve as a control. Their results showed that browsing activity resulted in 65% utilization of Arizona cliffrose (BLM 1993). This high level of utilization can reduce plant vigor and fecundity, cause lack of seedling establishment, and change the form class of Arizona cliffrose plants, causing them to look hedged. Under this level of utilization, more palatable, associated plant species may be overutilized, resulting in disturbed ecosystem functions and degraded ecological values. The BLM continued monitoring Arizona cliffrose utilization after a fence was constructed in 1989 to exclude cattle and burros from an approximately one square mile area. This large enclosure included the caged and uncaged plants that had been monitored since 1987. After the fence was built, utilization of the Arizona cliffrose plants dropped to 16% in 1989 and 18% in 1990 (BLM 1993). Utilization of caged plants was similar to uncaged plants. These results indicate that livestock and burros were responsible for most of the browsing activity on Arizona cliffrose. Some browsing continues within the enclosure, probably from mule deer and other wildlife. Livestock and burros may occasionally enter the enclosure if the fence is not maintained. Most plants appear to be responding favorably to the lower levels of browsing. However, it appears that some plants that were very heavily browsed over a long period of time may never recover. Only observational data are available regarding the effects of livestock grazing on the Bylas

Arizona cliffrose population. At the Graham County population, Bingham (1977) noted that no young plants were observed during a one hour search in the grazed open area, whereas juvenile plants were present along an adjacent fenced ungrazed highway right-of-way. In 1986, the BIA (/n litt. 1986) noted that the absence of quantities of dried manure and lack of hoofprints to the north of Highway 70 indicated low grazing pressure. They also noted that Arizona cliff rose plants south of Highway 70 were browsed, probably because nearby Poison Spring offers a source of water for livestock and wildlife. (USFWS, 1995)

**Stressor:** Roads and Utilities (USFWS, 1995)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** All of the Arizona cliffrose populations have roads and/or utility right-of-ways within or near them. The Burro Creek population is divided by a graded dirt road paralleled by the Southern Union Gas Company pipeline and Arizona Electric Power Cooperative Incorporated high voltage power line. The gas pipeline has been in existence since at least 1969 (Butterwick 1979). No estimate of the amount of habitat lost to these developments in the Burro Creek area has been made. The Kingman Resource Management Plan (Kingman RMP) (BLM 1993) proposed a one-mile wide utilities corridor that overlies Arizona cliffrose habitat. The BLM may grant right-of-ways through this utility corridor (BLM 1993). A graded dirt road (Forest Road 205) and a gated road (Forest Road 530) passes near one of the three Horseshoe Lake subpopulations. Forest Road 479 passes near a second subpopulation. U.S. Highway 70, a two-lane paved road, bisects the population near Bylas. Numerous paved and dirt roads pass through the Cottonwood population. Highway 89A nearly forms the eastern border and Rocking Chair Road passes through the Arizona cliffrose habitat. Its expansion is being planned. Other roads to access housing or for recreational purposes create a network through the habitat. Roads and trails have direct and indirect effects. Road surfaces constitute lost habitat. The amount of habitat and number of plants lost to roads have not been estimated. Roads can change the local hydrology, affecting the amount of precipitation received and absorbed in a local area, changing the direction and speed of runoff, and perhaps changing erosion rates and patterns. These changes can adversely or beneficially affect survivorship and fecundity of individuals. Soil compaction occurs in areas of moderate to heavy vehicle use. Roads can provide access to ORV and other users that may adversely affect Arizona cliffrose and its habitat. ORVs can destroy young plants, harm mature plants, prevent seedling establishment or seed germination, cause soil compaction, and otherwise disrupt the soil surface. Arizona cliffrose plants have colonized a lightly used vehicle trail on the Coconino National Forest. These plants indicate that Arizona cliffrose in the actively reproducing Verde Valley population can recover after light soil surface disturbance. Unknowingly, local residents of the Verde Valley have been using Arizona cliffrose habitat as a parking lot. The parking area is located at the intersection of Rocking Chair Road and U.S. Highway 89A. The area of impact has been expanding during recent years, increasing the number of plants and amount of habitat already lost. The Coconino Forest Plan (U.S. Forest Service 1987) states that the Forest will manage roads adjacent to the Verde Valley Botanical Area to prevent vehicular intrusion." In the same document, the Forest committed to blocking and obliterating existing roads entering the area within the first ten years of plan implementation. To date, road blocking and obliteration has not yet occurred. (USFWS, 1995)

**Stressor:** Recreation (USFWS, 1995)

**Exposure:**

**Response:****Consequence:**

**Narrative:** The Cottonwood population is adversely affected by recreation of several types. An unofficial shooting range near the eastern portion of this population on the Coconino National Forest has caused the loss of an unknown number of plants and acres of habitat. Shooters park within an Arizona cliffrose population at the base of a small hill and shoot into the population on the hill. The soil at the well-used parking area and roads leading to the shooting range is compacted and eroding, devoid of vegetation, and probably incapable of supporting cliffrose plants unless restored. The area is used not only by shooters, but also by nighttime recreationists. In addition to the shooting range, other spots in the Arizona cliffrose Cottonwood population are frequented by night-time recreationists. These "party spots" are generally severely impacted by vehicles, devoid of vegetation, and littered with trash. ORV recreationists drive through the Cottonwood population, in some cases ignoring signs or cutting fences to gain access to prohibited areas. A fence completely surrounds a section of Arizona State Trust land, which was used by ORV users despite trespass notices. The primary damage to Arizona cliff rose habitat in the Cottonwood area has occurred in Township 16 North, Range 3 East, section 36 by vehicles entering the section from the west. The State Land Department has been successful at notifying the offenders and eliminating this use (Denham /n I/U. 1994). Denham and Fobes (1992d) also noted ORV damage in the southeast corner of Township 16 North, Range 3 East, section 22 and the northeast corner of section 27. The ORV users entered a parcel of private land via the Coconino National Forest and rode across the property. ORVs are not currently a problem at Horseshoe Lake. The Tonto National Forest Plan (U.S. Forest Service 1985) closed the area to ORV use except where posted as open but has minimally enforced the closure. Despite the presence of a nearby lake and campground, ORV use has not yet been reported within the subpopulations. The amount of recreational activity occurring within the core Burro Creek subpopulation is poorly known. Increased recreational activity may occur within the Clay Hills Area of Critical Environmental Concern (ACEC) when the Burro Creek campground is developed (BLM 1993). The Burro Creek site is a wellknown destination for rock collecting enthusiasts. These visitors may affect Arizona cliffrose by turning over rocks and disturbing seedling establishment microsites. They also may occasionally drive short distances across country to reach collecting sites and crush plants. Whether or not these visitors adversely affect Arizona cliffrose is unknown. (USFWS, 1995)

**Stressor:** Control of Insect Pests (USFWS, 1995)

**Exposure:****Response:****Consequence:**

**Narrative:** General pesticides are often used to control cropland insect pests and sometimes used to control rangeland insect pests. Two Arizona cliffrose populations (Horseshoe Lake and Cottonwood) occur very close to lands under cultivation. A private parcel of land near Horseshoe Dam is being cultivated to provide food for livestock. We do not know if pesticides are currently being applied on the cultivated lands near Arizona cliffrose populations. Four Arizona cliffrose populations occur in areas that are grazed. High densities of rangeland pests have never been reported within Arizona cliffrose populations. If problem densities develop, however, they may be accompanied by proposals from Federal and State agencies to apply chemical controls, including general pesticides. General pesticides such as malathion, a commonly used rangeland and cropland pesticide, can drastically decrease target and non-target insect populations. Insect population sizes are regulated by a number of variables, including weather, inter-and intra-

specific competition, vertebrate predators, and insect predators and parasitoids (Belovsky 1989, Wang and Walgenbach 1989, Hostetter et al. 1989, Dysart and Onsager 1989, Lockwood 1993). General pesticides will kill target herbivorous insects as well as the insect predators and parasitoids that regulate the herbivores. Herbivorous insects and their predators and parasitoids are usually in a dynamic balance, rarely reaching high, damaging densities except in unnatural circumstances such as the introduction of nonnative pests or in association with various agricultural practices including livestock grazing (Auerbach 1991, Brusven and Fielding 1989, Belovsky 1989). For a review of the field experiments and models of arthropod predator-prey systems that demonstrate this dynamic ecosystem balance, see Hassell (1978). Herbivorous insects recover more quickly after pesticide applications than do their predators and parasitoids because herbivores tend to have a higher fecundity and shorter generation time. Consequently, herbivorous species will more quickly become resistant to chemicals, and their populations will rebound faster and typically at higher densities because predator/parasitoid controls are lost or reduced. Thus, general pesticide applications tend to exacerbate insect population imbalances rather than resolve them. Concern about applying chemical pesticides within or near endangered plant populations has tended to focus on the adverse effects of pesticides on pollinators. For plants that depend on insects for pollination, seed set may be drastically reduced when pollinator populations are reduced by pesticides (Tepedino and Griswold 1989). Avoiding the blooming period of endangered plants may not remove these adverse effects. Fitts et al. (1993) provide the following explanation: It is obvious that, for the plant, the most dangerous time to spray is during the blooming period. It is less obvious that it may also be risky to spray when bloom is past; many important pollinators are either eusocial, or multivoltine species, i.e., adults are present throughout the growing season, foraging on other plants. These adults are the progenitors of the next years' pollinator crop; removing them will eliminate progeny and, thus the number of pollinators flying in the following year. Information needed to effectively manage insects as part of the ecosystem containing Arizona cliffrose includes the identification of all insects beneficial to Arizona cliffrose, including pollinators, and an understanding of their life histories and habitat needs. Until such information is obtained, the U.S. Department of Agriculture, Animal and Plant Health Inspection Service has agreed to restrict certain pesticides within a 4.8 km (three-mile) radius of Arizona cliffrose populations. (USFWS, 1995)

**Stressor:** Herbicides (USFWS, 1995)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Herbicides are sometimes used to control plant growth along paved roads. Although paved roads pass through the Verde Valley and Bylas Arizona cliffrose populations, we do not know if herbicides are used there. Herbicides should not be used along roadsides within Arizona cliffrose populations because treated plants are destroyed. (USFWS, 1995)

**Stressor:** Inundation (USFWS, 1995)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Arizona cliff rose plants and habitat were probably inundated when Horseshoe Dam and its spillway were built on the Verde River in 1944-1946 (FraserDesign 1991). Additional plants and habitat were probably lost when the conservation pool level of Horseshoe Lake was raised in the 1950's to the current elevation of 618 in (2,026 feet). Habitat inundation most likely

occurred in the Chalk Mountain area. If the height of the conservation elevation is increased further, the action would probably inundate additional plants and habitat. The Salt River Project, a utility company, operates the reservoir on a daily basis without specific approvals from Reclamation (Project Manager, Arizona Projects Office, Bureau of Reclamation, in litt. 1994). (USFWS, 1995)

**Stressor:** Habitat Loss (USFWS, 2022)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In our 2013 5-year review, we reported that the proposed Bella Montaña Residential Community Development, a 283-hectare (700-acre) parcel, would remove 47 cliffrose plants in the eastern-most known extent of the Cottonwood Recovery Unit (USFWS 2007). We also reported conservation measures proposed as a part of the development to protect and enhance cliffrose habitat (USFWS 2007). At the time of this review, the development has not occurred yet, but the consultant for the project has notified us that the project proponent plans to move forward on this project in the near future (N. Sanders, pers. comm., 2021). The original Coconino National Forest Land and Resource Management Plan (Forest Plan) stated that the Forest Service would withdraw the Verde Valley Botanical Area, which contains approximately 50 to 60 percent of the plants in the Cottonwood Recovery Unit, from locatable mineral entry within 10 years of the implementation of the Forest Plan (USFS 1987). To date, the Forest Service has not completed this withdrawal. However, the current Forest Plan indicates that the Cottonwood Recovery Unit has low potential for mining activity and includes a guideline that botanical areas and areas with federally threatened or endangered species be considered for no surface occupancy or mining leases (USFS 2018) (USFWS, 2022).

**Stressor:** Herbivory (USFWS, 2022)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In our 2013 5-year review, we stated that the grazing allotments that contain the Horseshoe Recovery Unit were not active, and these allotments remain inactive. In their revised Land Management Plan, the Tonto National Forest included 3,590 acres, encompassing all the known occurrences of cliffrose in the Horseshoe Recovery Unit within the Horseshoe Recommended Botanical Area (USFS 2022). The Forest Service manages Botanical Areas to maintain or enhance their unique characteristics. Management standards for Recommended Botanical Areas prohibit livestock grazing, mineral extraction, and camping. Additional management guidelines restrict other activities unless necessary to restore or maintain natural conditions or protect natural resources. The finalization of the Horseshoe Botanical Area would address Recovery Actions 1b and 3b. In our 2013 5-year review, we reported that the BLM constructed a fence around the Clay Hills Research Natural Area of Critical Environmental Concern in 1989 to protect the Burro Creek Recovery Unit from the threat of herbivory by livestock and feral burros. After fence construction, browsing utilization of cliffrose decreased from about 65 percent to about 16 to 18 percent (Reichenbacher and Anderson 2022). The BLM continues to monitor the condition of the fence (USFWS 2013) and repaired damaged sections in late 2021 through early 2022 (J. Acton, pers. comm., 2022). Heavy browsing on cliffrose by native ungulates (e.g., mule deer [*Odocoileus hemionus*]) is evident in the Burro Creek and Horseshoe recovery units. This might be especially prevalent during drought conditions when ungulates

browse on a wider variety of available plants because of limited forage (Reichenbacher and Anderson 2022) (USFWS, 2022).

**Stressor:** Climate Change (USFWS, 2022)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In our 2013 5-year review, we identified climate change as a threat to the cliffrose, specifically through decreased seedling recruitment in response to increased aridity and decreased precipitation (USFWS 2013). Climate modeling for 2050 through 2074 projects that increased temperatures will lead to increased monthly mean vapor pressure deficit in Arizona (Alder 2014); thus, cliffrose will continue to experience drought conditions. While we have little quantitative data showing past effects of drought on vegetation in cliffrose habitat, photographs from 2022 repeated at photo points from the 1980s and 1990s in the Burro Creek, Cottonwood, and Horseshoe recovery units show increased dead shrubs and increased dead branches on shrubs, including cliffrose individuals (Reichenbacher and Anderson 2022). Most cliffrose plants in the three recovery units recently observed (Burro Creek, Cottonwood, and Horseshoe) have not flowered in two years and exhibit signs of stress (Reichenbacher and Anderson 2022) (USFWS, 2022).

### ***Recovery***

#### **Reclassification Criteria:**

We will consider Arizona cliffrose for downlisting when: (USFWS, 2019)

1. A single, long-term monitoring plan for all Arizona cliffrose populations and habitat is developed and implemented. (USFWS, 2019)
2. Land managers conserve existing habitat, in each recovery unit, in perpetuity to prevent further habitat loss and/or degradation. (USFWS, 2019)
3. Each of the four recovery units contains a population of Arizona cliffrose that is stable or increasing over a period of at least 10 years. (USFWS, 2019)

Recovery Priority Number: 8

#### **Delisting Criteria:**

In addition to meeting downlisting criteria 1 and 2, we will consider Arizona cliffrose for delisting when: (USFWS, 2019)

1. Each of the four recovery units contains a population of Arizona cliffrose that is stable or increasing over a period of at least 20 years. (USFWS, 2019)

#### **Recovery Actions:**

- Produce and implement management plans for each of the four recovery units. This recovery task must be completed before recovery criterion 3 can be met. Commitment of the appropriate Federal and State land management agencies and the San Carlos Indian Community towards managing this sensitive habitat is critical to the recovery and survival of

- Arizona cliffrose. If new populations are found, management plans covering those populations should be produced and implemented. (USFWS, 1995)
- Initiate research and other actions needed to monitor the species' status and guide recovery efforts. Best management efforts are guided by good biological and ecological information. Currently, too little is known about Arizona cliffrose to determine the most appropriate management actions to effect recovery and determine population stability. Research, studies, and other actions are needed to provide a sound basis for management. (USFWS, 1995)
  - Eliminate or minimize threats to the species. Threats which prevent the recovery of Arizona cliffrose should be eliminated. The most important current threats to Arizona cliffrose are habitat loss due to mineral exploration and development, urbanization, recreation, roads, and utilities, and habitat degradation due to livestock grazing and recreation. Reducing or eliminating these and all other threats will lead to the recovery of Arizona cliffrose. (USFWS, 1995)
  - Enforce and apply existing laws and regulations. Full use of all Endangered Species Act regulatory control should be used to manage and protect Arizona cliffrose populations. Arizona State law should also be applied and enforced. (USFWS, 1995)
  - Information and education. Exchange of information and ideas among private landowners, the scientific community, the public, and Federal, State and local agencies is essential to a successful recovery program. Scientific information, including results of field and greenhouse research, monitoring data, trip reports, agency reports, and scientific literature should be readily available to all parties interested in the management and survival of Arizona cliffrose. Ideas should be freely exchanged so that optimal recovery strategies can be outlined and implemented. Meetings of interested parties to discuss new information or management issues or strategies should be encouraged. Preliminary or refined research or monitoring data should be presented at local, regional, and national gatherings of professional scientists so that a broad professional audience may have opportunities to comment on, and potentially enhance, recovery of Arizona cliffrose. (USFWS, 1995)
  - Recommendations for Future Actions from 2013 5-Year Review: 1) We recommend the development or completion of management plans for the Cottonwood population (including the VVBA), the Horseshoe Lake population, and the Bylas population. The plans for each of these populations would be developed by the respective land managing agency (CNF, TNF, and the San Carlos Apache Tribe) with the offered assistance of the USFWS. These management plans should address newly understood or emerging threats such as climate change and invasive weeds. (USFWS, 2013)
  - Recommendations for Future Actions from 2013 5-Year Review: 2) We recommend the appropriate agencies analyze the monitoring data they have collected to date to determine demographic trends in their respective *P. subintegra* populations. This will allow the USFWS to determine whether a given population is viable or on a trend toward viability, in support of downlisting criteria one. The USFWS can assist in coordinating this effort to facilitate consistency and comparability between the various monitoring methods employed by each agency. (USFWS, 2013)
  - Recommendations for Future Actions from 2013 5-Year Review: 3) We recommend the modification or addition of standardized long-term demography monitoring techniques to existing monitoring schemes, or the establishment of standardized long-term monitoring protocols within all four populations. The USFWS can facilitate this process and assist in monitoring design and coordinating standardization between agencies. (USFWS, 2013)

- Recommendations for Future Actions from 2013 5-Year Review: 5) We recommend that the terms “viability” and “significant upward trend towards viability,” as used in the first downlisting criterion, be defined or described for *P. subintegra* for the purpose of developing an objective and measurable criterion. The USFWS will lead this effort in coordination with land managing agencies and subject matter experts. (USFWS, 2013)
- Since 1989, when a fence was set around the main Burro Creek subpopulation, the BLM has continued to monitor grazing on *P. subintegra* in the main population as well as the two subpopulations. Herbivory of *P. subintegra* has been low within the ACEC, recorded at 3 to 9.4 percent utilization for the past six years (Peck 2009b; Peck 2012). Grazing use in the two outlier populations has also been low, ranging from 2.5 to 8 percent. The BLM had predicted livestock grazing at these sites would be light because cattle would be less likely to travel in the area due to the rugged terrain and distance from water. Evidence of herbivory at all sites has been attributed to wildlife, and is well below the trigger of 20 percent for determining if reinitiation of formal consultation is necessary (Hall 1993). The ACEC fence is inspected annually and repaired as needed. The VVBA is within the Windmill Allotment. Section 7 consultations with the CNF were conducted in 1992 and 1997 for the Windmill Allotment Management Plan. Grazing has been excluded from the Rocking Chair and Cornville pastures since 1992, while seasonal grazing has continued in the Gyberg pasture under a deferred rest rotation system (USFWS 1995). Range inspection memoranda, from 2001 to 2006, state that there was light to no use of *P. subintegra* within the North Gyberg Pasture. The Horseshoe Lake *P. subintegra* population on the TNF is contained within three grazing allotments. Current management in the Sears Club/Chalk and the St. Clair allotments is non-use due to the allotments being vacant (Willard, pers. comm., 2012). The Sears Club/Chalk Allotment, which contains most of the population, is scheduled for evaluation, under the National Environmental Policy Act, in 2013. The three pastures in the Cartwright Allotment (Lime Creek, Professor, and Long Canyon) have been removed from grazing (USFS 2008). Currently, the threat from grazing appears to be at a low level at three of the populations; the level of grazing effects at the Bylas population is not quantified to our knowledge.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • We recommend the development or completion of management plans for the Cottonwood population (including the Verde Valley Botanical Area), the Horseshoe Lake population, and the Bylas population. The respective land managing agency (Coconino and Tonto National Forests, and the San Carlos Apache Tribe) would develop these plans with the offered assistance of the Service. These management plans should address newly understood or emerging threats such as climate change and invasive weeds. This action would address Recovery Action 1. • We recommend the land management agencies (i.e., BLM, Coconino and Tonto National Forests, and the San Carlos Apache Tribe) implement long-term demographic monitoring within all four populations. This will allow the Service to determine whether a given population is viable or on a trend toward viability. The Service can assist in coordinating this effort. This action would address Recovery Action 2c. • We recommend continued research on pollination, seed germination and seedling establishment, propagation, comparison of recruitment rates among populations, life history characteristics, and growth rates to better understand the threats of and potential measures to address climate change. This action would address Recovery Action 2. • We recommend land managers consider caging seedlings during years of high seed production (i.e., years of moderate or high precipitation) to increase recruitment of seedlings into the juvenile stage (Maschinski et al. 2004; Haskins et al. 2018). This action would address Recovery Action 3. • We

recommend collecting seed representing each of the four recovery units, with regular supplemental collections, and maintaining the collection in at least one Center for Plant Conservation partner botanical or seed storage institution. We did not include biobanking as a recovery action in the Recovery Plan. However, after we completed the Recovery Plan in 1995, researchers improved techniques and knowledge that increase the potential contribution of biobanking to cliffrose conservation. We therefore include this recommendation to preserve some of the species' genetic diversity for potential future population augmentations or reintroductions (USFWS, 2022).

## SPECIES ACCOUNT: *Quercus hinckleyi* (Hinckley oak)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 08/26/1988; Southwest Region (Region 2) (USFWS, 2016)

### **Physical Description**

*Quercus hinckleyi* is an evergreen shrub, most often forming patchy thickets that grow to a maximum height of 0.75 m. The plant usually has multiple stems, with relatively thin light brown twigs that may become waxy on second year growth. The buds are less than 1 mm long, and reddish brown with short hairs on the margins. The leaves have rose-colored petioles 1-2 mm long, and hairy stipules at the base, 2 mm long, that fall off later in the season. The leaf blades are very characteristic. They are thickened, gray-green, almost rounded, 5-15 mm long and broad, with a spiny tip and 2-3 spiny teeth on each margin. The flowers are unisexual, with the male flowers in 3-5 mm long catkins of only a few flowers each. The female flowers are tiny, inconspicuous, and densely hairy. Acorns are formed annually. They are oval, 8-12 mm broad, and usually only included in the cup at the base. The cup is shallow, up to 3 mm deep, and saucer-shaped. (USFWS, 1992)

### **Taxonomy**

The first known collection was made in 1950 from the Solitario (Presidio County, Texas), and is attributed to Dr. L. C. Hinckley. Dr. C. H. Muller collected specimens from the same location a month later, and eventually described it as a new species, named in honor of Dr. Hinckley (Muller 1951). He placed the species within his series *Glaucoideae*. The most notable features of this species are its leaves, which are small, smooth, broadly oval, noticeably thickened, and markedly spiny on the margins (superficially holly-like). This, combined with its small stature, thicket-forming habit with intricate, multiple-branched stems, and gray-green color make it easily recognizable and distinctive within its group (series *Glaucoideae*). (USFWS, 1992)

### **Current Range**

Known from the Chihuahuan Desert of West Texas. All of the populations known are in Presidio County. Other reports exist of additional populations in the area of Shafter, Texas, but these localities have not been recently verified. (USFWS, 1992)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Asexual (vegetative) (USFWS, 1992)

### **Reproduction Narrative**

Adult: All reproduction appears to be vegetative. (USFWS, 1992)

### **Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Desert (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Arid climate with large fluctuations in temperature and low rainfall (USFWS, 1992)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs at elevations between 1066.8 and 1372 m (3,500 to 4,500 ft) (USFWS, 1992)

**Spatial Arrangements of the Population**

Adult: Patchy (USFWS, 1992)

**Environmental Specificity**

Adult: Moderate, with some key requirements (USFWS, 1992)

**Tolerance Ranges/Thresholds**

Adult: Moderate to high (inferred from USFWS, 1992)

**Habitat Narrative**

Adult: *Quercus hinckleyi* prefers arid, rocky, limestone-derived soils or limestone outcrops at mid-elevations in Chihuahuan Desert shrublands. The development of more arid climates is postulated to have resulted in restriction of the species to a few sites within its old range of distribution, resulting in a patchy distribution of a few populations with relatively few individuals. *Quercus hinckleyi* occurs in an arid subtropical climate. Climatologists place it in the Trans—Pecos climatic area of Texas, which is extremely variable because of topographic differences. The area generally has great daily temperature fluctuations and an arid profile where evaporation exceeds precipitation. The average temperature is 30.4 C (86.8 F), with 178 days of 32.2 C (90 F) and above temperatures, and 44 days of temperatures below 0 C (32 F). The frost free season is 238 days. The average precipitation is 23.4 cm (9.2 inches). *Quercus hinckleyi* grows on dry limestone slopes between 1066.8 m and 1372 m (3,500 — 4,500 feet) elevation. Slopes where the species occurs are mostly north and west-facing. The plants are found growing in cracks of solid rocks or extremely rocky soils (Poole 1988a). (USFWS, 1992; NatureServe, 2015)

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends*****Population Trends:**

Not available.

**Number of Populations:**

9 (USFWS, 2020)

**Population Size:**

204 (USFWS, 2020)

**Population Narrative:**

We now know that there are 9 confirmed extant EOs in Presidio and extreme western Brewster counties (not 12, as stated in the previous 5-year review). Most new information about the species derives from recent genetic analyses (Banks 2014) of most of the extant populations. Only 123 genetically unique individuals were identified among 204 plants, and the two sites near Shafter had only 7 individuals among 58 plants. Despite the low numbers of individuals, the species has levels of genetic diversity and heterozygosity that are comparable to non-threatened oak species. This is likely due to the very long life spans of the species' clones — perhaps thousands of years. Genetic introgression has occurred between Hinckley oak and its two most closely-related species, sandpaper oak and Vasey shin oak, but this has not risen to the level of genetic swamping; 95 percent of individuals identified as Hinckley oak have little or no introgression from other oaks. Furthermore, existing Hinckley oak hybrids are reservoirs of the species' overall genetic diversity. Based on the elevation ranges and occupied geological formations of known populations, we estimate that 63,631 ha (157,231 ac) of potential habitat exists in Presidio and Brewster counties. It is likely that substantial amounts of potential habitat also exist in adjacent areas of Chihuahua and Coahuila, Mexico. We estimate an MVP size of 1,100 individuals, and recommend that in the specific case of Hinckley oak, this criterion should be applied to the numbers of observed plants rather than the numbers of genetically unique individuals. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Climate change (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Climatic changes of the last 8,000-11,000 years, have resulted in the reduction of suitable habitat and fragmentation of populations. These are the primary reason the plant is rare today (Miller and Powell 1982). (USFWS, 1992)

**Stressor:** Small population size (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The species is vulnerable today because few populations are known, and each has a small number of individuals. The population centers are relatively widespread, limiting any potential gene flow. These conditions make the species vulnerable to catastrophic destruction and loss of genetic viability. (USFWS, 1992)

**Stressor:** Genetic variability (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** All observers report a very low level of regeneration in the stands of *Quercus hinckleyi*, with no juveniles reported, though in some years there have been heavy acorn yields (Bacon 1989, 1990). All reproduction appears to be vegetative. Populations may already have become so isolated, and the numbers of individuals fallen so low, that low genetic diversity has developed in the populations, reducing both fertility and the genetic ability to adapt evolutionarily to the changing environment (Hilsenbeck 1989). (USFWS, 1992)

**Stressor:** Herbivory (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Native deer are known to browse the plants and eat the acorns (Miller and Powell 1982). Small mammals and birds are also known to eat the acorns, and some epidermal damage caused by disease or insect predation (webs have been found on the branches) has been noted at the type locality (Miller and Powell 1982, U.S. Fish and Wildlife Service 1987, Poole 1988a). (USFWS, 1992)

**Stressor:** Roads (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** One of the populations is very near a highway and roadway maintenance activities, or any further highway expansion or realignment, could constitute a threat to the species (Poole 1988a). (USFWS, 1992)

**Stressor:** Grazing (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In the past, all of the populations were on private land. At least nine of these populations were subject to browsing and acorn consumption by livestock and wildlife, and the possible introduction of exotic game species. Overstocking of cattle or sheep and the introduction of goats or other browsing animals represented a potential threat to the small populations of plants (U.S. Fish and Wildlife Service, 1988). With the 1988 acquisition by the Texas Parks and Wildlife Department, 9 of the 10 known populations are now in the Big Bend Ranch State Natural Area where the species is protected by State Law. Although a specific management plan for Hinckley oak that addresses policies governing cattle grazing or the introduction of exotic species is not yet in place, the Texas Parks and Wildlife Department is currently developing a plan for the Natural Area that should include considerations for this species. (USFWS, 1992)

**Stressor:** Collectors (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The rarity of the plant and its distinctive leaves have attracted the attention of collectors and horticulturists. Some taking of acorns in violation of State permit requirements and trespass laws has been reported (U.S. Fish and Wildlife Service 1988). In addition, acorns are

reportedly collected legally every year at the Shafter population, reducing the possible recruitment to the natural population (Poole 1988a). (USFWS, 1992)

**Stressor:** Hybridization (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Oak species are known to hybridize freely, and hybridization with *Quercus pungens* var. *vasevana* (Vasey oak) has been reported at one population of *Quercus hinckleyi* (U.S. Fish and Wildlife Service 1988). Genetic swamping by nearby native or introduced oak species is a potential problem, both for populations in the wild and any plants maintained under cultivation (Poole 1988a). (USFWS, 1992)

### ***Recovery***

**Reclassification Criteria:**

Reclassification criteria are not available.

**Delisting Criteria:**

1. Attain at least 20 viable self-sustaining populations in at least 4 geographically distinct population centers and attain a total of at least 10,000 individual plants. (USFWS, 1992)
2. Demonstrate population viability at recovery levels for 10 consecutive years. (USFWS, 1992)

**Recovery Actions:**

- Protect populations from present and future threats. (USFWS, 1992)
- Establish a reserve seed bank and cultivated population. (USFWS, 1992)
- Gather biological data necessary for management decisions. (USFWS, 1992)
- Search for new populations. (USFWS, 1992)
- Develop plans for reintroducing plants into suitable habitat. (USFWS, 1992)
- Determine exact habitat requirements. (USFWS, 2009)
- Develop a model, based on soil types and other appropriate habitat attributes for Hinckley oak, to predict areas of potentially suitable habitat and then survey those areas for the species. (USFWS, 2009)
- Establish a reserve germ bank/cultivated population with a responsible agency/institution. (USFWS, 2009)
- Evaluate present conditions and determine stability requirements for populations. (USFWS, 2009)
- Assess incidence of (and potential threat from) hybridization with nearby oak (*Quercus*) species and develop management strategies to address any threats associated with hybridization. (USFWS, 2009)
- Assess potential threats to the species associated with climate change and develop management strategies to address these threats. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Survey potential habitats on accessible lands in Presidio, Brewster, and adjacent counties (recovery plan action 41), as well as in Areas Naturales

Protegidas and Parques Nacionales in the Mexican states of Coahuila and Chihuahua. 2. Monitor condition of existing populations periodically, and conduct complete censuses approximately every 5 years (recovery plan action 15). Protect known hybrid individuals to conserve additional *Quercus hinckleyi* genetic diversity (Backs et al. 2016). Map individual clones to aid conservation of unique genotypes (Backs et al. 2015). 3. Support efforts to propagate, by seeds as well as cuttings or micropropagation, for augmentation, reintroduction, and ex-situ conservation (recovery plan actions 3211, 3212, and 334). Attempt hand pollination to maximize outcrossing and conserve unique genotypes (Backs et al. 2015). 4. Establish a germ plasm bank (refugium of live plants) for ex-situ conservation of as many of the species' unique genotypes as possible. Note that white oak acorns lose viability rapidly in storage; hence, seed banking is not a viable option. (Recovery plan action 2; Beckman et al. 2019). 5. Develop an augmentation and reintroduction program to increase size and genetic diversity of individual populations and to increase the number of populations (recovery plan action 42, 5, 6; Backs et al. 2015). 6. Conduct public outreach to promote public support for the species conservation (recovery plan action 7). 7. When possible, given workloads, conduct a Species Status Assessment (SSA), and use the SSA to revise the recovery plan. Establish recovery criteria that quantify the levels of resilience, redundancy, and ecological and genetic representation necessary for long-term species viability. Explain how each criterion and time frame was derived, how populations and metapopulations should be delimited, specify whether individuals may be ramets, genets, or both, and clarify whether sexual reproduction means simply the production of viable acorns or actual recruitment from acorns. Revise the reproduction and recruitment time frame to reflect realistic patterns observed in woody plants of the Chihuahuan Desert. Clarify that the species' recovery can include populations in Mexico, if any are discovered. (USFWS, 2020)

## SPECIES ACCOUNT: *Ranunculus aestivalis* (= *acriformis*) (Autumn Buttercup)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 07/21/1989; Mountain-Prairie Region (R6) (USFWS, 2016)

### Physical Description

A perennial herb, 3-6 dm tall that bears 6-10 bright yellow flowers, usually high above most of the deeply divided leaves. The late summer-early fall flowering season gives the plant its common name. A recent study by Van Buren et al. (1994) concluded that this is a distinct species, rather than a variety of *R. acriformis*. The taxon is probably a relict of the moister Pleistocene Era and is now severely limited to the little suitable habitat remaining in what is now a semi-arid region. (NatureServe, 2015)

### Taxonomy

The phylogenetic relationship of the autumn buttercup with closely related taxa has been studied since the completion of the Recovery Plan, but its taxonomic treatment continues to be disputed. The autumn buttercup was recommended to be a separate species based upon a genetic analysis of molecular markers that showed a clear separation of the autumn buttercup from other varieties of *Ranunculus acriformis* (Van Buren 1994; Van Buren et al. 1994). Environmental characteristics of the occupied habitat also clearly separated autumn buttercup habitat from habitat occupied by closely related taxa (Van Buren and Harper 1996); however, morphological characteristics were not so clear (Van Buren 1994). Due to genetic separation, Van Buren et al. (1994) recommended reclassifying the variety *R. acriformis* var. *aestivalis* to a full species *R. aestivalis*. A taxonomic review was later published in 1997 in the Flora of North America, and the author retained the varietal rank of *R. acriformis* var. *aestivalis* (Whittemore and Parfitt 1997). It must be noted that the author states it was his preference to retain the varietal rank and that the molecular results of Van Buren et al. "are consistent with either interpretation." The 4th edition of A Utah Flora, published in 2008, disagrees with both treatments, and considers it a variety of *R. acris* based upon morphological characteristics (Welsh et al. 2008). The latest taxonomic review was published in 2012 for the Intermountain Flora, and the authors accepted the species rank, *R. aestivalis*, recommended by Van Buren et al. (Holmgren et al. 2012). Two online plant databases accept the species rank, *R. aestivalis*, the USDA PLANTS Database (USDA PLANTS Database 2012) and The Biota of North America Program (Kartesz 2011). Given the recent taxonomic evaluation which accepts the autumn buttercup as a valid species rank, we recommend updating the synonymy (same identity) of *R. acriformis* var. *aestivalis* = *R. aestivalis* and find this taxonomic change does not affect the listing or protection of the autumn buttercup under the Act. The recovery priority number will change from 6 to 5 when the full species rank is accepted. We recommend the taxonomy be amended through a technical revision to the list at 50 CFR 17.12 (see section 4). We also will formally request the name be changed in ITIS database. Until the name can be changed in the Federal Register, we will continue to refer to this species as *R. acriformis* var. *aestivalis* (USFWS, 2013).

### Current Range

"The autumn buttercup is probably the rarest and most restricted plant in Utah. Marcus E. Jones first collected it during 1894 in a wet meadow near Panguitch, 38 km northwest of Bryce Canyon

National Park. Named for its late-summer flowering habit, the autumn buttercup was not formally described until 1948. It is among the most graceful and showy members of the genus in the western United States." (Spence, Van Pelt and Franklin 1991: 1). The General Federation of Womens Clubs Sevier River Valley Preserve was purchased in 1989 to protect the only known buttercup plants in the wild, chiefly through exclusion of livestock grazing. The Great Basin Field Office is responsible for stewardship of the 44-acre property. GENERAL ELEMENT OCCURRENCE LOCATION INFORMATION. *R. acriformis* var. *aestivalis*'s only known occurrence is in Garfield County, Utah. Due to the sensitivity of the site, directions may be obtained by contacting the Utah land steward of the Conservancy in Salt Lake City.

**Critical Habitat Designated**

No;

***Life History*****Food/Nutrient Resources****Reproductive Strategy**

Adult: Wind and insect pollinated (NatureServe, 2015)

**Lifespan**

Adult: Life expectancy of *R. acris* is about 3.8 years (NatureServe, 2015).

**Breeding Season**

Adult: Vegetative plants and reproductive plants with buds, flowers, fruits, or dehiscent achenes have all been observed between late August and early September. During this same time period, well-developed seedlings, with up to several leaves, have also been surveyed (Mutz 1984) and counted (Spence 1991) (NatureServe, 2015).

**Reproduction Narrative**

Adult: Phenotypic Patterns: *R. acriformis* var. *aestivalis* appears to reproduce sexually. To date, the only field observations have been in late summer or early fall. Vegetative plants and reproductive plants with buds, flowers, fruits, or dehiscent achenes have all been observed between late August and early September. During this same time period, well-developed seedlings, with up to several leaves, have also been surveyed (Mutz 1984) and counted (Spence 1991). The riparian environment may be instrumental in extending the bloom for this population; however, it is still curious that autumn buttercup blooms as late as it does (late July to early October). Its closest relatives flower in June and July. Floral initiation does not apparently occur in the first year of life. The age at which it does occur is unknown (Mutz 1984). According to Sarukhan and Harper (1973) the life expectancy of *R. acris* is about 3.8 years. The autumn buttercup is similar to this species in many respects. The *Ranunculus* genus includes species which reproduce through self-fertilization, out-crossing, and apomixis. To date, autumn buttercup has not exhibited any observed asexual reproductive strategies (Mutz 1984). Pollination: Pollination mechanisms for autumn buttercup probably include wind and insects. The only documented pollinators are unidentified bees, and various flies and moths (Schelz, personal communication). Ants inhabit several mounds in the area, but none have been observed on the flowers (Mutz 1984). Harper (1957) reports that the flowers of *Ranunculus* are visited by a great number of insect species including the honey bee. Seed Dispersal: Mutz (1984)

speculates that autumn buttercup's seeds dehisce independently, since both partially bare and completely bare receptacles have been observed (NatureServe, 2015). Seed Biology: Germination Strategies. Nothing of significance is known about autumn buttercup's seed longevity, dormancy, viability, germination, or seedling establishment and maintenance requirements. However, Sarukhan's (1974) study of *Ranunculus acris*, a closely related plant with very similar environmental requirements, indicate that the seeds may be depleted by the next seed producing season. In his study, after predation and germination had occurred *R. acris* showed a reduction of c. 90% in the living seed population. Leck (1989) indicates that wetland seed banks typically contain seed with one of four germination strategies. Types 1 and 2 are represented by large seed output with total volumes greater than 10 cubic mm. Type 3 is represented by seed with total volumes greater than 1 cubic mm and less than 10 cubic mm. The majority of Type 3 seed, in a wetland seed bank, is a transient component with a relatively smaller persistent component. The fourth germination strategy is represented by seed with a seed volume less than 0.1 cubic mm. These seeds provide a relatively large persistent seed bank with little annual recruitment. Type 4 seeds are more abundant in subsurface than surface samples (Leck 1989). *R. acrifolius* var. *aestivalis* seed can therefore be classified as either Type 2 or Type 3. England (1990) feels its seed volume is greater than 10 cubic mm and would therefore be Type 2. Type 2 seeds typically function as transient winter or summer seed bank components (Leck 1989). If, however, autumn buttercup's seed strategy is similar to that of Type 3, Leck's (1989) observations from studies of both Type 3 and Type 4 strategies could be useful. Seed distribution and establishment: Wetland seed bank studies revealed that seeds in bogs, swamps, and prairie marshes were deeply buried, with only 20 to 50 percent occurring in the top 5 cm (Leck 1989). Leck (1989) further states that seed distribution patterns are primarily related to variations in seed rain; that variable soil compression, seed survival, and seed bank strategies may also be related to distribution patterns; and that graminoids typically comprise more than 50 percent of seed in wetland seed banks. Seed ecology: Seedlings have been observed in small vegetative openings in friable soil on the mounds. The increased available light and solar radiation might be conducive for seed germination and seedling establishment in these clearings. However, unobserved seedlings may also be present but difficult to locate in more densely vegetated localities (NatureServe, 2015).

**Habitat Type**

Adult: Seeps/bogs (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Seeps/bogs

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (NatureServe, 2015)

**Site Fidelity**

Adult: High (NatureServe, 2015)

**Habitat Narrative**

Adult: Species is found in the Sevier River Valley, where fresh water seeps and springs surface, creating marshy or bog-like conditions. Within this wet environment, are slightly drier, peaty hummocks upon which most of the plants grow. In addition, plants have been found on a somewhat drier site not associated with hummocks. The surrounding region is semi-arid and sagebrush-dominated. The elevation is 1938-1965 m. BIOLOGICAL HABITAT: The autumn buttercup has only been found along the west slope of the Sevier River Valley where fresh water seeps and springs surface and create marsh\ bog conditions. Within this marshy environment are mesic islands of peaty hummocks upon which most of the autumn buttercups grow. However, in 1990 about 30 plants were found together on a drier site that does not contain the mounds. Spence (1991) provides a detailed, current description of the habitat at the more recently discovered site. The biological habitat is a low growing herbaceous community. It is characterized by the dominant species, *Juncus articus* var. *balticus* (Spence 1991). Forb-dominated mounds occur throughout the marsh, and the inter-mound areas are primarily graminoid. *R. acriformis* var. *aestivalis*'s frequently associated species are *Achillea millefolium* (infrequently found elsewhere in the studied area), *Juncus articus* var. *Balticus*, *Carex nebrascensis*, *Aster occidentalis*, *Plantago eriopoda*, *Glaux maritima*, *Trifolium* spp., *Carex aquatilis*, *Hordeum Jubatum* (Mutz 1984), *Dodecatheon* spp., and *Eleocharis* spp. (USFWS 1992). In addition, moss is frequently found between plants. Other forb-dominated mounds occur throughout the meadow which appear comparable to autumn buttercup's habitat, except that some of the inter-mound areas are persistently pooled with water. *R. cymbalaria*, an aquatic species, replaces *R. acriformis* var. *aestivalis* on these more saturated mounds (Mutz 1984). PHYSICAL HABITAT Climate: The dry semi-arid climate has an average annual temperature of 64.4 degrees F. This middle latitude, cold desert has a growing season of about 100 days. The mean January temperature for Panguitch is 23.5 degrees F and the mean July temperature is 64.6 degrees F. Recorded August temperatures range from 44.7 to 83.0 degrees F, September temperatures range from 38.8 to 76.9 degrees F, and October temperatures are between 27.8 and 60.1 degrees F (Mutz 1984). The regional climatological data also indicates 9.9 inches annual precipitation for Panguitch (6625 feet elevation) most of which (70%) is received between April and September (Mutz 1984). Air and Water Quality. Field tests indicate good quality water present at the site (Mutz 1984). The pH was tested at 7.6. There was less than 0.2 gm/l iron, and the moderate hardness of 395 mg/l is probably due to calcium. Mutz (1984) speculates that additional mounds which are similar to autumn buttercup in wetness may differ in water quality. The water originates from seeps and springs both on and off of the western edge of the property near the highway. The direction of water flow from the various sources is northeast through the wet areas of the preserve (Baird 1988). Since there is little traffic and no major industrial polluters in the area, the air quality is also presumed good (Mutz 1984). Topography and Physiography: The autumn buttercup habitat occurs in a transition zone between a well-developed, *Carex*-dominated bog community and a dry upland sagebrush area (USFWS 1992). The Sevier River Valley bottom is Quaternary alluvium which supports sagebrush communities as close as 24 yards from the river (Mutz 1984). Multiple springs occur along the river valley, and it is speculated that mesic areas near these springs could provide suitable habitat for the autumn buttercup (Baird 1988). Observations of the habitat indicate as much as 100% vegetation coverage (little rock or wood cover), a friable soil surface (perhaps a key factor in seed germination), and underlying sandy or gravelly layers which may be indicative of active stream beds of the past (Mutz 1984). Slope: The two known populations are located on a very gentle east-facing slope above the bottom of the Sevier River Valley. The plants and the

hummocks have various subtle exposures, but the general relief of autumn buttercup's habitat is relatively flat. Because the topography is rather level, the extant population has full exposure to the sun and wind throughout the growing season. Substrate: The peaty hummocks are about seven inches high, less than two feet in diameter, and probably are a result of long-term habitat alteration by livestock grazing. The soil is compacted between them. Near the base of these little hummocks is a band of lighter brown, loamy soil, approximately two inches thick (Mutz 1984). The knoll upon which the hummocks occur at one population may be a result of a raised peat bog uplifted by the up-welling waters of the surrounding spring (England 1989a). Schelz (personal communication) questions whether the uplifting action of the extensive vole and/or ant activity in the area may be the source of the mounds. The soil's composition is a very dark, clay loam which is high in organic matter (Spence 1991). The roots of the plants can reach up to and beyond 17 inches. The soil ranges from dry to saturated, and the low area surrounding the plants is not generally pooled with water, unlike the mounds which support *R. cymbalaria*. The absence of the autumn buttercups on these comparable forb-dominated mounds in more boggy areas may infer that a mesic soil is preferable to a constantly wet one (Mutz 1984). To date, there has been no known technical soil analysis, nor government soil surveys, conducted on the extant population's substrate. Spence (1991) lacked time and funds for a survey, and wished to minimize disturbance (NatureServe, 2015). High ecological of the community and site fidelity as well as low tolerance ranges are based on the specific habitat needs of the species and the need for a relatively pristine habitat (no grazing/trampling).

