# SPECIES ACCOUNT: *Abronia macrocarpa* (Large-fruited sand-verbena)

***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** LFSV

**Listing Status:** Endangered; 9/28/1988; Southwest Region (R2) (USFWS, 2016)

**Physical Description**

This species is a broad-leaved, tap-rooted, herbaceous perennial growing to 20 in (50 cm). The foliage is sticky from glandular hairs. The leaves are usually rounded, and about 0. 75-2. 0 in (2-5 cm) long and 0. 6-1. 4 in (1. 5-3. 5 cm) wide. The magenta flowers are grouped into rounded heads composed of 20-75 individual flowers. These flower heads have bracts at the base that are nearly oval and about 0. 25-0. 5 in (0. 6-1. 3 cm) long and 0. 13-0. 38 inch (0. 3-1. 0 cm) wide. Each flower has a tube about 0. 7-1. 3 in (1. 8-3. 3 cm) long that widens at the top into five nearly divided lobes 0. 3-0. 4 inch (0. 8-1. 0 cm) wide. The fruits are 0. 3-0. 6 inch (0. 8-1. 6 cm) long and 0. 2-0. 5 inch (0. 5-1. 3 cm) wide and papery with five often somewhat twisted wings. The seeds (achenes) are from 0. 06- 0. 19 inch (1. 5-4. 8 millimeters) long and brown. The species is most easily characterized by its large, thin-walled fruits (anthocarps), which are thinner and more papery than any other species of Abronia and among the largest in the genus (USFWS, 1992).

**Taxonomy**

In the Four-O'clock family (Nyctaginaceae) (NatureServe, 2015). The species' common name has been spelled with and without hyphenation. The Services have chosen to use hyphens, particularly to help clarify the confusion between “sand-verbenas”, which are members of the genus Abronia and family Nyctaginaceae, and “verbenas”, which are members of the genus Verbena and family Verbenaceae. Sand-verbenas and verbenas are not closely related (USFWS, 2010).

**Historical Range**

See Current Range.

**Current Range**

Known from Leon, Robertson, and Freestone counties in eastern Texas (USFWS, 2010).

**Critical Habitat Designated**

Yes;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated

**Lifespan**

Adult: perennial species (USFWS, 2022)

**Breeding Season**

Adult: Flowers in March or April and occasionally again in the fall following periods of high rainfall (USFWS, 1992). Williamson (1998) observed that A. macrocarpa seeds in the field have the highest germination rates in the fall and winter, while no seeds germinated from May to September. Laboratory studies revealed that the highest seed germination rates require scarification followed by warm and then cold stratification (Goodson 2007; Williamson 2008). Initial seedling growth is allocated primarily to development of the taproot rather than leaves and flowers (Williamson 1996). The seedling mortality rate ranged from 73 percent to 93 percent after 3 years (Williamson 1998). Abronia macrocarpa plants usually form rosettes from October through February, then begin flowering with the peak of anthesis and fruit set in April and May, followed by senescence of the above-ground portion from mid-May or June until October (Williamson 1996). However, the species occasionally flowers in the fall (Kennedy et al., 1990; Corlies 1991; U.S. Fish and Wildlife Service 1992). During the summer months, the plants perenniate as taproots found at depths of 1 to 12 cm (0.4 to 4.7 in) (Williamson 1996). Williamson (1998) found that 53 percent of 1 cohort of seedlings was flowering at 2 years of age, and 78 percent of another cohort flowered at 3 years of age. (Recovery actions 3234, 331, 332, 333, 322) (USFWS, 2010).

**Key Resources Needed for Breeding**

Adult: Pollinator observations included mostly moths including Noctuids and some Sphingids, Geometrids, and Pyralids; however, bumblebees and butterflies were also noted as potential pollinators (USFWS, 2022).