### ***Dispersal/Migration***

#### **Dispersal**

Adult: Wind/water/livestock (NatureServe, 2015)

#### **Dispersal/Migration Narrative**

Adult: Dispersal mechanisms are presumed to be wind, which can effectively whip the long pedicels; water, which can only transport the seed short distances due to its slow movement in the bog; and possibly livestock, through consumption and defecation of viable seeds (Mutz 1984). With *Ranunculus acris*, many seeds are eaten by birds but it is doubtful if much of this is still viable when voided (Harper, 1957) (NatureServe, 2015).

### ***Population Information and Trends***

#### **Population Trends:**

Unknown

#### **Number of Populations:**

1 - 5 (NatureServe, 2015)

#### **Population Narrative:**

Two known occurrences. Additional but as-yet unsurveyed potential habitat exists. (NatureServe, 2015). POPULATION TRENDS Summary: *Ranunculus acrifomis* var. *aestivalis* developed over the eons with two vital conditions that it seemingly requires for survival. The first is the historic availability of fresh water seeps and springs and the resulting marsh/bog habitat that was always there along the Sevier river (this water is what drives the whole system for the autumn buttercup). The second is the lack of intensive grazing by large animals such as

cows and horses. When white people moved into the area these two vital conditions disappeared. Settlers immediately diverted the water from the seeps and springs to ponds and irrigation ditches, effectively changing the habitat drastically. And, they unleashed untold numbers of large domestic grazing animals into the area. Thus the autumn buttercup was getting hit from both ends; no suitable habitat for its roots to sink into and draw nourishment, and constant flower and stem decapitation by the grazers (NatureServe, 2015). Low representation, resiliency and redundancy are based on the low number of known populations and individuals.

### ***Threats and Stressors***

**Stressor:** Livestock grazing (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals/habitat degradation

**Narrative:** We assign a high overall threat level for livestock grazing practices at the present time, not because grazing and trampling are inherently detrimental to autumn buttercup, but because an appropriate grazing regime is not currently implemented on the Preserve and we do not have sufficient population trend data to assess the suitability of the grazing regime at the Dale Ranch population. We will re-evaluate this threat level when we have more information regarding appropriate grazing practices (USFWS, 2013).

**Stressor:** Water Diversion for Agricultural Development (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** We do not have data on the hydrology of the wet meadow on the Preserve and no documentation to suggest the spring is affected by nearby agricultural water use. If water development commences in the future that may affect the autumn buttercup populations, or we have hydrologic data which suggests agricultural water use is affecting autumn buttercup habitat, we will re-evaluate the degree of threat this poses to the species (USFWS, 2013).

**Stressor:** Development of Buildings and Structures in Habitat (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** In the Recovery Plan, we identified construction of corrals and outbuildings associated with agricultural land use to be a threat to the autumn buttercup. We believed that structures would lead to an increased use of the immediate area around them and would likely degrade the wet meadow habitat. However, there have been no corrals or outbuildings built within the known habitat for the two extant populations. There is no concern of these structures being built on the Preserve, and there are no new structures on the Dale Ranch property. Given the high water table and periodic flooding that occurs in the wet meadows, it is unlikely that large structures will be built on the habitat. Therefore, we no longer believe this to be a threat because this threat is presently not occurring, nor has it occurred in the past 21 years. However, if future development does occur, we will re-evaluate the degree of threat this poses to the species (USFWS, 2013).

**Stressor:** Invasive Species (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Invasive species were not considered a threat to autumn buttercup in the Recovery Plan. However, in the years following livestock removal from the Preserve, a noxious weed, Scotch thistle (*Onopordum acanthium*) increased ten-fold and completely occupied some areas where autumn buttercup originally occurred (Spence 1996). The Nature Conservancy developed a weed management plan and began controlling the Scotch thistle in 1995 and the spread of Scotch thistle continues to be controlled as per their weed management plan (TNC 1995). Scotch thistle was not documented to be a threat to autumn buttercup on the Dale Ranch (USFWS 2011; USFWS 2012). We conclude that invasive species are a low threat since weeds are being controlled on the Preserve, and are negligible on Dale Ranch. The intensity of this threat is presently low as well and the exposure of this threat is low (USFWS, 2013).

**Stressor:** Predation (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Herbivory occurs at high intensity levels at one of the two extant populations. Small rodents may have devastating consequences for individual plants and populations. Therefore, we conclude the threat posed by small mammal herbivory is high, and is greater than previously assessed (USFWS, 2013).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** In summary, prior to listing, autumn buttercup had no significant State or Federal protections. Under the Act's protection, a review of Federal actions potentially impacting the species can be performed. Because the species occurs on private land, two of the three high threats to the species cannot be addressed by regulatory mechanisms (small mammal herbivory and inappropriate grazing practices). As documented in section 2.3.2.5, climate change is a high threat to the species that can be addressed by regulatory mechanisms, but the Clean Air Act of 1970 presently does not regulate greenhouse gas emission levels. We assign an overall threat level to this factor as high because climate change is a high threat to the species and is not adequately addressed by the existing Federal regulatory mechanisms (USFWS, 2013).

**Stressor:** Vulnerability due to Small Population Sizes (USFWs, 2013)

**Exposure:**

**Response:**

**Consequence:** Extinction

**Narrative:** The threat posed by small population size and small range of autumn buttercup is high when evaluated cumulatively with small mammal herbivory, invasive weed species, and climate change. We have attempted to alleviate this threat through three separate reintroduction efforts (see section 2.2.3.(6) after acknowledging that the greatest impediment to recovery was small population size (USFWS 2007)). However, these reintroduction efforts have not been successful (USFWS, 2013).

**Stressor:** Lack of Scientific Knowledge/Monitoring (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The lack of scientific knowledge to identify the meaningful threats contributing to the population decline of autumn buttercup has caused the species to be managed ineffectively. While not a threat in and of itself, lack of scientific knowledge and monitoring information affects our ability to manage and recover the species. We acknowledge the complexity of biotic interactions directly and indirectly affecting autumn buttercup. We could promote population growth on the Preserve if we could better quantify the threats the species faces and better understood how the threats could be alleviated. We consider this factor to have a high level of impact to the species because we believe that beneficial management is crucial to preventing the extinction of autumn buttercup by providing the essential ecological processes necessary to recover the species (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Our current understanding is that the habitat of autumn buttercup was sensitive to historic climate change in the region, and the restricted range of the species can be explained by the prolonged period of aridity during the Holocene post-glacial epoch (12,000 years before present). Autumn buttercup has not been able to maintain a large range or robust population under current climate conditions, and therefore does not appear to have the adaptive capacity (Glick et al. 2011; Dawson et al. 2011) to adjust to a future climate change scenario of prolonged arid conditions. Extinction risk from climate change is predicted to be higher for species such as autumn buttercup with small ranges, particularly for those species whose current distributions are constrained by climate variables (Schwartz et al. 2006). We conclude that autumn buttercup is vulnerable to climate change, and that the threat of climate change to autumn buttercup is high, mainly due to the range-wide scope, the imminent and future immediacy, and the high exposure of the threat. There are uncertainties in our threat evaluation since downscaled climate projections are not available for our specific location and aquifer, and a vulnerability assessment has not been performed for autumn buttercup. We will re-assess the degree of threat climate change poses on autumn buttercup when more information becomes available (USFWS, 2013).

## ***Recovery***

### **Reclassification Criteria:**

Reclassification criteria have not been established.

### **Delisting Criteria:**

The amended delisting criteria include the following: 1. Maintain the TNC population and at least three introduced populations at a level that demonstrates an increasing trend in the 5-year mean (average) adult plant abundance over a consecutive ten-year period. Adult plant abundance may fluctuate on an annual basis, but the defined populations should have an increasing 5-year mean over the ten year time period. Maintain the Junction population at a level that demonstrates a stable trend in the 5-year mean (average) adult plant abundance over

a consecutive ten-year period. Adult plant abundance may fluctuate on an annual basis, but the defined populations should have a stable 5-year mean over the ten-year time period. 2. Maintain an estimated range-wide total population size at or greater than 20,000 adult plants over a five year minimum period. This population estimate is based on the mean adult plant abundance measure identified in criterion 1, above. 3. The three introduced populations collectively demonstrate 80 percent of the genetic variation of the two natural populations over a minimum of five generations (a consecutive ten-year period). Genetic variation (measured as the number and frequency of unique alleles within a population) is anticipated to vary from year-to-year, but we expect this measure will provide a meaningful evaluation of population-level genetic diversity over time. 4. Long-term habitat protections and habitat management plans are in place for the five populations to protect autumn buttercup habitat and manage for habitat suitability, livestock grazing, small mammal herbivory, and other potential threats. Habitat protection on private and Federal lands can be achieved via fee acquisition, land trades, conservation easement, or long-term management agreements. Habitat management plans should include site-specific measures to address the maintenance of suitable habitat, herbivory, and weed control to improve plant establishment and minimize threats in occupied habitat. Consideration of the water source(s) and hydrologic regime should be included in habitat protections and management plans to the extent practicable. Management plans for spring-fed water sources likely need contingency plans for supplemental water during low-flow periods. The combination of habitat protection, maintenance of suitable habitat, and threat minimization will support increasing trends in adult plant abundance and population resiliency, as we state in criterion 1. 5. The two natural populations (TNC and Junction) are represented in an ex-situ seed collection that is managed according to the Center for Plant Conservation guidelines (Guerrant et al 2004). The ex-situ seed collection should contain existing levels of genetic diversity (or representation) of the two populations. (USFWS, 2020)

**Recovery Actions:**

- Taxonomy: We recommend revising the species' taxonomy in the Federal Register to reflect the best available scientific information (USFWS, 2013).
- Taxonomy: We recommend formally requesting the name be changed in the ITIS plant database (USFWS, 2013).
- Surveys: We recommend the Utah Heritage Program identify potential habitat and survey for autumn buttercup (USFWS, 2013).
- Research & Monitoring: We recommend that qualified scientists monitor and evaluate threats to autumn buttercup in conjunction with population monitoring of both extant and reintroduced autumn buttercup plants on the Preserve (USFWS, 2013).
- Research & Monitoring: Since there is a complex web of processes that occur within grazed wet meadow habitat (small mammal herbivory, vegetative competition, livestock trampling, weed suppression, litter removal), we recommend qualified scientists assess the relative importance of each process with regard to autumn buttercup abundance and distribution on the Preserve (USFWS, 2013).
- Research & Monitoring: We recommend qualified scientists assess whether small mammal herbivory is reduced when livestock grazing is reintroduced and to monitor their population levels in tandem with the autumn buttercup on the Preserve. We recommend the scientists identify measures to reduce small mammal populations and that The Nature Conservancy implement these measures on the Preserve at least in the near-term to reduce the threat of herbivory and encourage the recovery of autumn buttercup (USFWS, 2013).

- Research & Monitoring: We recommend initiating discussions with landowners about land use practices (stocking rates and seasonality of grazing) the ranchers believe would benefit the autumn buttercup (USFWS, 2013).
- Research & Monitoring: We recommend qualified scientists reinitiate a multi-year demography study of subpopulations both on the Preserve and other available populations to study survivorship, growth, and reproduction. This study should include a seedbank component to determine seed longevity in soil, and seedling recruitment patterns at different microsites (USFWS, 2013).
- Research & Monitoring: We recommend qualified scientists perform a minimum viable population analysis for the species based upon data collected from the demography study (USFWS, 2013).
- Research & Monitoring: We recommend qualified scientists document the identity and availability of pollinators, and determine the breeding system of autumn buttercup (USFWS, 2013).
- Research & Monitoring: We recommend qualified scientists perform a climate change vulnerability assessment of autumn buttercup (USFWS, 2013).
- Research & Monitoring: We recommend qualified scientists implement long-term monitoring of the hydrology in the wet meadow habitat on the Preserve to document water table fluctuations on a regular basis (USFWS, 2013).
- Research & Monitoring: We recommend The Arboretum at Flagstaff, or another qualified and permitted botanic garden, assess the drought tolerance and plant response to drought by evaluating plant establishment, growth and reproduction of autumn buttercup under different water regimes in a greenhouse setting (USFWS, 2013).
- Ex-situ Conservation: We recommend The Arboretum at Flagstaff, or another qualified and permitted botanic garden, collect seed annually of wild (not reintroduced) autumn buttercup plants (USFWS, 2013).
- Administrative Actions: We recommend the USFWS host an annual workshop to prioritize, assess, and fulfill recovery actions (USFWS, 2013).
- Administrative Actions: Once we have new survey and research data, we recommend that the USFWS revise the Recovery Plan to explicitly address the relevant listing factors. The number of plants and populations referenced in the current recovery plan that are required for long-term viability of autumn buttercup are unsupported by our current understanding of the population status. The revised Recovery Plan will include objective, measurable criteria which, when met, will result in a determination that the species be removed from the Federal List of Endangered and Threatened Plants. The Recovery Plan also will estimate the time required and cost to carry out those measures needed to achieve the goal for recovery and delisting (USFWS, 2013).
- Administrative Actions: We recommend that the USFWS support autumn buttercup recovery by providing personnel and fiscal resources yearly to implement recovery actions (USFWS, 2013).
- Administrative Actions: We recommend that the USFWS and The Nature Conservancy write a management plan for the Preserve (USFWS, 2013).

***Conservation Measures and Best Management Practices:***

- Recommended future actions: Based on recent discussions with conservation partners, we recommend implementing another plant reintroduction on TNC lands, securing habitat protection for private lands in the Junction population, managing for genetic diversity, and evaluating suitable

habitat followed by pilot introductions on BLM lands in the upper Sevier River drainage, the East Fork Sevier River drainage, and near Otter Creek (USFWS 2019). The suite of recommended future actions identified in the previous 5-year review still provides the full list of recommendations until more species-specific life history information is identified (USFWS 2013). (USFWS, 2020)

## SPECIES ACCOUNT: *Remya mauiensis* (Maui remya)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 01/14/1991; Pacific Region (R1) (USFWS, 2016)

#### **Physical Description**

A sprawling, many-branched shrub 1 - 2 m tall, forming loosely tangled clumps that sprawl on or among the branches of other vegetation. The flower heads are dark yellow (NatureServe, 2015).

#### **Taxonomy**

A member of the sunflower family (Asteraceae) (USFWS, 2016). The genus is endemic to Maui & Kauai, this species is restricted to west Maui (NatureServe, 2015).

#### **Historical Range**

It is known from west Maui (Wagner et al. 1999m, p. 353). Historically, this species also occurred in Maui's lowland wet ecosystem (TNC 2007; HBMP 2010) (USFWS, 2016).

#### **Current Range**

Current range includes West Maui (NatureServe, 2015). It occurs in Kauaula, Puehuhunui, Ukumehame, Papalaua, Pohakea, and Manawainui (USFWS 2012; 2014).

#### **Critical Habitat Designated**

Yes; 5/14/2003.

#### **Legal Description**

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Remya mauiensis* (Maui remya) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 18 detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

#### **Critical Habitat Designation**

The critical habitat designation for *Remya mauiensis* includes 18 CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Dry—Unit 5 consists of 3,615 ac (1,463 ha) of State land, and 43 ac (17 ha) of privately owned land, from Panaewa to Manawainui on the western and southern slopes of west Maui. This unit is occupied by the plants *Asplenium dielirectum*, *Bidens campylotheca* ssp. pentamera, *Cenchrus agrimonioides*, *Gouania hillebrandii*, *Kadua coriacea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and *Tetramolopium capillare*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 5 is not known to be occupied by *Ctenitis squamigera*, *Cyanea obtusa*, *Hesperomannia arbuscula*, *Hibiscus brackenridgei*, *Lysimachia lydgatei*, *Neraudia sericea*, *Schiedea salicaria*, *Sesbania tomentosa*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry

species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 6 consists of 3 ac (1 ha) of State land, and 237 ac (96 ha) of privately owned land, from Paleaahu Gulch to Puu Hona on the southern slopes of west Maui. This unit is occupied by the plants *Hibiscus brackenridgei* and *Schiedea salicaria*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 6 is not known to be occupied by *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonoides*, *Ctenitis squamigera*, *Cyanea obtusa*, *Gouania hillebrandii*, *Hesperomannia arbuscula*, *Kadua coriacea*, *Lysimachia lydgatei*, *Neraudia sericea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Spermolepis hawaiiensis*, *Tetramolopium capillare*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Mesic—Unit 2 consists of 1,034 ac (419 ha) of State land, and 113 ac (46 ha) of privately owned land, from Honokohau to Launiupoko on the western slopes of west Maui. This unit is occupied by the plants *Ctenitis squamigera*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, and *Zanthoxylum hawaiiense*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Mesic—Unit 2 is not known to be occupied by *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, or *Colubrina oppositifolia*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within its historical range. Due to its small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could approach recovery.

Maui—Lowland Mesic—Unit 3 (and) *Palmeria dolei*—Unit 1—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 1—Lowland Mesic This area consists of 477 ac (193 ha) of State land at Ukumehame on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). Although Maui—Lowland Mesic—Unit 3 is not currently occupied by the plants *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Zanthoxylum hawaiiense*, or by the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs for the reestablishment of wild populations within the historical ranges of the

species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 2 (and) *Palmeria dolei*—Unit 3—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 3— Lowland Wet (and) *Newcombia cumingi*—Unit 1—Lowland Wet This area consists of 65 ac (26 ha) of State land at Moomoku, on the northwestern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. Although Maui—Lowland Wet—Unit 2 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), or by the Newcomb's tree snail (*Newcombia cumingi*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 3 (and) *Palmeria dolei*—Unit 4—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 4— Lowland Wet This area consists of 1,247 ac (505 ha) of State land at Honanana Gulch on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta*, *Cyanea asplenifolia*, and *Pteris lidgatei*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 3 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 4 (and) *Palmeria dolei*—Unit 5—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 5— Lowland Wet This area consists of 864 ac (350 ha) of State land at Kahakuloa Valley on the northeastern slopes of west Maui. These units include the mixed

herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta* and *Cyanea asplenifolia*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 4 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 5 (and) *Palmeria dolei*—Unit 6—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 6—Lowland Wet This area consists of 30 ac (12 ha) of State land at Iao Valley on the eastern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 5 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 6 (and) *Palmeria dolei*—Unit 7—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 7—Lowland Wet This area consists of 136 ac (55 ha) of State land at Honokowai and Wahikuli valleys on the western slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 6 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia*

arborescens, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwiku (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 7 (and) *Palmeria dolei*—Unit 8—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 8—Lowland Wet This area consists of 898 ac (364 ha) of State land at Olowalu Valley, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Alectryon macrococcus*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 7 is not currently occupied by the plants *Asplenium dielarectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwiku (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 8 (and) *Palmeria dolei*—Unit 9—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 9—Lowland Wet This area consists of 230 ac (93 ha) of State land at upper Ukumehame Gulch, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 8 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielarectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwiku (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 2 (and) *Palmeria dolei*—Unit 19—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 19— Montane Mesic This area consists of 124 ac (50 ha) of State land at Helu and the upper reaches of Puehuhunui on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Lysimachia lydgatei*, *Remya mauiensis*, and *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 2 is not known to be occupied by the plants *Geranium hillebrandii*, *Huperzia mannii*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 3 (and) *Palmeria dolei*—Unit 20—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 20— Montane Mesic This area consists of 174 ac (70 ha) of State land at Lihau on the southwestern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plant *Geranium hillebrandii*, and contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 3 is not known to be occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Huperzia mannii*, *Lysimachia lydgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 4 (and) *Palmeria dolei*—Unit 21—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 21— Montane Mesic This area consists of 72 ac (29 ha) of State land at Halepohaku on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). Although Maui—Montane Mesic—Unit 4 is not known to be occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Geranium hillebrandii*, *Huperzia mannii*, *Lysimachia lydgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their

small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 5 (and) *Palmeria dolei*—Unit 22—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 22— Montane Mesic This area consists of 170 ac (69 ha) of State land at the upper reaches of Manawainui Gulch on the southeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Remya mauiensis* and *Santalum haleakalae* var. *lanaiense*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 5 is not known to be occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Geranium hillebrandii*, *Huperzia mannii*, *Lysimachia lydgatei*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 6 (and) *Palmeria dolei*—Unit 35—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 35— Wet Cliff This area consists of 1,858 ac (752 ha) of State land, and 253 ac (102 ha) of privately owned land, at the summit ridges of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). They are occupied by the plants *Alectryon macrococcus*, *B. conjuncta*, *Ctenitis squamigera*, *Cyrtandra munroi*, *Remya mauiensis*, and *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 6 is not known to be occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Bonamia menziesii*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyriformium*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, or *Tetramolopium capillare*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 7 (and) *Palmeria dolei*—Unit 36—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 36— Wet Cliff This area consists of 556 ac (225 ha) of State land along Honokowai ridge on the northwestern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units are occupied by the plants *Cyrtandra filipes* and *C. munroi*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the

expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 7 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 8 consists of 337 ac (137 ha) of State land along Kahakuloa ridge on the north side of west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Maui—Wet Cliff—Unit 8 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Remya mauiensis* critical habitat consists of five components. Lowland dry (west Maui), Lowland mesic (west Maui), Lowland wet (west Maui), Montane mesic (west Maui) and Wet cliff (west Maui) (81 FR 17790-18110):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*. Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psydrax*, *Scaevola*, *Wikstroemia*. Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Sicyos*.

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freyinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy:

Antidesma, Metrosideros, Myrsine, Pisonia, Psychotria. Subcanopy: Cibotium, Claoxylon, Kadua, Melicope. Understory: Alyxia, Cyrtandra, Dicranopteris, Diplazium, Machaerina, Microlepidia.

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: Acacia, Ilex, Metrosideros, Myrsine, Nestegis, Nothocestrum, Pisonia, Pittosporum, Psychotria, Sophora, Zanthoxylum. Subcanopy: Alyxia, Charpentiera, Coprosma, Dodonaea, Kadua, Labordia, Leptecophylla, Phyllostegia, Vaccinium. Understory: Ferns, Carex, Peperomia.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: Broussaisia, Cheirodendron, Leptecophylla, Metrosideros. Understory: Bryophytes, Ferns, Coprosma, Dubautia, Kadua, Peperomia.

### Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire,

drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

### ***Life History***

### **Food/Nutrient Resources**

### **Lifespan**

Adult: < 10 years (USFWS, 2010)

**Reproduction Narrative**

Adult: It is a short-lived perennial (fewer than 10 years) (USFWS, 2014).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Moist forests (NatureServe, 2015); mixed mesophytic forests (USFWS, 1997)

**Geographic or Habitat Restraints or Barriers**

Adult: 2,790 - 4,100 ft. elevation (USFWS, 1997)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS 2016; 1997)

**Habitat Narrative**

Adult: Inhabits moist forests on gulch slopes (NatureServe, 2015). *Remya mautensis* grows chiefly on steep, north or northeast-facing slopes at 850-1,250 meters (2,790-4,100 feet) elevation and is found primarily in mixed mesophytic forests, or the remnants of such forests (Herbst 1988) (USFWS, 1997). It occurs in the lowland mesic, montane mesic, wet cliff, and lowland dry ecosystems (USFWS, 2016).

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends*****Population Trends:**

Presumed extinct until rediscovery in 1971 (USFWS, 1997)

**Species Trends:**

Increasing (USFWS, 2014)

**Number of Populations:**

~10 (USFWS, 2022)

**Population Size:**

>190 (USFWS, 2022)

**Population Narrative:**

Overall, *Remya mauensis* has increased from 156 individuals reported in the last 5-year review to approximately 500 individuals in 6 locations (USFWS 2012; 2014). The species was thought to be extinct until its rediscovery on the slopes of Manawainui Gulch, West Maui, in 1971 by L.E. Bishop, W. Gagnd, and S. Montgomery (USFWS, 1997). New Status Information: • There are

three populations at one location, Kauaʻula, west Maui, totaling approximately 400 individuals (PEPP 2017; Oppenheimer 2018, in litt.) and one population at Pāpalaua-Manawainui Gulches (undetermined number of individuals) (PEPP 2017). There is no new information regarding the status of populations at Lihau, Pōhākea, and Ukumehame. • In 2016, 18 critical habitat units in five ecosystems (lowland dry, lowland mesic, lowland wet, montane mesic, and wet cliff) were designated on west Maui for *Remya mauiensis* (12,536 ac; 5,074 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018). At the time of the last 5-year review in 2017, there were an estimated 175–335 individuals at an estimated 10 populations. Only two previously known populations have been monitored since, Mākaha and Koaiʻe (Kishida and Perlman 2018; Perlman and Kishida 2017). Currently, the number of individuals at Mākaha remains unchanged; while approximately 15 new individuals were discovered at Koaiʻe (Kishida and Perlman 2018; Perlman and Kishida 2017). Currently, there are at least 190 wild individuals of *Remya kauaiensis* on Kauaʻi (USFWS, 2022)

### ***Threats and Stressors***

**Stressor:** Ungulates (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** It is clear that habitat well-suited for *Remya mautensis* and likely within its former range has been destroyed or degraded by cattle, goats, and pigs, and that the remaining extant individuals are found growing only in areas relatively inaccessible to these animals. Browsing and grazing by feral and domesticated livestock have impacted *Remya mautensis* and its habitat through outright destruction of the plants and secondarily through erosion that results from the loss of vegetation, trampling and rooting by these animals (Herbst 1988) (USFWS, 1997).

**Stressor:** Invasive plants (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Browsing and associated habitat disturbance caused by feral ungulates have favored the invasion and spread of numerous aggressive, alien plant species that may compete for space, light, water, or nutrients. Such alien species have replaced *Remya mautensis* throughout its presumed former habitat (Herbst 1988). Competition from alien plants may also be the reason for the low number of *Remya mautensis* in areas such as Manawainui Plant Sanctuary, where populations have been protected from ungulates (R. Hobdy, personal communication 1995) (USFWS, 1997).

**Stressor:** Invertebrate herbivory (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Not available

**Stressor:** Fire (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** *Remya mautensis* occurs in a fire-prone area (dry much of the year), and is jeopardized with extinction by brush fires set accidentally or intentionally (Herbst 1988) (USFWS, 1997).

**Stressor:** Climate change loss or degradation of habitat

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *Remya mauensis* is extremely vulnerable to the impacts of climate change, with a vulnerability score of 0.889 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, this species has no overlap between current and future climate envelopes, and is unlikely to tolerate expected changes in climate at its current location. This means that this species must persist within suitable microrefugia, or move to newly available climate-compatible areas to avoid extinction. Therefore, additional management actions, including the possibility of assisted translocations, are needed to conserve this taxon into the future (USFWS, 2018)

**Recovery****Reclassification Criteria:**

1. A total of five to seven populations should be documented on Maui and at least one other island where they now occur or occurred historically (USFWS, 1997).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1997).
3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 1997).

Recovery Priority Number: 5

**Delisting Criteria:**

1. A total of 8 to 10 populations should be documented on Maui and at least one other island where they now occur or occurred historically (USFWS, 1997).
2. Each population must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1997).
3. Each population should persist at this level for a minimum of five consecutive years (USFWS, 1997).

**Recovery Actions:**

- Protect current populations, manage threats and monitor (USFWS, 1997).

- Conduct research essential to conservation of the species (USFWS, 1997).
- Expand current populations (USFWS, 1997).
- Establish new populations as needed to reach recovery objectives (USFWS, 1997).
- Validate and revise recovery objectives (USFWS, 1997).
- Evaluate the status of *Remya mauiensis* in the Manawainui Plant Sanctuary enclosure; if warranted, initiate alien plant control (USFWS, 1997).
- Using seeds from existing populations, establish and maintain outplanted populations within the Manawainui Plant Sanctuary enclosure (USFWS, 1997).
- Captive propagation for genetic storage and reintroduction: Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species' vulnerability to climate change (USFWS, 2014).
- Reintroduction / translocation – Augment current natural populations to increase numbers of individuals (USFWS, 2014).
- Ungulate monitoring and control – Fence remaining populations to protect them from the impacts of feral ungulates (USFWS, 2014).
- Invasive plant monitoring and control – Control invasive introduced plant species within the vicinity of all known populations of *R. mauiensis* (USFWS, 2014).
- Population viability monitoring and analysis – Continue monitoring activities for all known populations of *R. mauiensis* (USFWS, 2014).
- Climate change adaptation strategy – Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change (USFWS, 2014).
- Alliance and partnership development – Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon (USFWS, 2014).
- New Management Actions:
  - Surveys and inventories—In 2016, the Plant Extinction Prevention Program (PEPP) noted that additional surveys of known populations on west Maui were needed to determine if elevation to PEPP status (fewer than 50 wild individuals) of this species was necessary (PEPP 2016).
  - Captive propagation for genetic storage and reintroduction—In 2017, Lyon Arboretum Micropropagation Laboratory reported three containers of propagules of *Remya mauiensis* from collections made in 2012 in storage. The Lyon Seed Conservation Laboratory reports over 99,000 seeds in storage from collections representing multiple individuals from populations at Kaua'ula and Pōhākea (Lyon Arboretum 2017).
- Recommendations for Future Actions: We are not aware of any new threats or significant new information regarding the species' biological status since the last 5-year review in 2014. Thus, the following recommendations for future actions are reiterated for 5-year review for 2018.
  - Surveys and inventories—Continue to survey for additional populations of *Remya mauiensis* in areas of potentially suitable habitat on west Maui. Reassess the status of populations at Lihau, Pōhākea, and Ukumehame.
  - Ungulate monitoring and control—Construct enclosure fences to protect currently unfenced populations from the negative impacts of feral pigs, goats, cattle, and axis deer.
  - Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations of *R. mauiensis*.
  - Captive propagation for genetic storage and reintroduction—
    - o Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range.
    - o Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage

due to this species' vulnerability to climate change. • Reintroduction and translocation—Augment known populations and reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. • Climate change adaptation strategy—Research the suitability of habitat for reintroducing this species in the future due to impacts of climate change. • Alliance and partnership development—Work with the West Maui Mountains Watershed Partnership to continue ecosystem-level restoration and management to benefit this species (USFWS, 2018).

***Conservation Measures and Best Management Practices:***

- Recommendations for Future Actions: No significant new information regarding the species' biological status has been reported since the last 5-year review in 2017. Thus, the following recommendations for future actions are reiterated and updated for the 5-year review for 2022. • Surveys and inventories— o The historical range of *Remya kauaiensis* should be surveyed intensively, preferably in Kaua'ula, Honopū, Kalalau, and Mōhihi. o Determine if historical populations are extirpated. o Determine sites that have the highest likelihood of maintaining reintroductions. • Ungulate monitoring and control—Continue to maintain fenced exclosures to protect individuals from the negative impacts of browsing by ungulates. • Invasive nonnative plant monitoring and control—Continue control of established ecosystem-altering nonnative invasive plant species, and those that compete with *Remya kauaiensis*. • Site and habitat protection—Develop and implement effective control measures to reduce the impact drought and landslides. • Fire prevention and control—Continue to develop and implement fire prevention management plans. • Climate change adaptation strategy—Research suitability of habitat for reintroduction of this species in the future due to the impacts of climate change, including hurricanes. • Predator and herbivore monitoring and control—Determine and implement effective methods to control rodents. • Captive propagation for genetic storage and reintroduction—Continue collection and propagation efforts for maintenance of genetic stock and for reintroduction. • Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species to build resiliency and redundancy to reduce impacts of reduced viability due to low numbers. • Population biology research— o Determine which species may act as pollinators and which may assist with fruit dispersal. o Conduct genetic studies to determine genetic variation within and between populations and plan an effective breeding program. • Alliance and partnership development—Continue to work with partners and other land managers in planning and implementation of ecosystem-level restoration and management to benefit this species. • Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides (USFWS, 2022).

## SPECIES ACCOUNT: *Rhodiola integrifolia* ssp. *leedyi* (Leedy's roseroot)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 04/22/1992; Great Lakes-Big Rivers Region (R3) (USFWS, 1992)

### **Physical Description**

Leedy's Roseroot is a perennial herb with multiple leafy stems from a scaly root crown that is usually visible in the rock crevices where the plants are growing. Leaves are glaucous, oblong, blue-green, and thick-succulent, with irregularly toothed to entire margins. The dark red and yellow flowers (May-August) are arranged in rounded clusters at the ends of the stems. (NatureServe, 2015)

### **Taxonomy**

Listed as a subspecies of *Sedum integrifolium*, a revised scientific name of *Rhodiola integrifolia* ssp. *leedyi*, as treated by Kartesz (1999) was accepted by the USFWS in 2010 (USFWS, 2010).

### **Historical Range**

Apparently the Leedy's roseroot is not known to have occurred in historical times in other locations than present. (USFWS, 2015)

### **Current Range**

Leedy's roseroot is found today in only six locations in two widely separated states. Four populations of several thousand plants each are found in Fillmore and Olmsted Counties, Minnesota. The other two are in upstate New York, a large population on the shores of Seneca Lake and a single plant at Watkins Glen. (USFWS, 2015). Also occurs at Harney Peak, Black Hills National Forest, South Dakota (Olfelt and Freyman 2014, p. 908). (USFWS, 2015b).

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Usually sexual reproduction; some vegetative (USFWS, 1998)

### **Dependency on Other Individuals or Species**

Adult: Bees and syrphus flies as pollinators (USFWS, 1998)

### **Breeding Season**

Adult: Flowers in June (USFWS, 1998)

### **Other Reproductive Information**

Adult: Olfelt (1998, p. 16) found a seed germination rate for Leedy's roseroot of 77% and described this as high for a rare plant, but lower than that of related subspecies. (USFWS, 2015b).

**Reproduction Narrative**

Adult: Flowering occurs in early June. Clausen (1975) reports bees and syrphus flies as pollinators; Sather (1993a) observed bees on New York plants. Seeds are winged and adapted for wind dispersal. Seeds produced by plants at Glenora Cliff, New York, sometimes germinate in their follicles and produce seedlings on the parent plant (Clausen 1975). Plants grown in a Minnesota greenhouse from seed flowered their first season after germination (Joel P. Olfelt, University of Minnesota, pers. comm. 1996). Although, newer growth on the long-lived rootstocks breaks off to form clones, which have lived at least 36 years in cultivation (Clausen 1975), Olfelt and Luby (in press) report finding little clonal reproduction. Of 81 stems they assayed, 75 had unique markers, indicating those 75 stems had not been produced by cloning. (USFWS, 1998)

**Habitat Type**

Adult: Cliff ledges and talus slopes (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Ground water or cool air (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from USFWS, 1998)

**Environmental Specificity**

Adult: Very narrow specialist (USFWS, 1998)

**Habitat Narrative**

Adult: The habitat is limited to north or east-facing talus slopes or cliff ledges where ground water (primarily in New York) or cool air (primarily in Minnesota) constantly seep through the strata or between the rocks, maintaining a cool, wet environment throughout the summer. (NatureServe, 2015; USFWS, 1998)

***Dispersal/Migration*****Motility/Mobility**

Adult: Low (inferred from USFWS, 1998)

**Dispersal**

Adult: Wind dispersal of seeds (USFWS, 1998)

**Dispersal/Migration Narrative**

Adult: Plants are specific to a particular habitat which limits dispersal. The preferred cold air cliff faces with seepages are rare. (USFWS, 1998)

***Population Information and Trends*****Population Trends:**

Unknown. Inferred from information (USFWS, 2021)

**Number of Populations:**

6 (USFWS, 2015)

**Population Size:**

&gt;4,000 individuals (USFWS, 2021)

**Adaptability:**

Low (inferred from NatureServe, 2015)

**Population Narrative:**

Populations may be increasing or decreasing (NatureServe, 2015). USFWS (2015) indicates that the four Minnesota populations have several thousand plants each, but NatureServe (2015) indicates only 1500-2000 plants in all Minnesota populations. The New York population at Seneca Falls consists of "a large population" (USFWS, 2015) or "several thousand plants" (NatureServe, 2015). There is one plant at Watkins Glen, NY; it is likely introduced. (USFWS, 2015; NatureServe, 2015). The South Dakota population of Leedy's roseroot occurs on Black Hills National Forest on a cliff at approximately 7,000 feet above sea level. White spruce (*Picea glauca*) is the dominant overstory species on the north-northeast facing slope directly below the cliff; and ponderosa pine (*Pinus ponderosa*) is the dominant tree species in the general vicinity (U.S. Forest Service, in litt.). About seven patches of Leedy's roseroot may inhabit only a total of 10-50 square meters of the cliff face (Fig. 4; U.S. Forest Service, in litt. 2001; 2011). (USFWS, 2015b). The most recent census data indicate that the population at the Glenora Cliffs site in New York has increased since the most recent census and remains above 4,000 plants. At the Glenora Falls site, the population of 45-50 plants did not change between 2017 and 2020. The single individual that makes up the Watkins Glen State Park population in New York was inadvertently destroyed during construction of a new trail. Partners at the State University of New York College of Environmental Science and Forestry have applied for Section 6 funding to collect seeds from plants at New York sites, propagate Leedy's roseroot in a greenhouse environment, and outplant individuals at Watkins Glen State Park (Wiley (NYFO) pers. comm. January 27, 2021). All Minnesota populations have increased since the most recent census in 2020, although overall trends since 1997 are mixed with the Whitewater WMA population declining and populations at Simpson Cliffs, Deer Creek, and Bear Creek being relatively stable (Olfelt 2020a; Appendix B). No changes were noted for the South Dakota population of Leedy's roseroot in 2016 and 2017 (USFWS, 2021).

**Threats and Stressors****Stressor:** Ground water contamination (USFWS, 1992)**Exposure:****Response:****Consequence:****Narrative:** Contamination of ground water is likely through filling or dumping in sink holes adjacent to the cliffs. Sink holes are highly vulnerable because they provide direct access to the ground water and are the main source of seepage on the cliffs. (USFWS, 1992)**Stressor:** Agricultural pesticides (USFWS, 1992)**Exposure:****Response:**

**Consequence:**

**Narrative:** The use of agricultural pesticides in adjacent upland farmland (cropland in Minnesota and vineyards in New York) may directly affect the quality of the ground water. (USFWS, 1992)

**Stressor:** Residential development (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In New York, homes are being built above the cliffs. Many homeowners have built stairs down the cliffs to Seneca Lake and some have cleared vegetation from the cliff or cut trees at the top of the cliff to enhance the view. Some trees have been simply dumped over the cliffs. (USFWS, 1992)

**Stressor:** Road building and quarrying (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Road building and quarrying in the karst region of Minnesota would affect the subsurface water flow in an area and change the required groundwater seepage at a cliff face. (USFWS, 1992)

**Stressor:** Erosion and rock slides (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The slopes where the roseroot occurs are unstable. Natural erosion of the cliffs occurs and may denude the vegetation. Heavy runoff may directly dislodge plants from cliffs or may result in gullies being cut into a population site. Logging above some of the Minnesota sites may also cause erosion affecting the cliffs. (USFWS, 1992)

**Stressor:** Grazing (USFWS, 1992)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Grazing may damage plants on the lower, gentler slopes of the cliffs where dislodged plants have again taken root.

**Stressor:** Climate change and catastrophic wildfire (USFWS, 2015b).

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Leedy's roseroot already inhabits the highest elevation habitat available in the ecoregion and would not be able to move to higher – and presumably cooler and moister – habitats if climate change rendered its current habitat unsuitable. In addition, as ponderosa pines succumb to mountain pine beetle, drop needles, and fall the risk of a wildfire in forest around the Leedy's roseroot population is likely to increase (C. Monks, pers. comm. 2014). (USFWS, 2015b).

***Recovery***

**Delisting Criteria:**

All three privately owned Minnesota populations must be protected by conservation easements or fee acquisition by a public agency or private conservation organization. (USFWS, 1998)

The Whitewater Wildlife Management Area, Minnesota, population must be protected from or removed from any confirmed contamination threat and has been demonstrated to be self-maintaining for five years. (USFWS, 1998 and USFWS 2021)

The Glenora Falls, New York, population must be protected. (USFWS, 1998)

Habitat for 4,000 plants in multiple sites, evenly distributed along a 2-mile stretch of Glenora Cliff, New York, must be protected. The two most-distant subpopulations protected at Glenora Cliff must be at least 1.5 miles apart. (USFWS, 1998)

Protected populations must be geographically distinct, self-sustaining, and have been protected for five consecutive years by measures that will remain effective following delisting. (USFWS, 1998)

**Recovery Actions:**

- Map all populations, and identify all affected landowners. (USFWS, 1998)
- Determine hydrologic relationships between upland areas and *S. integrifolium* ssp. *leedyi* populations. (USFWS, 1998)
- Establish and administer a permanent infrastructure for Leedy's roseroot site protection and secure funding for that protection. (USFWS, 1998)
- Contact landowners, landowner associations, and land trusts; secure their involvement in conservation strategies; compensate them for costs of fee acquisition, enrollment in conservation easements or other programs; prepare management plans for public and private protected areas. (USFWS, 1998)
- Establish, implement, and review a monitoring program. (USFWS, 1998)
- Provide public education, including advance landowner contact. (USFWS, 1998)
- Develop and maintain a genetic bank. (USFWS, 1998)
- 2015 recommended actions - 1. Review threats to the species, beginning with the information in this review, to ensure that recovery criteria are revised appropriately to address all significant threats to the species. Prepare a list of threats based on this assessment and have it reviewed by species' experts to ensure that it is complete and accurate. Finally, revise the recovery criteria, as appropriate. (USFWS, 2015b).
- 2015 - 1.1: Determine whether and to what degree any Leedy's roseroot populations are threatened by the instability of their cliff side habitats and whether heavy rains are likely to pose a threat any population. Use this information to determine whether the recovery criteria should be revised to address specific related threats and revise the criteria, if appropriate. (USFWS, 2015b).
- 2015 - 1.2: Determine whether and to what degree any Leedy's roseroot populations are threatened by gully formation or by poor soil conservation practices. Revise the recovery criteria to address this factor if it poses a threat. This potential threat may currently be most relevant to the population at Whitewater Wildlife Management Area in Minnesota. (USFWS, 2015b).

- 2015 - 1.3: Determine whether grazing or logging poses a direct or indirect threat to any Leedy's roseroot population. If they do, revise the recovery criteria to ensure that no site is considered to be protected unless the threats are adequately minimized. (USFWS, 2015b).
- 2015 - 1.4. Consider revising the recovery criteria to clarify that the protections required for each Leedy's roseroot population must preclude the following: 1.4.1. Filling or dumping material into any sink holes where that activity could result in exposure of Leedy's roseroot to harmful contaminants or alteration of groundwater flows to cliffs where Leedy's roseroot occurs; 1.4.2. The use of any pesticides or herbicides where it would result in the exposure of Leedy's roseroot to harmful compounds; and, 1.4.3. Road building or quarrying that would affect groundwater flows in any Leedy's roseroot cliff side habitats. (USFWS, 2015b).
- 2015 - 1.5: Consider revising the recovery criteria to require that protection of Leedy's roseroot habitat at the Glenora Cliff site in New York would preclude the construction of stairs, vegetation clearing (except for invasive species), laying of pipes, and dropping felled trees where these activities would likely cause adverse effects to Leedy's roseroot. (USFWS, 2015b).
- 2015 - 1.6. Consider revising the recovery criteria to further clarify that the populations around Seneca Lake must be protected from residential development, cliff-face alteration, and hydraulic fracturing (fracking) that could affect ground water quality and flow. (USFWS, 2015b).
- 2015 - 1.7. Review the preliminary hydrogeological assessment prepared for Leedy's roseroot in Minnesota (Spetzman and Cremers 1999) and develop a plan to assess the risk of groundwater contamination for each of the four Minnesota populations and measures that would protect the taxon from this threat. Consider engaging the appropriate regional hydrologist with the Minnesota Department of Natural Resources, Division of Ecological and Water Resources to help develop this plan. Ensure that the plan is sufficient to determine the following: 1.7.1. The extent to which transport of agricultural chemicals into sinkholes poses a risk of exposing Leedy's roseroot to contaminated groundwater. 1.7.2. The locations of sinkholes – or the areas in which they may occur – that should be protected to ensure that each Leedy's roseroot population is safe from effects to groundwater flows or groundwater contamination. 1.7.3. The area in which road building or quarrying may expose Leedy's roseroot to the effects of any changes in groundwater discharge. 1.7.4. The specific practices that would need to be implemented to mitigate any specific threats of exposing Leedy's roseroot to changes in groundwater discharge or to contaminated groundwater and to alleviate any ongoing exposure. It may also be prudent to carry out similar actions in New York. (USFWS, 2015b).
- 2015 - 2. Revise the recovery plan to address the Leedy's roseroot population that is now confirmed in South Dakota. (USFWS, 2015b).
- 2015 - 3. It may still be unclear whether the taxon may be conserved by relying only on the protection of the seven known extant populations. The seven populations include four in Minnesota; two in New York; and, one in South Dakota. Consider developing a range wide viability assessment that assesses the species' recovery criteria and determines whether extant populations would ensure sufficient redundancy and representation for the subspecies; and to develop criteria that may be used to determine whether or not the populations that are essential to recovery are sufficiently resilient. (USFWS, 2015b).
- 2015 - 4. Define "self-sustaining" per the recovery criteria or eliminate it from revised criteria. (USFWS, 2015b).

- 2015 - 5. Ensure that an adequate seed banking program is established for Leedy's roseroot. (USFWS, 2015b).
- Enrollment in permanent conservation easements, private land trusts, or landowner associations with effective land management plans to minimize impacts on *S. integrifolium* ssp. *leedyi* populations. (USFWS, 1998)
- Acquisition of fees to provide tax relief or other compensation to landowners. (USFWS, 1998)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: • Manage each population as a unique management unit o Prioritize conservation of large population centers at the Glenora Cliffs and WWMA sites o Prioritize conservation of genetic diversity at the Deer Creek site by collecting seeds • Evaluate abiotic and biotic factors associated with Leedy's roseroot in New York, Minnesota, and South Dakota sites o Use information to develop management recommendations • Revise recovery criteria to address threats related to cliff instability and heavy rains • Conduct DNA microsatellite analysis on South Dakota population and additional populations in New York (USFWS, 2021).

## SPECIES ACCOUNT: *Rhododendron chapmanii* (Chapman rhododendron)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 5/23/1979; Southeast Region (R4)

### Physical Description

Chapman's rhododendron is a small (0.5 - 2m in height), evergreen shrub with stiffly ascending branches. Leaves are alternate, 3 to 6cm long, obovate with tapered bases, obtuse or rounded apices, somewhat wrinkled, and with entire but curled undermargins. Shade leaves are less wrinkled and curled. Petioles are from 2 to 6mm long. New stems, petioles and under surface of leaves are usually scurfy, dotted reddish brown. Flowers, borne in terminal clusters, have light pink, funnel-shaped corollas about 3cm long with 5 fused petals. Fruit capsules, about 1cm long, are borne in clusters which persist several years and are present on almost all plants. It blooms prolifically with large clusters in late March to early April. (USFWS, 1983)

### Taxonomy

Asa Gray (1877) described *R. chapmanii* and credited Chapman (1860) with recognizing the taxon as a variety growing in the sandy pine barrens of west Florida (Duncan and Pullen, 1962). Recent authors treat as *R. minus* var. *chapmanii* (Godfrey, 1988; Duncan & Pullen, 1962; Luteyn et al., 1996). Kartesz (1994) treats as full species. *R. minus* var. *minus* occurs in Georgia and southern Appalachians (Duncan & Pullen, 1962) (NatureServe, 2015).

### Historical Range

Endemic to Florida, in Gulf, Liberty, Gadsden, and Clay counties. (USFWS, 2019a)

### Current Range

Endemic to Florida and restricted to Gulf, Liberty/Gadsden and Clay counties. (USFWS, 2019a)

### Critical Habitat Designated

No;

### Life History

### Food/Nutrient Resources

### Breeding Season

Adult: Blooms in mid-March to early April (USFWS, 2019a)

### Reproduction Narrative

Adult: Although *R. chapmanii* flowers and fruits abundantly, no seedlings were observed in the 1996 monitoring event (author, pers. obs.), and only one was found in the 1985 monitoring event (Hardin, et al., 1985). Plants are grown from seed for the nursery trade (Hardin, et al., 1985), so presumably they are reasonably easy to germinate and grow in captivity.; Ann Redmond made notes and diagrams of five plants that she excavated to a depth of ca 20 cm near the permanent monitoring plots in Gulf and Liberty/Gadsden counties (Redmond, 1985).

She observed that clumps of stems, which would have been considered several "plants" for monitoring purposes from an above-ground point of view, often were found to arise from the same underground rootstock when excavated. Thus there were actually fewer genetic individuals present than there were stem clumps tagged. She also noted evidence of areas in the rootstock where former stems had died and rotted away and evidence of grafting between stems from different sources. From her rough diagrams it appears that the underground biomass of rootstock plus roots would exceed the biomass of the aboveground stems. All of the excavations showed rhizomes heading out from the central rootstock to beyond the area of the excavation which generally covered an area of less than 1 square meter. PHENOLOGY: *Rhododendron chapmanii* has a fairly narrow two to three week flowering period which may begin from mid- March to early April (Duncan and Pullen, 1962; Hardin et al., 1985; Schultz and Johnson, 1996). A hard freeze in January and March 1985 may have delayed and reduced flowering in that year by killing the buds (Hardin, et al., 1985) (NatureServe, 2015).

**Habitat Type**

Adult: Between upland mesic or scrubby flatwoods and floodplain swamps or baygalls; mesic pine flatwoods (USFWS, 2019a)

**Habitat Vegetation or Surface Water Classification**

Adult: Terrestrial

**Dependencies on Specific Environmental Elements**

Adult: Acidic sandy soil (USFWS, 2019a)

**Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 2019a)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: *Rhododendron m. chapmanii* usually occurs in a transitional area between upland mesic or scrubby flatwoods and floodplain swamps or baygalls. This species is also found within mesic pine flatwoods or on the lower elevations of the sandhills. Consequently, it appears to require acidic sandy soil, good to moderately well-drained to somewhat poorly drained sandy soils of 0-5% slope, and no flooding. The Camp Blanding population grows on the edge of xeric hammock next to a stream bank. The plants tolerate full sun to moderate shade (Negrón-Ortiz, 2010, pers. observ.), and heavy shade once they are mature as at Camp Blanding (Hall 2005). (USFWS, 2019a)

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Declining (USFWS, 2019)

**Number of Populations:**

4 (USFWS, 2024)

**Population Size:**

approximately 3,000 clumps (USFWS, 2019a)

**Population Narrative:**

*Rhododendron m. chapmanii* is restricted to the Florida panhandle with only three known populations occurring in coastal Gulf County, Liberty and Gadsden counties in the vicinity of Hosford, and Clay County on the Camp Blanding Military Reservation. The population near Hosford is the largest and is privately owned by AgReserve Inc., which may maintain timber production and agricultural uses of the lands. The smallest and most geographically isolated of these populations is within the Florida National Guard post at Camp Blanding, about 165 miles east of the Hosford population. Throughout Florida, surveys and censuses collectively recorded about 55 occurrences or sites. Although we have limited information regarding trends, current data assessment suggest the presence of only 35 sites (about 36 % decline). In May 2019 FNAI performed a comprehensive review of all *R.m. chapmanii* element occurrences (EO2). The 55 areas where the species was observed are currently mapped as 23 EOs. This is based on NatureServe 2004 guidance (EO separation distance of 1 km) with the addition of separation based on differences in management practices, threats, and habitat conditions. If considering only the parameter of 1 km separation distance, the 23 EOs technically represent 15 EOs (J. Annis, FNAI, 07/02/2019, pers. comm.). (USFWS, 2019a). *Rhododendron chapmanii* is a small evergreen shrub presently comprised of four populations located in five Florida counties four of which are in the panhandle. A new occurrence was recorded in 2022, increasing the total occurrences to 16 and extending the geographic range 80km northwest from the nearest known population (USFWS, 2024).

**Threats and Stressors**

**Stressor:** Urbanization (USFWS, 2019)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** In addition to being one of the largest private landowners in northwest Florida, the St Joe Company is also one of the largest real estate operating companies in the Southeast. This Company develops both residential and commercial properties along roadways and near or within business districts in the region. Urbanized land in Florida, statewide, is projected to double by 2070 along with a growth of about 33.7 million residents—almost 15 million more people than in 2010 (University of Florida GeoPlan Center 2017). Since the species occurs on Company-owned property in Gulf, Liberty, and Gadsden counties, Florida, there is no guarantee that these properties will not be utilized for residential or commercial development in the near future. Therefore, residential or commercial development is a threat. (USFWS, 2019)

**Stressor:** Forestry practices (USFWS, 2019)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The timber industry in North Florida became well established in the 1850s. Privately owned companies grow trees for their byproducts by mechanically preparing the site for

planting, planting seedlings, and mechanically harvesting the trees. Harvesting typically involves thinning, and later clear cutting the site; the process is then repeated. The St. Joe Company had close to a million acres in timber in the eastern region of the panhandle and they plan to continue to harvest and replant indefinitely. Tree farming, i.e., privately owned forest managed (clearcutting, mechanical site preparation, and pine plantations) for timber production, is a primary threat since there are many thousands of acres of tree farms. In 2013, the St Joe Company sold more than 380,000 acres of its land to AgReserves, Inc., a for-profit company that has primarily focused on cattle grazing. The land sold included timberlands in Bay, Calhoun, Franklin, Gadsden, Gulf, Jefferson, Leon, Liberty and Wakulla counties. The safety of the Hosford population, sold to AgReserves, Inc., is undetermined because it is not protected. Also, the Gulf County population is primarily on tree farm land; therefore, tree farming is a threat to this species. (USFWS, 2019)

**Stressor:** Fire suppression (USFWS, 2019)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Suppression of fire continues to threaten pineland and savanna flora as fire is an important element in the maintenance of flatwoods (Abrahamson and Hartnett 1990). Fire influences community structure and composition (Abrahamson and Hartnett 1990), and with insufficient frequency in longleaf pine communities, a woody midstory quickly develops (Glitzenstein et al. 1995), negatively affecting the understory diversity. Several studies have shown that frequent prescribed fire regimes are important for maintenance of flatwoods diversity (Hiers et al. 2007). Prescribed burnings are needed to maintain optimal habitat for *R.m. chapmanii* populations; specifically to avoid the encroachment of *Cyrilla racemiflora* L. (swamp titi). (USFWS, 2019)

**Stressor:** Drainage (USFWS, 2019)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Drainage of adjacent bogs to increase areas of pine plantings affects seasonal hydrology. Drained sites become more desiccated, and this affect processes such as seed germination and seedling establishment. Therefore, drainage of adjacent bogs is still a threat due to tree farming activities. (USFWS, 2019)

**Stressor:** Overutilization (USFWS, 2019)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** The Recovery Plan identified this as a threat to *R.m. chapmanii*. Specifically, the Plan suggested that this species was taken from the wild for ornamental purposes (Tatum and Lake 1979). According to Simmons (1983), numerous plants were removed in the late 1940's from the Camp Blanding for the nursery trade. Similarly, 100-200 plants were removed from the Hosford population (USFWS 1983). Therefore, this species was a 'commercially exploited plant' and is still sold by several nurseries (e.g., <https://shop.shadygardensnursery.com/>). This activity does not currently seem to be a major problem because most cuttings and seeds come from plants collected in the past. However, we cannot discount the possibility of sporadic plant removal.

(USFWS, 2019)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2019)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** The Endangered Species Act (Act) of 1973, as amended prohibits the removal of federally listed threatened and endangered plants or the malicious damage of such plants on areas under federal jurisdiction, or the destruction of endangered plants on non-federal areas in knowing violation of state law or regulations or in the course of any violation of a state criminal trespass law. However, the Act does not provide protection for plants on private lands or unless it's in violation of state law. Several populations of *R.m. chapmanii* occur on private timberland. While the Act requires federal agencies to carry out programs for the conservation of endangered and threatened species, no such programs are stipulated for private landowners. Neither section of the Act provides protection for plants on private lands as long as the activity is permissible under state/local laws. Seeds of both threatened and endangered species found on federal lands are regulated under the Act. In addition, the seeds of an endangered species are regulated if they are going to be purchased/traded/bartered in interstate commerce. Since *R.m. chapmanii* is an endangered species, the seeds are regulated under the specified conditions. However, the seeds are not regulated if they are provided freely (no exchange of money, goods, or services; 7 CFR 319.37.2, USDA 2008). The State requires permission of private landowners for collecting of state-listed plants from their property. *Rhododendron m. chapmanii* is protected under Florida State Law, chapter 581.185: Preservation of native flora of Florida, which includes preventions of take, transport, and the sale of the plants listed under the State Law. The rule Chap. 5B-40, Florida Administrative Code, contains the "Regulated Plant Index" (5B-40.0055) and lists endangered, threatened, and commercially exploited plant species for Florida; defines the categories; lists instances where permits may be issued; and describes penalties for violations (Coile and Garland 2003). This law does not protect habitat. Based on the information summarized above, the existing regulatory mechanisms are deemed inadequate for plants. (USFWS, 2019)

## **Recovery**

### **Reclassification Criteria:**

1. The dense 10-acre population near Hosford is maintaining a stable or increasing population of healthy plants. (USFWS, 1983).
2. The remaining part of the Hosford population continues to occupy at least 200 acres with at least 500 plants. (USFWS, 1983)
3. The Gulf County population continues to occupy at least 200 acres with at least 500 plants. (USFWS, 1983)
4. The Camp Blanding population continues to have at least 20 plants. (USFWS, 1983)
5. There is a permanent increase of about 1,000 plants at any combination of sites 2, 3, and 4 to increase to a total of at least 2,000 plants at these sites. (USFWS, 1983)

Recovery Priority Number: 8C

**Delisting Criteria:**

1. The three (3) existing populations (Hosford, Gulf, and Clay) and their occupied habitat are conserved, restored, and properly managed, and monitoring demonstrates that the populations are stable or increasing over multiple prescribed burn cycles, evidenced by a type of natural recruitment and/or multiple size-classes (addresses Factors A and D). (USFWS, 2019b)
2. At least five (5) new populations are discovered or established within the historic range of the species on lands protected by a conservation mechanism, and exhibit stable or increasing trends over multiple prescribed burn cycles, evidenced by a type of recruitment and/or multiple size-classes (addresses Factors A and E). (USFWS, 2019b)
3. Threats (e.g. urban development, timbering, agriculture, inadequate fire management, invasive species) have been reduced and/or managed to a degree that *R. m. chapmanii* will remain viable into the foreseeable future (addresses Factors A and D). (USFWS, 2019b)

**Recovery Actions:**

- 1. Highest priority for the recovery of Chapman's rhododendron should be to reverse the habitat and population declines that are occurring in the wild population. This can be accomplished through a combination of protection, management and monitoring. Most important in accomplishing this goal is to establish and maintain a strong, friendly and longlasting working relationship with the St. Joe Paper Company, which owns over 99 percent of the wild population and its habitat. The Company has expressed a willingness to help (pers. comm.), and, indeed, has already taken some steps to protect the species and its habitat. Camp Blanding guards the small population there rather closely, and has expressed willingness to help manage the site. (USFWS, 1983)
- 2. Strengthening existing populations by planting nursery-grown plants is clearly less important than habitat protection and management. It may nevertheless prove to be essential for long-term survival of the species. It provides a tested (plantings have been done by Simons in the wild in Suwannee, Levy and Putnam Counties with 100 percent success rates) and easy method to quickly strengthen a population. (USFWS, 1983)
- 3. Establish new populations. Determine historical range. Locate suitable habitat. Obtain permission and cooperation for establishing planting. Collect seed. Grow plants and plant out in December - January at a 20 by 20 foot spacing (about 100 per acre). (USFWS, 1983)
- 4. Research is the lowest priority, because it seems least important from the standpoint of the immediate and near-term needs of the species. However, the farther one looks into the future, the more important research is. The amount of research recommended here is the minimum necessary to provide for implementation of this recovery plan. (USFWS, 1983)
- The level of occupancy of the three existing populations persists as at least: 5,000 acres for Hosford, 6,000 acres for Gulf County with a minimum of 2,000 clumps, and 30 clumps for Clay County (addresses Factors A and D) and management with prescribed fire is implemented on a 3 to 5 year return interval. (USFWS, 2019b)
- Foster a partnership with the current landowner of the AgReserves, Inc. to promote the protection of the Hosford population (found in Liberty and Gadsden counties) and help implement best management practices (e.g., prescribed fire, mowing/fuel reduction, invasive species removal) (addresses Factors A and D). (USFWS, 2019b)

- A long-term ex-situ conservation program is ongoing to help avert the risk of extinction from stochastic events, environmental catastrophes, or development. The living collection should emphasize the privately owned Hosford population and coastal areas (see Justification of criteria 1 and 3). The collection should be maintained at botanical gardens and other Service approved facilities for research, recovery, and public outreach (addresses Factors A and E, and representation). The full genetic diversity represented in the Hosford population needs to be protected through ex-situ management efforts. (USFWS, 2019b)
- The contribution of sexual reproduction to population maintenance is assessed via research related to in-situ soil seed bank, seed viability, and seedling recruitment (in-situ seed germination, seedling survival and growth) (addresses Factors A, D, E, and resiliency). (USFWS, 2019b)
- The genetic composition within and among populations is assessed to clarify species boundaries, define evolutionarily significant units, detect inbreeding, identify clonal reproduction, and determine effective management (addresses Factors A, D, E; informs the ecological principle of representation). (USFWS, 2019)
- Assess the *R. m. chapmanii* demographic responses (e.g., recruitment, reproduction, and mortality) to hurricane and fire disturbances (addresses Factor E and resiliency). (USFWS, 2019b)
- A comprehensive census is conducted throughout the present distribution and on new locations where appropriate habitat exists (addresses Factor A and redundancy). (USFWS, 2019b)
- Acquisition of the following private lands will benefit the status of this species: - Several land parcels adjacent to the SJSBP, Gulf County that has Chapman's Rhododendron and a suite of other rare species. - The Hosford population located in Liberty and Gadsden counties. (USFWS, 2019a)
- Complete a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) throughout the present distribution. Follow a standardized method for accurate population counts to ensure consistency in collected data. (USFWS, 2019a)
- Conduct surveys for new populations where similar habitat exists. This action can include the use of aerial photographs and species distribution modeling methods to initially determine potential sites, with subsequent validation or inspection of the sites for plants. Follow a standardized method for accurate population counts to ensure consistency in collected data. (USFWS, 2019a)
- Garden propagation and reintroduction. An ex-situ seed collection should be actively pursued and implemented to help avert the risk of extinction from stochastic events, environmental catastrophes, or development. The living collection should emphasize the privately owned Hosford population and coastal areas, and maintained at botanical gardens and other Service approved facilities for research, recovery, and public outreach. (USFWS, 2019a)
- Complete a population genetic study to determine the levels and distribution of genetic diversity within and among populations of *R. m. chapmanii*. The study should test whether the Camp Blanding population is an artificial (planted) population. The Recovery Plan deemed it "unlikely" that this population was planted, but this would provide a further test. (USFWS, 2019a)
- The contribution of sexual reproduction to population maintenance is assessed via research related to in-situ soil seed bank, seed viability, and seedling recruitment (in-situ seed

- germination, seedling survival and growth). (USFWS, 2019a)
- Assess the *R. m. chapmanii* demographic responses (e.g., recruitment, reproduction, and mortality) to hurricane disturbance. (USFWS, 2019a)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES • Foster a working relationship to establish protection and management agreements with private landowner AgReserve, Inc. • Hosford population: A comprehensive survey is needed to assess the status of the plants and corresponded habitat. This recommendation is a priority. • Conduct surveys/inventories/demographic studies on each known population every five years. Note: Atlanta Botanical Garden initiated a detailed demographic study of Chapman's rhododendron in 2021 at St. Joseph State Buffer Preserve (CP #F20AC10631). • Reintroduce plants within the historic range, specifically in the sites where the plants have been extirpated, or in potential suitable habitat suggested by the species distribution modeling developed by FNAI (2022). • Acquisition of land parcels adjacent to the St. Joseph State Buffer Preserve, Gulf County that has Chapman's rhododendron and a suite of other rare species (USFWS, 2024).

## SPECIES ACCOUNT: *Rhus michauxii* (Michaux's sumac)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 9/28/1989

### **Physical Description**

A low-growing, densely hairy, dioecious shrub, mostly 0.3 to 0.6 m tall. Leaves are pinnately compound with 7-13 leaflets that are coarsely toothed. Female plants produce erect clusters of greenish-yellow to white 4-5 parted flowers and conspicuous red drupes. Flowers from April to June. Fruits persist from August through September or October (NatureServe, 2015).

### **Taxonomy**

Andre Michaux discovered this species on July 20, 1794 in Mecklenburg County, NC (the area is now part of Union County). He named the species *Rhus pumila* in 1803; however, since the specific epithet *pumila* had already been used for another species, Sargent assigned the name *R. michauxii* in 1895 (Barden and Matthews 2004). There have been no changes to the taxonomic classification or nomenclature since *Rhus michauxii* was listed as endangered in 1989 (USFWS, 2014).

### **Historical Range**

Historically endemic to the Inner Coastal Plain and lower Piedmont of North Carolina, South Carolina, and Georgia (USFWS 1989). HISTORIC RANGE: From the time of its discovery in 1895 until 1989, half of the known occurrences of *Rhus michauxii* have been extirpated (USFWS 1989). Thirty-two occurrences were historically reported from 23 counties in NC, SC, and GA (USFWS 1989). Four occurrences historically known from Cobb, Columbia, Newton, and Rabun counties, GA, are believed extirpated (Murdock and Moore 1991, Patrick 1993). Historical collections are known from Florence, Kershaw, and Oconee counties, SC. Following extensive, unsuccessful searches of their last known locations, as well as other areas of suitable habitat, Michaux's sumac is believed extirpated from the state (USFWS 1989, Murdock and Moore 1991). Historical and/or extirpated NC records exist (year last seen in parentheses) for Durham (1949), Franklin (1914), Hoke (1981), Johnston (1833), Lincoln (prior to 1917), Mecklenburg (pre-1800s), Moore (1901), Orange (1964), Robeson (1982), Wake (1942), and Wilson (1958) counties (Murdock and Moore 1991, NCNHP 1993). Considered extirpated from Florida, where the original collection was made in 1961 in Alachua County (Murdock and Moore 1991). Apparently by 1989 the collection site had been developed and was occupied by at least one residential home. Kathy Burkes of FNAI notes: "Whether the plants seen in 1961 were waifs carried far afield from the Piedmont by humans or other animals in "recent" times, or were true relicts of a former wide distribution reaching south into Florida is another question. We may never know for sure about that." (NatureServe, 2015).

### **Current Range**

When the recovery plan was completed in 1993, *R. michauxii* was believed extant at 21 sites in NC and GA. No populations were known from VA at that time. *R. michauxii* was believed to be extinct at 20 sites in the coastal plain and piedmont of NC, South Carolina (SC), GA and Florida (FL). Since listing, additional occurrences have been found in GA, NC and VA. As of 2014, there are 43 parent populations, rangewide. The GANHP database currently lists four extant occurrences of *R. michauxii* and two additional subpopulations are considered historical or

extirpated. NCNHP records currently indicate a total of 33 extant populations. An additional 13 sites in NC are now considered historical, extirpated or failed to find. The VANHP database indicates that there are six occurrences extant within the state with no known historical or extirpated populations. This information is summarized in Table 1 and additional information about each element occurrence (EO) is included in Appendix C. Following current NatureServe methodology, some of these sites are now considered sub-populations or sub-sets of larger populations or principal EOs. See Table 1 for an additional explanation of this methodology. Several populations of *R. michauxii* are now considered historical or extinct, including all previously known sites in FL and SC. *Rhus michauxii* was collected in Alachua County, FL in 1961. Attempts to relocate this population in 2006 (and prior to 2006) were unsuccessful (Herring 2006). Three sites known from SC (one site each in Florence, Kershaw and Oconee counties) were considered extirpated before the species was federally listed as endangered in 1989. (USFWS, 2021)

**Critical Habitat Designated**

Yes;

***Life History*****Food/Nutrient Resources****Reproductive Strategy**

Adult: Asexual: vegetative (USFWS, 2014)

**Reproduction Narrative**

Adult: Most of the surviving populations appear to contain plants of only one sex and therefore reproduce only vegetatively, if at all. Due to the rhizomatous nature of the species, this may mean that the single-sex populations are clones of one or a few individuals; two populations sampled for genetic diversity by Sherman-Broyles et al. (1992) appeared to each consist of a single clone (USFWS, 1993). Single sex populations that are clonal in nature prohibit sexual reproduction and seed production in this species. In populations where seeds are produced, it appears that seed germination is very low (USFWS, 2014). Although specific pollinators are unknown, Michaux's sumac, like other species in the genus, is probably pollinated by insects. Sherman-Broyles et al. (1992) observed that bees visited the flowers of other sumac species and that birds dispersed the fruits (USFWS, 1993).

**Habitat Type**

Adult: Open Woodland (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Michaux's sumac occurs in sandy or rocky open woods, sometimes in association with circumneutral soils (USFWS 1990). In the fall line sandhills region it occurs in submesic loamy swales. In the eastern Piedmont, it occurs on sand soils derived from granite. In the central Piedmont, it occurs on clayey soils derived from mafic rocks (Weakley 2004). In all of its habitats, *Rhus michauxii* is dependent upon some form of disturbance to maintain the open quality of its habitat (USFWS 1989). Periodic, naturally occurring fires provided such disturbance historically. Today, however, many of the Michaux's sumac occurrences are in areas that are artificially disturbed, such as highway and railroad rights-of-way, pine plantations, edges of cultivated fields, and other cleared lands (USFWS 1989, TNC 1991-93, NCNHP 1993, Center for Plant Conservation 2002). Although roadside occurrences appear to be thriving in the presence of some level of disturbance (i.e., mowing), they are always under the constant threat of catastrophic disturbance. Roadbed widening or heavy equipment activity on cleared lands, for example, may dramatically reduce the number of individuals. These reductions, if they come at a crucial stage in the species' reproductive cycle (i.e., during flower or fruit production), could have severe long-term effects on the population. Although it appears that Michaux's sumac can rebound from large disturbances, it is not clear how much genetic diversity is lost with each disturbance. In the North Carolina Sandhills region, naturally occurring *Rhus michauxii* appears to be restricted to slightly loamy, but still well-drained, sites which are scattered through longleaf pine/scrub oak/wiregrass woodlands. Loamy soil sites are usually found in slight depressions, swales, or along lower slopes and are quickly recognized by their high diversity of herbs, especially with regard to their high number of legume, composite and grass species (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance range are inferred based on specific habitat needs and low number of populations.

***Dispersal/Migration*****Motility/Mobility**

Adult: Birds? (USFWS, 1993)

**Dispersal/Migration Narrative**

Adult: Sherman-Broyles et al. (1992) observed that bees visited the flowers of other sumac species and that birds dispersed the fruits (USFWS, 1993).

***Population Information and Trends*****Population Trends:**

Short-term Trend: Decline of <30% to relatively stable. Long-term Trend: Decline of 30-50% (NatureServe, 2015)

**Number of Populations:**

38 (USFWS, 2021)

**Population Narrative:**

Currently, state natural heritage programs recognize 38 extant natural populations (31 in North Carolina, one in Georgia and six in Virginia), plus four additional introduced populations in Georgia and one in North Carolina. Of these populations, 18 are ranked A or B by their respective natural heritage programs. According to natural heritage program records, the ranks of eight populations (13 occurrences) have improved and 34 populations (51 occurrences) have remained stable. The ranks of 11 populations (20 occurrences) have declined since the 2014 5-Year Review indicating that those occurrences have fewer stems than previously observed, or possibly even disappeared. (USFWS, 2021)

### ***Threats and Stressors***

**Stressor:** Fire suppression (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** This species is threatened by fire suppression and the ecological succession (competition and/or shading by woody species) that occurs in areas that are not burned on a regular basis (USFWS, 2014).

**Stressor:** Low reproductive capacity (NatureServe, 2015)

**Exposure:**

**Response:**

**Consequence:** Population degradation

**Narrative:** Low reproductive capacity resulting from the geographic isolation of small single-sex populations is a threat to this species (USFWS 1990) (NatureServe, 2015).

**Stressor:** Logging (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/Loss of plants

**Narrative:** Forested populations are threatened by timber operations. Logging activities can crush plants and 9 or compact the soil where they grow (USFWS, 2014).

**Stressor:** Herbicides (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of plants

**Narrative:** Sites located within utility rights-of way are threatened by herbicide use, mowing during critical growth periods, and ground disturbing activities (USFWS, 2014).

**Stressor:** Development (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Habitat destruction, the result of development or land conversion, also threatens this species (Boyer 1996) (USFWS, 2014).

**Stressor:** Climate change (USFWS, 2014)

**Exposure:****Response:****Consequence:** Loss of habitat

**Narrative:** The effects of climate change on this species are unknown at this time. However, since this species occurs on dry soils in fire maintained habitat, it seems reasonable to believe that it will not be negatively affected by the predicted increase in droughts and wildfires (USFWS, 2014).

***Recovery*****Delisting Criteria:**

1. It has been documented that at least 19 self-sustaining populations exist and that necessary management actions have been undertaken by the landowners or cooperating agencies to ensure their continued survival (USFWS, 1993).
2. All of the above populations and their habitat are protected from present and foreseeable human-related and natural threats that may interfere with the survival of any of the populations (USFWS, 1993).

**Recovery Actions:**

- Revisit known populations that have not been visited in the past three years; monitor the habitat condition of each site including threats and fire regime; monitor population size and evidence of reproduction (sexual, asexual and seed viability); discuss conservation options with landowners where appropriate; update Natural Heritage Program files with this information (USFWS, 2014).
- Search for additional populations throughout the range of the species (USFWS, 2014).
- Prioritize known sites for protection (USFWS, 2014).
- Protect additional populations through fee simple acquisition, conservation easements, etc. (USFWS, 2014).
- Develop management plans including the use of prescribed fire for all protected populations (USFWS, 2014).
- Develop standardized monitoring protocols, initiate long-term population monitoring and determine the criteria for sustaining populations (USFWS, 2014).
- Reinstate monitoring that was initiated in the early 1990s by Boyer (1996) (USFWS, 2014).
- Conduct research on general biology of the species including life history and reproductive biology (breeding systems, seed production and seedling survivorship) (USFWS, 2014).
- Compare, genetically, the populations of questionable taxonomy in VA with those known from NC and GA (especially populations suspected of hybridizing with other species of *Rhus*) (USFWS, 2014).
- Work with NC Botanical Garden to conserve seeds and germplasm, and develop propagation protocols (USFWS, 2014).
- Consider augmenting populations to increase genetic variation (USFWS, 2014).

***Conservation Measures and Best Management Practices:***

- **RECOMMENDATIONS FOR FUTURE ACTIONS** The recommended actions listed in the 2014 5-Year Review remain important to the conservation and recovery of *Rhus michauxii* and efforts to accomplish those actions should continue. Since the 2014 5-Year Review, progress has been made on several recommendations for future actions. • Surveys have resulted in the discovery of four new

populations and one new subpopulation of *Rhus michauxii*. • The Georgia Plant Conservation Alliance has augmented *Rhus michauxii* populations with plants of the opposite sex and created three new safeguarding populations with male and female plants from different locations. *Rhus michauxii* has been reintroduced to a previously known site in North Carolina. • Research has been conducted on the pollination ecology of *Rhus michauxii*. • A genetics study looking at purported hybrids of *Rhus michauxii* is ongoing at Virginia Tech Conservation Management Institute. • The NCBG, SBG and ABG conserve seeds and maintain live *Rhus michauxii* plants in their collections for research, reintroductions and education. • The Service has encouraged land managers to develop and implement management plans by providing a template management plan to managers. The Service recommends initiating or continuing the following efforts that will contribute to the recovery of the species: • Consider updating/amending the recovery plan to include quantifiable downlisting criteria. • Revisit known populations that have not been visited in recent years. • Monitor the habitat condition of each site including threats and fire regime. • Monitor population size and evidence of reproduction (sexual, asexual and seed viability). • Discuss conservation options with landowners, where appropriate. • Provide updates about each population visited to natural heritage programs. • Search for additional populations throughout the range of the species. • Prioritize unprotected sites for protection. • Protect additional populations through fee simple acquisition, conservation easements, etc. • Encourage the development of updated management plans, including the use of prescribed fire, for all protected populations. • Develop standardized monitoring protocols, initiate long-term population monitoring and determine the criteria for self-sustaining populations. • Conduct research on general biology of the species including life history and reproductive biology (breeding systems, seed production and seedling survivorship). • Identify which populations contain hybrids and determine if they pose harm to the species and/or need special management considerations. • Work with the North Carolina Botanical Garden to conserve seeds and germplasm, and develop propagation and out-planting protocols. • Develop a plan to augment single-sex populations in order to increase genetic variation. (USFWS, 2021)

## SPECIES ACCOUNT: *Ribes echinellum* (Miccosukee gooseberry)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 8/19/1985; Southeast Region (R4)

### **Physical Description**

A bushy shrub that reaches 1 m in height and often forms patches that are several meters in diameter. Leaves are small (1-2 cm long), closely spaced, and more-or-less 3-lobed. Stems are armed with spines. Flowers (late February into early April) are inconspicuous, greenish-white. Fruits are spiny green berries (NatureServe, 2015).

### **Taxonomy**

Recent work using molecular phylogenetic approaches has confirmed the distinctness of this very rare shrub (Morgan & Soltis 1993, Sinters & Soltis 2003, Shultheis & Donoghue. 2004) (NatureServe, 2015).

### **Historical Range**

See Current

### **Current Range**

Occurs in three locations: along the shores of Lake Miccosukee in Jefferson County, Florida, and along Stevens Creek and a site on the Sumter National Forest, Edgefield Ranger District in McCormick County, South Carolina. (NatureServe, 2015)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Vegetative/Sexual (USFWS, 2015)

### **Other Reproductive Information**

Adult: Details of *R. echinellum*'s reproductive biology (protandry, andromonoecy), pollination and insect visitation (most abundant visitors: *Bombus impatiens* and *Habropoda laboriosa*), and vegetative reproduction (common by cuttings and by rooting at the stem whenever the decumbent branches come in contact with the ground) can be found in the last 5-year review (USFWS, 2022).

### **Reproduction Narrative**

Adult: Vegetative reproduction is common by cuttings and by rooting at the stem whenever the decumbent branches come in contact with the ground (Jones 1986; Engstrom 2011). Fire appears to promote clonal reproduction by increasing the number of plant clumps (Slapcinsky and Gordon 2005). No evidence of strong clonality was found by the genetic study of Oleas et al. (2014); however, in SC putative clonality was higher and especially high at the Sumter NF. The

Sumter NF subpopulation is represented by one large cluster and eight small subgroups (each 1–2 m<sup>2</sup>), which might explain the clonality results. Sexual reproduction might occur (Jones 1986), but recruitment appears to be limited or absent (Negrón-Ortiz 2014). Seed germination potential assessed with 1% tetrazolium solution indicated that out of 173 Florida seed tested, 60 % were viable (Negrón-Ortiz, 2014, pers. observ.) In addition, an ongoing in-situ study indicated 25 % seed germination. However, none of the Florida seedlings survive a full year (Negrón-Ortiz 2014, pers. observ.) (USFWS, 2015). Floral biology and flower visitors were observed and described for the Florida and South Carolina populations (Caitling 1998). The author concluded that pollinators and/or visitors were not the limiting factor determining the species' abundance. Below is a detailed account of the findings. a. Floral biology and behavior at anthesis. The stamens are the first reproductive structure elongating within one or two days of floral anthesis. It is followed by reflexing of the calyx lobes and dehiscence of the anthers. The style elongates within one to three days of stamen elongation, separates into two parts, reaching an equal or longer length than the stamen. This floral maturation suggests protandry (male function precedes female function), a breeding system that promotes outcrossing. Interestingly, the style failed to elongate in 20% of the flowers, but unfortunately, the author did not provide a description of these flowers to assess whether these flowers are female sterile. If they are female-sterile, the breeding system is not simple protandry, but also andromonoecious (species that have bisexual and male flowers on the same plant). b. Insect visitation and pollination. The author recorded five different visitors to the flowers, with *Bombus impatiens* Cresson (bumble bee) and *Habropoda laboriosa* Fab. (southeastern blueberry bee) as the two most abundant visitors for both Florida and South Carolina populations. Visitation movements occurred between and within plants (USFWS, 2015).

**Habitat Type**

Adult: Hardwood forest (USFWS, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (USFWS, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS, 2015)

**Site Fidelity**

Adult: High (inferred from USFWS, 2015)

**Habitat Narrative**

Adult: Jefferson County, Florida: Miccosukee gooseberry is found over an area of 105-110 acres between 24.4 to 36.6 m of elevation, at sites of high floristic diversity (Table 3), on mesic and well drained soils with underlying limestone (Schultz and Hardin 1985, USFWS 2000). These sites are dominated by deciduous species (Table 3, Harper 1925), with the west-facing slope dominated by a mixed hardwood forest containing trees such as hickories, elms, white ash, hackberries, and oaks (Table 3) (Catling 1998, USFWS 2000) and a shrub layer dominated by buckeye and poison ivy. The site, located in the bottomland hammock is dominated by American beech and southern magnolia. McCormick County, South Carolina Steven's Creek Heritage

Preserve: The plants are found over an area of 35 acres along Steven's Creek on a steep north facing slope containing stands of deciduous hardwood trees. The forest community was described by Radford (1959) as mixed mesophytic. It is also floristically very rich with species of *Carya* and *Quercus* accounting for over 50% of the composition of the tree size-class (Table 3). The soil texture is considered a sandy loam with high pH (6.7 to 7.4) and calcium levels (Jones 1986). Sumter National Forest, Long Cane Ranger District The site is characterized by a lower slope with an easterly aspect. The plants are found over an area of 30 acres. The forest, a mature (<100 years) hardwood forest with a sparse understory, is dominated by cherrybark oak, swamp chestnut oak, painted buckeye, and southern sugar maple. In addition, scarlet oaks, beech, witch hazel and ironwood are common members of the community. The soil is Tatum, a derivative from fine-grained phyllite, with pH ranging from 6.2 to 6.4 (USFWS, 2015). Narrow environmental specificity and clumped spatial arrangement of the population are based on the species specific habitat needs and known populations. High ecological integrity of the community and site fidelity as well as low tolerance range are inferred based on the specific habitat needs of the species and the small number of populations known to exist.

### ***Dispersal/Migration***

#### **Dispersal/Migration Narrative**

Adult: Coville (1924) postulated that birds with long bills (mockingbirds, catbirds, or thrushes) would be adapted to opening the berries to eat the seed. The daily range of these species would be limited, therefore the potential dispersal distance would be limited. Dissemination by these agents would be by internal means (NatureServe, 2015).

### ***Population Information and Trends***

#### **Number of Populations:**

2 (USFWS, 2022)

#### **Population Size:**

Florida ~ 5,000 plants, South Carolina ~ 9,870 plants (USFWS, 2015)

#### **Population Narrative:**

Grows extremely densely with as many as 500 stems in a .04 ha circular plot (USFWS 2008). The population at the type locality in Florida was estimated to be approximately 5000 plants (Schultz and Hardin 1985 cited by USFWS 2008). As many as 9,870 clumps are present at the Steven's Creek, South Carolina site (Gaddy 2008). The Sumter National Forest, South Carolina site has approximately 270 ramets (USFWS 2008). Two occurrences in close proximity are believed extant in Jefferson County, Florida. In the disjunct area of McCormick County, South Carolina, it is known from two sites, Steven's Creek Heritage Preserve and Sumter National Forest, Edgefield Ranger District. (NatureServe, 2015) Short-term Trend Comments: The Steven's Creek site may be declining (USFWS 2008). The Sumter National Forest and Florida sites appear to be stable (USFWS 2008). Low representation, resiliency and redundancy are inferred based on low number of populations and specific habitat needs of the species. *Ribes echinellum* (Coville) Rehder (Miccosukee gooseberry) is a small shrub known from only two disjunct populations (Figure 1). In Florida, *R. echinellum* is located along the north shoreline of Lake Miccosukee near Monticello, Jefferson County. In South Carolina, it is found at two main sites (or subpopulations) in McCormick County: 1) Stevens Creek Preserve, a site 1.5 m northeast of Clark Hill, and 2)

Sumter National Forest, Long Cane Ranger District (Catling et al. 1998; Figure 1). The Florida population was discovered in 1924, and the South Carolina sites were found in 1957 and 1981. It has a critically imperiled (G1) global status and is considered a species of highest priority under the SC Wildlife Action Plan (<https://www.dnr.sc.gov/swap/main/chapter2-prioritiespecies.pdf>) (USFWS, 2022).

### ***Threats and Stressors***

**Stressor:** Development (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The threat of habitat destruction or alteration is greatest at the Florida site where *R. echinellum* occurs exclusively on private property. There is no guarantee that the properties will not be developed for home-sites, agriculture, logging of associated hardwoods, recreational facilities, or other purposes in the future, although the owners have not given any indication that they intend to do so (USFWS, 2015).

**Stressor:** Predation (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Deer browsing, feral hogs rooting and fruit predation by the cotton mouse are listed as threats to this species (USFWS, 2015).

**Stressor:** Non-native species (USFWS, 2015)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The proliferation of non-native (invasive) species represents a threat to *R. echinellum* in the Steven's Creek population and to some extent at Sumter NF and in Florida. In Florida, the invasive species Japanese climbing fern (*Lygodium japonicum*) and Chinese privet (*Ligustrum* spp.) were observed on the Mays Pond conservation easement property (Negrón-Ortiz, 2007, pers. observ.). Chinese privet, coral ardisia (*Ardisia crenata*), and nandina (*Nandina domestica*) are abundant in places on Norias Plantation (Engstrom, 2010, pers. comm.). Thus this threat is not a significant concern at the current time. The manager for Steven's Creek (M. Bunch) noted significant invasion of the gooseberry site by Chinese privet and Japanese honeysuckle (*Lonicera japonica*), predominantly in the riparian area and on the north facing outcrops. The SC Department of Natural Resources hosted several volunteer workdays, and staff has worked on the problem at Steven's Creek reducing the Chinese privet, mostly by manual removal. They have conducted a limited amount of cutting and painting Chinese privet stumps using glyphosate and started controlling the Japanese honeysuckle by hand pulling. The riparian area, which was most heavily covered with Chinese privet, is now greatly improved with about 70% of this invasive removed. The same invasives have been reported for the Sumter NF subpopulations, but this threat is not currently significant (USFWS, 2015).

**Stressor:** Drought (USFWS, 2015)

**Exposure:**

**Response:****Consequence:** Loss of habitat**Narrative:** Prior to 2007, the South Carolina and Florida populations were facing a severe drought. Currently, drought is not a threat for the FL population (USFWS, 2015).**Recovery****Reclassification Criteria:**

Not relevant.