**Other Reproductive Information**

Adult: Large-fruited sand-verbena flowers open from 3:00 or 4:00 pm until 9:00 or 10:00 am and produces a strong sweet aroma resembling honeysuckle that increases until early evening. These floral characteristics are commonly associated with moth pollination (Corlies 1991, p. 12). Williamson et al. (1994, p. 339) observed, captured, and identified several floral visitors of LFSV which included Sphynx and Noctuid moths (family Sphingoidea and Noctuidae, respectively) such as the black alder or pawpaw sphynx (Dolba hyloeus), lettered sphynx (Deidamia inscripta), obscure sphynx (Erinnyis obscura), and large necklace moth (Hypsoroph monilisi). The probosci of these moths were dusted with LFSV pollen, making them likely pollinators. Furthermore, the larval food sources for these likely pollinators have been noted at all of the LFSV sites and include yaupon (Ilex decidua), grape (Vitis spp.), and milkweed (Asclepias spp.) (Figure 3, In Williamson 2008, p. 18; Table 9, In USFWS 2010, pp. 18-22). Among the diurnal floral visitors, some incidental pollination may be due to bees (genus Bombus and Apis) (Williamson et al. 1994, p. 339). Noted pollinator observations of various other Abronia species including Yellowstone sandverbena, pink sand-verbena, and Ramshaw Meadows sand-verbena (A. alpina, RMSV) support the notion that species of Abronia are moth pollinated (Saunders and Sipes 2006, p. 80; Jabis et al. 2011, p. 1587; Doubleday 2012, p. 23). Pollinator observations included mostly moths including Noctuids and some Sphingids, Geometrids, and Pyralids; however, bumblebees and butterflies were also noted as potential pollinators. While observational studies provide insight into potential pollinators, it is important to determine if those visitations result in plant reproductive output (i.e., the production of fruit and seed set and effective pollination). Doubleday and Eckert (2018, p. 71) found floral visitation of pink sand-verbena was higher during the day (8.67 percent) compared to those visits at night. Yet nocturnal visitation by Sphingid moths resulted in significantly higher seed set, suggesting Sphingid moths are the primary pollinators. Moreover, while honeybees were observed during this study their visitations resulted in no fruit/seed set suggesting that these insects are acting as potential pollen thieves, collecting floral pollen/nectar but not necessarily pollinating the flowers (USFWS, 2022).

**Reproduction Narrative**

Adult: Williamson (1998) observed that A. macrocarpa seeds in the field have the highest germination rates in the fall and winter, while no seeds germinated from May to September. Laboratory studies revealed that the highest seed germination rates require scarification followed by warm and then cold stratification (Goodson 2007; Williamson 2008). Initial seedling growth is allocated primarily to development of the taproot rather than leaves and flowers (Williamson 1996). The seedling mortality rate ranged from 73 percent to 93 percent after 3 years (Williamson 1998). Abronia macrocarpa plants usually form rosettes from October through February, then begin flowering with the peak of anthesis and fruit set in April and May, followed by senescence of the above-ground portion from mid-May or June until October (Williamson 1996). However, the species occasionally flowers in the fall (Kennedy et al., 1990; Corlies 1991; U.S. Fish and Wildlife Service 1992). During the summer months, the plants perenniate as taproots found at depths of 1 to 12 cm (0.4 to 4.7 in) (Williamson 1996). Williamson (1998) found that 53 percent of 1 cohort of seedlings was flowering at 2 years of age, and 78 percent of another cohort flowered at 3 years of age. (Recovery actions 3234, 331, 332, 333, 322) (USFWS, 2010).

**Habitat Vegetation or Surface Water Classification**

Adult: Post oak savanna (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**

Adult: Elevations of 360-450 feet (USFWS, 1992)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 1992)

**Habitat Narrative**

Adult: Occurs in deep, well-drained sands, sometimes on actively blowing sand dunes, within a post oak-grassland mosaic vegetation type. The species is one of many herbaceous plants that temporarily dominate these bare sands during spring (NatureServe, 2015). Soils are relatively infertile and unstable; water availability is low and unreliable; and temperatures are extreme and variable both diurnally and seasonally (USFWS, 1992).

***Dispersal/Migration***

**Motility/Mobility**

Adult: Abiotic (EPA, 2016)

**Dispersal/Migration Narrative**

Adult: Dispersed by wind; "Clumped-contagious" distribution (EPA, 2016).

***Population Information and Trends***

**Population Trends:**

Not available.

**Species Trends:**

Stable (inferred from USFWS, 2010)

**Number of Populations:**

10 (USFWS, 2022

**