Recovery Priority Number: 11

**Delisting Criteria:**

Not developed - a recovery plan has not been issued. (USFWS, 2015)

**Recovery Actions:**

- There is no Recovery Plan for this species. (USFWS, 2015)
- Management: Foster a working partnership between Tall Timbers, the Service, and the Mays Pond conservation easement for the Florida population. (USFWS, 2015)
- Management: Foster a working partnership with the Norias Plantation and Reed property landowners. (USFWS, 2015)
- Management: Fence a larger area at Steven's Creek to protect the plants from deer herbivory and to better assess the impact of browsing on *R. echinellum*.
- Management: Monitoring and managing for invasive species i. Frequent inventories or surveys of the Florida population for invasive plant species should be established, which will help with the early detection and eradication of small patches of exotic invasive plants within the sites. This is an ongoing action for the South Carolina populations conducted by SC DNR staff and volunteers and by Sumter NF staff. ii. Eradicate the feral hog population at the Steve's Creek and Long Cane sites. Starting in May 2015, USDA APHIS has been trapping hogs for the Forest Service in compartment 314 as an effort to protect *R. echinellum* from hog damage. This should reduce hog damage in both the SNF and Steven's Creek. iii. Fence a larger area at Steven's Creek to protect the plants from feral hog damage. Fencing should consist of woven wire at least 28 inches in height to exclude feral hogs. The fence should be staked tightly against the ground to prevent uprooting and access to protected areas. (USFWS, 2015)
- Management: Fire management: Slapcinsky et al. (2010) reported that *R. echinellum* is not fire-dependent, although plant density increased gradually for three years post-fire, and reproduction increased the second year post-fire. This species has responded in different ways to fire. Management protocols cannot be implemented until a comprehensive study is conducted. i. Monitor the effect of fire (if the areas are burned) on density, fecundity, and size structure. ii. Address the following questions: What is the effect of local fire temperature, or the range of fire temperatures tolerable for the persistence of the species? How often should a prescribed fire be performed? Determine whether the lower size classes, (<30 cm tall), that were increased after fire represent 1) seedlings recruited from a seed bank present in the soil, 2) rooting branches no longer connected to the plants and growing as new clumps, and/or resprouts of fire killed stems. (USFWS, 2015)

- Management: Silvicultural practices: South Carolina population: Silvicultural practices in pine plantations upslope from *R. echinellum* are recommended to promote open woodlands dominated by native pines (shortleaf or longleaf) (SCDNR 2013). Upslope from the Sumter NF population is an area soon to be proposed for longleaf pine woodland restoration, creating more open conditions for pollinators. (USFWS, 2015)
- Research: Reproductive biology studies: The lack of sexual reproduction over long-term may threaten this species, and requires further evaluation (Gordon, 2008, pers. comm.; Negrón-Ortiz, 2012-2014, pers. observ.). a. Since recruitment from seed appeared rare (Negrón-Ortiz, 2013-2014, pers. observ.), seed germination and seedling survival studies should be expanded and continue at the FL population, and initiated at the South Carolina population. It would be desirable to compare open pollinated to hand-crossed (within source population, and between FL-SC) in seed set and seed germination. b. Establish an experimental garden Since the two populations of *R. echinellum* show low genetic diversity, signatures of bottlenecks, and excess of heterozygous which might be caused by overdominance (heterozygote has higher fitness than either homozygote; Oleas et al. 2014), an experimental garden comprising plants from both populations (FL-SC) could be established allowing natural pollination or using manual pollen transfer. The site could be where a population could be controlled (e.g. botanical garden). Fruits from crosses may then be planted, and seed germination and seedling establishment monitored. (USFWS, 2015)
- Research: Expand the seed predation study carried out by Engstrom and Radzio (2014): To answer whether the small cotton mouse is driving changes in seedling recruitment, a series of exclosures and control plots could be established at the FL population. The exclosure plots will prevent small-mammals access the plots. To determine predation of fruits, fruits should be counted before they ripen; then seed germination, seedling recruitment and plant establishment should be monitored in the experimental plots for up to three years. (USFWS, 2015)
- Research: Determine the effect of spring moisture on seed germination and recruitment.
- Research: Ex-situ initiatives: Germplasm should be separately collected from the two different populations, as the Bayesian genetic structure indicates that the FL and the SC represent different genetic clusters. Within populations, cuttings should be obtained from individuals located at greater spatial distances. Seeds from two Florida subpopulations (FL3 and FL4, see Oleas et al. 2014) should be chosen for ex situ collection because both are the localities with the highest genetic diversity. (USFWS, 2015)
- Research: The genetic study by Oleas et al. (2014) can inform reintroduction (establishment of *R. echinellum* in an area which was once part of its historical range) and augmentation (addition of *R. echinellum* plants to an existing population with the goal of strengthen numbers or provide a more varied genetic structure). According to the study, Florida subpopulation FL 4 shows higher level of genetic diversity and the individuals of this group might be considered good candidates for augmentation or reintroduction programs within the FL population. (USFWS, 2015)
- Research: Establish or implement monitoring for both Florida and South Carolina populations, as needed. Note: The Sumter NF already has a monitoring program, and Steven's Creek began a long-term study in February 2008. Given the limited distribution of the species, a monitoring program should be implemented. Jones (1986) suggested a monitoring program at 10 year intervals, which was implemented to some extent by TNC but at one year interval from 1992 to 2001 in Florida. a. In Florida, TNC transects are well-

established with the re-bar and metal labels in Mays Pond North and Mays Pond South. Data should be collected on these transects every five years to monitor these subpopulations. In the future, all trees >10 cm DBH and all *R. echinellum* patches should be mapped within each transect. This will provide guidance for positioning the survey tape and monitoring clumps (a rooted stem or tight cluster of stems that is separated by at least 10 cm from the next closest rooted stem; Engstrom 2011) within patches (group of clumps that are at least 1 m from any other clump or patch; Engstrom 2011) will provide another dimension to *R. echinellum* dynamics. b. The entire Florida population, which has been geo-referenced, should be re-surveyed every five years. The approximate number of clumps, patches, flowers and fruits should be noted at each GPS point. c. For both the Florida and the South Carolina populations, permanent plots could be established, and for each plot: Establish size classes (clump length and width), and estimate population size (density and abundance of individuals and/or clumps) and reproductive clumps (no. of flowering plants, and no. of flowers, fruits and seeds/fruits per plant). The length of longest stem should be used as one of the monitoring clump. This is an ongoing effort for the FL population. (USFWS, 2015)

- Research: Conduct surveys/inventories on potentially new sites, between Northern Florida and South Carolina. This action can include the use of GIS to initially determine potential sites, and later inspection for plants. South Carolina DNR recommend additional surveys of both the steeper bluffs with basic mesic forests and the drier sites along the Steven's/Turkey Creek drainage throughout the adjoining Sumter NF. (USFWS, 2015)
- Research: Population genetic studies: Molecular studies will help clarify the extent and pattern of genetic variability throughout these populations and potential sources of rarity (e.g., unique alleles). A genetic study of the South Carolina sites is encouraged. (USFWS, 2015)
- Research: The development of a Biological Species Status Assessment is recommended for this species. The assessment will provide an in-depth account of the species' overall viability and extinction risk. (USFWS, 2015)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES Assessing Florida Population 1. Establish a working group to support regional conservation work for *R. echinellum* The Southeastern Plant Conservation Alliance (SE PCA) is managed by the Atlanta Botanical Garden (ABG). A pilot project funded (\$15K) by the Service in 2020 will contribute to assess the status of the Florida private lands population (reproductive status, provide baseline data, and collect fruit per Center for Plant Conservation guidelines for propagation and seed banking) to prevent extirpation. Efforts to date: • 2021-2022: Pilot project will be initiated in FY22. The ABG applied for FWS funding for additional demographic and ex situ/ in situ work, including baseline demography and additional work in both states. Since proposal was not awarded, the SE PCA will attempt to find further funding to compliment and leverage the \$15K pilot project that will go towards the 1st year work in FL - this would also allow SE PCA to work in both states to maximize benefits and accomplish several Recovery actions. ♦ Assess the species' overall viability, and the risk of endangerment / extirpation of the FL population. • ABG recruited and will be advising Emory Univ. graduate student Joseph Stockert. Joseph will be monitoring *R. echinellum* survival, growth, and reproduction across the species range from 2022-2025. Data will be used to parameterize structured demographic models to provide a comprehensive assessment of the status of these remnant populations, i.e., projected growth rate of each population. Management 1. Foster a working partnership between Tall Timbers, the

Service, and the Mays Pond conservation easement for the Florida population. 2. Foster a working partnership with the Norias Plantation and Reid property landowners. Ongoing by several partners. 3. Fence a larger area at Stevens Creek to protect the plants from deer herbivory and to better assess the impact of browsing on *R. echinellum*. 4. Monitoring and managing for invasive species i. Frequent inventories or surveys of the Florida population for invasive plant species should be established, which will help with the early detection and eradication of small patches of exotic invasive plants within the sites. This is an ongoing action for the South Carolina populations conducted by SC DNR staff and volunteers and by Sumter NF staff. ii. Eradicate the feral hog population at the Steve's Creek and Long Cane sites. Starting in May 2015, USDA APHIS has been trapping hogs for the Forest Service in compartment 314 as an effort to protect *R. echinellum* from hog damage. This should reduce hog damage in both the SNF and Stevens Creek. iii. Fence a larger area at Stevens Creek to protect the plants from feral hog damage. Fencing should consist of woven wire at least 28 inches in height to exclude feral hogs. The fence should be staked tightly against the ground to prevent uprooting and access to protected areas. iv. Most of the habitat where *R. echinellum* occurs is relatively free of invasive nonnative plants. However, the transitional area from the slope forest (north) to the swamp hammocks (south) has some dense Chinese privet and coral ardisia populations. The gooseberry could benefit by eradicating these non-natives, and controlling the high densities of Carolina laurel cherry (*T. Engstrom*, 2021, pers. comm.) 5. Fire management Slapcinsky et al. (2010) reported that *R. echinellum* is not fire-dependent, although plant density increased gradually for three years post-fire, and reproduction increased the second-year post-fire. This species has responded in different ways to fire; therefore, management protocols cannot be implemented until a comprehensive study is conducted. We suggested studies to assess the effect of fire on density, fecundity, and size structure. Address the following questions: 1. What is the effect of local fire temperature, or the range of fire temperatures tolerable for the persistence of the species? 2. How often should a prescribed fire be performed? 3. Determine whether the lower size classes, (<30 cm tall), that were bank present in the soil, rooting branches no longer connected to the plants and growing as new clumps, and/or resprouts of fire killed stems. 6. Silvicultural practices South Carolina population: Silvicultural practices in pine plantations upslope from *R. echinellum* are recommended to promote open woodlands dominated by native pines (shortleaf or longleaf) (SCDNR 2013). Upslope from the Sumter NF population is an area soon to be proposed for longleaf pine woodland restoration, creating more open conditions for pollinators. Research 1. Reproductive biology studies The lack of sexual reproduction over long-term may threaten this species and requires further evaluation (Negrón-Ortiz 2018). a. Since recruitment from seed appeared rare (Negrón-Ortiz 2018), seed germination and seedling survival studies should be expanded and continue at the Florida population, and initiated at the South Carolina population. It would be desirable to compare open pollinated to hand-crossed (within source population, and between FLSC) in seed set and seed germination. In addition, the effect of spring moisture on seed germination and recruitment could also be explored. b. Establish an experimental garden at a botanical garden. Since the two populations of *R. echinellum* show low genetic diversity, signatures of bottlenecks, and excess of heterozygous which might be caused by overdominance (heterozygote has higher fitness than either homozygote; Oleas et al. 2014), an experimental garden comprising plants from both populations (FL-SC) could be established allowing natural pollination or using manual pollen transfer. Fruits from crosses may then be planted, and seed germination and seedling establishment monitored. 2. Ex-situ initiatives Germplasm should be separately collected from the two different populations, as the Bayesian genetic structure indicates that the Florida and the South Carolina represent different genetic clusters. Within populations, cuttings should be obtained from individuals located at greater spatial distances. Seeds from Mays Pond FL3 and FL4 (Oleas et al. 2014) should be chosen for ex situ collection because both are the localities with the highest genetic

diversity. 3. Expand the seed predation study carried out by Engstrom and Radzio (2014) To answer whether the small cotton mouse is driving changes in seedling recruitment, a series of exclosures and control plots could be established at the Florida population. The exclosure plots will prevent small mammals access the plots. To determine predation of fruits, fruits should be counted before they ripen; then seed germination, seedling recruitment and plant establishment should be monitored in the experimental plots for up to three years. 4. In-situ initiatives:

**Augmentation/Reintroduction** The genetic study by Oleas et al. (2014) can inform reintroduction (establishment of *R. echinellum* in an area which was once part of its historical range) and augmentation (addition of *R. echinellum* plants to an existing population with the goal of strengthen numbers or provide a more varied genetic structure). According to the study, Mays Pond FL4 shows higher level of genetic diversity and the individuals of this group might be considered good candidates for augmentation or reintroduction programs within the Florida population. 5. Establish or implement monitoring for both Florida and South Carolina populations, as needed. Note: The Sumter NF already has a monitoring program, and Stevens Creek began a long-term study in February 2008. Given the limited distribution of the species, a monitoring program should be implemented. Jones (1986) suggested a monitoring program at 10-year intervals, which was implemented to some extent by TNC but at one year interval from 1992 to 2001 in Florida. a. In Florida, TNC transects are well-established with the re-bar and metal labels in Mays Pond North and Mays Pond South. Data should be collected on these transects every 5-10 years to monitor these subpopulations. In the future, all trees >10 cm DBH and all *R. echinellum* patches should be mapped within each transect. This will provide guidance for positioning the survey tape and monitoring clumps (a rooted stem or tight cluster of stems that is separated by at least 10 cm from the next closest rooted stem; Engstrom 2011) within patches (group of clumps that are at least 1 m from any other clump or patch; Engstrom 2011) will provide another dimension to *R. echinellum* dynamics. b. The entire Florida population, which has been geo-referenced, should be re-surveyed every 10 years. The approximate number of clumps, patches, flowers and fruits should be noted at each GPS point. c. For both the Florida and the South Carolina populations, permanent plots could be established, and for each plot: Establish size classes (clump length and width) and estimate population size (density and abundance of individuals and/or clumps) and reproductive clumps (no. of flowering plants, and no. of flowers, fruits and seeds/fruits per plant). The length of longest stem should be used as one of the monitoring clumps. This is an ongoing effort for the Florida population. 6. Conduct surveys/inventories a. On potentially new sites, between Northern Florida and South Carolina. This action can include the use of GIS to initially determine potential sites, and later inspection for plants. South Carolina DNR recommend additional surveys of both the steeper bluffs with basic mesic forests and the drier sites along the Stevens/Turkey Creek drainage throughout the adjoining Sumter NF. b. Map the entire boundary of *R. echinellum* every 10-15 years. The distribution of the FL population was mapped in 1985 and a re-survey of the same location, 25 years later, verified its boundary remains the same. 7. Population genetic studies Molecular studies will help clarify the extent and pattern of genetic variability throughout these populations and potential sources of rarity (e.g., unique alleles). A genetic study to understand diversity and clonality of the South Carolina sites is encouraged (USFWS, 2022).

## SPECIES ACCOUNT: *Rorippa gambellii* (Gambel's watercress)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Southwest (R8) (USFWS, 2015)

### **Physical Description**

A perennial rhizomatous (with creeping underground stems) branched herb that can grow up to 2 meters (6 feet) tall (this height is confirmed by John Chesnut [in litt. 1998] at Oso Flaco Lake). It roots at lower stem nodes, while the upper stem generally remains erect (Figure 2, Photo 2). It blooms from April to July, producing dense inflorescences (flower clusters) with white flowers; the lateral inflorescences may bloom through August. The inflorescences produce 15 to 30 fruits with about 10 to 30 seeds each (Price 1989). The plant has pinnate (feather-shaped) leaves with 7 to 13 uniform leaflets, which are angular and dentate (toothed) in the upper leaves. Small lobes are present at the base of the leaf stalk. Lower flower stalks often have bracts (specialized leaves), and pedicel (flower stalk) junctions with the main stem are flat. These characters separate this taxon from a look-alike, watercress (*Rorippa nasturtium-aquaticum*), whose three to seven lateral leaflets are entire or wavy-margined and smaller than the terminal leaflet; the leaflets are more lobed than angular in the upper leaves. The smaller flowers of *Rorippa nasturtium aquaticum* are supported by pedicels without bracts or flat stem junctions. Moreover, the linear and narrower fruits of *Rorippa gambellii* have more finely reticulate (net-patterned) seeds, which are arranged in one row per chamber, versus two rows per chamber in *Rorippa nasturtium-aquaticum*. (USFWS, 1998)

### **Taxonomy**

*Nasturtium gambellii* was originally described as *Cardamine gambellii* in 1876 based on a specimen collected by William Gambel in 1844 in the vicinity of Santa Barbara (Watson 1876). *Nasturtium gambellii*, the currently recognized name, was originally listed by the Service as endangered under the name *Rorippa gambellii* (Service 1993). While the circumscription of the species (the limits of the species characters and range) has remained constant since its original description, it has been recognized under several different names (some of the names have similar spelling, but because they were recorded with slightly different names they are listed separately), including *Cardamine gambellii* (Watson 1876, Abrams 1944), *Cardamine gambellii* (Jepson 1923; Munz 1959, 1968, 1970, 1974; Hoover 1970; Roberts 1989), *Rorippa gambellii* (Smith 1976, 1998; Roberts 1998; Service 1998, CNPS 2001), *Rorippa gambellii* (Al-Shehbaz and Rollins 1988, Rollins 1993, Service 1993, Skinner and Pavlik 1994), *Nasturtium gambellii* (Al-Shehbaz and Price 1998), and *Nasturtium gambellii* (Index of California Plant Names 2009). (USFWS, 2011)

### **Historical Range**

Historically, *Nasturtium gambellii* occurred in cismontane regions (on the coastward side of the mountains) of central and southern California, in Orange, San Bernardino, Los Angeles, Santa Barbara, and San Luis Obispo Counties, California. (USFWS, 2011)

### **Current Range**

Pure *Nasturtium gambellii* plants are currently known from one remaining wild population on Vandenberg Air Force Base in Santa Barbara County, California (Keil 1997, CNDDDB 2010), and one additional site where plants were introduced in October 2008 on the Refuge in San Luis

Obispo County, California. (USFWS, 2011)

**Critical Habitat Designated**

No;

***Life History*****Food/Nutrient Resources****Reproductive Strategy**

Adult: Self-pollinating (NatureServe, 2015)

**Reproduction Narrative**

Adult: Pollinator exclusion experiments have been conducted on this species in the field (Mazer et al. 1994) and demonstrated seed set in bagged specimens. No pollinators were ever seen in 2 seasons of fieldwork. Soil cores taken from the sites where *Rorippa* are still extant show a viable seed bank in the soil throughout the spring and summer growing season. These seeds germinated under greenhouse conditions. Detailed mortality and longevity data are not yet available for these dormant seeds. The average lifetime fruit and seed production for the Black Lake Canyon population of *Rorippa* has been estimated at 85.8 fruits and 882 seeds.; *Rorippa gambelii* requires permanent fresh or brackish wetland areas. It is intolerant of competition and seems to require clearings to survive. Encroaching eucalyptus trees are competing for water and light, and alleopathic effects from the trees may also be harming the *Rorippa* population. No known diseases or pests attack *Rorippa*. The very limited distribution of this species and changes in local hydrology are threatening it with extinction.; Predominantly selfing (NatureServe, 2015).

**Habitat Type**

Adult: Wetlands (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Species inhabits permanent wetlands, fresh or brackish, in marshes or along the borders of lakes and slow-flowing streams or ditches. Soils are acidic sandy peats. Sea level to 450 m elevation. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the limited number of populations and the specific habitat requirements of this species.

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Seed dispersal needs further research (USFWS, 1998)

***Population Information and Trends*****Population Trends:**

Decreasing (NatureServe, 2015)

**Number of Populations:**

1 (USFWS, 2022)

**Population Narrative:**

There is currently only one extant, non-hybridized Gambel's watercress population at VSFB, consisting of two separate colonies that occupy a total of 0.024 hectare/0.06 acre (Lum 2021, pers comm). Abundance is unknown due to difficulty of discerning genetically unique individuals above-ground. Currently, we do not have any proposed outplanting projects for the species. (USFWS, 2022) . In 2020, the Service funded a project designed to evaluate the hybridization potential of Gambel's watercress and learn more about its reproductive biology and breeding strategy in an ex situ, greenhouse setting. Santa Barbara Botanic Garden (SBBG) staff made three bulk Gambel's watercress seed collections from the two extant patches at VSFB to start this work in August of 2021. They collected a total of 3,371 seeds from the eastern patch and 1,888 seeds from the western patch. SBBG will bank any seeds not used in direct support of the project (Schneider 2021, pers comm). These banked seeds are of use for additional seed bulking efforts, outplanting recovery projects, and can serve as backup in the event of catastrophic loss of the species. (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Development/Urbanization (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Since the time of listing, there has been a loss and degradation of habitat due to development and urbanization and a conversion of marsh habitat due to the collateral, but indirect, effects from development and urbanization. Some of this habitat loss has occurred in watersheds that are classified as impaired by the Regional Water Quality Control Board due to excessive amounts of nitrogen and other nutrients (California State Water Resources Control Board 2006a). The vegetation in these watersheds exhibits excessive growth that is consistent with biostimulation and eutrophication (California State Water Resources Control Board 2006a, California State Water Resources Control Board 2006b, Central Coast Ambient Monitoring Program 2002, Dodds et. al. 1998). The excessive growth of some vegetation (e.g., willows, bulrush, Typha (cattails)) causes type conversion of habitat (such as at Black Lake Canyon and Oso Flaco Lake) and a decline in the quantity and quality of habitat suitable for *Nasturtium gambelii*. Most of the historical populations and their surrounding areas are urbanized and/or indirectly impacted by urbanization, which has further limited this species' ability to colonize adjacent suitable habitat. These conditions also limit sites and opportunities for successful

introductions and reintroductions. (USFWS, 2011).

**Stressor:** Predation (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Herbivory has been noted on plants at the introduced site on the Refuge (M.A. Elvin, pers. obs. 2009) and on plants under propagation at University of California, Irvine (UCI) Arboretum (Barry Nerhus, U.C. Irvine, pers. comm. 2006). While this plant may be able to withstand some herbivory, the herbivory may cause a reduction in its reproductive success due to the loss of flowers and the corresponding reduction in the production of seeds. The extent of this threat is not known, but the loss of even a few flowers due to herbivory, if it led to an even slight decrease in reproductive success, may have a significant effect on the long-term survival of *N. gambelii* because there are so few individuals remaining in the wild. Therefore, the relative threat from predation is greater now than was thought to be the case at the time of listing, because there are fewer populations and fewer individuals per population than at the time of listing (USFWS, 2011).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** From the time of listing until recently, existing regulatory mechanisms appear to have done little to ameliorate threats to *Nasturtium gambelii*, and substantial threats remain; however, recent efforts to improve protections may provide additional benefit to the species in the future. Other Federal and State regulatory mechanisms (e.g., CEQA, California Coastal Act) provide discretionary protections for the species based on current project review and permitting practices (USFWS, 2011).

**Stressor:** Small population size (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Extinction/lack of genetic diversity

**Narrative:** The conservation biology literature commonly notes the vulnerability of taxa known from very few locations or from small and highly variable populations (e.g., Shaffer 1981, 1987; Primack 2006; Groom et al. 2006). The small size of the gene pool of the species (Mazer et al. 2000) may depress reproductive vigor, or increase the likelihood that a single human-caused or natural environmental disturbance (e.g., flood, drought, disease) could cause the extinction of *Nasturtium gambelii*. Small populations are threatened by inbreeding depression (Ellstrand and Elam 1993). Small plant populations can have significantly lower germination rates than larger populations of the same species due to high levels of homozygosity (having identical pairs of alleles for any given gene), which could result in the expression of disadvantageous traits (Menges 1991). Genetic stochasticity results from changes in gene frequencies due to founder effect, random fixation, or inbreeding (Shaffer 1981). The low levels of genetic variation among and within populations could impair the species' ability to adapt to changes in the environment or contribute to inbreeding depression (i.e., loss of reproductive fitness or vigor). The existence of less than five populations and the small number of individuals in these populations places *Nasturtium gambelii* at extreme risk of extinction due to low levels of genetic diversity (USFWS,

2011).

**Stressor:** Other natural or manmade factors (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/extinction

**Narrative:** Natural catastrophes such as fire, landslide, or prolonged drought could result in the loss of populations (Shaffer 1981), particularly for species with fewer than five populations. An increase in urban development has reduced the range of *Nasturtium gambelii* considerably. Indirect effects from urbanization in the watershed include changes in hydrology, changes in vegetation, and an increase in nonnative species. Increasing development in the area will likely increase threats from stochastic events. We believe that the existence of one known wild population and the small number of individuals in the population exacerbate the risk of extinction to *Nasturtium gambelii* from stochastic events.

**Stressor:** Competition with nonnative species (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The effects of competition with nonnative species are most problematic immediately adjacent to urban areas and in habitat that has been isolated or fragmented by development (Alberts et al. 1993). These factors may not be enough to threaten the survival of *Nasturtium gambelii* independently, but taking into account its limited range, the cumulative and synergistic effects of all of these factors combined could be a threat to the survival and recovery of *N. gambelii* (USFWS, 2011).

**Stressor:** Nutrient loading in watersheds (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Threats identified since the time of listing include excessive amounts of nitrogen and other nutrients in watersheds that either currently support or historically supported *Nasturtium gambelii*. These nutrient levels can cause excessive growth of vegetation (biostimulation) in some species that may out-compete *N. gambelii* plants. The excessive growth of other vegetation (both native and nonnative) can have direct effects on *N. gambelii* individuals. The other plants can outcompete *N. gambelii* individuals for essential physical and biological elements (i.e., space for growth, food, water, light, minerals). This stress likely effects the survival of some individual plants or occurrences and increases the impact of threats to the species from stochastic events (USFWS, 2011).

**Stressor:** Climate change (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Park et al. (1989) projected that of the saltmarshes along the coast of the contiguous United States, 30 percent would be lost with a 1.6-foot (0.5-m) SLR, 46 percent with a 3.3-foot (1-m) SLR, 52 percent with a 6.6-foot (2-m) SLR, and 65 percent with a 9.8-foot (3-m) SLR. While we cannot project directly to California from the estimates of Park et al. (1989) who focused on the

east coast and Gulf coast of the United States, we can anticipate that with a projected SLR of up to almost 6.6 feet (2 m) that much of the coastal saltmarshes in California would be lost by 2100. Beaches, dunes, and coastal areas would be subject to greater and more frequent wave attack, with a general rule of thumb that 50 to 100 feet (15 to 30 m) of beach width will be lost from use for every foot of sea level rise by the year 2100 (CCC 2001, Heberger et al. 2009). This is estimated to result in erosion and shoreline retreat between 459 and 1,083 feet (140 and 330 m), corresponding to an estimated loss of approximately 1.4 square miles (896 acres) of dunes in San Luis Obispo County by the year 2100 (CCC 2001, Heberger et al. 2009). Because *Nasturtium gambelii* historically occurred in coastal dune habitats throughout its range, erosion of these areas caused by an estimated rise in sea level could cause a loss of individual plants and seed banks for this species (USFWS, 2011).

**Stressor:** Genetic swamping (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Lack of genetic variability

**Narrative:** The *N. gambelii* plants at Oso Flaco Lake appear to be genetically compromised and introgressed with the locally abundant nonnative species *N. officinale* based on morphological and molecular evidence of hybridization (Mazer et al. 2000; Prince 2008a, 2008b; CNDDDB 2009, 2010; CNPS 2009). The *N. gambelii* population (at VAFB) has at least two individuals that may be of hybrid origin with *N. officinale* (Prince 2008a, 2008b). The introgression of *N. gambelii* plants at Oso Flaco Lake and the potential introgression of two *N. gambelii* plants at VAFB (Mazer et al. 2000; Prince 2008a, 2008b; CNDDDB 2009, 2010; CNPS 2009) suggest the species is in danger of extinction.

### **Recovery**

#### **Reclassification Criteria:**

1. When new plants are established so that there are at least 5 populations of at least 500 individuals each (USFWS, 1998)
2. When some of the populations occur in permanently protected habitats within the Black Lake Canyon and the dune lakes area (USFWS, 1998)
3. When some of the populations are in other areas of suitable habitat with the species' historical range in the United States (USFWS, 1998)
4. When the populations remain viable for at least 5 years. Viable populations are defined as those that are showing natural reproduction and either stable or increasing in size over time, without artificial augmentation (USFWS, 1998)

#### **Delisting Criteria:**

1. If threats are reduced or eliminated so that protected populations are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species. The most outstanding management needs currently are: a) controlling competition with nonnative species and hybridization with common watercress, and b) managing water conditions, particularly flow and nutrient loads, that the species depends on. (USFWS, 2019)

2. If populations are established across the species ecological settings (in addition to Black Lake Canyon and the Dune Lakes area in San Luis Obispo County), including suitable site(s) in the Santa Barbara County and Ventura County region (e.g.; the San Antonio Creek drainage on Vandenberg Air Force Base or comparable sites); and coastal wetlands in Los Angeles, Orange, or San Bernardino Counties (USFWS, 2019)

3. If the populations remain viable for at least 10 years. Because this species has narrow microhabitat conditions that it will tolerate, particularly with respect to water flow and nutrient loads, and in light of fluctuations that can occur with climatic conditions and local water availability and nutrient loading, the persistence of populations with these varying conditions over time needs to be confirmed. (USFWS, 2019)

**Recovery Actions:**

- 1. Protect, maintain, and enhance species habitats. The most important immediate objective in the recovery plan for *Rorippa gambelii* is the protection of its habitat. - Coordinate among agencies involved in recovery activities. - Define and maintain the sensitive Resource Area boundary and restrictions at Black Lake Canyon. - . Establish protection agreements. - Acquire key land parcels and conservation easements. Enhance existing habitat at Black Lake Canyon. - Continue to protect, maintain, and enhance habitat in the Dune Lakes area. - . Communicate species and habitat protection information to all concerned parties. (USFWS, 1998)
- 2. Document and monitor population and habitat characteristics. - Conduct plant surveys. - Protect newly discovered populations. - Monitor all populations and habitats. (USFWS, 1998)
- 3. Conduct research on the ecology and biology of the species. - Identify potential impacts of conducting research. - Determine population characteristics and life history of the species. - evaluate species' tolerances. - Investigate the effects of genetic diversity. (USFWS, 1998)
- 4. Augment existing populations. In addition to protecting existing and newly discovered habitats of *Rorippa gambelii*, monitoring these populations and their habitats, and conducting research on the biology and ecology of the species, attempts should be made to augment existing populations. (USFWS, 1998)
- 5. Establish new populations. Because *Rorippa gambelii* currently has very restricted distribution in California, establishment of new populations within the historic range of the species at potentially suitable sites other than at historic sites should be attempted. If new populations are successfully established, it will reduce the likelihood that a catastrophic event could result in the extinction of the species with its current restricted distribution. (USFWS, 1998)
- 6. Evaluate Progress and Update Management and Recovery Guidelines. Results of all recovery activities should be evaluated and incorporated into updated management and recovery guidelines for the species. All relevant information should be distributed. (USFWS, 1998)
- Work with the U.S. Air Force at Vandenberg Air Force Base to implement site-specific management activities in the immediate future to avoid and alleviate threats (such as from stochastic events) to prevent the loss of the last, known remaining wild population (USFWS, 2011).

- Work with others to establish new populations in the near future to reduce the risk of extinction to *Nasturtium gambelii* in each of the two ecological regions of its historical range in California (coastal central California and coastal southern California) (USFWS, 2011).
- Work with others to establish and maintain ex situ stock populations with at least one institution in each of the three ecological regions of its historical ranges (USFWS, 2011).
- Work with the Central Coast Regional Water Quality Control Board to determine nutrient levels in the watersheds which historically supported *Nasturtium gambelii* in the recent past (particularly Black Lake Canyon and Oso Flaco Lake) to determine what may have led to the loss of *N. gambelii* from these sites, and work with local landowners and stakeholders to alleviate (and remove) any threats to *N. gambelii* that are associated with water quality (USFWS, 2011).
- Continue genetic analyses to determine the extent of variation within and between *Nasturtium gambelii* populations and the magnitude of the threat of gene swamping from *N. officinale* to help determine an appropriate recovery and reintroduction strategy (USFWS, 2011).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Conduct annual monitoring of both the VSFB and Oso Flaco Lake Gambel's watercress populations. Include counting and reporting the number of above ground vertical stems and global positioning system (GPS) mapping of occupied spatial area, co-occurring and co-dominant vegetation, presence of natives versus nonnative species, percent canopy cover, hydrological conditions, timing of phenology, and presence of potential insect pollinators. Consistent data collection and reporting will allow for meaningful comparisons and analyses of trends. 2. Implement threats management activities at each population, including vegetation management such as trimming and removal, invasive weed abatement, and sediment removal and erosion controls. 3. Document the presence and extent of common watercress within the San Antonio Creek and Oso Flaco Lake watersheds. Improve assessment of morphological traits of pure versus hybrid Gambel's watercress to better facilitate rapid visual assessments of introgression in the field. Conduct control and eradication of common watercress where appropriate. 4. Develop an effective rapid method for sequencing and genotyping to characterize Gambel's watercress genetic population structure and accurately evaluate abundance. 5. Determine if the seed bank harbors additional Gambel's watercress genetic diversity. If so, introduction/reintroduction projects may utilize such grown out plants and potentially restore lost genetic integrity to the species. 6. Determine how vegetative succession and other hydrological changes associated with eutrophication and biostimulation are affecting the species and employ remedial measures to restore occupied habitats to optimal conditions for recovery. 7. Research the species reproductive biology to evaluate and quantify hybridization with common watercress, including self-compatibility, breeding system, seed viability, and morphology of pure and hybrid lineages. Work to better understand the species pollinators, fruiting and seed production, and optimal ecological factors that favor Gambel's watercress growth and population expansion. 8. Conduct genetic studies and other controlled experiments to evaluate the hypothesis that hybrid individuals have reduced viability and that when we remove common watercress, selective forces may act over successive generations to return genotypes back to pure Gambel's watercress forms. (USFWS, 2022)

## SPECIES ACCOUNT: *Sanicula purpurea* (No common name)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

### **Physical Description**

*Sanicula purpurea* is a stout and erect perennial member of the Apiaceae (parsley family). It ranges in height from 8 to 36 cm (3.1 to 14.2 in) with stems originating from numerous kidney-to heart-shaped basal leaves that are 3 to 7-lobed and 2 to 8 cm (0.8 to 3.1 in) wide. The small purple or cream-colored flowers form branched terminal umbels of 6 to 10 flowers. Fruits are spherical, prickly, and 2.0 to 3.5 mm (0.08 to 0.14 in) long and 2 to 3 mm (0.08 to 0.12 in) wide (Wagner et al. 1999).

### **Historical Range**

See current range/distribution

### **Current Range**

*Sanicula purpurea* is known from Oahu and Maui. On Oahu, it occurred along the Koolau Mountain summit crest from 700 to 1,698 m (2,300 to 5,570 ft) elevation on wet, windswept slopes. Currently, on Oahu, 45 individuals are found as part of six occurrences at Helemano-Punaluu divide (10 individuals), north Kaukonahua-Punaluu Summit (8), Kaukonahua-Kahana summit (22), Waimalu-Kahaluu summit divide (1), Puu Keahiakahoe (1), and Wailupe-Waimanalo summit divide (3) (HINHP Database 2001; K. Kawelo, U.S. Army, pers. comm. 2003; J. Lau, HINHP, pers. comm. 2003). On West Maui, 200 individuals are distributed throughout seven scattered occurrences along 2.5 km (1.6 mi) of the Puu Kukui trail and on the West Maui Natural Area Reserve in the Puu Kukui watershed. In total, there are 245 individuals of *S. purpurea* known to remain in the wild (Service 1999b; K. Kawelo, U.S. Army, pers. comm. 2003; J. Lau, HINHP, pers. comm. 2003).

### **Critical Habitat Designated**

Yes; 3/30/2016.

### **Legal Description**

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Sanicula purpurea* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two critical habitat units (CHUs), in Hawaii (81 FR 17790-18110). On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Sanicula purpurea* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Sanicula purpurea* (77 FR 57648-57862). The critical habitat designation includes 14 critical habitat units, which encompass approximately 30,056 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Sanicula purpurea* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

**Critical Habitat Designation**

The critical habitat designation for *Sanicula purpurea* includes seven CHUs in Maui County, Hawaii. Approximately 1,399 ac (567 ha) of federal, private and state land on the Island of Maui (west Maui) are being designated as critical habitat for *Sanicula purpurea*. (81 FR 17790-18110).

Maui—Montane Wet—Unit 6 (and) *Palmeria dolei*—Unit 15—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 15—Montane Wet This area consists of 1,113 ac (451 ha) of State land, and 286 ac (116 ha) of privately owned land, at the summit and surrounding areas on west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta*, *Calamagrostis hillebrandii*, *Cyanea kunthiana*, *Geranium hillebrandii*, *Myrsine vaccinioides*, and *Sanicula purpurea*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 6 is not known to be occupied by the plants *Acaena exigua*, *Cyrtandra oxybapha*, *Huperzia mannii*, *Phyllostegia bracteata*, or *Platanthera holochila*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

The critical habitat designation for *Sanicula purpurea* includes 14 critical habitat units, covering two ecosystem types, which encompass approximately 30,056 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Wet—Units 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16; Oahu—Wet Cliff—Units 6, 7, 8.

Oahu—Lowland Wet—Unit 6 [790 ac (320 ha)]. This area consists of 790 ac (320 ha) of privately owned land in the lowland wet ecosystem, in privately owned land on the windward side of the Koolau Mountains, and includes Kahawainui, Ihiihi, Waialele, and Koloa gulches. Oahu—Lowland Wet—Unit 7 [1,787 ac (723 ha)]. This area consists of 1,499 ac (606 ha) of State land and 288 ac (117 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, within the Kaipapau and Haula Forest Reserves and Sacred Falls State Park, from Puukainapuaa to Kaluanui (Sacred Falls). Oahu—Lowland Wet—Unit 8 [3,041 ac (1,231 ha)]. This area consists of 1,386 ac (561 ha) of State land and 1,655 ac (670 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, partially within the Ahupuaa O Kahana State Park, including Waihoi Springs, and Punaluu, Kahana, Waikane, Waikeekee, and Uwao streams. Oahu—Lowland Wet—Unit 9 [15,728 ac (6,365 ha)]. This area consists of 3,827 ac (1,545 ha) of State land, 147 ac (60 ha) of City and County of Honolulu land, 4,509 ac (1,825 ha) of Federal land (U.S. Fish and Wildlife Service), and 7,245 ac (2,932 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, partially within the Ewa FR Waimano Section and the Oahu Forest National Wildlife Refuge. This area extends along the Koolau summit from Waipio to Manaiki Stream. Oahu—Lowland Wet—Unit 10 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) of privately-owned land in the lowland wet ecosystem in private land on the windward side of the Koolau Mountains, along Kaalaea Stream. Oahu—Lowland Wet—Unit 11 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) in the lowland wet ecosystem, owned by the City and County of

Honolulu on the windward side of the Koolau Mountains, along Waihee Stream. Oahu—Lowland Wet—Unit 12 [53 ac (21 ha)]. This area consists of 28 ac (11 ha) of City and County of Honolulu land and 26 ac (10 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Kahaluu Stream and tributary. Oahu—Lowland Wet—Unit 13 [75 ac (30 ha)]. This area consists of 74 ac (30 ha) of City and County of Honolulu land and 1 ac (0.5 ha) of State land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Heeia Stream and tributaries. Oahu—Lowland Wet—Unit 14 [478 ac (193 ha)]. This area consists of 274 ac (111 ha) of State land, 195 ac (79 ha) of City and County of Honolulu land, and 9 ac (4 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, extending from the Wilson Tunnel area southeast to Moole Stream. Oahu—Lowland Wet—Unit 15 [407 ac (165 ha)]. This area consists of 407 ac (165 ha) in the lowland wet ecosystem in State of Hawaii Department of Land and Natural Resources Land Division land on the windward side of the Koolau Mountains in Maunawili Valley, including Omao and Maunawili streams and Kapakahi and Pikoakea Springs. Oahu—Lowland Wet—Unit 16 [2,507 ac (1,014 ha)]. This area consists of 1,533 ac (621 ha) of State land, 365 ac (148 ha) of City and County of Honolulu land, and 608 (246 ha) of privately owned land in the lowland wet ecosystem in on the leeward side of the Koolau Mountains, partly within the Honolulu Watershed Forest Reserve, extending from the eastern side of Nuuanu Valley southeast along the Koolau summit to Kulepeamo Ridge.

Oahu—Wet Cliff—Unit 6 [151 ac (61 ha)]. This area consists of 151 ac (61 ha) in the wet cliff ecosystem on State land on the windward side of the Koolau Mountains in Kaipapau Gulch, entirely within the Kaipapau Forest Reserve. Oahu—Wet Cliff—Unit 7 [144 ac (58 ha)]. This area consists of 144 ac (58 ha) in the wet cliff ecosystem in State land on the windward side of the Koolau Mountains in Hauula Gulch, entirely within the Hauula Forest Reserve. Oahu—Wet Cliff—Unit 8 [4,649 ac (1,881 ha)]. This area consists of 1,479 ac (598 ha) of State land, 1,281 ac (519 ha) of City and County of Honolulu land, 5 ac (2 ha) of Federal land, and 1,884 ac (762 ha) of privately owned land, in the wet cliff ecosystem along the summit of the Koolau Mountains, overlapping portions of Sacred Falls State Park, the Waiahole FR (Waiahole and Iolekaa sections), the Kaneohe and Honolulu Watershed FRs, and the Nuana Pali State Wayside.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Sanicula purpurea* critical habitat consists of one component (81 FR 17790-18110):

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: Ferns, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*. Species-specific physical or biological features: Bogs.

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Sanicula purpurea* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Sanicula purpurea* occurs within the Lowland wet and Wet cliff ecosystems in the Koolau Mountain caldera complex:

Oahu—Lowland Wet—Units 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. (E) Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. (F) Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Oahu—Wet Cliff—Units 6, 7, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: >65 degree slope, shallow soils, weathered lava. (D) Canopy: None. (E) Subcanopy: *Broussaia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. (F) Understory: Bryophytes, Ferns, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

### Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the

critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Sanicula purpurea* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

***Life History*****Food/Nutrient Resources****Reproduction Narrative**

Adult: Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors for *S. purpurea* are unknown. *S. purpurea* is considered to be a short-lived perennial (Service 1999b).

**Habitat Type**

Adult: Montane bogs

**Habitat Narrative**

Adult: *Sanicula purpurea* occurs in open mixed montane bogs or *Metrosideros* polymorph-dominated mixed montane bogs and windswept shrublands within the cloud zone between 415 and 959 m (1,361 and 3,146 ft) elevation. Associated native plant species include *Bidens* spp., *Cheirodendron* spp., *Dicanthelium koolauense*, *Gahnia beechyi*, *Leptecophylla tameiameia*, *Lycopodium* spp., *Machaerina angustifolia*, *Plantago pachyphylla*, *Sadleria pallida*, and *Vaccinium* spp. (HINHP Database 2001).

***Dispersal/Migration******Population Information and Trends*****Number of Populations:**

4 (USFWS, 2022)

**Population Size:**

27 total (USFWS, 2022)

**Population Narrative:**

New Status Information: • In 2012, Army Natural Resources reported 76 immature individuals, three mature, and two seedlings at East Range (O'ahu) (Army Natural Resources 2018). Currently, two populations on west Maui total fewer than 10 individuals, and two populations in the Ko'olau Mountains of O'ahu total approximately 16 individuals (PEPP 2015, 2016, 2017a, 2017b, 2018; Oppenheimer 2018, in litt.). There is no new information regarding the status of populations on west Maui at Paunau and the 'Eke Crater area (last observed in the early 2000s). The O'ahu population at the Ko'olau summit at Wailupe has not been monitored since 2013 (Ching 2018, in litt.). The IUCN recently estimated as many as 60 individuals in eight subpopulations for both islands (Keir et al. 2016). • In 2012, critical habitat was designated in 14 units on O'ahu in two ecosystems (lowland wet and wet cliff) (30,058 ac; 12,162 ha) (77 FR 57648, September 18, 2012). In 2016, two critical habitat units in one ecosystem (montane wet) were designated on west Maui for *Sanicula purpurea* (1,479 ac; 599 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018). Currently, there is one known population on Maui at Honokōhau totaling three mature and one immature individual (Plant Extinction Prevention Program (PEPP) 2022). Two additional populations known from Maui, at Honokōhau and Honokōwai, were monitored in 2020 and no individual plants were observed (PEPP 2020, 2022). On O'ahu, three populations

are known from Helemano, Kaukonahua, and Schofield-Waikāne totaling 21 mature plants (Ching-Harbin et al. 2020; 2021; Ching-Harbin and Thomas 2021). Approximately four additional populations from O'ahu and Maui have not been monitored in over 15 years, and the status of the plants is unknown. The International Union for the Conservation of Nature (IUCN) assessment of *Sanicula purpurea* from 2016 estimated as many as 60 individuals in eight subpopulations for both islands (Keir et al. 2016). • Currently, there are approximately 11 founder lines represented in ex situ storage and propagation collections, including seeds in seed banks and plants in a nursery or living collection (USFWS, 2022).

### **Threats and Stressors**

**Stressor:**

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Threats to *Sanicula purpurea* on Oahu include potential effects of on-going and future Army training activities, habitat degradation by feral pigs, competition from non-native plant species, reduced reproductive vigor, and a risk of extinction due to the small number of existing occurrences and stochastic events. The non-native plant species *Axonopus fissifolius* and *Clidemia hirta* threaten *S. purpurea* by altering its habitat and competing with it for nutrients, light, and space (HINHP Database 2001; Service 1999b).

**Stressor:** Climate change loss or degradation of habitat

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *Sanicula purpurea* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.705 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions may be needed to conserve this taxon into the future (USFWS, 2018).

### **Recovery**

**Recovery Actions:**

- A State-wide management plan should be developed and implemented for the long-term conservation of all known occurrences of *Sanicula purpurea*. This plan should also include broader landscape actions that are needed for the recovery of this plant throughout its range. The recovery plan for this species identifies the following important conservation actions: construction of exclosures protect the known occurrences from feral pigs and goats, subsequent control and/or removal of ungulates, and removal of competitive non-native plant species. Priority for all of these actions should be given to those occurrences with only a few individuals (e.g., Waimalu-Kahaluu Summit Divide, Puu Keahiakahoe). Additional surveys are also needed throughout suitable habitat to locate new occurrences and update the status of those occurrences that have not been seen in recent years (Service 1999b).  
Ongoing Conservation Actions: *Sanicula purpurea* is found in bog habitat in the Puu Kukui watershed owned by Maui Land and Pineapple on Maui. Since 1988, Maui Land and

Pineapple has managed Puu Kukui Watershed and is receiving funding from the Service to survey for rare plants on their lands and build feral ungulate exclosures to protect listed species, including *S. purpurea*, that occur in the watershed. Maui Land and Pineapple have also constructed a boardwalk in Puu Kukui that spans the known range of this occurrence of *S. purpurea*. Entry into this area is strictly regulated to prevent the inadvertent introduction of competitive non-native plant species (Service 1999b; 68 FR 25934).

- **New Management Actions:**
  - **Surveys and inventories**—In 2016, the Plant Extinction Prevention Program (PEPP) noted that *Sanicula purpurea* on O‘ahu should be elevated to “POP” status (potential PEPP, with fewer than 50 individuals in the wild) and that additional surveys of known populations on west Maui were needed to determine if elevation to a “POP” status was necessary (PEPP 2016).
  - **Captive propagation for genetic storage and reintroduction**—
    - o In 2017, collections were made from five of 10 founders from Helemano (Oahu) and two of 27 founders from East Range (Oahu) (PEPP 2017b).
    - o The Oahu Army Natural Resource Program’s seed bank stores seeds from one founder from Opaepa and five founders from Helemano (Army Natural Resources 2018).
    - o In 2017, the Lyon Seed Conservation Laboratory reported 53 seeds in storage from Honokōhau (west Maui) and 81 seeds in storage from Honokōwai (west Maui) (Lyon Arboretum 2017) (USFWS, 2018).
- **Recommendations for Future Actions:** We are not aware of any new threats or significant new information regarding the species’ biological status since the last 5-year review in 2011. Thus, the following recommendations for future actions are reiterated for 5-year review for 2018.
  - **Surveys and inventories**—Continue to survey for additional populations of *Sanicula purpurea* in areas of potentially suitable habitat on west Maui. Reassess the status of populations at Paunau and ‘Eke on west Maui, and the status of the population at the Ko‘olau summit at Waimānalo on Oahu.
  - **Ungulate monitoring and control**—Maintain existing fences to protect populations from the negative impacts of feral pigs.
  - **Invasive plant monitoring and control**—Control established ecosystem-altering nonnative invasive plant species around all populations of *S. purpurea*.
  - **Rodent predation and herbivory**—Control rats in the vicinity of known populations.
  - **Slug herbivory**—Develop and implement methods to control slugs.
  - **Captive propagation for genetic storage and reintroduction**—Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range.
  - **Reintroduction and translocation**—Augment known populations and reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species.
  - **Human disturbance**—Continue to maintain fencing to protect populations from hiking and trail maintenance impacts.
  - **Stochastic events**—Reduced viability—Research life-cycle aspects of the species that affect seed production, viability, and regeneration.
  - **Climate change adaptation strategy**—Assess the modeled effects of climate change on this species and use to determine future landscape needed for its recovery.
  - **Alliance and partnership development**—Work with the west Maui and Oahu land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2018).

***Conservation Measures and Best Management Practices:***

- **Recommendations for Future Actions:** No significant new information regarding the species’ biological status has been reported since the last 5-year review in 2018. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2023.
  - **Surveys and inventories**—
    - o The historical range of *Sanicula purpurea* should be surveyed, including populations at Paunau and ‘Eke on Maui, and populations on Oahu.
    - o Continue surveys for populations of *S.*

purpurea in areas of potentially suitable habitat on Maui and O‘ahu. o Determine suitable locations for reintroductions. • Ungulate monitoring and control—Continue to maintain fenced exclosures and construct new fences to protect individuals from the negative impacts of browsing by ungulates. • Invasive nonnative plant monitoring and control—Continue control of established ecosystem-altering nonnative invasive plant species, and those that compete with *Sanicula purpurea* within and around all wild populations. • Fire prevention and control—Develop and implement fire prevention management plans and monitor populations after fire occurrence. • Climate change adaptation strategy—Research suitability of habitat for viability of species, including where to conduct translocations in the future due to the impacts of climate change, including increasing temperatures, periods between rain events, and frequency and intensity of hurricanes. Additional management actions may be needed, such as locating microsites that overlap with current and future climate envelopes for translocation efforts. • Predator and herbivore monitoring and control—Determine and implement effective methods for control of rodents and slugs around wild populations. • Captive propagation for genetic storage and reintroduction—Continue collection and propagation efforts for maintenance of genetic stock and initiate plans for reintroductions. • Build resiliency, redundancy, and representation — Increase species’ viability through habitat restoration, threat control, and reintroduction and translocation. Continue reintroduction into suitable habitat that is being managed for known threats to this species to reduce impacts of erosion, treefall, flooding, and hurricanes. • Alliance and partnership development—Continue to work with partners and other land managers in planning and implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2022).

## SPECIES ACCOUNT: *Sarracenia oreophila* (Green pitcher-plant)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 10/21/1979

### **Physical Description**

A perennial, carnivorous herb arising from rhizomes. The leaves consist of two types: tubular or pitcher-shaped leaves, appearing in the spring, that grow 2-7.5 dm tall, which, in late summer begin to wither and are replaced by flat, prostrate leaves that persist until the following spring. Flowers 5-parted, with yellow petals 4-5.5 cm long; pendent, borne singly on an erect, leafless scape to 7 dm tall. Flowering Season: early May to early June (NatureServe, 2015).

### **Taxonomy**

Distinct species, one of only three species of *Sarracenia* with a geographical distribution outside the coastal plain (NatureServe, 2015).

### **Historical Range**

Historically, the distribution of *Sarracenia oreophila* spanned five different geographical provinces: The Cumberland Plateau, Blue Ridge, Piedmont, Ridge and Valley, and East Gulf Coastal Plain (U.S. Fish and Wildlife Service 1985) (NatureServe, 2015).

### **Current Range**

Restricted to areas of the Cumberland Plateau and the Ridge and Valley province in these four regions: Coosa Valley, Lake Chatuge, Lookout Mountain, and Sand Mountain (USFWS 2013). Extent of occurrence was calculated during the 2015 conservation status review to be approximately 9,000 sq. km. (NatureServe, 2015)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Food/Nutrient Narrative**

Adult: Carnivory is the most striking interaction between members of the genus *Sarracenia* and other species, though the precise benefit to pitcher plants from this highly specialized adaption is not understood. Christensen (1976) found that when insects were fed to *Sarracenia flava*, there was no consequent increase in Ca, Mg, or K in the plants' leaf tissue. However, nitrogen and phosphorus did increase, indicating that carnivory may be useful in soils low in these elements. Folkerts (1982) suggests that carnivory may be used to obtain micronutrients, such as molybdenum, which are present at very low levels in a low pH environment. Folkerts (1982) also proposes that carnivory may be important at times of nutrient stress since nutrient levels in bogs decrease over the course of the growing season. Another possibility is that the breakdown of prey detritus from decaying pitchers may help fertilize the soil around the plants (Christensen 1976) (USFWS, 2013).

**Breeding Season**

Adult: The flowers of the green pitcher plant mature in late April at lower elevations, and mature in May at higher elevations (Troup 1982) (NatureServe, 2015).

**Reproduction Narrative**

Adult: *Sarracenia oreophila* reproduces both sexually and asexually, though in some situations, reproduction may be limited to asexual means, resulting in large spreading clones (Troup and McDaniel 1980). Humphrey (1987) estimates that green pitcher plants do not become sexually mature until they are 6-7 years old. The flowers of the green pitcher plant mature in late April at lower elevations, and mature in May at higher elevations (Troup 1982). Cross pollination is needed for seed to set (Troup and McDaniel 1980). Insects associated with *S. oreophila* flowers which may act as pollinators include flies (*Sarcophaga* spp.), honeybees (*Apis* spp.) and bumblebees (*Bombus* spp.) (Troup and McDaniel 1980). Fruits mature in early autumn, but seed may not be released right away (Troup and McDaniel 1980). Seeds are apparently water dispersed (Troup and McDaniel 1980) (NatureServe, 2015).

**Habitat Type**

Adult: Streambanks/Bogs/Flatwoods (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Sandy and highly acidic soils (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow. Specialist or community with key requirements common. (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Historically, the distribution of *Sarracenia oreophila* spanned five different geographical provinces: The Cumberland Plateau, Blue Ridge, Piedmont, Ridge and Valley, and East Gulf Coastal Plain (U.S. Fish and Wildlife Service 1985). The present distribution of *S. oreophila* is restricted to the Cumberland Plateau, Blue Ridge, and Ridge and Valley provinces (U.S. Fish and Wildlife Service 1985), with known, extant populations in northeastern Alabama (Jackson, Marshall, DeKalb, Cherokee and Etowah Counties), northeastern Georgia (Towns county) and adjacent North Carolina (Clay County) (Humphrey 1987). Three distinct habitat types have been described for *S. oreophila*. They are sandstone streambanks, with 13 extant colonies in the Cumberland Plateau; mixed oak or pine flatwoods, with 5 extant colonies in the Cumberland Plateau; and seepage bogs, with 5 extant colonies in the Cumberland, 2 colonies in the Blue Ridge, and 2 colonies in the Ridge and Valley provinces (U.S. Fish and Wildlife Service 1985). The soils in all of these habitats are sandy and highly acidic. Woodland and bog soils are sandy clays and loams with an upper layer of organic material, while the streambank soils are composed almost purely of sand (U.S. Fish and Wildlife Service 1985) (NatureServe, 2015). High ecological integrity of the community and site fidelity along with low tolerance ranges are inferred based on the specific habitat needs of this species.

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Seed dispersal is poorly understood for this species. However, a study of a related, wide-spread pitcher plant species, *Sarracenia purpurea*, indicates that seed dispersal distance from parent plants is typically only a few inches (Ellison and Parker 2002). These authors further suggest that water may facilitate dispersal over longer distances for *Sarracenia* species. Indeed, flooding events are thought to be responsible for the establishment of some green pitcher plant colonies (G. Folkerts 1992). For example, flooding may have transported seeds from upland bog colonies to suitable streambanks within the Little River watershed (Emanuel 1998) (USFWS, 2013).

***Population Information and Trends*****Population Trends:**

Decreasing (NatureServe, 2015)

**Population Growth Rate:**

Likely stable as fires were allowed to burn freely and naturally across the landscape, covering thousands of acres. Only recently, within the past 60 years, has public sentiment changed in opposition to free-ranging fires, due to impacts such fires have on timber production, agriculture, and development. Consequently, a broad range of fire maintained species, including *S. oreophila*, have become critically imperiled (NatureServe, 2015).

**Number of Populations:**

13 (USFWS, 2020)

**Adaptability:**

Given proper habitat conditions, this species has demonstrated high fecundity - able to grow quickly and reproduce. (NatureServe, 2015)

**Population Narrative:**

At this time, green pitcher plant continues to meet the definition of endangered under the ESA. Since completion of the last 5-year review (available online at [https://ecos.fws.gov/docs/five\\_year\\_review/doc4366.pdf](https://ecos.fws.gov/docs/five_year_review/doc4366.pdf)), available information on the species' populations and trends indicate that the species is in an overall decline. This overall trend is driven in large part by the apparent losses of two populations within the Little River system in Alabama. As such, there are currently 13 extant populations of green pitcher plant. Continued conservation work (e.g., habitat management) has contributed to the species' continued existence throughout its historic range. However, inconsistent and unavailable monitoring of various populations increases the uncertainty associated with this assessment. Continued and improved monitoring is needed to adequately understand and assess the status, trends, and threats to green pitcher plant, particularly for populations occurring on public and conservation lands. Currently, eight populations occur at least in part on public or conservation lands, which is less than occurred on such lands at the time of the 2014 5-year review. Conservation of the remaining populations requires continued support and cooperation of private landowners, without which, these populations may decline and become extirpated. Green pitcher plant

conservation efforts have been encouraged, engaged in, and/or funded by the U.S. Fish and Wildlife Service, National Park Service, TNC, universities, state Plant Conservation Alliances, and various state agencies. (USFWS, 2020)

### ***Threats and Stressors***

**Stressor:** Development (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/Loss of populations

**Narrative:** Development of land for agriculture and housing is a threat to this species (USFWS, 2013).

**Stressor:** Fire suppression (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Fire is an integral part of maintaining green pitcher plant bog habitats (Service 1994; Boyer and Carter 2011; NatureServe 2013). In the absence of regular fires, competing plant species encroach on green pitcher plant habitats and out-compete the pitcher plants for resources (e.g., nutrients and light) (Troup and McDaniel 1980; Jennings and Rohr 2011). Encroachment of competing vegetation can lead to the eventual elimination of green pitcher plants (44 FR 54922). Furthermore, excessive fuel accumulation may occur at sites where fire has been excluded or occurs rarely, thus increasing the risk of re-introduced fires having potentially detrimental effects to green pitcher plants (Hermann 2014, in litt.). Alternatively, burning too frequently (e.g., multiple annual fires) or regularly burning during unfavorable seasons (e.g., winter) may reduce habitat suitability for green pitcher plants (Service 1994). Similarly, frequent application of early growing season burns may eliminate seedling recruitment (Determann 2013c, in litt.) (USFWS, 2013).

**Stressor:** Over-collection (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of individual plants/loss of populations

**Narrative:** Over-collection was cited as a reason for listing the green pitcher plant in 1979 (44 FR 54922) and was considered a serious threat when the current recovery plan was revised 15 years later (Service 1994). Recent reviews of threats to carnivorous species note that over-collection of wild plants and plant parts remain a persistent threat to *Sarracenia* species (McPherson 2007; Jennings and Rohr 2011). More recently, over-collection pressure from plant poachers may have declined as evidence (e.g., holes in the ground) of removal of whole green pitcher plants is limited, but not absent (Emanuel 2002; ALNHP 2012; Byrd 2013a; Determann 2013b, in litt.; Hermann 2013, in litt.; Hodges 2013c, in litt.; Shew 2013c, in litt.). Collection pressure may have been somewhat ameliorated by limited, legal interstate sale of commercially grown green pitcher plants from 16 U.S. Fish and Wildlife Service issued Section 10 permitted growers and sellers. However, Hermann (2013, in litt.) proposed that poaching of individual green pitcher plants may not be readily apparent as evidence of poaching could be easily obscured. Alternatively, Hodges (2013b, in litt.) suggested that poaching of plants may have shifted to unauthorized seed collection. Byrd (2013a) stated that several green pitcher plant populations are easily accessible

and, thus, are vulnerable to illegal collection by poachers. Indeed, Byrd (2013a) noted that plants from at least one of these populations were recently poached (USFWS, 2013).

**Stressor:** Inadequacy of regulatory mechanisms (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of individual plants/loss of populations

**Narrative:** Green pitcher plant receives some legal protection in Georgia and North Carolina; however, these laws do not protect against habitat destruction. Collection of green pitcher plants on public lands without a permit is prohibited in Georgia under the Georgia Wildflower Preservation Act of 1973. No such provisions are afforded to plants found on privately-owned lands in the State. North Carolina General Statute 106-202.12- 202.19, also known as the Plant Protection and Conservation Act, authorizes the State to establish a list of protected plants and regulate the collection, sale, and transport of plants on this list. Green pitcher plant is included on the North Carolina's list of protected plants. The species does not receive any specific legal protections from State laws or regulations in Alabama (USFWS, 2013).

**Stressor:** Genetics (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of genetic variability

**Narrative:** As summarized by Godt and Hamrick (1996), small population sizes have been associated with low genetic diversity and reduced fitness in a variety of plant species. Within populations of *S. oreophila*, genetic diversity is relatively low and related to population size and geographic isolation. Specifically, small and isolated populations exhibit less genetic diversity than larger, less isolated populations (Godt and Hamrick 1996). Effects of small population size and low genetic diversity on *S. oreophila*'s fitness have yet to be assessed. However, together, low genetic diversity, small population sizes, and isolation of some populations may limit *S. oreophila*'s ability to respond and adapt to stochastic environmental events and future climate change (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The precise magnitude and impacts of climate change on the southeastern United States are uncertain, but models have projected that climate change in the region may include increased temperatures of 2 to 4°C (3.6 to 7.2°F) accompanied by reduced average annual precipitation by the end of the century (Joyce et al. 2011). Climate change has the potential to affect distribution and abundance of plants by influencing seasonal weather patterns, frequency and timing of severe weather events, and myriad plant physiological responses (Hawkins et al. 2008). The specific impacts of climate change on green pitcher plant populations are poorly understood; however, a variety of impacts are possible. For example, climate change may threaten green pitcher plant populations if the habitats that the species relies on become drier as a result of higher temperatures and reduced rain (Devall and Parresol 1998; Wilcox 2012). Indeed, Wilcox (2012) notes that pitcher plant declines at a TNC preserve in North Carolina were associated with two droughts and lower water tables during the early 2000s. However, Davenport (2007) suggests that climate change's effects might be somewhat ameliorated for this

species if drier climates increase the frequency of fires that maintain green pitcher plant habitats. In addition, climate change may disrupt plant-pollinator interactions via phenological shifts in flowering and/or pollinator activity (Memmott et al. 2007; Hawkins et al. 2008), which may thereby reduce sexual reproduction of green pitcher plants. Any disruption in pollinator efficacy may further threaten isolated green pitcher plant populations that are already pollinator limited (sensu D. Folkerts 1999). While disease is not currently known to threaten green pitcher plants, climate change has the potential to promote the spread of infectious diseases among plants, particularly if arthropod vectors become more widespread and abundant (Anderson et al. 2004; Garrett et al. 2006; Hawkins et al. 2008). Given the variety and complexity of the potential effects of climate change on plant species and communities (cf. Hawkins et al. 2008; Walther 2010), more research is needed to assess its potential long-term impacts on green pitcher plant populations and habitats (USFWS, 2013).

**Stressor:** Livestock disturbance (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Degradation of habitat

**Narrative:** Trampling and soil disturbance from cattle have destroyed or degraded several green pitcher plant habitats and populations (Service 1994; Gunn 1994, in litt., 1996, in litt.; Emanuel 2002; NCNHP 2012) (USFWS, 2013).

**Stressor:** Logging (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Logging/forestry activity is listed as a threat to this species (USFWS, 2013).

## ***Recovery***

### **Recovery Actions:**

- Work with federal and state entities, non-governmental organizations, and private individuals to permanently protect and manage existing habitats and populations, including the development and implementation of management plans, as needed (USFWS, 2013).
- • Continue use of prescribed fires at protected sites and encourage owners of unprotected sites to conduct prescribed fires as frequently as possible (USFWS, 2013).
- Study and evaluate efficacy of a variety of prescribed fire regimes (USFWS, 2013).
- Study and evaluate efficacy of alternative management strategies to prescribed fire, such as hand clearing, mowing, and limited herbicide application (USFWS, 2013).
- Update population inventories, create detailed maps of all populations and their habitats to assist with population management, and attempt to relocate populations (USFWS, 2013).
- Characterize genetic diversity and representation of current ex situ safeguarded collections. Expand ex situ preservation of genetic stock, including long-term cryopreservation of seeds as well as live collections, to represent all populations with increased emphasis placed on preserving and safeguarding individual genets within and across populations (USFWS, 2013).
- Continue and expand conservation genetics work to include all populations and determine effective population sizes (USFWS, 2013).

**Conservation Measures and Best Management Practices:**

- **RECOMMENDATIONS FOR FUTURE ACTION** The previous 5-year review included a list of recommendations to improve recovery of the species. Accomplishments toward these recommended actions are summarized below.
- The Service, non-government conservation organizations (e.g., TNC, APCA), State (ADCNR) and Federal (NPS) agencies, are cooperating together and with private landowners to manage existing populations. One site with green pitcher plant in Alabama has been purchased by NPS, expanding federal ownership and protections of this species.
- Prescribed fires continue to be implemented on private and publicly owned green pitcher plant populations where appropriate. The Service and partners (e.g., TNC) continue to promote and support prescribed fires on private lands.
- While prescribed fires are being implemented, no new studies have been conducted to improve prescribed fire's efficacy as a management tool.
- No new studies have been conducted to improve prescribed fire's efficacy as a management tool.
- Monitoring has continued to be conducted at various populations, including some population mapping. Attempts to relocate populations that have not been revisited in years have been made with limited success.
- Characterizing genetic diversity and representation of current ex situ safeguarded collections remains a need, as does expansion of ex situ safeguarding collections.
- Some genetics work has been conducted, but key conservation genetics questions remain, such as effective population sizes and inclusion of all known populations to genetics studies. (USFWS, 2020)

## SPECIES ACCOUNT: *Sarracenia rubra ssp. alabamensis* (Alabama canebrake pitcher-plant)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 3/10/1989

### **Physical Description**

An insectivorous perennial herb with light green, red-veined leaves that form erect, vase-like structures, 1-5 dm tall (in late summer, these are enlarged and turn yellow-green). Flowers are 5-merous, with maroon petals that are constricted medially, to 2.5 cm in width and 3.6 cm in length; pendent, borne singly on an erect, leafless scape to 60 cm in height. Flowering season: late April to early June (NatureServe, 2015).

### **Taxonomy**

There is taxonomic uncertainty within the genus *Sarracenia* as a whole but the Services and others recognize the taxon as a subspecies within the "rubra complex" (i.e., *Sarracenia rubra ssp. alabamensis*) (USFWS, 2018).

### **Historical Range**

The Alabama canebrake pitcher plant is a carnivorous plant that is endemic to central Alabama, with all known populations, extant and extirpated, found in the Fall Line Hills ecoregion (USFWS, 2019). Species historically occurred in Autauga, Chilton, and Elmore Counties, Alabama. In Autauga County one population has since been extirpated (Byrd 2016) and the remaining five now represent three populations, with two populations continuing as distinct populations and three of the former populations now representing three sub-populations comprising one population. No extant populations are known to occur in Elmore County (USFWS, 2018).

### **Current Range**

There are currently seven natural, extant populations of Alabama canebrake pitcher plant known (Autauga County – 3; Chilton County – 4) (USFWS, 2018). All are found in the Fall Line Hills ecoregion (see Griffith et al. 2001 for ecoregion description). Furthermore, within this ecoregion, most of the species' populations are known from the Upper Alabama subbasin (8-digit hydrologic unit code: 03150201) while the remaining populations are known from the Lower Coosa subbasin (03150107) (USFWS, 2019).

### **Critical Habitat Designated**

Yes;

### ***Life History***

### **Food/Nutrient Resources**

### **Food/Nutrient Narrative**

Adult: This is a carnivorous plant, although it is unclear what benefit it receives from its carnivory (USFWS, 1992). Studies found that Alabama canebrake pitcher plants captured comparatively more flying insects than crawling insects, likely due to the species' relatively tall

stature (USFWS, 2018).

**Reproductive Strategy**

Adult: Vegetatively

**Lifespan**

Adult: Perennial herb, 60+ years (USFWS, 2012)

**Dependency on Other Individuals or Species**

Adult: Likely pollinators for this species are small bumblees (USFWS, 2018).

**Reproduction Narrative**

Adult: Seedling recruitment was reported to be absent from the majority of populations (Brewer and Chesser 2009), further inhibiting recovery efforts, as well as long-term viability and evolutionary potential. Because the species can reproduce vegetatively, seedling recruitment may not be paramount at sites experiencing light to moderate levels of fire exclusion; however, vegetative reproduction may not compensate for mortality or the lack of sexual reproduction at some sites (Brewer and Chesser 2009) (USFWS, 2012). Likely pollinators are small bumblebees (*Bombus* spp.) which have a flight distance of 1 mile; at distances greater than 1 mile, pollen flow (and consequent gene flow) is restricted by the inability of pollinators to traverse this distance (USFWS, 2018).

**Habitat Type**

Adult: Hillside seepage bogs and in bottomland or streamside vegetation(USFWS, 2012)

**Environmental Specificity**

Adult: Narrow. Specialist or community with key requirements common. (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: *Sarracenia rubra* ssp. *alabamensis* inhabits two distinct habitat types that share similar floristic composition. The majority of sites are characterized as hillside seepage bogs, permanently saturated areas that attain their greatest development where an impervious layer of clay lies in close proximity to the ground surface. Precipitation, once reaching this clay zone, becomes restricted and is gradually propelled along a sloping gradient until surfacing further downslope. The other habitat type occurs in association with bottomland or streamside vegetation. Unlike the foregoing habitat, moisture conditions are generally maintained with greater connection to topography and precipitation amounts (USFWS, 2012). All extant populations of *S. rubra* ssp. *alabamensis* occur in close association with the following combination of arborescent and herbaceous species (which therefore serve as the best indicators of suitable habitat): *Osmunda cinnamomea* (cinnamon fern), *Rhynchospora chalarocephala* (loosehead beak sedge), *Dichanthelium scoparium* (velvet panicgrass), *Xyris torta* (twisted yellow-eyed grass), *Eriocaulon decangulare* (tenangle pipewort), *Arundinaria*

*gigantea* (giant cane), *Cleistes bifaria* (small spreading pogonia), *Calopogon tuberosus* (tuberous grass pink), *Platanthera ciliaris* (yellow-fringed orchid), *Viola primulifolia* (white violet), *Rhexia nashii* (maid Marian), *Eryngium integrifolium* (blue coyotethistle), *Asclepias rubra* (red milkweed), *Magnolia virginiana* (sweetbay magnolia), *Solidago rugosa* (wrinkle-leaf goldenrod), *Eupatorium fistulosum* (joe pye weed), *Fuirena squarrosa* (hairy umbrella-sedge), and *Sphagnum* spp. Bottomland and streamside populations generally contain a greater proportion of woody species and *A. gigantea* (U.S. Fish and Wildlife Service 1992, Garrett 2004, Schotz 2006) (USFWS, 2012). It is most vigorous in open bogs and declines when the habitat becomes overgrown with woody vegetation (NatureServe, 2015).

### ***Dispersal/Migration***

#### **Dispersal**

Adult: Seed dispersal is poorly understood but studies with similar pitcher plants indicate seed dispersal distances from parent plants at typically a few inches and water or birds may facilitate dispersal over longer distances, but this remains unstudied for Alabama canebroke pitcher plant (USFWS, 2018).

#### **Dispersal/Migration Narrative**

Adult: Brewer and Chesser (2009) at the University of Mississippi recently completed a study correlating seedling recruitment and population dynamics in relation to site differences. They found that seedling recruitment was greater on sites with higher soil moisture content as opposed to drier sites. This correlation held true even when comparing unmanaged wet sites to managed dry sites (USFWS, 2012).

### ***Population Information and Trends***

#### **Population Trends:**

Stable (USFWS, 2018)

#### **Species Trends:**

Stable (USFWS, 2018)

#### **Number of Populations:**

8 (USFWS, 2023)

#### **Population Narrative:**

Given proper habitat conditions, this species has demonstrated high fecundity - able to grow quickly and reproduce. According to anecdotal information furnished by wildflower enthusiasts, some sites historically contained thousands of plants. Was likely stable when fires were allowed to burn freely and naturally across the landscape, covering thousands of acres. Only recently, within the past 60 years, has public sentiment changed in opposition to free-ranging fires, due to the impact such fires have on timber production, agriculture, and development. Consequently, a broad range of fire maintained species, including *Sarracenia rubra* ssp. *alabamensis*, have become critically imperiled (NatureServe, 2015). Short-term trends indicate that species has remained stable, despite the recent loss of one small population and apparent local population declines at some sites which are likely offset by population increases at the largest sites. Currently, there are seven natural, extant populations of this species (3 in Autauga

County and 4 in Chilton County) where a population is considered distinct if separated by at least 1 mile from nearest known neighbors; no new populations have been discovered since 2012. Currently, individual subpopulations range in size from 3 or 4 plants to well over 200 and all populations are privately owned. Only 3 populations are comprised of 100 or more individuals, while 2 populations have fewer than 10 individuals (Byrd 2016, 2017, Yawn 2018). Several attempts to augment and establish populations are known but information on sites is limited and their contribution to recovery is uncertain. Conservation efforts in cooperation with various entities has occurred and 3 populations are permanently protected and managed by TNC but three populations have been extirpated since the species was listed (USFWS, 2018). The species is currently only found in Autauga and Chilton Counties and is considered extirpated in Elmore County, Alabama. Of Alabama canebroke pitcher-plant's 12 known populations, 8 are extant (including one small population consisting entirely of transplanted individuals and their progeny), and 4 are extirpated. While one population was discovered since the 2018 5-year review, another population has since been extirpated. In addition to few extant populations, small population size remains a threat with most (5 of 8) populations having less than 100 plants. Only 3 populations have 100 or more plants and only 1 population has over 1,000 plants. Two populations occur on conservation lands; however, one of these protected populations is also the largest known population (encompassing nearly threequarters of the species' entire known population in the wild). While overall population size has increased since the mid-1990s by over 48%, active recruitment of the species is generally low, with recent observations noting seedlings at only 3 populations, which represent only a small fraction of individuals within each of these populations. Discovery of additional populations and population augmentation have also contributed to recent population increases (USFWS, 2023).

### ***Threats and Stressors***

**Stressor:** Woody succession (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The inability to regularly burn some sites has reduced habitat suitability by allowing continued encroachment of woody species that increase shade for this shade-intolerant species (USFWS, 2012).

**Stressor:** Fire suppression (USFWS, 2012)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** All populations occur in fire-maintained habitat, requiring an active prescribed burning regimen to sustain species viability and site integrity. As with all pitcher-plants, *S. rubra* ssp. *alabamensis* is intolerant of shade, quickly becoming depauperate and unable to reproduce with the encroachment of woody vegetation. Therefore, site integrity and viability of all populations are inherently linked to regular prescribed burning. Efforts by U.S. Fish and Wildlife Service, ALNHP, TNC, and Atlanta Botanical Gardens to adequately maintain specific populations have been hampered by difficulties in obtaining permission to apply prescribed fires at some of the known populations and unfavorable burning condition (USFWS, 2012).

**Stressor:** Gravel mining (USFWS, 2012)

**Exposure:****Response:**

**Consequence:** loss of habitat

**Narrative:** Gravel mining in close proximity to another population has adversely altered the hydrology of the site, further hampering recovery efforts (Byrd 2011, Tassin in litt. 2011b) (USFWS, 2012). However, the cooperation and interest in conserving this site by the landowner has allowed land management activities to reduce the impacts of gravel mining induced hydrologic alterations (Byrd 2016, 2017, ANHP 2018, Yawn 2018) (USFWS, 2018).

**Stressor:** Drainage of wetlands/bogs (USFWS, 2012)

**Exposure:****Response:**

**Consequence:** loss of habitat

**Narrative:** Alabama canebrake pitcher plant populations continue to be threatened by development and incompatible land use, such as drainage for agriculture and livestock grazing (USFWS, 2012).

**Stressor:** Habitat modification (USFWS, 2018).

**Exposure:****Response:**

**Consequence:**

**Narrative:** The species continues to be threatened by development, agricultural activities, gravel mining, and livestock management (Schotz 2006, Byrd 2016, 2017, ANHP 2018, Yawn 2018), which can exacerbate threats posed by inadequate habitat management (e.g., fire exclusion) and encroachment of competing vegetation (including non-native invasive species)(USFWS, 2018).

**Stressor:** Hydrologic alterations (USFWS, 2018)

**Exposure:****Response:**

**Consequence:**

**Narrative:** Two populations have historically been subjected to hydrological alterations as a result of beaver (*Castor canadensis*) activities, one of which was nearly extirpated by flooding. Beaver trapping has occurred at one of these populations to reduce their impact (USFWS, 2018).

**Stressor:** Inadequate habitat management (USFWS, 2018)

**Exposure:****Response:**

**Consequence:**

**Narrative:** Inadequate habitat management threatens the long-term viability of some populations. All populations occur in habitat requiring periodic fire to maintain site ecological integrity and population viability. The lack of prescribed fire or periodic mowing and hand clearing of competing vegetation at some sites allows for unchecked growth of woody species and other fast-growing herbaceous species that can increase shade and competition for resources. Alabama canebrake pitcher plant is intolerant of shade, with individual plants and, ultimately, populations, quickly becoming depauperate and unable to reproduce following woody species encroachment and consequent increased shade. Prescribed fires and other vegetation clearing activities help to maintain Alabama canebrake pitcher plant's necessary open, sunny habitat. In addition, over the years, ANHP, TNC, and ABG have occasionally had difficulties

obtaining landowner permission to apply prescribed fires at some sites, thus hampering necessary efforts to adequately maintain these sites (Byrd 2016, ANHP 2018). One small population was recently lost, possibly due to incompatible road right-of-way maintenance, such as herbicide application (Byrd 2016). Habitat management is needed to promote seedling recruitment. Alabama canebrake pitcher plant continues to be extremely vulnerable due to the small number of populations and small population size at many of these sites (USFWS, 2018).

### **Recovery**

#### **Reclassification Criteria:**

1. At least 10 geographically distinct populations of sufficient size within the Fall Line Hills ecoregion in Alabama exhibit stable or increasing population trends, as evidenced by natural recruitment and multiple generations over an appropriate time span. Populations are considered to be geographically distinct when they are separated by at least 1 mile (1.6 kilometer) from their nearest neighbors. (Addresses Factors A, B, E) (USFWS, 2019).
2. These 10 populations are protected by a conservation mechanism that addresses the conservation needs of the Alabama canebrake pitcher plant. (Addresses Factors A, D) (USFWS, 2019).
3. Protected populations are managed to promote open canopies, integrity of native plant communities, and Alabama canebrake pitcher plant growth. (Addresses Factors A, E) (USFWS, 2019).

Recovery Priority Number: 6

#### **Delisting Criteria:**

In addition to meeting downlisting criteria, the Alabama canebrake pitcher plant will be considered for delisting when the following criteria are met:

4. At least 10 additional geographically distinct populations of sufficient size (as described in Criterion 1) within the Fall Line Hills ecoregion in Alabama exhibit stable or increasing population trends, as evidenced by natural recruitment and multiple generations over an appropriate time span. (Addresses Factors A, B, D, E) (USFWS, 2019).
5. The Upper Alabama and Lower Coosa sub-basins within Fall Line Hills ecoregion each support at least three (3) viable populations protected by a conservation mechanism. (Addresses Factors A, E) (USFWS, 2019).

#### **Recovery Actions:**

- A. Continue use of prescribed fires at protected sites and encourage owners of unprotected sites to conduct prescribed fires as frequently as possible (USFWS, 2012).
- B. Continue to track population trends and evaluate management needs as a means to gather baseline data and implement long-term monitoring efforts (USFWS, 2012).
- C. Continue surveys in vicinity of known populations and revisit all known historical sites regularly (USFWS, 2012).
- D. Work to secure protection, either through conservation easements or acquisition, of privately-owned populations (USFWS, 2012).

- E. Renew contact with state and county highway departments to ensure proper protective measures are implemented for those areas where plants occur on roadside rights-of-way (USFWS, 2012).
- F. Continue to preserve genetic material from all populations to the extent possible through long-term seed storage and propagation efforts at the Atlanta Botanical Gardens, Georgia (USFWS, 2012). Efforts have expanded to include Auburn University's Donald E. David Arboretum (USFWS, 2018).
- G. Implement all other tasks identified in the recovery plan, as appropriate (USFWS, 2012).
- H. Update the recovery plan, as appropriate (USFWS, 2012).
- Continue use of prescribed fires at protected sites and encourage owners of unprotected sites to conduct prescribed fires as frequently as possible (USFWS, 2012).
- Continue to track population trends and evaluate management needs as a means to gather baseline data and implement long-term monitoring efforts (USFWS, 2012).
- Continue surveys in vicinity of known populations and revisit all known historical sites regularly (USFWS, 2012).
- Work to secure protection, either through conservation easements or acquisition, of privately-owned populations (USFWS, 2012).
- Renew contact with state and county highway departments to ensure proper protective measures are implemented for those areas where plants occur on roadside rights-of-way. 10 (USFWS, 2012).
- Continue to preserve genetic material from all populations to the extent possible through long-term seed storage and propagation efforts at the Atlanta Botanical Gardens, Georgia (USFWS, 2012).
- Implement all other tasks identified in the recovery plan, as appropriate (USFWS, 2012).
- Update the recovery plan, as appropriate (USFWS, 2012).

***Conservation Measures and Best Management Practices:***

- **RECOMMENDED FUTURE ACTIVITIES** Current recovery criteria are presented in the Recovery Plan Amendment (Service 2019) while the Recovery Plan (Service 1992) provides a detailed discussion of necessary recovery actions. During this status review, new and/or targeted potential recovery activities were identified and are included below. These actions are recommended to support and promote recovery of the Alabama canebrake pitcher-plant. Use of a numbered list for these recommendations is for convenient reference only and does not necessarily imply prioritization of any activity over others. Recovery Activities 1. Continue the use of prescribed fire at protected sites and encourage and cooperate with landowners of unprotected sites to conduct prescribed fire as frequently as possible to maintain favorable habitat conditions. 2. Where use of prescribed fire is not feasible, use fire surrogates such as hand clearing and mowing of competing vegetation to maintain favorable habitat conditions. 3. Work with landowners and cooperators to secure adequate protection of privately-owned populations. 4. Work with state, county, and local transportation departments to ensure proper protective measures are implemented for those areas where Alabama canebrake pitcher-plants occur within roadside rights-of-way. 5. Continue to preserve genetic material from all populations through long-term seed storage and live plant collections ex situ (off-site). Monitoring and Research Activities 1. Continue to track population trends and evaluate management needs and efficacy. 2. Expand surveys in the vicinity of known populations and revisit known historical sites regularly to locate and/or relocate populations. 3. Determine the extent that current ex situ collections represent the genetic diversity of in situ populations and expand ex situ collections if necessary (USFWS, 2023).

## SPECIES ACCOUNT: *Sarracenia rubra ssp. jonesii* (Mountain sweet pitcher-plant)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Southeast Region (R4) (USFWS, 2015) 9/30/1988

### Physical Description

An insectivorous perennial herb with waxy-green, maroon-veined leaves that form erect, vase-like "pitchers" with ascending "lids." The pitchers are usually about 4.5 dm tall and are often partially filled with a broth of decaying insects. The sweet-smelling flowers are borne singly, each nodding on erect flowering stems that are usually taller than the pitcher. Flower petals are pendulous, maroon on the outside and yellowish, tinged with red on the inner surface. Blooms in spring. (NatureServe, 2015)

### Taxonomy

Treated as a subspecies of *Sarracenia rubra* by Kartesz (1994 checklist), but considered a distinct species (*S. jonesii*) by North Carolina Heritage Program (1993), CITES (2001), and FNA (vol. 8, 2009). (NatureServe, 2015)

### Historical Range

See current range/distribution.

### Current Range

Endemic to a few mountain bogs and waterslides in southwest North Carolina and northwest South Carolina on both sides of the Blue Ridge divide (U.S. Fish and Wildlife Service 1990). Four populations are in the French Broad River drainage in Henderson and Transylvania Counties, North Carolina, five are in the Saluda River drainage in Greenville County, South Carolina, and one population is in the Enoree River drainage also in Greenville County, South Carolina (U.S. Fish and Wildlife Service 1990). (NatureServe, 2015)

### Critical Habitat Designated

No;

### Life History

### Food/Nutrient Resources

### Food/Nutrient Narrative

Adult: Carnivory is the most striking interaction between members of the genus *Sarracenia* and other species, though the precise benefit to pitcher plants from this highly specialized adaption is not understood. Christensen (1976) found that when insects were fed to *Sarracenia flava*, there was no consequent increase in calcium, magnesium, or potassium in the plants' leaf tissue. However, nitrogen and phosphorus did increase, indicating that carnivory may be useful in soils low in these elements. Folkerts (1982) suggests that carnivory may be used to obtain micronutrients, such as molybdenum, which are present at very low levels in a low pH environment. Folkerts (1982) also proposes that carnivory may be important at times of nutrient

stress since nutrient levels in bogs decrease over the course of the growing season. Another possibility is that the breakdown of prey detritus from decaying pitchers may help fertilize the soil around the plants (Christensen 1976). In addition to carnivory, pitcher plants have intricate relationships with several different animal taxa. Members of the genus *Sarracenia* are the exclusive food of at least five species of moth (Damman and French 1987), and other insects are known to live inside pitchers (U.S. Fish and Wildlife Service 1990). Some insects may be restricted to *S. jonesii* (T. Gibson, pers. comm., in U. S. Fish and Wildlife Service 1990).

**Reproductive Strategy**

Adult: Asexual and sexual (NatureServe, 2015)

**Lifespan**

Adult: Perennial herb (USFWS, 1990)

**Breeding Season**

Adult: Flowering occurs from April to June, with fruits ripening in August (U.S. Fish and Wildlife Service 1990) (NatureServe, 2015).

**Reproduction Narrative**

Adult: REPRODUCTION: Reproduction in *S. jonesii* occurs by seed and by fragmentation of the rhizomes, but the relative importance of sexual versus vegetative reproduction is not known (U.S. Fish and Wildlife Service 1990). Flowering occurs from April to June, with fruits ripening in August (U.S. Fish and Wildlife Service 1990). Pollinators of *S. jonesii* are not known, but bumblebees are important pollinators of other species of *Sarracenia* (U.S. Fish and Wildlife Service 1990). Water is the only known means of seed dispersal (U.S. Fish and Wildlife Service 1990). GENETICS: Many populations of *S. jonesii* are small and have likely been isolated for a long time. Consequently, inbreeding depression may be occurring (U.S. Fish and Wildlife Service 1990).; ASEXUAL; Perfect; Predominantly outcrossing; SEXUAL; Vegetative spread; ABIOTIC; Water; BIOTIC; Insects, other (NatureServe, 2015).

**Habitat Type**

Adult: Bogs (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/Specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: The mountain sweet pitcher plant occurs in two types of habitat, depression bogs and cataract bogs. Most commonly, this species is found in depression bogs with flat to gently

sloping topography in valley bottoms not subjected to flooding (Schafale and Weakley 1990; U.S. Fish and Wildlife Service 1990). The soils of these bogs are deep, poorly drained loam/sand/silt, with high organic matter and acidic pH. The soil series is usually Toxaway silt loam or Hatboro loam (U.S. Fish and Wildlife Service 1990). These bogs are palustrine and usually fed by seepages. The moisture level within the bogs ranges from permanently saturated to intermittently dry (Schafale and Weakley 1990). In the cataract bog habitat, the pitcher plants grow in thin strips along the edges of the waterfall, or on soil islands actually on the granite rock face where moisture conditions are appropriate (U.S. Fish and Wildlife Service 1990; S. Benjamin, pers. observ.). Shrub species associated with *Sarracenia jonesii* populations include *Rhus vernix* (poison sumac), *Aronia arbutifolia* (chokeberry), *Alnus serrulata* (alder), *Rhododendron maximum* (rhododendron), *Rhododendron viscosum* (azalea), *Viburnum cassinoides* (viburnum), *Kalmia angustifolia* (sheep laurel) and *Kalmia latifolia* (mountain laurel) (U.S. Fish and Wildlife Service 1990). Associated herb species include several sedges (*Carex leptalea*, *C. muricata*, *C. folliculata*, and *C. collinsii*), twigrush (*Cladium mariscoides*), beak rush (*Rhynchospora alba*), bulrush (*Scirpus expansus*), and several *Sphagnum* species (U.S. Fish and Wildlife Service 1990) (NatureServe, 2015). Clumped spatial arrangement of the population, high ecological integrity of the community and site fidelity and low tolerance ranges are inferred based on the specific habitat requirements of this species and the relatively low number of known populations.

### ***Dispersal/Migration***

#### **Dispersal/Migration Narrative**

Adult: At least some seed dispersal is by water; however, little else is known, including how far seeds can be dispersed by this vector and others and what conditions are optimal for dispersal (USFWS, 1990).

### ***Population Information and Trends***

#### **Population Trends:**

Short term trend: Decline of 10-30% (NatureServe, 2015)

#### **Number of Populations:**

15 (USFWS, 2021)

#### **Population Narrative:**

The species persists in 12 extant populations across North and South Carolina, in remnant bog habitats that are subject to repeated threats from the continued alteration of the surrounding landscape, particularly the ecological processes (namely hydrologic regimes) which render these wetlands suitable for species such as *S. jonesii* (USFWS, 2013). NatureServe (2015) notes that there is a short-term population decline of 10-30%. Low resiliency, representation and redundancy are inferred based on the low number of populations and the specific habitat requirements of this species.

### ***Threats and Stressors***

**Stressor:** Stream channelization (USFWS, 2013)

**Exposure:**

**Response:****Consequence:** Loss of habitat**Narrative:** This, in conjunction with stream channelization efforts throughout the surrounding watershed, continues to work against the processes which create new wetland acreage, which in turn forces those species that are dependent upon these habitats to be confined to whatever remnant acreage that remains (USFWS, 2013).**Stressor:** Lack of beaver dams (USFWS, 2013)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** Beavers were largely eliminated from much of the southern Appalachian landscape by the turn of the last century. Although still active, their effectiveness at creating new wetland habitat is severely hindered by humans who regard beavers as a nuisance species, and repeatedly breach beaver impoundments (USFWS, 2013).**Stressor:** Wetland draining (USFWS, 2013)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** Because many bogs are located in low-lying flat areas favored for agriculture, they often have been the focus of wetland ditching and draining efforts which have left the hydrology of these sites inherently altered. Further compounded by a nearly complete absence of natural disturbance regimes (such as grazing and/or fire) that may have played a role in keeping woody vegetation at low densities, the structure and composition of southern Appalachian wetlands faces a nearly constant and synergistic set of threats (USFWS, 2013).**Stressor:** Lack of fire (USFWS, 2013)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** Periodic fire may have also played an historical role in keeping some mountain bog habitats structurally open, with the higher light levels favored by species such as *S. jonesii*. Most *Sarracenia* species occur in fire-prone habitats, and many *Sarracenia* species decline during periods of prolonged fire suppression. The historical role of fire in mountain bogs is less clear than in coastal plain habitats, but the presence of fire-adapted species such as pitch pine (*Pinus rigida*) certainly suggests a role for fire in the formation and maintenance of these habitats. However, the extent to which fire suppression may be causing or exacerbating woody vegetation encroachment in bog habitats is presently speculative, at best (USFWS, 2013).**Recovery****Delisting Criteria:**

Criterion 1: It has been documented that at least four populations within each drainage (Enoree, French Broad, and Saluda Rivers) are self-sustaining and that necessary management actions have been undertaken by the landowners or cooperating agencies to ensure their continued survival (USFWS, 2013).

Criterion 2: ...All 12 of the above populations and their habitat are protected from present and foreseeable human-related and natural threats that may interfere with the survival of any of the populations (USFWS, 2013).

**Recovery Actions:**

- Protect existing populations and essential habitat. Develop interim research and management plans in conjunction with landowners. Search for additional populations. Determine habitat protection priorities. Evaluate habitat protection alternatives (USFWS, 1990).
- Determine and implement management necessary for long-term reproduction. establishment. maintenance, and vigor. Determine population size and stage-class distribution for all populations. Study abiotic and biotic features of the species' habitat. Conduct long-term demographic studies. Determine the effects of past and ongoing habitat disturbance. Define criteria for self-sustaining populations and develop appropriate habitat management guidelines based upon the data obtained from Tasks 2.2 through 2.4. Implement appropriate management techniques as they are developed from previous tasks. Develop techniques and reestablish populations in a suitable habitat within the species' historic range (USFWS, 1990).
- Develop a cultivated source of plants and provide for long-term seed storage (USFWS, 1990).
- Enforce laws protecting the species and/or its habitat (USFWS, 1990).
- Develop materials to inform the public about the status of the species and the recovery plan objectives. Prepare and distribute news releases and informational brochures. Prepare articles for popular and scientific publications (USFWS, 1990).
- Annually assess success of recovery efforts for the species (USFWS, 1990).
- Recovery Task 2.1: Determine population size and stage class distribution for all populations
  - Map the spatial extent of each population, assess flower abundance and (of lower priority, only if time permits) the abundance of pitchers/clumps. Perform these assessments in a manner that ensures comparability to the baseline maps and other data obtained for these sites in 1991 and 1992 (Rudd and Sutter 1998 and references therein). Assess whether the spatial extent and/or abundance of populations has remained stable, increased or decreased since that time, accounting for any increases due to population augmentation efforts. Record information on environmental parameters that can impact the plant (e.g., light availability and depth to water table) to examine possible correlations with these parameters and the population size and stage class distribution for all populations (USFWS, 2013).
- Recovery Task 2.7: Develop techniques and re-establish populations in suitable habitat within the species' historic range.
  - Work with the Atlanta Botanical Garden (ABG) to summarize prior reintroduction, augmentation and introduction activities across all populations. Using this information, conduct site visits as needed to obtain current estimates of transplant survivorship for prior augmentation efforts.
  - Use this information, supplemented by updated data on overall spatial extent (obtained from mapping) and estimates of flower/pitcher abundance, to assess each population for its current potential to be self-sustaining without augmentation. For populations where augmentation is deemed necessary (this may currently be most populations), establish preliminary population objectives clarifying the minimum desired number of plants at each location, and a strategy and timeline for meeting this objective through augmentation. Work with ABG and

landowners to implement actions required to meet this objective at as many sites as possible, and then discontinue additional augmentation while monitoring is undertaken to determine transplant survivorship and population trends at the new (augmented) baseline (USFWS, 2013).

- Recovery Task 3: Develop a cultivated source of plants and provide for long-term seed storage • Review the provenance of material currently held as seeds or otherwise represented in exsitu holdings at botanical gardens (esp. ABG but also the North Carolina Botanical Garden) to ensure that all known extant populations are represented. • Work with ABG to assess the viability of seed collections, and the longevity of seeds held in long-term storage (USFWS, 2013).
- Recovery Task 6: Annually assess success of recovery efforts • The two existing recovery criteria (for de-listing) are largely redundant; revise criteria that are more specific, objective, and measurable. • Establish down-listing criteria (for reclassification from endangered to threatened). • Finalize technical revision to the federal list of threatened and endangered plant species, changing taxonomy from *Sarracenia rubra* ssp. *jonesii* to *Sarracenia jonesii*.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTION The 2013 5-year review included a list of recommendations to improve recovery of the species. These actions, listed below, remain applicable to species recovery. x Map the spatial extent of each population, assess flower abundance and (of lower priority, only if time permits) the abundance of pitchers/clumps. Perform these assessments in a manner that ensures comparability to the baseline maps and other data obtained for these sites in 1991 and 1992 (Rudd and Sutter 1998 and references therein). Assess whether the spatial extent and/or abundance of populations has remained stable, increased or decreased since that time, accounting for any increases due to population augmentation efforts. x Work with the Atlanta Botanical Garden (ABG) to summarize prior reintroduction, augmentation, and introduction activities across all populations. Using this information, conduct site visits as needed to obtain current estimates of transplant survivorship for prior augmentation efforts. x Use this information, supplemented by updated data on overall spatial extent (obtained from mapping) and estimates of flower/pitcher abundance, to assess each population for its current potential for self-sustainability without augmentation. For populations where augmentation is deemed necessary (this may currently be most populations), establish preliminary population objectives clarifying the minimum desired number of plants at each location, and a strategy and timeline for meeting this objective through augmentation. Work with ABG and landowners to implement actions required to meet this objective at as many sites as possible, and then discontinue additional augmentation while monitoring is undertaken to determine transplant survivorship and population trends at the new (augmented) baseline. x Review the provenance of material currently held as seeds or otherwise represented in exsitu holdings at botanical gardens (especially ABG but also the North Carolina Botanical Garden) to ensure that all known extant populations are represented. x Work with ABG to assess the viability of seed collections, and the longevity of seeds held in long-term storage. x The two existing recovery criteria (for de-listing) are largely redundant; devise revised criteria that are more specific, objective, and measurable (in accordance with Service Recovery Planning Guidance). x Devise downlisting criteria (for reclassification from endangered to threatened) similarly in accordance with Service Recovery Planning Guidance. x Finalize technical revision to the federal list of threatened and endangered plant species (previously submitted to the Service Atlanta Regional Office), changing taxonomy from *Sarracenia rubra* ssp. *jonesii* to *Sarracenia jonesii*. In light of new information, additional future actions are recommended below: x Work with partners and species experts to develop a standardized monitoring protocol that could be used on many different types

of mountain sweet pitcher plant sites. x Work with partners and land managers to conduct range-wide monitoring. x Provide support and, if feasible, pool resources for management and monitoring. x Continue to support research efforts investigating species biology, hybridization, and management techniques. x Determine what constitutes a “self-sustaining” population and determine the appropriateness of the criterion for a species dependent on active management. (USFWS, 2021)

## SPECIES ACCOUNT: *Scaevola coriacea* (Dwarf naupaka)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Region (R1) (USFWS, 2016)

### **Physical Description**

A prostrate perennial herb, barely woody in older portions. Flowers are yellowish green externally, cream-colored within. (NatureServe, 2015)

### **Taxonomy**

Genus found in Australia, coasts of tropical Asia, Africa, and Polynesia. Although this species has been collected on all of the major Hawaiian Islands, the evidence suggests that it was never well established on any but Maui island. (NatureServe, 2015)

### **Historical Range**

historical occurrences from Mokuhooniki Islet (off Coast of East Molokai), Niihau, Kauai, Oahu, Lanai, and Hawaii. (NatureServe, 2015)

### **Current Range**

Island Distribution: Found on Molokai and Maui. Extirpated on Kauai, Nihau, Oahu, Lanai and Hawaii (USFWS, 2021c)

### **Critical Habitat Designated**

Yes;

### ***Life History***

### **Food/Nutrient Resources**

### **Breeding Season**

Adult: Flowers year-round (USFWS, 1997).

### **Reproduction Narrative**

Adult: This species is salt-tolerant, relatively long-lived, and flowers year round (USFWS, 1997).

### **Habitat Type**

Adult: Coastal sand dunes (USFWS, 1997; NatureServe, 2015)

### **Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 1997)

### **Environmental Specificity**

Adult: Narrow/specialist (USFWS, 1997)

### **Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS, 1997)

**Site Fidelity**

Adult: High (inferred from USFWS, 1997)

**Habitat Narrative**

Adult: Species inhabits dry coastal shrublands on consolidated calcareous sand dunes and thin basaltic soils. (NatureServe, 2015). *Scaevola coriacea* usually occurs in relatively hot, dry coastal sites on low, consolidated sand dunes near sea level. The sites receive high insolation, and most of the vegetation is at or near ground level (USFWS, 1997). Clumped spatial arrangement of the population and narrow environmental specificity are based on the geography of the known locations and the unique habitat requirements of this species. High ecological integrity of the population and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the relatively small geographic range in which it is known to occur.

***Dispersal/Migration******Population Information and Trends*****Population Trends:**

Decreasing (USFWS, 2014)

**Number of Populations:**

~3 (USFWS, 2021c)

**Population Size:**

103 (USFWS, 2021c)

**Population Narrative:**

Fragility unknown. Only current occurrence consists of about 100 plants. 1 current (between 1982 and 1997) occurrence and 15 historical occurrences, one of which is destroyed. (NatureServe, 2015). New status information: In addition to those populations cited in the previous 5-year review, new observations include the following: ? The Plant Extinction Prevention Program [PEPP] (2010) reported three individuals of *S. coriacea* on Mokapu Islet off of Molokai. ? On Maui, there were 98 wild mature individuals and 2 immature individuals of *S. coriacea* (PEPP 2011). ? On Moku Hooniki Islet, off of Molokai, two of the four wild individuals remained (PEPP 2013). Overall, the numbers of individuals have decreased from approximately a 108 wild individual reported in the previous 5-year review to approximately 103 wild mature individuals (PEPP 2010, 2011, 2013) (USFWS, 2014).

***Threats and Stressors***

**Stressor:** Ungulates (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Habitat degradation and herbivory by ungulates is listed as a threat to this species (USFWS, 2014).

**Stressor:** Invasive introduced plants (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Invasive introduced plants are listed as a threat to this species (USFWS, 2014).

**Stressor:** Development (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Development is listed as a threat to the at least one population of this species (USFWS, 2014).

**Stressor:** Off-road vehicles (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Off-road vehicles are listed as a threat to the at least one population of this species (USFWS, 2014).

**Stressor:** Landslides and flooding (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Landslides and flooding are listed as a threat to the at least one population of this species (USFWS, 2014).

**Stressor:** Over-collection (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Collecting impacts are listed as a threat to this species (USFWS, 2014).

**Stressor:** Rodents (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Rodent predation/herbivory is listed as a threat to the at least one population of this species (USFWS, 2014).

**Stressor:** Snails (USFWS, 2014)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Invertebrate herbivory is listed as a threat to the at least one population of this species (USFWS, 2014).

**Stressor:** Slugs (USFWS, 2014)

**Exposure:****Response:****Consequence:** Loss of individuals**Narrative:** Slug herbivory is listed as a threat to the at least one population of this species (USFWS, 2014).**Stressor:** Fire (USFWS, 2014)**Exposure:****Response:****Consequence:** Loss of habitat/loss of individuals**Narrative:** Fire is listed as a threat to the at least one population of this species (USFWS, 2014).**Stressor:** Low numbers (USFWS, 2014)**Exposure:****Response:****Consequence:** Extinction**Narrative:** Low numbers are listed as a threat to the at least one population of this species (USFWS, 2014).**Stressor:** Climate change**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** Climate change is listed as a threat to this species (USFWS, 2014).**Recovery****Reclassification Criteria:**

This species is a short-lived perennial. For downlisting, a total of five to seven populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. In certain cases, however, a particular taxon maybe eligible for downlisting even if all five to seven of the populations are on only one island, provided all of the other recovery criteria have been met and the populations in question are widely distributed and secure enough that one might reasonably conclude that the taxon is not in danger of extinction throughout all or a significant part of its range. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 1997).

**Delisting Criteria:**

This species is a short-lived perennial. For delisting, a total of 8 to 10 populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. As with downlisting, there maybe cases in which a particular taxon maybe eligible for delisting even if all 8 to 10 of the populations are on only one island, provided all of the other recovery criteria have been met and the populations in question are widely distributed and secure enough that one might reasonably conclude that the taxon is not likely to become an

endangered species within the foreseeable future throughout all or a significant portion of its range. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of five consecutive years (USFWS, 1997).

**Recovery Actions:**

- Surveys/inventories – Survey geographical and historical range for a current assessment of the species' status (USFWS, 2014).
- Captive propagation genetic storage and reintroduction o Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. o Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species' high vulnerability to climate change (USFWS, 2014).
- Ungulate monitoring and control – Fence remaining populations to protect them from the impacts of feral ungulates (USFWS, 2014).
- Invasive plant monitoring and control – Control invasive introduced plant species within the vicinity of all known *S. coriacea* populations (USFWS, 2014).
- Predator / herbivore monitoring and control – Control slugs, giant African snails (*Achatina fulica*), and rodents within the vicinity of all known *S. coriacea* populations (USFWS, 2014).
- Population viability monitoring and analysis – Continue monitoring wild and outplanted individuals (USFWS, 2014).
- Climate change adaptation strategy – Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. As a species likely to wink out by 2100, ensure that adequate genetic storage is maintained as viable material (USFWS, 2014).
- Alliance and partnership development – Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon (USFWS, 2014).

## SPECIES ACCOUNT: *Schenkia (=Centaurium) sebaeoides* (Awiwi)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 10/29/1991; Pacific Region (Region 1) (USFWS, 2016)

### **Physical Description**

It is an annual herb about 6 to 20 cm (2.4 to 8 in) tall. The leaves are rather fleshy, inversely ovate or elliptic, and 0.7 to 3.2 cm (0.3 to 1.3 in) long by less than 2 cm (1 in) wide. Flowers are stalkless and are arranged along the stems near their ends. The fused sepals are 8 mm (0.3 in) long and are divided into uneven lobes. The white or pale pink petals are fused into a tube up to 10 mm (0.4 in) long, with lobes up to 4.5 mm (0.2 in) long. The cylindrical capsules are up to 9.5 mm (0.4 in) long and contain numerous tiny brown seeds. (USFWS, 1999)

### **Taxonomy**

A new taxonomic treatment of the polyphyletic genus *Centaurium* was published in 2004. This new classification defines monophyletic groups reflecting the phylogenetic relationships within the subtribe Chironiinae of the Gentianaceae family. For this purpose, the establishment of a new genus, *Zeltnera*, along with the reinstatement of the genera *Gyrandra* and *Schenkia*, resulted in numerous new species combinations. Fifteen genera were recognized, to include 108 species. Of them the genus *Schenkia* comprises only five species: *S. spicata* is broadly distributed in Eurasia and north Africa; *S. australis*, *S. clementii*, and *S. japonica* are confined to Australia and the Pacific region; while *S. sebaeoides* is the only species endemic to Hawaii (Mansion 2004). (USFWS, 2010)

### **Historical Range**

Historically, *Centaurium sebaeoides* was known from scattered localities on State and private land on the islands of Kauai, Oahu, Molokai, Lanai, and Maui (Wagner et al. 1990). (USFWS, 1999)

### **Current Range**

Island Distribution: Found on Kauai, Lanai, Maui, Molokai and Oahu. (USFWS, 2021c)

### **Critical Habitat Designated**

Yes; 6/17/2003.

### **Legal Description**

On March 18, 2003 (Revised March 30, 2016), the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Centaurium sebaeoides* (Awiwi) (aka *Cyrtandra oxybapha*) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 10 detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schenkia (=Centaurium) sebaeoides* (Awiwi) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Schenkia (=Centaurium) sebaeoides* (77 FR 57648-57862). The critical habitat designation includes 15 critical habitat units, which encompass approximately 1,332 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Schenkia* (=Centaureum) *sebaeoides* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

On February 27, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Alectryon macrococcus* (Mahoe) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Hawaii (68 FR 9116-9479).

### Critical Habitat Designation

The critical habitat designation for *Centaureum sebaeoides* includes 10 CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that contain this species (number of units is unknown because detailed unit descriptions for Lanai are not available) (81 FR 17790-18110).

Molokai—Coastal—Unit 1 consists of 70 ac (28 ha) of privately owned land, and 54 ac (22 ha) of federally owned land (U.S. Coast Guard) at Laau Point, from Kahaiaawa to Keawakalani, along the western coast of Molokai. This unit is occupied by the plant *Marsilea villosa*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 1 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 2 consists of 263 ac (106 ha) of State land, and 710 ac (287 ha) of privately owned land, from Ilio Point to Kaa Gulch, along the northwestern coast of Molokai. This unit is occupied by the plant *Marsilea villosa* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 2 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 3 consists of 794 ac (321 ha) of State land, and 3 ac (1 ha) of federally owned land (Kalaupapa National Historical Park), from Kahu Point to Wainene, along the north-central coast of Molokai. This unit is occupied by the plants *Pittosporum halophilum*, *Schenkia sebaeoides*, and *Tetramolopium rockii*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 3 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Peucedanum sandwicense*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 4 consists of 10 ac (4 ha) on Mokapu Island on the northern coast of Molokai. This area is State-owned, and is classified as a State Seabird Sanctuary. This unit is occupied by the plants *Peucedanum sandwicense* and *Pittosporum halophilum*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 4 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 5 consists of 1 ac (0.5 ha) on Huelo islet on the northern coast of Molokai. This area is State-owned, and is classified as a State Seabird Sanctuary. This unit is occupied by the plants *Brighamia rockii*, *Peucedanum sandwicense*, and *Pittosporum halophilum*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 5 is not known to be occupied by *Bidens wiebkei*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 6 consists of 190 ac (77 ha) of State land, and 1,685 ac (682 ha) of privately owned land, from Kaholaiki Bay to Halawa Bay, on the northeastern coast of Molokai. This unit is occupied by the plants *Bidens wiebkei*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, and *Ischaemum byrone*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 6 is not known to be occupied by *Brighamia rockii*, *Hibiscus brackenridgei*, *Marsilea villosa*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 7 consists of 49 ac (20 ha) of privately owned land from Alanuihipaka Ridge to Kalanikaula, on the northeastern coast of Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Molokai—Coastal—Unit 7 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 9 consists of 170 ac (69 ha) of State land and 0.3 ac (0.1 ha) of privately owned land, from Poelua Bay to Mokolea Point on the northwestern coast of west Maui. This unit is occupied by the plants *Schenkia sebaeoides* and *Sesbania tomentosa*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Coastal—Unit 9 is not known to be occupied by *Brighamia rockii*, we have determined this area to be essential for the conservation and recovery of this coastal species because it provides the PCEs necessary for the reestablishment of wild populations within its historical range. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could approach recovery.

Maui—Coastal—Unit 10 consists of 147 ac (60 ha) of State land and 26 ac (10 ha) of privately owned land, from Kahakuloa Head to Waihee Point on the northeastern coast of west Maui. This unit is occupied by the plant *Schenkia sebaeoides*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also

contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Coastal—Unit 10 is not known to be occupied by *Brighamia rockii* or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within its historical range. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could approach recovery.

Maui—Coastal—Unit 11 consists of 6 ac (3 ha) of State land on Mokeehia Island on the northeastern coast of west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Maui—Coastal—Unit 11 is not currently occupied by *Brighamia rockii*, *Schenkia sebaeoides*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

The critical habitat designation for *Schenkia* (=Centaurium) *sebaeoides* includes 15 critical habitat units, covering one ecosystem type, which encompasses approximately 1,332 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Coastal—Units 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15.

Oahu—Coastal—Unit 1 [958 ac (388 ha)]. This area consists of 946 ac (383 ha) of State land, 11 ac (4 ha) of Federal land, and 2 ac (1 ha) of privately owned land in the coastal ecosystem along the northwestern coast of Oahu from Kaena Point east to Kauhao Pali and southeast to Keawaula. This unit is partially within Kaena Point State Park. Oahu—Coastal—Unit 2 [12 ac (5 ha)]. This area consists of 12 ac (5 ha) in the coastal ecosystem on Mokuauia, an islet east of Kalanai Point on the northeastern coast of Oahu. This unit is State-owned and is classified as a State Seabird Sanctuary. Oahu—Coastal—Unit 3 [15 ac (6 ha)]. consists of 15 ac (6 ha) in the coastal ecosystem, on the larger of two islets (Moku Manu) off the windward coast of Oahu near Mokapu Peninsula. This unit is Stateowned, classified as a State Seabird Sanctuary. Oahu—Coastal—Unit 4 [3 ac (1 ha)]. This area consists of 3 ac (1 ha) in the coastal ecosystem, the smaller of two islets (Moku Manu) off the windward coast of Oahu near Mokapu Peninsula. This unit is Stateowned, classified as a State Seabird Sanctuary. Oahu—Coastal—Unit 5 [12 ac (5 ha)]. This area consists of 12 ac (5 ha) in the coastal ecosystem, the larger of two islands (Mokulua Islands) off the windward coast of Oahu near Wailea Point. This unit is State-owned, classified as a State Seabird Sanctuary. Oahu—Coastal—Unit 6 [9 ac (4 ha)]. This area consists of 9 ac (4 ha) in the coastal ecosystem, on the smaller of two islands (Mokulua Islands) off the windward coast of Oahu near Wailea Point. This unit is Stateowned, classified as a State Seabird Sanctuary. Oahu—Coastal—Unit 7 [67 ac (27 ha)]. This area consists of 67 ac (27 ha) in the coastal ecosystem, on the larger of two islands (Manana Island) off the windward coast of Oahu near Makapuu Point. This unit is Stateowned, classified as a State Seabird Sanctuary. Oahu—Coastal—Unit 8 [10 ac (4 ha)]. This area consists of 10 ac (4 ha) in the coastal ecosystem, on the smaller of two islands (Kaohikaipu Island) off the windward coast of Oahu near Makapuu Point. This unit is Stateowned, classified as a State Seabird Sanctuary. Oahu—Coastal—Unit 9 [80

ac (33 ha)]. This area consists of 80 ac (33 ha) of State land in the coastal ecosystem on the leeward side of Makapuu Point (Puuokipahulu). Oahu—Coastal—Unit 10 [74 ac (30 ha)]. This area consists of 74 ac (30 ha) in the coastal ecosystem, owned by the City and County of Honolulu at Halona Point on the leeward side of Koko Crater, extending from Sandy Beach to Kahauloa. Oahu—Coastal—Unit 11 [20 ac (8 ha)]. This area consists of 20 ac (8 ha) of privately owned land in the coastal ecosystem, at Ihihilauakea on Koko Head (Kaihuokapuaa). Oahu—Coastal—Unit 12 [11 ac (5 ha)]. This area consists of 11 ac (5 ha) of City and County land in the coastal ecosystem, at Nonoula on Koko Head (Kaihuokapuaa). Oahu—Coastal—Unit 13 [23 ac (10 ha)]. This area consists of 19 ac (8 ha) of City and County land, 1 ac (0.5 ha) of State land, and 3 ac (1 ha) of privately owned land in the coastal ecosystem at Kalaeloa. Oahu—Coastal—Unit 14 [4 ac (2 ha)]. This area consists of 2 ac (1 ha) of City and County of Honolulu land, and 2 ac (1 ha) of Federal land (U.S. Coast Guard) in the coastal ecosystem at Kalaeloa. Oahu—Coastal—Unit 15 [33 ac (13 ha)]. This area consists of 9 ac (4 ha) of State land, 2 ac (1 ha) of privately owned land, and 21 ac (9 ha) of Federal (Pearl Harbor NWR) land at Kalaeloa.

The critical habitat designation for *Alectryon macrococcus* includes one CHU in Kauai County, Hawaii (68 FR 9116-9479).

Kauai 11—*Centaurium sebaeoides*—a: This unit is critical habitat for *Centaurium sebaeoides* and is 155 ha (385 ac) on State land (Hono o Na Pali NAR, Puu Ka Pele Forest Reserve, and Milolii, Nualolo, and Na Pali Coast State Parks). This unit contains Awaawapuhi, Honopu, Kalalau, Milolii, and Nualolo Valleys; Hanakoa, Hoolulu, Kalalau, and Waiahuakua Streams; Mukuaiki and Puanaiea Points; and Kalalau Beach. This unit provides habitat for four populations of 500 mature, reproducing individuals of the annual *Centaurium sebaeoides* and is currently occupied with between 22 and 52 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. It provides habitat for the westernmost range of the species. The habitat features contained in this unit that are essential for this species include, but are not limited to, volcanic or clay soils or cliffs in arid coastal areas. This unit provides for four populations within this multi-island species' historical range on Kauai that are some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

### Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Centaurium sebaeoides* critical habitat consists of two components. Coastal (west Maui and Molokai) and Lowland dry (Lanai) (81 FR 17790-18110):

Ecosystem: Coastal. Elevation: <980 ft (<300 m). Annual precipitation: <20 in (<50 cm). Substrate: Well-drained, calcareous, talus slopes; dunes; weathered clay soils; ephemeral pools; mudflats. Canopy: Hibiscus, Myoporum, Santalum, Scaevola. Subcanopy: Gossypium, Sida, Vitex. Understory: Eragrostis, Jacquemontia, Lyceum, Nama, Sesuvium, Sporobolus, Vigna.

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: Diospyros, Myoporum, Pleomele, Santalum. Subcanopy: Chamaesyce, Dodonaea, Leptecophylla,

Osteomeles, Psydrax, Scaevola, Wikstroemia. Understory: Alyxia, Artemisia, Bidens, Chenopodium, Nephrolepis, Peperomia, Sicyos.

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schenkia* (=Centaurium) *sebaeoides* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Schenkia* (=Centaurium) *sebaeoides* occurs within the indicated ecosystem in the Waianae Mountain caldera complex and the Koolau Mountain caldera complex:

(i) Oahu—Coastal—Units 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15. Coastal. (A) Elevation: <980 ft (<300 m). (B) Annual Precipitation: <20 in (<50 cm). (C) Substrate: Well-drained, calcareous, talus slopes; dunes; weathered clay soils; ephemeral pools; mudflats. (D) Canopy: Hibiscus, Myoporum, Santalum, Scaevola. (E) Subcanopy: Gossypium, Sida, Vitex. (F) Understory: Eragrostis, Jacquemontia, Lyceum, Nama, Sesuvium, Sporobolus, Vigna.

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Alectryon macrococcus* critical habitat consists of two components (68 FR 9116-9479):

(i) Volcanic or clay soils or on cliffs in arid coastal areas and containing one or more of the following native plant species: *Artemisia* spp., *Bidens* spp., *Chamaesyce celastroides*, *Cyperus phleoides*, *Dodonaea viscosa*, *Fimbristylis cymosa*, *Heteropogon contortus*, *Jacquemontia ovalifolia*, *Lipochaeta* spp., *Lycium sandwicense*, *Lysimachia mauritiana*, *Melanthera integrifolia*, *Panicum fauriei*, *Panicum torridum*, *Scaevola sericea*, *Sida fallax*, or *Wikstroemia uva-ursi*; and

(ii) Elevations between 0 and 147 m (0 and 483 ft).

### Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua*

coriacea, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C.*

magnicalyx, C. mannii, C. maritae, C. mceldowneyi, C. profuga, C. solanacea, Cyrtandra filipes, C. munroi, Diplazium molokaiense, Dubautia plantaginea ssp. humilis, Geranium hanaense, G. multiflorum, Hesperomannia arborescens, Huperzia mannii, Kadua laxiflora, Lysimachia lydgatei, L. maxima, Melicope balloui, M. ovalis, Phyllostegia hispida, P. mannii, P. pilosa, Plantago princeps, Platanthera holochila, Pteris lidgatei, Remya mauiensis, Santalum haleakalae var. lanaiense, Schiedea laui, Stenogyne bifida, S. kauaulaensis, Wikstroemia villosa, and Zanthoxylum hawaiiense) found on steep slopes and cliffs, or in narrow gulches.

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Schenkia* (=Centaurium) *sebaeoides* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Existing manmade features and structures within the boundaries of the mapped areas, such as buildings; roads; aqueducts and other water system features, including but not limited to pumping stations, irrigation ditches, pipelines, siphons, tunnels, water tanks, gaging stations, intakes, reservoirs, diversions, flumes, and wells; existing trails; campgrounds and their immediate surrounding landscaped area; scenic lookouts; remote helicopter landing sites; existing fences; telecommunications equipment towers and associated structures and equipment; electrical power transmission lines and distribution, and communication facilities and regularly maintained associated rights-of-way and access ways; radars, telemetry antennas; missile launch sites; arboreta and gardens; heiau (indigenous places of worship or shrines), and other archaeological sites; airports; other paved areas; and lawns and other rural residential landscaped areas do not contain one or more of the primary constituent elements described for each species and therefore are not included in the critical habitat designations.

### ***Life History***

#### **Food/Nutrient Resources**

#### **Lifespan**

Adult: 1 year (USFWS, 1999)

#### **Breeding Season**

Adult: April (USFWS, 1999)

#### **Key Resources Needed for Breeding**

Adult: Rainfall (USFWS, 1999)

#### **Reproduction Narrative**

Adult: *Centaurium sebaeoides* has been observed flowering in April. Flowering may be induced by heavy rainfall. Populations are found in dry areas, and plants are more likely to be found following heavy rains (USFWS 1995). (USFWS, 1999)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Shrubland/chaparral (NatureServe, 2015)

**Environmental Specificity**

Adult: Medium, with some key requirements (USFWS, 1999)

**Habitat Narrative**

Adult: This species is found on dry shrublands primarily at coastal sites with coralline or basaltic substrates. On Molokai, *Schenkia sebaeoides* grows in volcanic or clay soils or on cliffs in arid dune ecosystems at elevations between sea level and 409 meters (0 and 1,341 feet). On Kauai, *Schenkia sebaeoides* typically grows in volcanic or clay soils or on cliffs in arid coastal areas at elevations between sea level and 147 meters (483 feet). On Oahu, *Schenkia sebaeoides* typically grows in volcanic or clay soils or on cliffs in arid coastal areas or on coral plains below 368 meters (1,207 ft) elevation. (USFWS, 1999; USFWS, 2010; NatureServe, 2015)

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends*****Population Trends:**

Not available.

**Number of Populations:**

~20 (USFWS, 2021c)

**Population Size:**

thousands? (USFWS, 2021c)

**Population Narrative:**

Currently, on Kauai there are a total of three populations with approximately 22 to 52 individuals on State-owned land. On Molokai, there are at least four populations containing thousands of individuals. On Oahu, two populations have between 100 to 130 individuals total. On West Maui, the most recent estimates are 7 to 8 populations, with several 1,000 plants. Lanai had one population in Maunalei Valley with approximately 23 individuals (Hawaii Biodiversity and Mapping Program 2009; USFWS 1999). The number of individuals fluctuates dramatically with the seasons. The total number of populations statewide is estimated to be 17 or 18, with as many as 6,000 individuals when rainfall is abundant. (USFWS, 2010)

***Threats and Stressors***

**Stressor:** Rats (USFWS, 2013)

**Exposure:**

**Response:****Consequence:**

**Narrative:** Rats are a newly described threat to this species at the Halona Gulch area (S. Ching, pers. comm. 2011). (USFWS, 2013)

**Stressor:** Drought (USFWS, 2013)

**Exposure:****Response:****Consequence:**

**Narrative:** Drought is another threat not previously mentioned for this species, as reported at Halona Gulch and Kaena Point (S. Ching, pers. comm. 2011). (USFWS, 2013)

**Stressor:** Fire (USFWS, 2013)

**Exposure:****Response:****Consequence:**

**Narrative:** In July 2009, a fire in the Manini/Alau vicinity of Kaena Point burned designated critical habitat for *Schenkia sebaeoides* (U.S. Army Garrison 2009). Fire was not previously reported as a threat at this location. (USFWS, 2013)

**Stressor:** Invasive plant species (USFWS, 2010)

**Exposure:****Response:****Consequence:**

**Narrative:** On Molokai, other major threats to this species include competition with invasive introduced woody plant species such as *Casuarina equisetifolia* (ironwood), *Casuarina glauca* (saltmarsh), *Leucaena leucocephala* (koa haole), *Prosopis pallida* (kiawe), *Schinus terebinthifolius* (Christmasberry), *Syzygium cumini* (Java plum), and *Tournefortia argentea* (tree heliotrope). On Maui, competing invasive introduced plant species include *Cynodon dactylon* (Bermuda grass), *Digitaria ciliaris* (crabgrass), and *Pluchea indica* (Indian fleabane) (Hawaii Biodiversity and Mapping Program 2009; National Tropical Botanical Garden 2009; Wood 2009). The major threats to this species on Kauai include competition from invasive introduced plant species (Factor E) including *Casuarina equisetifolia*, *Bryophyllum pinnatum* (airplant), *Furcraea foetida* (Mauritius hemp), *Pluchea carolinensis* (sourbush), *Portulaca pilosa* (pigweed), *Plantago lanceolata* (narrow-leaved plantain), *Lantana camara* (lantana), *Leucaena leucocephala* (haole koa), *Prosopis pallida*, *Schinus terebinthifolius*, *Syzygium cumini* (Java plum), and *Tournefortia argentea* (tree heliotrope). The major threats on Oahu include competition from invasive introduced plant species *Leucaena leucocephala*, *Casuarina equisetifolia*, *C. glauca*, *Leucaena leucocephala*, *Prosopis pallida*, *Schinus terebinthifolius*, *Syzygium cumini*, and *Tournefortia argentea*. Site invasion by *Casuarina* spp. appears to be particularly damaging because of the smothering leaf litter layers that exclude most other plant species. (USFWS, 2010)

**Stressor:** Overgrazing (USFWS, 2010)

**Exposure:****Response:****Consequence:**

**Narrative:** Indirect effects of overgrazing, such as trampling and erosion, are also likely contributors to the decline or disappearance of the species depending on the severity, timing,

longevity, and nature of the disturbance. (USFWS, 2010)

**Stressor:** Off-road vehicles (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Destruction of plants growing in coastal sites by off-road vehicles may also be an important source of mortality (Medeiros et al. 2000). (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Climate change may also pose a threat to *Schenkia sebaeoides*. However, current climate change models do not allow us to predict specifically what those effects, and their extent, would be for this species. (USFWS, 2010)

### ***Recovery***

#### **Reclassification Criteria:**

1. A total of five to seven populations of each taxon should be documented on islands where they now occur or occurred historically. (USFWS, 1999)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure with the following minimum numbers of mature individuals per population: 100 for long-lived perennials, 300 for short-lived perennials, and 500 for the annual taxa. (USFWS, 1999)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1999)

#### **Delisting Criteria:**

1. A total of 8 to 10 populations of each taxon should be documented on islands where they now occur or occurred historically. (USFWS, 1999)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with the following minimum numbers of mature individuals per population: 100 for long-lived perennials, 300 for short-lived perennials, and 500 for the annual taxa. (USFWS, 1999)
3. Each population should persist at this level for a minimum of five consecutive years. (USFWS, 1999)

#### **Recovery Actions:**

- Exclosures should be constructed around the known populations of *Centaureum sebaeoides* on State and private land to reduce impacts from feral ungulates. Subsequent control or removal of ungulates from these areas will alleviate their impact on native ecosystems. Additionally, those populations that have only a few remaining individuals, such as at Mokio Point and Manaepapa on Molokai should be fenced and protected immediately. (USFWS,

1999)

- A long-range management plan to control alien plants such as koa haole needs to be developed. Additionally, populations that have only a few remaining individuals such as those at Mokio Point and Manaepapa on Molokai should be weeded and protected immediately. (USFWS, 1999)
- Implement a coordinated effort of fire protection actions for endangered plant species on State and private land where just a few individuals occur. (USFWS, 1999)
- Construct exclosures and remove ungulates in wild populations. (USFWS, 2013)
- Control invasive introduced plant species in wild populations. (USFWS, 2013)
- Develop and implement fire management plans for populations at risk of fire. (USFWS, 2013)
- Monitor populations which are fluctuating or ephemeral based on rainfall, since the former presence of the species at a given location would indicate that a seed bank might be present. (USFWS, 2013)
- Collect material for genetic storage and propagation for reintroduction. (USFWS, 2013)
- Initiate planning and contribute to implementation of ecosystem level restoration and management to benefit this taxon. (USFWS, 2013)

***Conservation Measures and Best Management Practices:***

- Recommendations for Future Actions: We are not aware of any new threats or significant new information regarding the species' biological status since the last 5-year review in 2013. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2020.
  - Surveys and inventories—
    - o The historical range of *Schenkia sebaeoides* should be surveyed intensively.
    - o Determine if historical populations are extirpated.
    - o Determine sites that have the highest likelihood of maintaining reintroductions.
  - Ungulate monitoring and control—Continue to maintain fenced exclosures to protect individuals from the negative impacts of browsing by ungulates.
  - Invasive plant monitoring and control—Continue control of established ecosystem-altering nonnative invasive plant species, and those that compete with *Schenkia sebaeoides*.
  - Site and habitat protection—Develop and implement effective control measures to reduce the impact of drought.
  - Fire monitoring and control—Continue to develop and implement fire prevention management plans.
  - Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species.
  - Predator and herbivore monitoring and control—Determine and implement effective methods to control insect pests.
  - Captive propagation for genetic storage and reintroduction—Continue collection and propagation efforts for maintenance of genetic stock and for reintroduction.
  - Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species to build resiliency and redundancy to reduce the impacts of drought and fire.
  - Population biology research—
    - o Determine which species may act as pollinators and which may assist with fruit dispersal.
    - o Conduct genetic studies to determine genetic variation within the population (and between populations) and plan an effective breeding program.
  - Alliance and partnership development—Continue to work with partners and other land managers in planning and implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2021b)
- New Management Actions:
  - Surveys and inventories— PEPP continues to monitor individuals of *Schenkia sebaeoides* in existing populations on Kaua'i and O'ahu (PEPP 2021).
  - Captive propagation for genetic storage and reintroduction—
    - 3 o The Lyon Seed Conservation Laboratory reports 422,371 seeds in storage from 95 wild plants from Kaua'i, O'ahu, and Maui and an additional 1,170

seeds for research purposes (Lyon 2020). o National Tropical Botanical Garden (NTBG) reports approximately 1,000 seeds from 2 wild plants from Kaua'i (NTBG 2020). o Maui Nui Botanical Garden (MNBG) reports 3,750 seeds from 7 founders (MNBG 2020). • Reintroduction—There are currently no outplantings of *Schenkia sebaeoides*. (USFWS, 2021b)

## SPECIES ACCOUNT: *Schiedea haleakalensis* (No common name)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Region (R1) (USFWS, 2016)

#### **Physical Description**

A shrub about 3-6 dm tall, with numerous ascending to erect stems. Leaves narrow. Flowers are borne in terminal clusters. (NatureServe, 2015)

#### **Taxonomy**

Genus endemic to Hawaiian Islands, species endemic to east Maui. (NatureServe, 2015)

#### **Historical Range**

See current range/distribution.

#### **Current Range**

Endemic to crater of Haleakala, East Maui. (NatureServe, 2015)

#### **Critical Habitat Designated**

Yes; 3/30/2016.

#### **Legal Description**

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea haleakalensis* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

#### **Critical Habitat Designation**

The critical habitat designation for *Schiedea haleakalensis* includes six CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Subalpine—Unit 1 (and) *Palmeria dolei*—Unit 24—Subalpine (and) *Pseudonestor xanthophrys*—Unit 24— Subalpine This area consists of 10,785 ac (4,365 ha) of State land, 1,622 ac (656 ha) of privately owned land, and 3,568 ac (1,444 ha) of federally owned land (Haleakala National Park), from Kanaio north to Puu Nianiau on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the subalpine ecosystem (see Table 5). They are occupied by the plants *Bidens micrantha* ssp. *kalealaha* and *Geranium arboreum*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Subalpine—Unit 1 is not known to be occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Asplenium peruvianum* var. *insulare*, *Geranium multiflorum*, *Phyllostegia bracteata*, *Schiedea haleakalensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these subalpine species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and

space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Subalpine—Unit 2 (and) *Palmeria dolei*—Unit 25—Subalpine (and) *Pseudonestor xanthophrys*—Unit 25— Subalpine This area consists of 50 ac (20 ha) of privately owned land, and 9,836 ac (3,981 ha) of federally owned land (Haleakala National Park), from the summit north to Koolau Gap and east to Kalapawili Ridge on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the subalpine ecosystem (see Table 5). They are occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Geranium multiflorum*, and *Schiedea haleakalensis*, and by the forest bird, the *akohekohe* (*Palmeria dolei*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui— Subalpine—Unit 2 is not known to be occupied by the plants *Asplenium peruvianum* var. *insulare*, *Bidens micrantha* ssp. *kalealaha*, *Geranium arboreum*, *Phyllostegia bracteata*, or *Zanthoxylum hawaiiense*, or by the forest bird, the *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these subalpine species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 1 (and) *Palmeria dolei*—Unit 26—Dry Cliff (and) *Pseudonestor xanthophrys*—Unit 26— Dry Cliff This area consists of 755 ac (305 ha) of federally owned land (Haleakala National Park), from Pakaoao to Koolau Gap on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). Although Maui—Dry Cliff— Unit 1 is not known to be occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Diplazium molokaiense*, *Geranium multiflorum*, *Plantago princeps*, or *Schiedea haleakalensis*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 2 consists of 688 ac (279 ha) of federally owned land (Haleakala National Park) from Haupaakea Peak to Kaupo Gap on east Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). It is occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Geranium multiflorum*, *Plantago princeps*, and *Schiedea haleakalensis*, and contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Dry Cliff—Unit 2 is not known to be occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, or *Diplazium molokaiense*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations

within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 3 (and) *Palmeria dolei*—Unit 27—Dry Cliff (and) *Pseudonestor xanthophrys*—Unit 27—Dry Cliff This area consists of 200 ac (81 ha) of federally owned land (Haleakala National Park) near Papaanui on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). It is occupied by the plant *Plantago princeps*, and contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Dry Cliff—Unit 3 is not currently occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Diplazium molokaiense*, *Geranium multiflorum*, or *Schiedea haleakalensis*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 4 (and) *Palmeria dolei*—Unit 28—Dry Cliff (and) *Pseudonestor xanthophrys*—Unit 28—Dry Cliff This area consists of 315 ac (127 ha) federally owned land (Haleakala National Park), along Kalapawili Ridge on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). Although Maui—Dry Cliff—Unit 4 is not currently occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Diplazium molokaiense*, *Geranium multiflorum*, *Plantago princeps*, or *Schiedea haleakalensis*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea haleakalensis* critical habitat consists of two components. Sub-alpine (east Maui) and Dry cliff (east Maui) (81 FR 17790-18110):

Ecosystem: Subalpine. Elevation: 6,500–9,800 ft (2,000–3,000 m). Annual precipitation: 15–40 in (38–100 cm). Substrate: Dry ash, sandy loam, rocky, undeveloped soils, weathered lava. Canopy: *Chamaesyce*, *Chenopodium*, *Metrosideros*, *Myoporum*, *Santalum*, *Sophora*. Subcanopy: *Coprosma*, *Dodonaea*, *Dubautia*, *Geranium*, *Leptecophylla*, *Vaccinium*, *Wikstroemia*. Understory: Ferns, *Bidens*, *Carex*, *Deschampsia*, *Eragrostis*, *Gahnia*, *Luzula*, *Panicum*, *Pseudognaphalium*, *Sicyos*, *Tetramolopium*.

Ecosystem: Dry Cliff. Elevation: unrestricted. Annual precipitation: <75 in (<190 cm). Substrate: >65 degree slope, rocky talus. Canopy: None. Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

### Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special

management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Probably requires cross-pollination by small insects for seed set. Small flies and moths have been noted visiting the flowers at both known populations (Loope and Medeiros 1994c) (USFWS, 1997).

### **Breeding Season**

Adult: Fruits and seeds have been observed in August/ September (USFWS, 1997).

### **Reproduction Narrative**

Adult: Little is known about the life history of *Schiedea haleakalensis*. This species is known to be gynodioecious (bearing female and both-sexed flowers on separate plants) (Stephen Weller,

University of California at Irvine and A.C. Medeiros, personal communication 1994) and, hence, probably requires cross-pollination by small insects for seed set. Small flies and moths have been noted visiting the flowers at both known populations (Loope and Medeiros 1994c). These insects are generally relatively short- flighted. Fruits and seeds have been observed in August/ September. There are no obvious dispersal devices for seeds other than gravity and water-borne movement (USFWS, 1997).

**Habitat Type**

Adult: Dry subalpine cliffs (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from USFWS, 1997)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from USFWS, 1997)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS, 1997)

**Site Fidelity**

Adult: High (inferred from USFWS, 1997)

**Habitat Narrative**

Adult: Dry subalpine cliffs with native shrubs. (NatureServe, 2015). The current habitat of *Schiedea haleakalensis* is in rock cracks on sheer cliffs at 1,800 and 2,440 meters (5,910 and 8,010 feet) elevation adjacent to barren lava and predominantly native subalpine shrublands and grasslands. The substrate is cinder, weathered volcanic ash, or bare lava with little or no soil development. Periodic freezing temperatures occur in this habitat. Associated native species include *Artemisia mauiensis*, *Bidens micrantha*, *Dubautia mensiezii*, *Styphelia tameiameia*, *Vaccinium reticulatum*, and *Viola chamissoniana* (Medeiros, Loope, and Holt 1986) (USFWS, 1997). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations. Species only survives on precipitous cliff faces not accessible to goats (USFWS, 1997)

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: There are no obvious dispersal devices for seeds other than gravity and water-borne movement (USFWS, 1997).

***Population Information and Trends*****Population Trends:**

Unknown

**Number of Populations:**

2 (USFWS, 2023)

**Population Size:**

8 individuals (USFWS, 2023)

**Population Narrative:**

New Status Information: • In 2011, there were 18 observed individuals at Kaupō Gap. Currently, *Schiedea haleakalaensis* is found in two occurrences, one at Leleiwi Pali (seven individuals) and one at Kaupō Gap (one individual) (Robertson 2016, in litt.) • In 2016, six critical habitat units in two ecosystems (subalpine and dry cliff) were designated on east Maui for *Schiedea haleakalensis* (27,819 ac; 11,258 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018).

**Threats and Stressors**

**Stressor:** Feral goats (USFWS, 1997)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** The primary threat historically responsible for the endangerment of this species is habitat degradation and herbivory by feral goats (USFWS, 1997).

**Stressor:** Small population size (USFWS, 1997)

**Exposure:**

**Response:**

**Consequence:** Extinction

**Narrative:** The very small remaining number of individuals of *Schiedea haleakalensis* and the limited and scattered distribution of the species are threats since a single natural or human-caused environmental disturbance could be catastrophic to all or a significant part of the populations. In addition, the limited gene pool may depress reproductive vigor. Just as importantly, a very small, scattered population may not receive adequate cross-pollination (USFWS, 1997).

**Stressor:** Slugs (USFWS, 1997)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Feeding by slugs (*Milax gagates*): Based on recent unpublished evidence, recruitment of *Schiedea* germinants [seedlings] can be catastrophically suppressed by herbivory of alien slugs in the Waianae Mountains of Oahu (Steve Weller and Ann Sakai, University of California at Irvine, personal communication 1994). Nocturnal herbivory by the invasive garden slug *Milax gagates* has been observed to partially defoliate larger, established plants of *Schiedea haleakalensis* in the western Kaupo population (A.C. Medeiros, personal observation 1994). This slug is now widespread on upper Haleakala Volcano in a variety of high-elevation sites, arid to wet, and has been observed feeding on such rare native plants as the green sword (*Gagne* 1983) (USFWS, 1997).

**Stressor:** Ants (USFWS, 1997)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/Loss of pollinators

**Narrative:** Invasion of habitat and elimination of pollinators by the Argentine ant (*Iridomyrmex humilis*): This ant species is capable of reducing or eliminating native pollinators wherever it invades on Haleakala Volcano (Cole et al. 1992). As of 1994, the invasion had descended from Kalahaka on the rim of Haleakala Crater to the crater floor very near the Holua population of *Schiedea haleakalensis* (USFWS, 1997).

**Stressor:** Feral ungulates (USFWS, 1997)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Feral ungulates: Although feral goats have been removed from Haleakala National Park by a program of active management and are no longer an immediate threat to native plant species within the park, the potential for the ingress and reestablishment of goats exists. Maintenance of a goat-free situation requires continuation of an active management program, which requires substantial sustained commitment by Haleakala National Park and funding for fence maintenance and goat removal (USFWS, 1997).

**Stressor:** Fire (USFWS, 1997)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** The possibility of fire is a threat to the existence of *Schiedea haleakalensis*; a single fire could affect a significant portion of the population of *Schiedea haleakalensis* (A.C. Medeiros, personal communication 1990) (USFWS, 1997).

**Stressor:** Nonnative invasive plants

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Two additional nonnative invasive plants, *Pinus radiata* (Monterey pine) and *Cortaderia jubata* (pampas grass) are observed to be a threat to *Schiedea haleakalensis*, by modifying and degrading habitat, and by direct competition (Robertson 2016, in litt.) (USFWS, 2018).

**Stressor:** Drought degradation of habitat

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Drought is observed to be a threat to populations of *S. haleakalensis* at Leleiwi Pali and Kaupō Gap (Robertson 2016, in litt.). Over the last 100 years, the Hawaiian Islands have experienced an annual decline in precipitation of over nine percent, increasing to as much as 15 percent within the last 20 years (US-NSTC 2008; Chu and Chen 2005; Diaz 2005). Drought affects plants directly by desiccation. The increase in drought frequency and intensity leads to a self-perpetuating cycle of increase in cover of nonnative plants, increase in the number of fires, and an increase of erosion (US-GCRP 2009; Warren 2011) (USFWS, 2018).

**Stressor:** Climate change loss or degradation of habitat

**Exposure:****Response:****Consequence:**

**Narrative:** We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *S. haleakalensis* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.605 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions may be needed to conserve this taxon into the future (USFWS, 2018).

**Recovery****Reclassification Criteria:**

For downlisting, a total of five to seven populations of *Schiedea haleakalensis* should be documented on islands where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 2011).

Recovery Priority Number: 2

**Delisting Criteria:**

For delisting, a total of eight to ten populations of *Schiedea haleakalensis* should be documented on islands where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with 300 mature individuals per population for long-lived perennials. Each population should persist at this level for a minimum of five consecutive years before delisting is considered (USFWS, 2011).

**Recovery Actions:**

- Continue to collect seeds and other propagules for genetic storage and reintroduction (USFWS, 2011).
- Maintain the fences around existing populations to provide protection from the negative impacts of feral ungulates (USFWS, 2011).
- Control invasive introduced species around known populations (USFWS, 2011).
- Survey areas where *Schiedea haleakalensis* has been reported to determine current status of the species (USFWS, 2011).
- Develop and implement methods to control slugs and ants (USFWS, 2011).
- Control rats in the vicinity of these populations (USFWS, 2011).
- Propagate to augment the existing populations (USFWS, 2011).
- Research limiting factors to reintroduction success and possible solutions (USFWS, 2011).
- Establish additional populations within protected suitable habitat (USFWS, 2011).
- Work with the National Park Service, Plant Extinction Prevention Program, and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2011).

- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species (USFWS, 2011).
- New Management Actions:
  - Captive propagation for genetic storage and reintroduction—
    - o Haleakalā National Park (HNP) maintains a living collection of *S. haleakalensis*, and hand-pollination has produced more than 5,000 seeds for storage and propagation (Robertson 2016, in litt.). The HNP reported 900 seeds representing five individuals in storage in 2013; 58 plants representing four individuals in storage in 2015; and 119 plants representing four individuals in storage in 2016.
    - o Lyon Arboretum Micropropagation Laboratory reported 32 containers of propagules of *S. haleakalensis* in storage, representing one founder (Lyon Arboretum 2017).
    - o The University of California–Irvine reported one plant representing one individual in storage in 2014 (USFWS, 2018).
- Recommendations for Future Actions: Drought and two nonnative invasive plants are additional threats; however, we are not aware of any significant new information regarding the species' biological status since the last 5-year review in 2011. Thus, the following recommendations for future actions are added or reiterated for the 5-year review for 2018.
  - Surveys and inventories—Survey areas where *Schiedea haleakalensis* has been reported to determine current status of the species on east Maui.
  - Ungulate monitoring and control—Maintain fencing to provide protection from negative impacts of feral ungulates.
  - Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species around all populations of *S. haleakalensis*.
  - Captive propagation for genetic storage and reintroduction—Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range.
  - Reintroduction and translocation—
    - o Augment known populations and reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species.
    - o Research limiting factors contributing to failure of reintroduced individuals and populations.
  - Rodent predation and herbivory—Control rats in the vicinity of all populations.
  - Invertebrate predation and herbivory—Develop and implement methods to control slugs and ants.
  - Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species.
  - Alliance and partnership development—Work with the National Park Service, the Plant Extinction Prevention Program, and other land managers to initiate planning and contribute to ecosystem-level restoration and management to benefit this species (USFWS, 2018).

***Conservation Measures and Best Management Practices:***

- Recommendations for Future Actions: No significant new information regarding the species' biological status has been reported since the last 5-year review in 2018. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2023.
  - Surveys and monitoring—Survey for additional populations of *Schiedea haleakalensis* in areas of potentially suitable habitat.
  - Ungulate monitoring and control—Continue to maintain fenced exclosures and construct new fences to protect reintroduced individuals from the negative impacts of browsing by ungulates.
  - Invasive nonnative plant monitoring and control—Initiate control of established ecosystem-altering nonnative invasive plant species, and those that compete with *Schiedea haleakalensis* within and around all wild and translocated populations.
  - Fire prevention and control—Develop and implement fire prevention management plans.
  - Climate change adaptation strategy—Research suitability of habitat for viability of species, including where to conduct translocations in the future due to the impacts of climate change, including increasing temperatures, periods between rain events, and frequency and intensity of hurricanes. Additional

management actions may be needed, such as locating microsites that overlap with current and future climate envelopes for translocation efforts. • Predator and herbivore monitoring and control—Determine and implement effective methods for rodents and slugs around wild and translocated populations. • Captive propagation for genetic storage and reintroduction—Continue collection and propagation efforts for maintenance of genetic stock and for reintroduction. • Build resiliency, redundancy, and representation — Increase species' viability through habitat restoration, threat control, and reintroduction and translocation. Continue reintroduction into suitable habitat that is being managed for known threats to this species to reduce impacts of erosion, treefall, flooding, and hurricanes. • Research— o Conduct genetic studies to determine genetic variation and plan an effective breeding program. • Alliance and partnership development—Continue to work with partners and other land managers in planning and implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2023).

## SPECIES ACCOUNT: *Schiedea hawaiiensis* (Ma`oli`oli)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Region (R1) (USFWS, 2016)

#### **Physical Description**

Perennial herbs or subshrubs, pale yellowish green throughout or stems purple-tinged in lower portion of the plant. Stems 3-7 dm long or perhaps longer, ascending to sprawling when longer. Leaves opposite. Leaf blades 4-5.8 cm long, 1.7-2.8 cm wide, ovate to elliptic-ovate. Inflorescences panicle-like, 30-40 cm long. Capsules broadly ovoid, 3.5-4 mm long. (NatureServe, 2015)

#### **Taxonomy**

Kartesz (1999) includes *Schiedea hawaiiensis* in *S. diffusa*, however, Wagner et al. (1999) resurrect it from synonymy (the 1990 edition included it). Only known from one individual discovered in 1996 (per Wagner 1999). Also accepted as distinct by Wagner et al. (2012). (NatureServe, 2015)

#### **Historical Range**

*Schiedea hawaiiensis* is endemic to the island of Hawaii in the Hawaiian Islands. It has been recorded from only two locations, both in the northern part of the island. It is on the Pohakuloa Training Area in the saddle between Mauna Kea and Mauna Loa (volcanoes). (NatureServe, 2015)

#### **Critical Habitat Designated**

Yes; 4/11/2024.

#### **Legal Description**

We, the U.S. Fish and Wildlife Service (Service), designate critical habitat for 12 federally endangered species on the island of Hawai'i under the Endangered Species Act of 1973 (Act), as amended. In total, approximately 119,326 acres (48,289 hectares) on the island of Hawai'i, in the State of Hawaii, fall within the boundaries of the critical habitat designation. This rule extends the Act's protections to these species' designated critical habitats.

#### **Critical Habitat Designation**

Hawaii 55—*Schiedea hawaiiensis*-a, identified in the legal descriptions in paragraph (k) of this section, constitutes critical habitat for *Schiedea hawaiiensis* on Hawaii Island. In unit Hawaii 55—*Schiedea hawaiiensis*-a

#### **Primary Constituent Elements/Physical or Biological Features**

the physical and biological features of critical habitat in dry forest ecosystem are:

- (i) Elevation: Less than 9,500 ft (2,900 m).
- (ii) Annual precipitation: Less than 79 in (200 cm).

(iii) Substrate: Well-drained, sandy loams or loams from volcanic ash or cinder; weathered basaltic lava.

(iv) Canopy contains one or more of the following native plant genera: Acacia, Colubrina, Diospyros, Erythrina, Melicope, Metrosideros, Myoporum, Myrsine, Sophora.

(v) Subcanopy contains one or more of the following native plant genera: Achyranthes, Euphorbia, Leptecophylla, Nototrichium.

(vi) Understory contains one or more of the following native plant genera: Dodonaea, Doryopteris, Heteropogon, Pellaea.

### ***Life History***

#### **Food/Nutrient Resources**

#### **Reproduction Narrative**

Adult: No information found.

#### **Habitat Type**

Adult: Montane dry ecosystem (USFWS, 2013)

#### **Habitat Narrative**

Adult: Currently, *S. hawaiiensis* is known from 25 to 40 individuals on the U.S. Army's Pohakuloa Training Area (PTA) in the montane dry ecosystem, in the saddle area between Moana Loa and Mauna Kea (Gon III and Tierney 1996 in Wagner et al. 2005d, p. 92; Wagner et al. 2005d, p. 92; Evans 2011, in litt.). In addition, there are over 150 individuals outplanted at PTA (Kipuka Alala and Kalawamauna), Puu Huluhulu, Puu Waawaa, and Kipuka Oweowe (Evans 2011, in litt.) (USFWS, 2013).

### ***Dispersal/Migration***

#### **Dispersal/Migration Narrative**

Adult: No information available.

### ***Population Information and Trends***

#### **Population Trends:**

Unknown

#### **Number of Populations:**

1 (USFWS, 2020)

#### **Population Size:**

12 (6 mature, 6 immature) (USFWS, 2020)

#### **Population Narrative:**

There is one population of six mature and six immature wild individuals of *Schiedea hawaiiensis* on the island of Hawai'i. A landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections was made by Fortini et al. (2013) and, although their analysis was not conducted specifically for *S. hawaiiensis*, at the genus level, *Schiedea* has one of the highest vulnerability scores. Feral ungulate control is ongoing within exclosures for the wild and reintroduced populations; however, fencing must be maintained and monitored for ingress. Nonnative plant control is conducted at wild and reintroduced populations. More than 900 individuals have been reintroduced and recruitment has been observed; however, survivability is very low (only 67 individuals currently survive). Experimental reintroductions have been conducted at two other habitats in an attempt to address this issue; however, the long-term success is unknown. (USFWS, 2020)

### ***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Adverse impacts on habitat of this species have been identified from nonnative animals (pigs, goats, sheep, and mouflon), nonnative plants, fire, hurricanes, and drought. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Severe episodes of drought cannot only directly kill individuals of a species or entire populations, but drought frequently leads to an increase in the number and intensity of forest and brush fires. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

**Stressor:** Predation and herbivory (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Predation and herbivory by nonnative animal species (pigs, goats, sheep, mouflon, and rats) is considered an ongoing threat to *Schiedea hawaiiensis* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

**Stressor:** Small populations (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** *Schiedea hawaiiensis* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). Habitat destruction or direct predation by ungulates, nonnative plants, drought, and fire are threats to the 25 to 40 individuals of *Schiedea hawaiiensis* (USFWS, 2013).

**Stressor:**

**Exposure:**

**Response:**

**Consequence:**

**Narrative:**

**Stressor:** Ungulate degradation and destruction of habitat (USFWS, 2020)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:**

**Stressor:** Degradation and destruction of habitat by established ecosystemaltering invasive plant species (USFWS, 2020)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:**

**Stressor:** Fire degradation and destruction of habitat (USFWS, 2020)

**Exposure:**

**Response:**

**Consequence:**

**Exposure:**

**Response:**

**Consequence:**

**Narrative:**

**Stressor:** Predation and herbivory by ungulates (USFWS, 2020)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:**

**Stressor:** Predation and herbivory by rats (USFWS, 2020)

**Exposure:**  
**Response:**  
**Consequence:**  
**Narrative:**

**Stressor:** Herbivory by nonnative game birds (USFWS, 2020)

**Exposure:**  
**Response:**  
**Consequence:**  
**Narrative:**

**Stressor:** Inadequacy of regulatory mechanisms (USFWS, 2020)

**Exposure:**  
**Response:**  
**Consequence:**  
**Narrative:**

**Stressor:** Low numbers of individuals and populations (USFWS, 2020)

**Exposure:**  
**Response:**  
**Consequence:**  
**Narrative:**

## ***Recovery***

### **Reclassification Criteria:**

Recovery priority numbers are assigned to species or subspecies based on the degree of threat, the potential for recovery, and their taxonomic status (i.e., full species vs. subspecies ) and range from 1C (highest, "C" indicating the potential for conflict with human economic activities) to 18 (lowest) (USFWS 1983a, 1983b). All of the 15 species have a high degree of threat to their habitat and continued existence (Table 2). These threats are ongoing and include habitat loss and degradation by invasive nonnative plant species, feral ungulates, predation or herbivory by nonnative invertebrates and vertebrates, diseases, climate change, and the stochastic and demographic consequences associated with a low number of individuals and populations. *Pittosporum hawaiiense* and *Pritchardia lanigera* are assigned a recovery priority number of 2 based on a high degree of threat, a high potential for recovery because their threats are well understood and can be alleviated, and because of their status as full species. *Bidens micrantha* ssp. *ctenophylla* is assigned a recovery priority number of 3, based on a high degree of threat, a high potential for recovery because its threats are understood and can be alleviated, and because of its status as a subspecies. *Cyanea marksii*, *Cyanea tritomantha*, *Cyrtandra nanawaleensis*, *Cyrtandra wagneri*, *Drosophila digressa*, *Phyllostegia floribunda*, *Platydesma remyi*, *Schiedea hawaiiensis*, *Stenogyne cranwelliae*, and *Vetericaris chaceorum* are assigned a recovery priority number of 5, based on a high degree of threat, a low potential for recovery due to a small number of individuals and some threats being well understood while others are difficult to mitigate, and because of their status as a species. *Bidens hillebrandiana* ssp. *hillebrandiana* and *Schiedea diffusa* ssp. *macraei* are assigned a recovery priority number of 6, based on a high degree of threat, a low potential for recovery due to a small number of individuals and some threats being well understood while others are difficult to mitigate, and

because of their status as subspecies (USFWS, 2019).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Surveys and inventories—Continue to search suitable habitat for individuals of *Schiedea hawaiiensis* in recent and historical locations. • Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect wild and reintroduced individuals from the negative impacts of feral ungulates. Monitor exclosures for ingress. • Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species and those that compete with *S. hawaiiensis* at all populations. • Fire prevention and control—Implement more effective fuel load control. • Predation and herbivory by ungulates—Continue to fence and monitor populations for ungulates. • Predation and herbivory by rats—Implement alternate methods to rodenticide to better protect wild and reintroduced *S. hawaiiensis* and to protect the Hawaiian hawk. • Predation and herbivory by nonnative game birds—Develop and implement effective controls for game birds. • Captive propagation for genetic storage and reintroduction—Continue to collect seeds for storage and propagation efforts. • Reintroduction and translocation—Continue to establish and augment populations to increase numbers of populations and individuals in suitable habitat to reduce the impacts of competition with nonnative plants; ungulate, rat, and game bird predation; drought, fire, climate change, and hurricanes. • Climate change adaptation strategy—Research suitability of habitat in the future due to the impacts of climate change. • Alliance and partnership development—Continue to collaborate with partners in planning and implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2020)

## SPECIES ACCOUNT: *Schiedea kealiae* (Ma`oli`oli)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

#### **Physical Description**

A subshrub with weakly ascending to sprawling stems 2 - 5 dm long that form loose clumps. Small flowers are borne in terminal clusters (NatureServe, 2015).

#### **Taxonomy**

A member of the pink family (Caryophyllaceae) (USFWS, 2003).

#### **Historical Range**

The species is endemic to Oahu, Hawaii (NatureServe, 2015). Historically, *Schiedea kealiae* was known from the northern Waianae Mountains and one collection from the Palikea area, near the southern end of the same mountain range (USFWS 1996b; 1998).

#### **Current Range**

Currently, populations are located on the cliffs above Dillingham Airfield and Camp Erdman and at Kaena Point at the northern end of the Waianae Mountains (USFWS, 2003).

#### **Critical Habitat Designated**

Yes; 6/17/2003.

#### **Legal Description**

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea kealiae* (Ma`oli`oli) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Schiedea kealiae* (77 FR 57648-57862). The critical habitat designation includes 10 critical habitat units, which encompass approximately 1,493 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Ctenitis squamigera* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

#### **Critical Habitat Designation**

The critical habitat designation for *Schiedea kealiae* includes 10 critical habitat units, covering two ecosystem types, which encompass approximately 1,493 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Coastal—Units 1, 13, 14, 15, Oahu— Lowland Dry—Units 1, 2, 8, 9, 10, 11.

Oahu—Coastal—Unit 1 [958 ac (388 ha)]. This area consists of 946 ac (383 ha) of State land, 11 ac (4 ha) of Federal land, and 2 ac (1 ha) of privately owned land in the coastal ecosystem along the northwestern coast of Oahu from Kaena Point east to Kauhao Pali and southeast to Keawaula. This unit is partially within Kaena Point State Park. Oahu—Coastal—Unit 13 [23 ac (10 ha)]. This area consists of 19 ac (8 ha) of City and County land, 1 ac (0.5 ha) of State land, and 3 ac (1 ha) of

privately owned land in the coastal ecosystem at Kalaeloa. Oahu—Coastal—Unit 14 [4 ac (2 ha)]. This area consists of 2 ac (1 ha) of City and County of Honolulu land, and 2 ac (1 ha) of Federal land (U.S. Coast Guard) in the coastal ecosystem at Kalaeloa. Oahu—Coastal—Unit 15 [33 ac (13 ha)]. This area consists of 9 ac (4 ha) of State land, 2 ac (1 ha) of privately owned land, and 21 ac (9 ha) of Federal (Pearl Harbor NWR) land at Kalaeloa.

Oahu—Lowland Dry—Unit 1 [102 ac (41 ha)]; This area consists of 49 ac (20 ha) of State land and 53 ac (22 ha) of privately owned land in the Waianae Mountains, extending from Haili Gulch to Kawaipahai. Oahu—Lowland Dry— Unit 2 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland dry ecosystem in the Waianae Mountains, on Federal land within Kaena Point State Park. Oahu—Lowland Dry—Unit 8 [99 ac (40 ha)]. Oahu—This area consists of 96 ac (40 ha) of privately owned land and 3 ac (1 ha) of State land as part of the old railroad right-of-way in the lowland dry ecosystem, at the Kalaeloa Barber's Point Harbor area. Oahu—Lowland Dry—Unit 9 [37 ac (15 ha)]. This area consists of 17 ac (7 ha) of City and County land, 3 ac (1 ha) of privately owned land, 1 ac (0.5 ha) of State land, and 16 ac (6 ha) of Federal (Pearl Harbor NWR) land in the lowland dry ecosystem at Kalaeloa. Oahu—Lowland Dry— Unit 10 [43 ac (17 ha)]. This area consists of 43 ac (17 ha) of State land (DHHL) in the lowland dry ecosystem at Kalaeloa. Oahu—Lowland Dry—Unit 11 [166 ac (67 ha)]. This area consists of 166 ac (67 ha) of federal land (U.S. Navy) in the lowland dry ecosystem at Kalaeloa.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea kealiae* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Schiedea kealiae* occurs within the Coastal and Lowland dry ecosystems in the Waianae Mountain caldera complex:

Oahu—Coastal—Units 1, 13, 14, 15. (A) Elevation: <980 ft (<300 m). (B) Annual Precipitation: <20 in (<50 cm). (C) Substrate: Well-drained, calcareous, talus slopes; dunes; weathered clay soils; ephemeral pools; mudflats. (D) Canopy: Hibiscus, Myoporum, Santalum, Scaevola. (E) Subcanopy: Gossypium, Sida, Vitex. (F) Understory: Eragrostis, Jacquemontia, Lyceum, Nama, Sesuvium, Sporobolus, Vigna.

Oahu— Lowland Dry—Units 1, 2, 8, 9, 10, 11. (A) Elevation: <3,300 ft (<1,000 m). (B) Annual Precipitation: <50 in (<130 cm). (C) Substrate: Weathered silty loams to stony clay, rocky ledges, little weathered lava. (D) Canopy: Diospyros, Myoporum, Pleomele, Santalum, Sapindes. (E) Subcanopy: Chamaesyce, Dodonaea, Leptecophylla, Osteomeles, Psydrax, Scaevola, Wikstroemia. (F) Understory: Alyxia, Artemisia, Bidens, Chenopodium, Nephrolepis, Peperomia, Plumbago, Sicyos, Sida, Waltheria.

#### **Special Management Considerations or Protections**

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Schiedea kealiae* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat

areas identified for this species.

### ***Life History***

#### **Food/Nutrient Resources**

#### **Reproductive Strategy**

Adult: Sexual: cross-pollination, self-pollination (USFWS, 1998)

#### **Lifespan**

Adult: < 10 years (USFWS, 2013)

#### **Breeding Season**

Adult: December (USFWS, 1998)

#### **Key Resources Needed for Breeding**

Adult: Wind (USFWS, 2013)

#### **Reproduction Narrative**

Adult: The species is considered to be wind pollinated (S. Weller, University of California, Irvine, pers. comm. 2012). This species is a short-lived perennial (fewer than 10 years) (USFWS, 2013). It has been observed in flower in December. A series of self pollinations, within-population crosses, and crosses among occurrences has demonstrated that many related *Schiedea* species experience moderately strong inbreeding depression (USFWS, 1998).

#### **Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

#### **Habitat Vegetation or Surface Water Classification**

Adult: Dry shrublands and forests (NatureServe, 2015); *Erythrina sandwicensis* or *Pisonia sandwicensis* forest (USFWS, 2010)

#### **Geographic or Habitat Restraints or Barriers**

Adult: 200 - 1,000 ft. elevation (USFWS, 2010)

#### **Habitat Narrative**

Adult: Inhabits dry shrublands and forests on headlands, cliffs and cliff ledges not far from the coast (NatureServe, 2015). *Schiedea kealiae* is usually found on steep slopes and cliff faces at elevations from 60 to 305 meters (200 to 1,000 feet), in dry remnant *Erythrina sandwicensis* (wiliwili) or *Pisonia sandwicensis* (aalu, papala kepau, alaa) forest (USFWS, 2010).

### ***Dispersal/Migration***

#### **Dispersal/Migration Narrative**

Adult: Not available

### ***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

4 (USFWS, 2003)

**Population Size:**

at least 150 mature and 100 immature (USFWS, 2019)

**Population Narrative:**

Currently, there are 4 occurrences totaling between 265 and 315 plants (USFWS, 2003). Currently there are at least 150 mature and 100 immature individuals of *Schiedea kealiae* in the Wai'anae mountains of O'ahu. A landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections was made by Fortini et al. (2013) and their analysis showed that *S. kealiae* is extremely vulnerable to the effects of climate change. Predation by Giant African Snails is a threat to seedlings. Collection and propagation for storage is ongoing (USFWS, 2019)

**Threats and Stressors**

**Stressor:** Nonnative plants (USFWS, 2003)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** It is threatened by competition with the nonnative plant species *Leucaena leucocephala*, *Panicum maximum*, and *Schinus terebinthifolius* (USFWS, 2003).

**Stressor:** Climate change (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Climate change may pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species (USFWS, 2013).

**Stressor:** Predation (USFWS, 2003)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Seedlings of *Schiedea* species occurring in mesic or wet sites are apparently consumed by introduced unidentified slugs and snails, which have been observed feeding on *Schiedea membranacea*, a mesic forest species from Kauai (USFWS, 2010).

**Stressor:** Lack of pollinators (USFWS, 2003)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Not available

**Stressor:** Small population size (USFWS, 2003)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** This species is at risk of extinction from naturally occurring events and/or reduced reproductive vigor due to the small number of existing occurrences. The Kaena Point occurrence is additionally threatened by naturally occurring rock slides and fire (HINHP Database 2001; Service 1998b; 61 FR 53089) (USFWS, 2003).

**Stressor:** Habitat destruction and modification (USFWS, 2010)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Feral ungulates, especially goats (*Capra hircus*) and pigs (*Sus scrofa*), as well as fires and landslides (Perlman 2008) (USFWS, 2010).

### ***Recovery***

#### **Reclassification Criteria:**

1. A total of five to seven populations of the species should be documented on Oahu and at least one other island where it now occurs or occurred historically (USFWS, 1998).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1998).
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1998).

#### **Delisting Criteria:**

1. A total of 8 to 10 populations of the species should be documented on Oahu and at least one other island where it now occurs or occurred historically (USFWS, 1998).
2. Oahu and at least one other island where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1998).
3. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 1998).

#### **Recovery Actions:**

- Protect habitat and control threats (USFWS, 1998).
- Expand existing wild populations (USFWS, 1998).
- Conduct essential research (USFWS, 1998).
- Develop and maintain monitoring plans (USFWS, 1998).
- Reestablish wild populations within historic range (USFWS, 1998).

- Validate and revise recovery criteria (USFWS, 1998).
- Control competing alien plant species (USFWS, 1998).
- Control of introduced snails and slugs (USFWS, 1998).
- Research on pollinators (USFWS, 1998).
- Reduce substrate loss (USFWS, 1998).
- Provide protection from fire (USFWS, 1998).
- Captive propagation for genetic storage and reintroduction - Continue collecting material for genetic storage and propagation for reintroduction. Investigate new propagation methods (USFWS, 2013).
- Invertebrate control research - Investigate slug herbivory and appropriate insect control methods (USFWS, 2013).
- Ungulate exclosures - Fence remaining populations to protect them from the impacts of feral ungulates (USFWS, 2013).
- Ecosystem-altering invasive plant species control - Remove competing invasive introduced plant species within fenced areas and maintain those areas free of invasive introduced plants (USFWS, 2013).
- Fire protection – Develop and implement fire prevention plans to protect the most vulnerable populations (USFWS, 2013).
- Population biology research - Implement genetic studies to assess the viability of remaining populations. Investigate the causes of reproductive failure and techniques to improve natural recruitment (USFWS, 2013).
- Surveys / inventories – Survey geographical and historical range for a thorough current assessment of the species status (USFWS, 2013).
- Alliance and partnership development - Initiate planning and contribute to implementation of ecosystem level restoration and management to benefit this taxon (USFWS, 2013).
- Threats research – Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species (USFWS, 2013).

***Conservation Measures and Best Management Practices:***

- Recommendations for Future Actions: We are not aware of any new threats except for additional data on this taxon's vulnerability to climate change and predation and herbivory by Giant African Snails. There is no significant new information regarding the species' biological status since the last 5-year review in 2013. Thus, the following recommendations for future actions are added or reiterated for the 5-year review for 2019. • Surveys and inventories—Survey geographical and historical range for a thorough assessment of the species' status. • Ungulate monitoring and control—Fence the remaining population to protect plants from impacts of feral ungulates. • Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species, and those that compete with *Schiedea kealiae* at the remaining population. • Fire protection—Develop and implement fire prevention plans to protect the most vulnerable populations. • Drought remediation—Protect populations from competition by nonnative plants and fence and remove feral ungulates to prevent further effects of drought such as erosion. • Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species. • Invertebrate control and research—Implement effective slug and nonnative snail control at all populations, focusing especially on the Giant African snails at Keālia. • Captive propagation for genetic storage and reintroduction—Continue seed collection for genetic storage and propagation for reintroduction. Investigate effective propagation methods. • Reintroduction—Establish new populations and

- augment existing populations, keeping close track of maternal source used for ex situ propagation. • Population biology research—
  - o Continue to conduct genetic studies to assess the genetic variability and the viability of remaining population.
  - o Continue to investigate the causes of reproductive failure and implement techniques to improve natural recruitment.• Alliance and partnership development—Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2019)
- New Management Actions: • Captive propagation for genetic storage and reintroduction—
  - o The Army Natural Resources Program-O'ahu (ANRP) reports collection and storage of 2,586 seeds from one population representing 10 individuals (U.S. Army 2018).
  - o The Lyon Seed Conservation Laboratory reports 7,408 seeds in storage collected in 2014 representing 22 individuals from one population (Lyon Arboretum 2018).
  - o Waimea Arboretum reports nine plants in refugia representing two wild individuals in 2013, 60 plants representing two wild individuals in 2014, four plants representing one wild individual in 2015, and 2 plants representing one wild individual in 2017 (Waimea Arboretum 2013, 2014, 2015, 2017).
  - o Pahole Rare Plant Facility (PRPF) reports seven plants in refugia representing one individual from Keālia (PRPF 2018). (USFWS, 2019)

**Listing Status:** Endangered; Pacific Region (R1) (USFWS, 2016)

#### **Physical Description**

A subshrub 3-10 dm tall, with somewhat fleshy leaves, and congested clusters of 7-12 white and green flowers. (NatureServe, 2015)

#### **Historical Range**

Historically, this species was known from the northern and southern parts of the Waianae Mountains (USFWS, 2016)

#### **Current Range**

Endemic to Waianae Mountains of Oahu (NatureServe, 2015).

#### **Critical Habitat Designated**

Yes; 6/17/2003.

#### **Legal Description**

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea obovata* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Schiedea obovata* (77 FR 57648-57862). The critical habitat designation includes 11 critical habitat units, which encompass approximately 7,332 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Schiedea obovata* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

#### **Critical Habitat Designation**

The critical habitat designation for *Schiedea obovata* includes 11 critical habitat units, covering two ecosystem types, which encompass approximately 7,332 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 1, 2, 3; Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch.

Oahu—Dry Cliff—Unit 1 [49 ac (20 ha)]. This area consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley. Oahu—Dry Cliff—Unit 2 [412 ac (167 ha)]. This area consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo. Oahu—Dry Cliff—Unit 3 [450 ac (182 ha)]. This area consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge. Oahu—Dry Cliff—Unit 4 [24 ac (10 ha)]. This area consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys. Oahu—Dry Cliff—Unit 6 [149 ac (60 ha)]. This area consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. Oahu—Dry Cliff—Unit 7a [68 ac (27 ha)]. This area consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. Oahu—Dry Cliff—Unit 7b [38 ac (16 ha)]. This area consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea. Oahu—Dry Cliff—Unit 8 [259 ac (105 ha)]. This area consists of 259 ac (105 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Nanakuli Valley from Palehua to Puumanawanua, and partially within the Nanakuli Forest Reserve.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea obovata* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Schiedea obovata* occurs within the Lowland mesic and Dry cliff ecosystems in the Waianae Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. (E) Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. (F) Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: < 75 in (<190 cm). (C) Substrate: >65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: Antidesma, Chamaesyce, Diospyros, Dodonaea. (F) Understory: Bidens, Eragrostis, Melanthera, *Schiedea*.

#### **Special Management Considerations or Protections**

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Schiedea obovata* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat

areas identified for this species.

### ***Life History***

#### **Food/Nutrient Resources**

#### **Reproductive Strategy**

Adult: Self-fertilizing (USFWS, 2016)

#### **Lifespan**

Adult: 3-6 years (USFWS, 2016)

#### **Breeding Season**

Adult: Flowers and fruit are produced year-round, especially in response to rainfall during winter and spring (USFWS, 2016).

#### **Reproduction Narrative**

Adult: Plants generally flower after two years of growth, and are normally self-fertilizing (Makua Implementation Team 2003). Flowers and fruit are produced year-round, especially in response to rainfall during winter and spring. Seed dispersal mechanism is unknown, although the plant's "false berry" possibly may attract fruit-eating birds that may disperse the seeds (Makua Implementation Team 2003). Plants survive 3 to 6 years, or less under drought conditions (Service 1995a, Service 1998a). Population units in the wild have been known to disappear for a number of years and then reappear after large rainfall events, apparently owing to persistence of seeds in the soil seed bank (U.S. Army Garrison 2004a). Other demographic information for *S. obovata* in the wild is unknown, including number of seeds produced, survivorship to sexual maturity, number of years in reproductive condition, survivorship during reproductive life, seed dispersal, vegetative reproduction and specific environmental requirements (USFWS, 2016).

#### **Habitat Type**

Adult: Forested ridges and slopes (USFWS, 2016)

#### **Habitat Narrative**

Adult: *Schiedea obovata* occurs on ridges and slopes in lowland diverse mesic forests dominated by *Acacia koa* and *Metrosideros polymorpha*, at elevations of 560 to 760 m (1,837 to 2,494 ft) (USFWS, 2016).

### ***Dispersal/Migration***

#### ***Population Information and Trends***

#### **Population Trends:**

Unknown

#### **Number of Populations:**

One wild (2 subpopulations). 3 reintroduced populations (USFWS, 2024)

#### **Population Size:**

23 wild; 1,073 reintroduced (USFWS, 2024)

**Population Narrative:**

Currently, two population units, Kahanahaiki to Pahole and Keawapilau to West Makaleha, total 389 individuals located on Federal and State lands (68 FR 35950) (Table SB 36). The Kahanahaiki to Pahole population unit has met numerical criteria for stabilization (defined for this species as 100 mature individuals per population unit) (Makua Implementation Team 2003). The existing population units also are located within low and very low fire risk zones for training-related wildfire. Demographic data indicate *Schiedea obovata* is increasing in numbers only due to augmentation efforts and the discovery of a new population unit in North West Makaleha. About 82 percent of all of individuals are augmentations from greenhouse-propagated stock. Recruitment of seedlings and immature plants into the mature population is limited by predation by non-native slugs and snails that feed on and damage leaves and stems (Makua Implementation Team 2003; U.S. Army Garrison 2004a; U.S. Army Garrison 2005b). One study noted, for example, that seedling mortality doubled when exposed to slug herbivory (U.S. Army Garrison 2005b). Furthermore, slugs have the potential to completely halt seedling regeneration in several sites (U.S. Army Garrison 2004a, 2005b). Thus, *S. obovata* is characterized by declining in the current range and two existing population units with low numbers, of which one is exceeding minimum numerical criteria for stabilization and increasing through augmentation and discovery of new individuals (USFWS, 2016). Currently there are approximately 425 wild individuals (96 percent are immature plants) of *Schiedea obovata* in the Wai'anae mountains of O'ahu. A landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections was made by Fortini et al. (2013) and their analysis showed that *S. obovata* is extremely vulnerable to the effects of climate change. Collection, propagation, and reintroductions into fenced and managed areas are ongoing. Currently, the reintroductions consist of 124 mature plants and 168 immature plants, with 200 seedlings recruiting. (USFWS, 2019). Currently, there are two wild subpopulations in one population unit (Ke'awapilau to Makaleha) totaling 17 mature and 6 immature individuals (Army Natural Resources Program on O'ahu [ANRPO] 2023a, p. 114; Appendix 4-1). Additionally, there are 1,073 total reintroduced individuals across three population units (Kahanahāiki to Pahole, Ke'awapilau to Makaleha, and Mākaha), of which 340 individuals are mature plants (ANRPO 2023b, Appendix 4-1). • Currently, there are approximately 96 founder lines represented in ex situ storage and propagation collections, including seeds in seed banks, explants in tissue culture, vegetative material, and plants in a nursery or living collection (ANRPO 2023b, Appendix 4-3) (USFWS, 2024).

**Threats and Stressors**

**Stressor:** Slugs and snails (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** *Schiedea obovata* is particularly vulnerable to predation by non-native slugs and snails (Makua Implementation Team 2003; U.S. Army Garrison 2005b) (USFWS, 2016).

**Stressor:** Residential development (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Residential development is listed as a threat to this species (USFWS, 2016).

**Stressor:** Reforestation (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Reforestation with non-native trees is listed as a threat to this species (USFWS, 2016).

**Stressor:** Military installations (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Establishment of military installations is listed as a threat to this species (USFWS, 2016).

**Stressor:** Trampling/collection

**Exposure:**

**Response:**

**Consequence:** Loss of individuals

**Narrative:** Trampling and illegal collecting by people is listed as a threat to this species (USFWS, 2016).

**Stressor:** Stochastic events (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Extinction

**Narrative:** Population units of *S. obovata* are vulnerable to extirpation from naturally occurring events such as rockslides and/or reduced reproductive vigor due to small population size and limited distribution (56 FR 55770; 68 FR 35950; Service 1995a, 1998a) (USFWS, 2016).

**Stressor:** Drought (USFWS, 2016)

**Exposure:**

**Response:**

**Consequence:** Population fluctuation

**Narrative:** This species experiences large population fluctuations related to drought and its natural recruitment is severely reduced by slug predation (U.S. Army Garrison 2005c) (USFWS, 2016).

**Stressor:** Climate change loss or degradation of habitat (USFWS, 2019)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** —Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Schiedea obovata* is extremely

vulnerable to the impacts of climate change, with a vulnerability score of 0.944 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions may be needed to conserve this taxon into the future, such as locating key microsites that overlap with current and future climate envelopes for outplanting efforts. (USFWS, 2019)

### **Recovery**

#### **Reclassification Criteria:**

Recovery Priority Number: 5

#### **Delisting Criteria:**

Conservation actions that should be implemented for the recovery of *Schiedea obovata* are described in the introduction to the “Status and Environmental Baseline of the Species and Critical Habitat” section. Due to limited knowledge of life history requirements for short-term and long-term survival, the recovery plan for this species specifies interim objectives to downlisting and delisting that involve stabilization of all existing populations (Service 1995a, 1998a). At least 50 mature, reproducing individuals are needed per population unit to attain stabilization criteria for short-lived perennials. However, because of the common, large declines or fluctuations in numbers of *S. obovata*, the Makua Implementation Team (2003) identified a stabilization target of at least 100 mature individuals for each population unit of this species. An increased stabilization criterion is needed because any adverse disturbance during a major low point in a population unit’s fluctuation could extirpate that unit. In addition to stabilizing the two existing population units, a third population unit must be established by reintroduction and managed for stabilization outside the action area. Research on slug control in forest settings is needed to find ways to reduce this threat to *S. obovata* and associated native plants (USFWS, 2016).

The Makua Implementation Team (2003) has developed stabilization protocols for *Schiedea obovata*, which are incorporated in the Army’s Makua Implementation Plan Addendum (U.S. Army Garrison 2005a). This species occurs in the Kahanahaiki, Pahole, and West Makaleha Management Units where it will benefit from population unit and/or ecosystem-level protection. The Army and the Hawaii Division of Forestry and Wildlife have been outplanting this species within fenced exclosures since 1999. The Kahanahaiki to Pahole population unit is located within the fenced Kahanahaiki and Pahole Management Units, and the North West Makaleha site within the Keawapilau to West Makaleha population unit is fenced. Fence construction is planned for the entire West Makaleha Management Unit in 2007. Invasive weeds are controlled at extant *S. obovata* sites, but not at historical sites. *Schiedea obovata* seed can be successfully stored and remain viable for several years, and outplantings have been successful (U.S. Army Garrison 2005b). In 2005, this species was represented in the following ex situ collections: one cutting in a nursery (Army Environmental Division, Oahu), 14 plants in a botanical garden (Waimea Valley Audubon Center), 161 seeds in micropropagation (Harold L. Lyon Arboretum), 236,814 seeds in seed storage (Lyon Arboretum Seed Storage Facility), and 13 seedlings in micropropagation (Harold L. Lyon Arboretum) (Service 2005b) (USFWS, 2016).

#### **Conservation Measures and Best Management Practices:**

- Recommendations for Future Actions: Other than the new data on this taxon’s vulnerability to climate change, we are not aware of any new threats. There is no significant new information

regarding the species' biological status since the last 5-year review in 2012. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2019. • Surveys and inventories—Continue to survey geographical and historical range for a thorough assessment of the species' status. • Ungulate monitoring and control—Continue to fence and monitor wild and reintroduced populations to protect plants from impacts of feral ungulates. • Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species, and those that compete with *Schiedea obovata* at all wild and reintroduced population. • Fire protection—Implement fire management plans and coordinate fire response efforts. • Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species. • Rodent control—Continue to implement effective rat control at all populations. • Invertebrate control—Continue to implement effective slug and nonnative snail control at all populations. • Captive propagation for genetic storage and reintroduction—Continue seed collection for genetic storage and propagation for reintroduction. • Reintroduction—Continue to establish new populations and augment existing populations, keeping close track of maternal source used for ex situ propagation. • Population biology research—Study populations of *Schiedea obovata* with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. • Alliance and partnership development—Work with the ANRP, the Division of Forestry and Wildlife, and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2019)

- New Management Actions: • Ungulate control—The ANRP and State of Hawai'i Native Ecosystems Protection and Management group has constructed fences and maintain the integrity of fences in the areas protecting wild and outplanted populations at Kahanahāiki, Ke'awapilau, West Makaleha, and Mākaha (ANRP 2018). • Nonnative invasive plant control—The ANRP reports that nonnative plant control is conducted at Makaleha West, Kahanahāiki to Pahole, and at Mākaha (ANRP 2018). • Rodent predation or herbivory—The ANRP has found that Goodnature™ A24 rat traps are more effective than the Victor® snap traps, and these traps are deployed in the Kahanahāiki to Pahole management areas (ANRP 2018). • Slug control—Testing showed that Ferroxx® is a more effective slug control than Sluggo®, and this toxicant is currently used to protect individuals of *Schiedea obovata* from herbivory by slugs at the Pahole and West Makaleha management units (U.S. Army Garrison 2010). • Captive propagation for genetic storage and reintroduction—
  - o The ANRP reports that while the Kahanahāiki to Pahole population sites are now extirpated, five individuals were collected from prior to their extirpation and are adequately represented in ex situ collections. There are 86 wild plants represented in ex situ collections from the Ke'awapilau to West Makaleha populations (ANRP 2018).
  - o The Lyon Seed Micropropagation Laboratory reports one wild plant from Pahole represented by 148 explants (Lyon Arboretum 2018.).
 • Reintroductions—The ANRP reports outplanting sites containing 91 mature, 167 immature plants at Kahanahāiki to Pahole (with 200 seedlings recruiting), with some sites comprised of a mix of outplanted individuals and individuals that naturally-recruited from these outplanting efforts. There are 13 mature and 1 immature outplants in Ke'awapilau to West Makaleha, and 20 mature outplants in Mākaha. Thorough monitoring at all three outplanting sites have shown a decline in population size (ANRP 2018). (USFWS, 2019)
- Recommendations for Future Actions: No significant new information regarding the species' biological status has been reported since the last 5-year review in 2019. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2024. • Surveys and inventories—
  - o Continue surveys for populations of *Schiedea obovata* in areas of potentially suitable habitat.
  - o Determine suitable locations for reintroductions.
 • Ungulate monitoring and

control—Continue to maintain fenced exclosures and construct new fences to protect individuals from the negative impacts of browsing by ungulates. • Invasive nonnative plant monitoring and control—Continue control of established ecosystem-altering nonnative invasive plant species, and those that compete with *S. obovata*. • Site and habitat protection—Develop and implement effective threat control measures to reduce the impact of small population size. • Fire prevention and control—Continue to develop and implement fire prevention management plans. • Climate change adaptation strategy—Research suitability of habitat for viability of species, including where to conduct translocations in the future due to the impacts of climate change, including increasing temperatures, periods between rain events, and increasing frequency and intensity of hurricanes. Additional management actions may be needed, such as locating key microsites that overlap with current and future climate envelopes for translocation efforts. • Predator and herbivore monitoring and control—Determine and continue to implement effective methods to control rats and slugs. • Captive propagation for genetic storage and reintroduction—Continue collection and propagation efforts for maintenance of genetic stock and for reintroduction. • Build resiliency, redundancy, and representation — Increase species' viability through habitat restoration, threat control, and reintroduction and translocation into suitable habitat that is being managed for known threats to this species to reduce impacts of climate change degradation and nonnative plant competition. • Alliance and partnership development—Continue to work with partners and other land managers in planning and implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2024).

## SPECIES ACCOUNT: *Schiedea salicaria* (No common name)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; Pacific Region (R1) (USFWS, 2016)

#### **Physical Description**

An erect subshrub or shrub, 3-18 dm tall. Inflorescences terminal, 8-11 cm long. (NatureServe, 2015)

#### **Taxonomy**

Hawaiian endemic genus of 22 species, species endemic to west Maui. No varieties recognized by Wagner et al. (NatureServe, 2015)

#### **Historical Range**

See current range/distribution.

#### **Current Range**

Endemic to the southern and eastern side of West Maui, state of Hawaii. (NatureServe, 2015).  
Distribution: Maui (USFWS, 2021)

#### **Critical Habitat Designated**

Yes; 3/30/2016.

#### **Legal Description**

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea salicaria* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two detailed critical habitat units (CHUs), in Maui County in Hawaii (81 FR 17790-18110).

#### **Critical Habitat Designation**

The critical habitat designation for *Schiedea salicaria* includes two CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Dry—Unit 5 consists of 3,615 ac (1,463 ha) of State land, and 43 ac (17 ha) of privately owned land, from Panaewa to Manawainui on the western and southern slopes of west Maui. This unit is occupied by the plants *Asplenium dielerectum*, *Bidens campylotheca* ssp. pentamera, *Cenchrus agrimonioides*, *Gouania hillebrandii*, *Kadua coriacea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and *Tetramolopium capillare*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 5 is not known to be occupied by *Ctenitis squamigera*, *Cyanea obtusa*, *Hesperomannia arbuscula*, *Hibiscus brackenridgei*, *Lysimachia lydgatei*, *Neraudia sericea*, *Schiedea salicaria*, *Sesbania tomentosa*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations

within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 6 consists of 3 ac (1 ha) of State land, and 237 ac (96 ha) of privately owned land, from Paleaahu Gulch to Puu Hona on the southern slopes of west Maui. This unit is occupied by the plants *Hibiscus brackenridgei* and *Schiedea salicaria*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 6 is not known to be occupied by *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonoides*, *Ctenitis squamigera*, *Cyanea obtusa*, *Gouania hillebrandii*, *Hesperomannia arbuscula*, *Kadua coriacea*, *Lysimachia lydgatei*, *Neraudia sericea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Spermolepis hawaiiensis*, *Tetramolopium capillare*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

#### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea salicaria* critical habitat consists of one component. Lowland dry (west Maui) (81 FR 17790-18110):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*. Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psydrax*, *Scaevola*, *Wikstroemia*. Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Sicyos*.

#### **Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The

125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some

occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

**Life History****Food/Nutrient Resources****Reproductive Strategy**

Adult: Obligate outcrosser (USFWS, 2021)

**Lifespan**

Adult: Short-lived perennial shrub (USFWS, 2021)

**Reproduction Narrative**

Adult: No information found.

**Habitat Type**

Adult: Dry shrublands (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (inferred from USFWS, 2016)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from USFWS, 2016)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from USFWS, 2016)

**Site Fidelity**

Adult: High (inferred from USFWS, 2016)

**Habitat Narrative**

Adult: Species inhabits dry shrublands on steep slopes and ridgetops. (NatureServe, 2015). Currently, this species is found in three occurrences: Kaunoahua gulch (500 to 1,000 individuals), Puu Hona (about 50 individuals), and Waikapu Stream (3 to 5 individuals), in the lowland dry ecosystem on west Maui (TNC 2007; Oppenheimer 2010k, in litt.; Oppenheimer 2010l, in litt.) (USFWS, 2016). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community

are inferred based on the species unique habitat requirements and the low number of known populations.

### ***Dispersal/Migration***

#### **Dispersal/Migration Narrative**

Adult: No information found.

### ***Population Information and Trends***

#### **Population Trends:**

Decreasing (NatureServe, 2015)

#### **Number of Populations:**

3 (USFWS, 2021)

#### **Population Size:**

853-1,405 (USFWS, 2021)

#### **Population Narrative:**

While there are no historic records of numbers of populations or individuals, qualitative accounts indicate this species was not uncommon on West Maui (Russell 2004). Decline of 30-70% Original estimated total for this species ranges from about 1,000 to about 2,000. Although, U.S Fish and Wildlife Service currently have an 2005 estimate as 100 to 300 (USFWS 2006). Total number of occurrences are 5, of those 4 are known extant occurrences found on the island of Maui. (NatureServe, 2015). There are between 853 to 1,405 individuals of *Schiedea salicaria* within three wild population units on west Maui. A landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections was made by Fortini et al. (2013) and their analysis showed that *S. salicaria* is extremely vulnerable to the effects of climate change. There are seeds and propagules in collection. Collection and propagation are ongoing. (USFWS, 2020)

### ***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Adverse impacts on habitat of this species have been identified from nonnative animals (goats, axis deer, and cattle), nonnative plants, fire, drought, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants.

Drought destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities.. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential impacts from climate change have also been identified (USFWS, 2013).

**Stressor:** Predation and herbivory (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Predation and herbivory by nonnative animal species (axis deer, cattle, and goats) is considered an ongoing threat to *Schiedea salicaria* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

**Stressor:**

**Exposure:**

**Response:**

**Consequence:**

**Narrative:**

**Stressor:**

**Exposure:**

**Response:**

**Consequence:**

**Narrative:**

### ***Recovery***

#### **Reclassification Criteria:**

Number of populations and individuals needed for each plant species to meet Preventing Extinction Stage target based on population and life history characteristics: Number of Populations: 3. Mature Individuals per population: 100. (USFWS, 2021) Number of populations and individuals needed for each plant species to meet the Interim Stage target based on population and life history characteristics: Number of Populations: 3. Mature Individuals per population: 600. (USFWS, 2021) Number of population and individuals needed for downlisting based on population and life history characteristics: Number of Populations: 5. Mature Individuals per population: 1000. (USFWS, 2021)

#### **Delisting Criteria:**

Number of populations and individuals needed for delisting based on population and life history characteristics: Number of Populations: 10. Mature Individuals per population: 1000. (USFWS, 2021)

#### **Recovery Actions:**

- No information found.

**Conservation Measures and Best Management Practices:**

- **RECOMMENDATIONS FOR FUTURE ACTIONS** • Surveys and inventories—Continue to assess the status of known occurrences of *Schiedea salicaria* in historical locations and potentially suitable habitat. • Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect individuals from the negative impacts of feral ungulates. • Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species and those that compete with *S. salicaria*. • Captive propagation for genetic storage and reintroduction—Continue to collect seeds and other propagative materials for storage and reintroduction. • Reintroduction and translocation—Increase numbers of populations and individuals in suitable habitat to build resiliency and redundancy and reduce the impacts of habitat degradation by feral ungulates, nonnative plants, fire, and events associated with climate change; and predation/herbivory by feral ungulates. • Climate change adaptation strategy—Research suitability of habitat in the future due to the impacts of climate change. • Alliance and partnership development—Continue to contribute to planning and implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2020)
- **Current Management Actions:** • Surveys and monitoring—The Maui Nui PEPP monitors occurrences of *Schiedea salicaria* (Oppenheimer 2019a, b, pers. comm.). • Ungulate control—The wild population of *Schiedea salicaria* at Waikapū is fenced and the fence is monitored for breeches (Oppenheimer 2019b, pers. comm.). The remaining wild populations are not fenced. • Nonnative plant control—The Maui Nui PEPP and partners removed invasive plants within the fenced exclosure at Waikapū (Oppenheimer 2019b, pers. comm.). • Captive propagation for genetic storage and reintroduction—
  - o The Lyon Arboretum Seed Conservation Laboratory reported more than 4,500 seeds in storage from two accessions representing more than 13 founders of *S. salicaria* from the population located at Kaunoahua Ridge (Lyon Arboretum 2018).
  - o In 2018, the Olinda Rare Plant Facility had 16 potted plants of *S. salicaria* growing in their nursery from plants collected at Waikapū (Olinda Rare Plant Facility 2018). (USFWS, 2020)

## SPECIES ACCOUNT: *Schiedea sarmentosa* (No common name)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2017)

#### **Physical Description**

A many-branched subshrub 30-45 cm tall. The flowers are borne in terminal clusters.  
(NatureServe, 2015)

#### **Taxonomy**

*Schiedea sarmentosa* is being resurrected by W.L. Wagner (W.L. Wagner, pers. comm. to Christa Russell, 1994); Kartesz's 1994 Checklist included *S. sarmentosa* in synonymy of *S. menziesii*, but the 1999 Synthesis recognizes the taxon as a distinct species. *Schiedea menziesii* had Candidate, Category 2 status in the 1990 and 1993 USFWS notices of review, but in Oct., 1995, only *S. sarmentosa* was proposed for listing and the Oct. 10, 1996 determination to list *S. sarmentosa*, explains that the switch is due to the fact that, "*S. sarmentosa* was included in *S. menziesii* by Wagner et al. (1990). Warren Wagner and Stephen Weller, who are preparing a monograph of the genus, now consider *S. sarmentosa* to be a separate species." *S. menziesii* is not mentioned in the Oct. 31, 1996 reprint of the List of Endangered and Threatened Wildlife and Plants or in the Sept. 1997 notice of review. (NatureServe, 2015) A member of the pink family (Caryophyllaceae) (USFWS, 2016).

#### **Historical Range**

Historically no additional range. (NatureServe, 2015)

#### **Current Range**

Current range includes Molokai. (NatureServe, 2015)

#### **Critical Habitat Designated**

Yes; 3/30/2016.

#### **Legal Description**

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea sarmentosa* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one detailed critical habitat unit (CHU), in Maui County in Hawaii (81 FR 17790-18110).

#### **Critical Habitat Designation**

The critical habitat designation for *Schiedea sarmentosa* includes one CHU in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Molokai—Lowland Mesic—Unit 1 (and) *Palmeria dolei*—Unit 37—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 37— Lowland Mesic This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waiānui Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea*

lydgatei, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielirectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*, *Festuca molokaiensis*, *Flueggea neowawraea*, *Isodendron pyriformis*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania tomentosa*, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

### **Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea sarmentosa* critical habitat consists of one component. Lowland mesic (Molokai) (81 FR 17790-18110):

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

### **Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*,

*Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii*

ssp. haleakalaensis, C. duvalliorum, C. hamatiflora ssp. hamatiflora, C. horrida, C. kunthiana, C. magnicalyx, C. mannii, C. maritae, C. mceldowneyi, C. profuga, C. solanacea, Cyrtandra filipes, C. munroi, Diplazium molokaiense, Dubautia plantaginea ssp. humilis, Geranium hanaense, G. multiflorum, Hesperomannia arborescens, Huperzia mannii, Kadua laxiflora, Lysimachia lydgatei, L. maxima, Melicope balloui, M. ovalis, Phyllostegia hispida, P. mannii, P. pilosa, Plantago princeps, Platanthera holochila, Pteris lidgatei, Remya mauiensis, Santalum haleakalae var. lanaiense, Schiedea laui, Stenogyne bifida, S. kauaulaensis, Wikstroemia villosa, and Zanthoxylum hawaiiense) found on steep slopes and cliffs, or in narrow gulches.

### ***Life History***

#### **Food/Nutrient Resources**

#### **Reproductive Strategy**

Adult: Possibly wind pollinated, sexual (USFWS, 1998)

#### **Reproduction Narrative**

Adult: The flowers are female on some plants and bisexual on others. The population in Makolelau Gulch has a frequency of females of 31 percent. Based on analyses of pollen-ovule ratios, pollen size, inflorescence structure, and comparison to other Schiedea species tested in a wind tunnel, Schiedea sarmentosa could be wind-pollinated (Steven Weller, University of California, Irvine, personal communication 1997). No other life history information for this species is available (USFWS, 1998).

#### **Habitat Type**

Adult: Steeply sloped shrubland (USFWS, 1998)

#### **Habitat Vegetation or Surface Water Classification**

Adult: Lwoland dry or mesic shrubland (USFWS, 1998)

#### **Dependencies on Specific Environmental Elements**

Adult: Lwoland mesic ecosystem (see population narrative)

#### **Geographic or Habitat Restraints or Barriers**

Adult: 2,000 - 2,600 ft. elevation (USFWS, 1998)

#### **Spatial Arrangements of the Population**

Adult: Clumped (Inferred from NatureServe, 2015 and USFWS, 1998)

#### **Environmental Specificity**

Adult: Narrow/specialist (Inferred from NatureServe, 2015 and USFWS, 1998)

#### **Tolerance Ranges/Thresholds**

Adult: Low (Inferred from NatureServe, 2015 and USFWS, 1998)

#### **Site Fidelity**

Adult: High (Inferred from NatureServe, 2015 and USFWS, 1998)

**Habitat Narrative**

Adult: Dry and moist forests and shrublands. Often on rocky gulch slopes and cliffs. (NatureServe, 2015). *Schiedea sarmentosa* is typically found on steep slopes in ohia-Dodonaea viscosa (aalii) lowland dry or mesic shrubland between 610 and 790 meters (2,000 and 2,600 feet) elevation (I-THP 1991b, 1993b; HPCC 1991b, 1992). Associated species include *Syphelia tameiameia* (pukiawe), *Chenopodium oahuensis* (aheahea), *Alyxia oliviformis* (maile), *Pleomele* sp. (hala pepe), and *Chamaesyce* sp. (akoko) (HHP 1993b; HPCC 1991b, 1992) (USFWS, 1998). lumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends*****Population Trends:**

Increasing (USFWS, 2011)

**Number of Populations:**

1 (USFWS, 2023)

**Population Size:**

> 1000 (USFWS, 2023)

**Population Narrative:**

New Status Information: • There is one population estimated to total more than 1,000 individuals on Moloka'i (Bakutis 2018, in litt.) • Visits to the Kawela population in 2018 documented suspected hybrids between *Schiedea lydgatei* and *S. sarmentosa* (Weisenberger 2018, in litt.). • In 2016, one critical habitat unit in the lowland mesic ecosystem was designated on Moloka'i for *Schiedea sarmentosa* (8,770 ac; 3,549 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018). • Currently, there is one population on Moloka'i at Kawela gulch, estimated to total more than 1,000 individuals (Bakutis, pers. comm. 2023). • Currently, there are approximately ten founder lines represented in ex situ storage and propagation collections, including seeds in seed banks and plants in cultivation (National Tropical Botanical Garden (NTBG) 2022; University of California-Irvine, 2017) (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Feral goats, rats and slugs (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Goats, rats (*Rattus* spp.), and slugs (unidentified species) may eat parts of this plant (Perlman 2010; Wood 2010). Spittle bugs (the juvenile stage of certain leafhoppers) were observed on this species in April 2009 (Oppenheimer 2010). In addition, goats degrade the

habitat through trampling the species (USFWS, 2011).

**Stressor:** Invasive plants (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** Invasive plants are listed as a threat to this species (USFWS, 2011).

**Stressor:** Climate change loss or degradation of habitat

**Exposure:**

**Response:**

**Consequence:** Loss of habitat

**Narrative:** We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *S. sarmentosa* is extremely vulnerable to the impacts of climate change, with a vulnerability score of 0.977 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future, such as locating key microsites that overlap with current and future climate envelopes for outplanting efforts (USFWS, 2018).

## **Recovery**

### **Reclassification Criteria:**

A total of five to seven populations of each taxon should be documented on Molokai. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 2011).

Recovery Priority Number: 8

### **Delisting Criteria:**

A total of 8 to 10 populations of each taxon should be documented on Molokai. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 2011).

### **Recovery Actions:**

- Conduct surveys where *Schiedea sarmentosa* has been reported to determine current status of the species (USFWS, 2011).
- Continue collection of seeds or cuttings for genetic storage and reintroduction (USFWS, 2011).
- Monitor known populations (USFWS, 2011).
- Fence all populations to provide protection from the negative impacts of feral ungulates (USFWS, 2011).
- Control invasive introduced plant species around all populations (USFWS, 2011).
- Control rats in the vicinity of these populations (USFWS, 2011).

- Develop and implement methods to control slugs and spittle bugs (USFWS, 2011).
- Establish additional populations within protected suitable habitat (USFWS, 2011).
- Develop and implement a wildfire management plan (USFWS, 2011).
- Work with the East Molokai Watershed Partnership and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2011).
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species (USFWS, 2011).
- New Management Actions: • Captive propagation for genetic storage and reintroduction—In 2014, the University of California—Irvine reported 12 plants from Mākolelau in storage, representing 12 different individuals (USFWS, 2018).
- Recommendations for Future Actions: Hybridization may be a new threat to this species; however, we are not aware of any significant new information regarding the species' biological status since the last 5-year review in 2011. Thus, the following recommendations for future actions are added or reiterated for the 5-year review for 2018. • Surveys and inventories—Survey areas where *Schiedea sarmentosa* has been reported to determine current status of the species on Moloka'i. • Ungulate monitoring and control—Fence existing populations to provide protection from negative impacts of feral ungulates. • Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations of *S. sarmentosa*. • Fire destruction or degradation of habitat—Develop and implement a wildfire management plan. • Captive propagation for genetic storage and reintroduction—Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. • Reintroduction and translocation—
  - o Augment known populations and reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species.
  - o Research methods to increase and maintain numbers of female individuals within populations.
  - o Study the possible effects of hybridization on this species.• Rodent predation and herbivory—Control rats in the vicinity of all populations. • Invertebrate predation and herbivory—Develop and implement methods to control slugs and spittle bugs. • Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species. • Alliance and partnership development—Work with the East Molokai Watershed Partnership program, the Hawai'i Division of Forestry and Wildlife, and other land managers to initiate planning and contribute to ecosystem-level restoration and management to benefit this species.

***Conservation Measures and Best Management Practices:***

- Recommendations for Future Actions: No significant new information regarding the species' biological status has been reported since the last 5-year review in 2018. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2023. • Surveys and monitoring—Survey for additional populations of *Schiedea sarmentosa* at historical populations and areas of potentially suitable habitat. • Ungulate monitoring and control—Continue to maintain fenced exclosures to protect individuals from the negative impacts of browsing by ungulates. • Invasive nonnative plant monitoring and control—Continue control of established ecosystem-altering nonnative invasive plant species, and those that compete with *Schiedea sarmentosa* within and around all wild populations. • Climate change adaptation strategy—Research suitability of habitat for viability of species, including where to conduct translocations in the future due to the

impacts of climate change, including increasing temperatures, periods between rain events, and frequency and intensity of hurricanes. Additional management actions may be needed, such as locating microsites that overlap with current and future climate envelopes for translocation efforts.

- Predator and herbivore monitoring and control—Determine and implement effective methods for rodents and slugs around wild populations.
- Captive propagation for genetic storage and reintroduction—Continue collection and propagation efforts for maintenance of genetic stock and for future reintroduction.
- Build resiliency, redundancy, and representation — Increase species' viability through habitat restoration, threat control, and reintroduction and translocation. Continue attempts at reintroduction into suitable habitat that is being managed for known threats to this species to reduce impacts of erosion, treefall, flooding, and hurricanes.
- Alliance and partnership development—Continue to work with partners and other land managers in planning and implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2023).

## SPECIES ACCOUNT: *Schiedea trinervis* (No common name)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Endangered; 10/29/1991; Pacific Region (R1) (USFWS, 2016)

#### **Physical Description**

An erect, branched subshrub 3-8 dm tall. The white and green flowers are borne in clusters of 7-20. (NatureServe, 2015)

#### **Taxonomy**

No new taxonomic information has been received since the last 5-year review (USFWS 2009). However, the 2012 supplement to the Manual of the Flowering Plants of Hawaii (Wagner et al. 2012) reiterates the change from the genus *Alsinidendron* to the currently accepted *Schiedea*. In 2012, USFWS revised the taxonomic status for this species when it revised critical habitat on Oahu, with no change in range or distribution (USFWS 2012). This species is now listed as *Schiedea trinervis* (USFWS, 2013).

#### **Historical Range**

See current range/distribution

#### **Current Range**

Current range: Waianae Mountains of Oahu. Historically no additional range.

#### **Critical Habitat Designated**

Yes; 6/17/2003.

#### **Legal Description**

September 18, 2012, the U.S. Fish and Wildlife Service (Service), revised critical habitat for *Schiedea trinervis* on Oahu.

#### **Critical Habitat Designation**

Oahu—Montane Wet—Unit 1, Oahu—Dry Cliff—Unit 1, Oahu—Dry Cliff—Unit 2, Oahu—Dry Cliff—Unit 3, Oahu—Dry Cliff—Unit 4, Oahu—Dry Cliff—Unit 6, Oahu—Dry Cliff—Unit 7a, Oahu—Dry Cliff—Unit 7b, Oahu—Dry Cliff—Unit 8, Oahu—Wet Cliff—Unit 1, Oahu—Wet Cliff—Unit 2, Oahu—Wet Cliff—Unit 3, Oahu—Wet Cliff—Unit 4, and Oahu—Wet Cliff—Unit 5 constitute critical habitat for *Schiedea trinervis* on Oahu.

Oahu—Montane Wet—Unit 1 consists of 18 ac (7 ha) of City and County of Honolulu land, 352 ac (142 ha) of State land, and less than 1 ac (less than one ha) of privately-owned land in the montane wet ecosystem at the summit of the Waianae Mountains at Kaala, and partially within the Mokuleia Forest Reserve and the Kaala Natural Area Reserve. This unit is occupied by the plants *Cyanea acuminata*, *C. calycina*, *Labordia cyrtandrae*, *Melicope christophersenii*, and *Schiedea trinervis*, and includes the wet forest and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 4). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations.

Oahu—Dry Cliff—Unit 1 consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley. This unit is on State land within the Pahole Natural Area Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). This unit is occupied by the plants *Alectryon macrococcus*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Kadua degeneri*, *Plantago princeps* var. *princeps*, and *Schiedea obovata*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 1 is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Chamaesyce kuwaleana*, *Diellia falcata*, *D. unisora*, *Dubautia herbtsobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua parvula*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. saint-johnii*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. trinervis*, *Silene lanceolata*, *S. perlmannii*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, *T. lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 2 consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo. This unit is almost entirely within the Makua Keaau Forest Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). Dry Cliff—Unit 2 is occupied by the plants *Abutilon sandwicense*, *Alectryon macrococcus*, *Dubautia herbtsobatae*, *Gouania vitifolia*, *Kadua parvula*, *Lepidium arbuscula*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *Nototrichium humile*, *Peucedanum sandwicense*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Sanicula mariversa*, *Schiedea hookeri*, *Tetramolopium filiforme*, and *Viola chamissoniana* ssp. *chamissoniana*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 2 is not currently occupied by *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua degeneri*, *Korthalsella degeneri*, *Lipochaeta lobata* var. *leptophylla*, *Melicope saint-johnii*, *Neraudia angulata*, *Phyllostegia kaalaensis*, *Plantago princeps*, *Pteralyxia macrocarpa*, *Schiedea obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmannii*, *Spermolepis hawaiiensis*, or *Tetramolopium lepidotum* ssp. *lepidotum*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for

expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 3 consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge. This unit is partially within the Waianae Kai Forest Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). This unit is occupied by the plants *Abutilon sandwicense*, *Alectryon macrococcus*, *Bonamia menziesii*, *Diellia falcata*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *Isodendron laurifolium*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *Silene lanceolata*, *Tetramolopium filiforme*, and *Viola chamissoniana* ssp. *chamissoniana*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 3 is not currently occupied by *Achyranthes splendens* var. *rotundata*, *Cenchrus agrimonoides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia unisora*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua degeneri*, *K. parvula*, *Melicope saint-johnii*, *Plantago princeps*, *Platydesma cornuta* var. *decurrans*, *Sanicula mariversa*, *Schiedea obovata*, *S. trinervis*, *Silene perlmanii*, *Spermolepis hawaiiensis*, or *Tetramolopium lepidotum* ssp. *lepidotum*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 4 consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys. This unit is partially within the Waianae Kai Forest Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). This unit is occupied by the plants *Alectryon macrococcus*, *Chamaesyce kuwaleana*, and *Spermolepis hawaiiensis*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 4 is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Cenchrus agrimonoides*, *Chamaesyce herbstii*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua degeneri*, *K. parvula*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. saintjohnii*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Plantago princeps*, *Platydesma cornuta* var. *decurrans*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmanii*, *Tetramolopium filiforme*, *T. lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs

necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 6 consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). The unit is occupied by the plants *Cenchrus agrimonioides*, *Diellia unisora*, *Flueggea neowawraea*, *Lepidium arbuscula*, *Lobelia niihauensis*, *Melicope saintjohnii*, *Neraudia angulata*, *Plantago princeps*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, and *Tetramolopium lepidotum* ssp. *lepidotum*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 6 is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Alectryon macrococcus*, *Bonamia menziesii*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua degeneri*, *K. parvula*, *Korthalsella degeneri*, *Lipochaeta lobata* var. *leptophylla*, *Melanthera tenuifolia*, *Melicope makahae*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Platydesma cornuta* var. *decurrens*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmanii*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, or *Viola chamissoniana* ssp. *chamissoniana*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 7a consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4), and is occupied by the plants *Flueggea neowawraea*, *Kadua parvula*, *Melicope saint-johnii*, *Plantago princeps*, *Platydesma cornuta* var. *decurrens*,

*Pleomele forbesii*, *Silene perlmanii*, and *Viola chamissoniana* ssp. *chamissoniana*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 7a is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Alectryon macrococcus*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua degeneri*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Pteralyxia*

macrocarpa, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, or *T. lepidotum* ssp. *lepidotum*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 7b consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). Although Oahu—Dry Cliff—Unit 7b is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Alectryon macrococcus*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyriforme*, *Kadua degeneri*, *K. parvula*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. saintjohnii*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Plantago princeps*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmannii*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, *T. lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Wet Cliff—Unit 1 consists of 167 ac (68 ha) of State land, 68 ac (28 ha) of City and County of Honolulu land, and less than 1 ac (less than 1 ha) of privately owned land in the wet cliff ecosystem in the Waianae Mountains, near the summit of Kaala, and partially within the Mokuleia and Waianae Kai FRs and the Kaala Natural Area Reserve. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 4). Wet Cliff—Unit 1 is occupied by the plants *Cyanea calycina*, *Melicope christophersenii*, and *Schiedea trinervis*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations.

Oahu—Wet Cliff—Unit 2 consists of 3 ac (1 ha) of State land in the wet cliff ecosystem in the Waianae Mountains at Puuhapapa, within a small area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 4). Wet Cliff—Unit 2 is occupied by the plants *Cyanea calycina* and *Melicope christophersenii*. This unit also contains unoccupied habitat that is essential to the conservation of these species by

providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Wet Cliff—Unit 2 is not currently occupied by *Cyanea acuminata*, *Labordia cyrtandrae*, *Lobelia oahuensis*, *Phyllostegia hirsuta*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *S. kaalae*, or *S. trinervis*, the Service has determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Wet Cliff—Unit 3 consists of 16 ac (6 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukanehoa, partially within an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 4). Although Oahu—Wet Cliff—Unit 3 is not currently occupied by *Cyanea acuminata*, *C. calycina*, *Labordia cyrtandrae*, *Lobelia oahuensis*, *Melicope christophersenii*, *Phyllostegia hirsuta*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *S. kaalae*, or *S. trinervis*, the Service has determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Wet Cliff—Unit 4 consists of 23 ac (9 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukaua, partially overlapping an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 4). This unit is occupied by the plants *Phyllostegia hirsuta* and *Schiedea hookeri*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Wet Cliff—Unit 4 is not currently occupied by *Cyanea acuminata*, *C. calycina*, *Labordia cyrtandrae*, *Lobelia oahuensis*, *Melicope christophersenii*, *Pteralyxia macrocarpa*, *Schiedea kaalae*, or *S. trinervis*, the Service has determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Wet Cliff—Unit 5 consists of 31 ac (13 ha) of State land in the wet cliff ecosystem in the Waianae Mountains, at Palikea and north of Palikea. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 4). Although Oahu—Wet Cliff—Unit 5 is not currently occupied by *Cyanea acuminata*, *C. calycina*, *Labordia cyrtandrae*, *Lobelia oahuensis*, *Melicope christophersenii*, *Phyllostegia hirsuta*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *S. kaalae*, or *S. trinervis*, the Service has determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small

numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

**Primary Constituent Elements/Physical or Biological Features**

(i) In unit Oahu—Montane Wet—Unit 1, the physical and biological features of critical habitat are: (A) Elevation: 3,300 to 6,600 ft (1,000 to 2,000 m). (B) Annual precipitation: Greater than 75 in (190 cm). (C) Substrate: Well-developed soils, montane bogs. (D) Canopy: Acacia, Charpentiera, Cheirodendron, Metrosideros. (E) Subcanopy: Broussaisia, Cibotium, Eurya, Ilex, Myrsine. (F) Understory: Ferns, Carex, Coprosma, Leptecophylla, Oreobolus, Rhynchospora, Vaccinium.

(ii) In units Oahu—Dry Cliff—Unit 1, Oahu—Dry Cliff—Unit 2, Oahu—Dry Cliff—Unit 3, Oahu—Dry Cliff—Unit 4, Oahu—Dry Cliff—Unit 6, Oahu—Dry Cliff—Unit 7a, Oahu—Dry Cliff—Unit 7b, and Oahu—Dry Cliff—Unit 8, the physical and biological features of critical habitat are: (A) Elevation: Unrestricted. (B) Annual precipitation: Less than 75 in (190 cm). (C) Substrate: Greater than 65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: Antidesma, Chamaesyce, Diospyros, Dodonaea. (F) Understory: Bidens, Eragrostis, Melanthera, Schiedea.

(iii) In units Oahu—Wet Cliff—Unit 1, Oahu—Wet Cliff—Unit 2, Oahu—Wet Cliff—Unit 3, Oahu—Wet Cliff—Unit 4, and Oahu—Wet Cliff—Unit 5, the physical and biological features of critical habitat are: (A) Elevation: Unrestricted. (B) Annual precipitation: Greater than 75 in (190 cm). (C) Substrate: Greater than 65 degree slope, shallow soils, weathered lava. (D) Canopy: None. (E) Subcanopy: Broussaisia, Cheirodendron, Leptecophylla, Metrosideros. (F) Understory: Bryophytes, Ferns, Coprosma, Dubautia, Kadua, Peperomia.

***Life History*****Food/Nutrient Resources****Reproductive Strategy**

Adult: Little information found although NatureServe (2015) notes the species reproduces sexually.

**Reproduction Narrative**

Adult: SEXUAL; (NatureServe, 2015). Alsineidendron trinerve flowers and fruits throughout the year with the possible exception of fall (USFWS 1995) (USFWS, 1998).

**Habitat Type**

Adult: Wet/mesic forest (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 2013)

**Environmental Specificity**

Adult: Narrow/specialist (USFWS, 1998; USFWS, 2013)

**Tolerance Ranges/Thresholds**

Adult: Low (USFWS, 1998; USFWS, 2013)

**Site Fidelity**

Adult: High (USFWS, 1998; USFWS, 2013)

**Habitat Narrative**

Adult: Species inhabits slopes or ridges in wet forest or wetter portions of diverse mesic forest. Also found in drier forests. (NatureServe, 2015). *Alsinidendron trinerve* typically grows on slopes in wet forest or the wetter portions of diverse mesic forest dominated by ohia and flex anomala (kawau) at an elevation of 900 to 1,200 meters (3,000 to 4,000 feet) (USFWS 1995). Associated plants include *Coprosma* sp. (pilo), *Gunnera* (apeape), *Melicope* sp. (alani), *Cibotium* sp. (hapuu), *Antidesma platyphylla* (hame), and mamaki (USFWS 1995) (USFWS, 1998). USFWS (2013) notes that there is only one known population. Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations (One).

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: No information found.

***Population Information and Trends*****Population Trends:**

Increasing (USFWS, 2013)

**Number of Populations:**

1 (USFWS, 2019)

**Population Size:**

300-350 individuals (USFWS, 2019)

**Population Narrative:**

Currently there are approximately 300 mature and 350 immature individuals of *Schiedea trinervis* in one population (from East Makaleha to Pu'u Kalena) in the Wai'anae mountains of O'ahu. No observations have been made since 2015 (Army Natural Resources Program-O'ahu (ANRP) 2018). (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Ungulates (USFWS, 2013)

**Exposure:**

**Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** Trampling from feral animals (especially pigs) is listed as a threat to this species (USFWS, 2013)

**Stressor:** Military training activities (USFWS, 2013)

**Exposure:****Response:**

**Consequence:** Loss of habitat/loss of individuals

**Narrative:** This species sole population is found on an army installation. Military training activities are a threat to this species (USFWS, 2013).

**Stressor:** Alien plant species (USFWS, 2013)

**Exposure:****Response:**

**Consequence:** Loss of habitat

**Narrative:** Alien plant species are known to alter the ecosystem and are listed as a threat to this species (USFWS, 2013).

**Stressor:** Human trampling (USFWS, 2013)

**Exposure:****Response:**

**Consequence:** Loss of individuals

**Narrative:** Trampling by humans is listed as a threat to this species (USFWS, 2013).

**Stressor:** Over-collection (USFWS, 2013)

**Exposure:****Response:**

**Consequence:** Loss of individuals

**Narrative:** Collection by humans is listed as a threat to this species (USFWS, 2013).

**Stressor:** Slugs (USFWS, 2013)

**Exposure:****Response:**

**Consequence:** Loss of individuals

**Narrative:** Predation by slugs is listed as a threat to this species (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)

**Exposure:****Response:**

**Consequence:** Loss of habitat

**Narrative:** Climate change may pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative (PICCC) funded climate modeling that will help resolve these spatial limitations. High spatial resolution climate outputs are expected in 2013 (USFWS, 2013).

***Recovery*****Reclassification Criteria:**

For downlisting, a total of five to seven populations of each taxon should be documented on Oahu and at least one other island where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum

of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1998).

#### **Delisting Criteria:**

A total of 8 to 10 populations of each taxon should be documented on Oahu and at least one other island where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 1998).

#### **Recovery Actions:**

- Surveys/inventories
  - o Search for additional individuals of *Schiedea trinervis* in its historical range.
  - o Continue mapping the entire range of populations (USFWS, 2013).
- Population biology research
  - o Study *Schiedea trinervis* populations with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats.
  - o Determine if additional populations should be reintroduced or if this species can be recovered with one large population (USFWS, 2013).
- Genetic research - Assess genetic variability within the one extant population (USFWS, 2013).
- Existing population management and restoration
  - o Protect, manage within current wild populations
  - o Manage all individuals of *Schiedea trinervis* (USFWS, 2013).
- Alliance and partnership development - Continue planning and contribute to implementation of ecosystem-level management and restoration to benefit this species with the U.S. Army Garrison, Hawaii Division of Forestry and Wildlife, and other landowners (USFWS, 2013).
- Captive propagation for genetic storage and reintroduction: Complete collection of fruit from wild individuals; augment these collections with seed from reintroduced individuals to add genetic diversity of ex situ seed storage (USFWS, 2013).
- Ecosystem-altering invasive plant species control: Control introduced invasive plant species around wild and reintroduced plants (USFWS, 2013).
- Ungulate exclosures - Construct large-scale fences to control feral ungulates around entire population and reintroduced individuals (USFWS, 2013).
- Reintroduction / translocation - Continue reintroducing individuals into protected suitable habitat within historical range (USFWS, 2013).
- Threats research - Investigate techniques to improve natural recruitment, including the development of an effective slug control method (USFWS, 2013).

#### **Conservation Measures and Best Management Practices:**

- New Management Actions:
  - Ungulate control—The ANRP reports ungulates are controlled by fencing at East Makaleha to Pu'u Kalena (ANRP 2018).
  - Nonnative invasive plant control—The ANRP reports nonnative plant control is ongoing at East Makaleha to Pu'u Kalena (ANRP 2018).
  - Captive propagation for genetic storage and reintroduction—
    - o The ANRP reports that the population from East Makaleha to Pu'u Kalena has met its goals of genetic representation in collections with 90 wild plants represented in the ANRP seed bank (ANRP 2018).
    - o Since the last 5-year review in 2013, the

Lyon Seed Micropropagation Laboratory reports 119 explants total representing both individuals at the Makaleha and Ka'ala subpopulations. The Lyon Seed Conservation Laboratory reports storage of more than 1,000 seeds representing at least one individual from Ka'ala. • Reintroductions—None (U.S. Army 2018). (USFWS, 2019)

- Recommendations for Future Actions: Other than the new data on this taxon's vulnerability to climate change, we are not aware of any new threats. There is no significant new information regarding the species' biological status since the last 5-year review in 2013. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2019. • Surveys and inventories—Continue to survey geographical and historical range for a thorough assessment of the species' status. • Ungulate monitoring and control—Continue to fence and monitor wild and reintroduced populations to protect plants from impacts of feral ungulates. • Invasive plant monitoring and control—Continue to control established ecosystemaltering nonnative invasive plant species, and those that compete with *Schiedea trinervis* at all wild and reintroduced population. • Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species. • Invertebrate control—Implement effective slug and nonnative snail control at all wild and reintroduced populations. • Captive propagation for genetic storage and reintroduction—Continue seed collection for genetic storage and propagation for reintroduction. • Reintroduction—Continue to establish new populations and augment existing populations, keeping close track of maternal source used for ex situ propagation. • Population biology research—
  - o Study populations of *Schiedea trinervis* with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats.
  - o Determine if additional populations should be established or if this species can be recovered as one large population.
  - o Assess the genetic variability within the population.• Alliance and partnership development—Continue to work with the ANRP, the Hawai'i Division of Forestry and Wildlife, and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2019)

## SPECIES ACCOUNT: *Schoenocrambe argillacea* (Clay reed-mustard)

---

### *Species Taxonomic and Listing Information*

**Listing Status:** Threatened; 01/14/1992; Mountain-Prairie Region (Region 6) (USFWS, 2016)

### **Physical Description**

A perennial herbaceous plant in the mustard family, with sparsely leafed stems 15 to 30 cm (6 to 12 in) tall arising from a woody root crown. The leaves are very narrow with a smooth margin, 10 to 35 mm (0.4 to 1.4 in) long and, usually, less than 2 mm (0.1 inch) wide. The leaf blades are alternately arranged on the stem and, for the most part, are attached directly to the stem without a petiole. The narrow, fleshy leaves are covered with a white, waxy surface. The flowers of clay reed-mustard have petals that are pale lavender to whitish with prominent purple veins and measure 8 to 11 mm (0.3 to 0.4 inch) long and 3.5 to 4.5 mm (0.14 to 0.18 inch) wide. The entire flowers are about 1 cm (0.4 inch) across in full anthesis and are displayed in a raceme of 3 to 20 flowers at the end of the plant's leafy stems. Flowers are pale lavender to whitish with conspicuous purple veins. Blooms in late April and early May. (USFWS, 2016; NatureServe, 2015)

### **Taxonomy**

The species was first discovered and recorded by Dr. Duane Atwood in 1976. It was described as *Thelypodium argillacea* in 1977, moved to the genus *Schoenocrambe* in 1982, and most recently renamed *Hesperidanthus argillaceus* (Al-Shehbaz 2010). The latter is the name now accepted for this species by the Flora of North America and the integrated taxonomic information system (Al-Shehbaz 2010; ITIS 2017). (USFWS, 2019)

### **Current Range**

Endemic to the Uinta Basin (Book Cliffs area) in Uintah County, northeast Utah. Known range is only about 24 km x 12 km, from the west side of the Green River to the east side of Willow Creek (USFWS 1994). Franklin (2005) describes the three population areas as follows: "along the east slopes of Big Pack Mountain and in Broome Canyon to the east; along the west slopes of Wild Horse Bench, from the vicinity of Kings Canyon and south nearly to The Wrinkles; and along the slopes of the canyons above Ray's Bottom, on the west side of the Green River." (NatureServe, 2015)

### **Critical Habitat Designated**

No;

### ***Life History***

### **Food/Nutrient Resources**

### **Reproductive Strategy**

Adult: Sexual (USFWS, 1994)

### **Breeding Season**

Adult: April to May (USFWS, 1994)

**Reproduction Narrative**

Adult: Flowering occurs from April to May and fruiting occurs May to June in all three species. Reproduction in each of the three species is sexual. (USFWS, 1994)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Bare rock/talus/scree, barrens, desert (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs at elevations between 1440 to 1765 meters (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Occurs within shadscale, Indian ricegrass, pygmy sagebrush, and other mixed desert shrub communities on precipitous, typically north-facing slopes. On these slopes (elevations from 1440 to 1765 m), plants grow in both exposed and protected sites, with protected sites usually having the more robust plants. Substrates consist of at-the-surface bedrock, scree, and fine-textured soils, often clay soils rich in gypsum (shale barrens) overlain with sandstone talus. Occurs about the zone of contact between the Tertiary lower Uinta Formation and the Evacuation Creek Member of the upper Green River shale Formation. Commonly associated species include *Eriogonum corymbosum*, *Ephedra torreyana*, *Atriplex confertifolia*, *Atriplex gardneri* var. *cuneata*, *Elymus salinus*, *Tetradymia nuttallii*, and *Amelanchier utahensis*; other associates include *Agropyron smithii*, *Arabis pendulina*, *Arabis pulchra*, *Artemisia nova*, *Astragalus chamaeleuce*, *Astragalus convallarius*, *Brickellia oblongifolia*, *Castilleja chromosa*, *Chrysothamnus viscidiflorus*, *Cryptantha rollinsii*, *Cymopterus fendleri*, *Eriogonum ovalifolium*, *Euphorbia fendleri*, *Leptodactylon pungens*, *Penstemon carnosus*, *Petradoria pumila*, *Cymopterus terebinthinus*, *Stipa hymenoides*, *Tetradymia spinosa*, and *Thelesperma subnudum*. (NatureServe, 2015)

***Dispersal/Migration*****Dispersal/Migration Narrative**

Adult: Not available.

***Population Information and Trends*****Population Trends:**

Unknown (NatureServe, 2015)

**Number of Populations:**

3 (USFWS, 2011)

**Population Size:**

~6,000 (USFWS, 2011)

**Population Narrative:**

Schoenocrambe argillacea occurs in six populations in Uintah County. In 1992, the Utah Natural Heritage Program completed an extensive survey of potential habitat for Schoenocrambe argillacea and estimated the total number of S. argillacea was 6,000 plants (Franklin 1992; Service 1994). (USFWS, 2011)

**Threats and Stressors**

**Stressor:** Oil and gas development (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Oil and gas development remains a significant threat to Schoenocrambe argillacea populations and habitat (Service 1990; 1994). All Federal lands on which known populations of S. argillacea occur are leased for oil and gas development (Utah Division of Oil, Gas, and Mining (UDOGM) 2011). To date, oil and gas development within known S. argillacea areas has been moderate. The Service does not know the actual ground disturbance at this point from oil and gas development, but the Service estimates approximately 5 acres (2 hectares) of total disturbance per well, including roads and infrastructure. After excluding directional wells (which are usually drilled from existing well pads), the Service calculated that at least 130 acres are disturbed within S. argillacea populations as mapped, and an additional 85 acres could be disturbed as currently approved oil and gas wells are drilled within the next 2 years (UDOGM 2011). Oil and gas development remains a significant threat to Schoenocrambe argillacea populations and habitat (Service 1990; 1994). All Federal lands on which known populations of S. argillacea occur are leased for oil and gas development (Utah Division of Oil, Gas, and Mining (UDOGM) 2011). To date, oil and gas development within known S. argillacea areas has been moderate. The Service does not know the actual ground disturbance at this point from oil and gas development, but the Service estimates approximately 5 acres (2 hectares) of total disturbance per well, including roads and infrastructure. After excluding directional wells (which are usually drilled from existing well pads), the Service calculated that at least 130 acres are disturbed within S. argillacea populations as mapped, and an additional 85 acres could be disturbed as currently approved oil and gas wells are drilled within the next 2 years (UDOGM 2011). (USFWS, 2011)

**Stressor:** Habitat fragmentation (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Schoenocrambe argillacea exists in small, low-density populations that are likely prone to negative effects from habitat fragmentation. For example, small plant populations fluctuate more widely over time and the smaller the remnant, the more susceptible the population is to extinction (Soulé et al. 1992; Forman and Alexander 1998; Menges 2002; Lienert 2004). Small plant populations can lose genetic variation and their population viability decreases (Ellstrand and Elam 1993; Lienert 2004; Kolb 2008). Fruit set, germination rate, offspring survival, and total numbers of flowers per plant are higher in large populations than in small populations (Paschke et al. 2002). Similarly, the number of capsules per plant and the number of seedlings per plant are positively correlated with population size (Schmidt and Jensen 2000). Roads associated with

energy exploration and development cause a high level of habitat fragmentation. Increased oil and gas developments result in more roads developed near and potentially in *Schoenocrambe argillacea* habitat. Ecological effects of roads to plants can extend more than 328 feet (100 meters) from the road (Angold 1997; Forman 2000; Forman and Deblinger 2000). Disturbance can occur directly from construction or indirectly from road dust, discussed further below (Eller 1977; Spatt and Miller 1981; Thompson et al. 1984; Farmer 1993; Angold 1997; Sharifi et al. 1997; Trombulak and Frissell 2000; Hobbs 2001; Myers-Smith et al. 2006). There is a strong correlation between vegetation composition and health with distance from a road, although it may take decades for the full effects of road development to be realized (Auerbach et al. 1997; Myers-Smith et al. 2006). (USFWS, 2011)

**Stressor:** Road dust (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** *Schoenocrambe argillacea* may be impacted by the indirect effects of road dust associated with oil and gas development. Road traffic mobilizes and spreads dust (Farmer 1993; Trombulak and Frissell 2000), and for every vehicle traveling 1 mile (1.6 kilometers) of unpaved roadway once a day, every day for a year, approximately 2.5 tons of dust are deposited along a 1,000-foot (~300-meter) corridor centered on the road (Sanders pers. comm. 2008). Dust deposition tends to be highest near the road and decreases with increasing distance from the road (Everett 1980; Spatt and Miller 1981; Walker and Everett 1987; Santelmann and Gorham 1988; Myers-Smith et al. 2006). For example, in one study, 97 percent of dust was deposited within 410 feet (125 meters) of the road (Walker and Everett 1987). The distance from a road at which dust can affect vegetation varies (see McCrea 1984; Myers-Smith et al. 2006), but negative impacts can occur up to 984 feet (300 meters) away from the road (Everett 1980). Using information from these studies, the BLM now implements a buffer of 300 feet (91 meters) for surface disturbance activities near *S. argillacea* occupied habitat and a requirement for monitoring plants where surface disturbance occurs within the 300-foot (91-meter) buffer. Dust negatively affects photosynthesis, respiration, transpiration, water use efficiency, leaf conductance, growth rate, plant vigor, gas exchange, and allows the penetration of phytotoxic gaseous pollutants (Eller 1977; Spatt and Miller 1981; Thompson et al. 1984; Farmer 1993; Sharifi et al. 1997; Trombulak and Frissell 2000; Hobbs 2001). Dust comprised of finer particulates caused more improper functioning of the stomata than larger particles (Ricks and Williams 1974; Eller and Brunner 1975; Eveling and Bataille 1984; Rawson and Clarke 1988; Hirano et al. 1995). Improperly functioning stomata result in increased water loss in two ways: due to an increased transpiration rate because of increased leaf temperatures and due to clogged stomata that are unable to close at night (Hirano et al. 1995). Dust also can inhibit sunlight from reaching plant surfaces (Sharifi et al. 1997). Additionally, dusted leaves were 4 to 5°F (2 to 3°C) warmer (Sharifi et al. 1997) than undusted, control leaves (Hirano et al. 1995). Dust from roads also impacts soil quality and vegetation type. Soils near roads can have significantly lower nutrient levels, altered organic horizon depth, higher bulk density, and lower moisture (Auerbach et al. 1997). Furthermore, soil characteristics and plant community composition can remain significantly different up to 28 years after road development (Myers-Smith et al. 2006). (USFWS, 2011)

**Stressor:** Plant-pollinator interactions (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Many of the negative effects of habitat fragmentation to plants are due to effects on plant-pollinator interactions (Debinski and Holt 2000; Moody-Weis and Heywood 2001; Aizen et al. 2002; Gathmann and Tschardt 2002; Lennartsson 2002; Kolb 2008). Fragmented plant populations appear to be less attractive to insect pollinators, which spend more time in larger, unfragmented plant habitats (Aizen et al. 2002; Goverde et al. 2002; Lennartsson 2002; Kolb 2008). Furthermore, insect pollinator diversity increases in larger populations (Mustajärvi et al. 2001) and decreases in isolated habitats with smaller plant population size (Steffan-Dewenter and Tschardt 1999). Lower pollinator visitation rates were associated with lower seed sets and reproductive success in fragmented sites compared to intact sites (Jennersten 1988). Bumblebees visit more flowers on fewer flower stalks in sparser plant populations (Mustajärvi et al. 2001; Goverde et al. 2002). This leads to increased self-pollination or near-neighbor pollination and contributes to inbreeding (Goverde et al. 2002; Lennartsson 2002). Inbred plants produce fewer flowers and seeds, have smaller plant height and smaller leaf-size, and reduced reproductive success (Steffan-Dewenter and Tschardt 1999; Lienert 2004; Kolb 2008). (USFWS, 2011)

**Stressor:** Erosion and sedimentation (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** Although oil and gas development may not occur directly on the steep habitat *Schoenocrambe argillacea* occupies, erosion or sedimentation could still impact this species, particularly if the plants are downslope of development activities. In fact, development-related erosion and sedimentation may be a particular concern to this species because it grows on precipitous hillsides. Because of this unique vulnerability, the BLM Vernal Field Office requires energy companies to get site-specific approval from both the BLM and the Service when disturbance will occur upslope of habitat (BLM 2008a). This conservation measure is in effect because the species is listed as threatened by the ESA. (USFWS, 2011)

**Stressor:** Predation (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** When we listed *Schoenocrambe argillacea*, the Service believed sheep and cattle grazing may have had an historical impact on this species. However, by 1994 grazing was no longer expected to impact *S. argillacea* due to changes in grazing management, namely reduced numbers of sheep and cattle on the land (Service 1994). Grazing levels have not increased appreciably since then, and thus the Service still concludes that grazing is not impacting *S. argillacea*. Elk were reported in *S. argillacea* habitat, but the Service has not determined whether they browse on this species (Glisson 2005). Insect and small mammal herbivory occurs on *S. argillacea* fruits (Glisson 2005), but the Service does not have any information that this is occurring at a level that negatively impacts the species. (USFWS, 2011)

**Stressor:** Small populations (USFWS, 2011)

**Exposure:**

**Response:**

**Consequence:**

**Narrative:** When *Schoenocrambe argillacea* was listed, it was known to occur in 2 general areas—around the Green River and Willow Creek—in 6 populations with fewer than 6,000 individuals, and most sites contained fewer than 200 individuals. Estimates for the Recovery Plan did not indicate significant changes, and the Service does not have more recent comprehensive data indicating changes in population size. Small populations and species with limited distributions are vulnerable to relatively minor environmental disturbances (Given 1994). Small populations also are at an increased risk of extinction due to the potential for inbreeding depression, loss of genetic diversity, and lower sexual reproduction rates (Ellstrand and Elam 1993; Wilcock and Neiland 2002). Lower genetic diversity may, in turn, lead to even smaller populations by decreasing the species' ability to adapt, thereby increasing the probability of population extinction (Barrett and Kohn 1991; Newman and Pilson 1997). On the other hand, many naturally rare species have persisted for long periods within small geographic areas, and many naturally rare species exhibit traits that allow them to persist, despite their small population sizes. Species with limited climatic ranges and restricted habitat requirements are typically the most vulnerable to extinction (Intergovernmental Panel on Climate Change (IPCC) 2002; Machinski et al. 2006). The risk of extinction is expected to increase for species with low population numbers (IPCC 2002; Jump and Penuelas 2005). (USFWS, 2011)

**Stressor:** Invasive species (USFWS, 2011)
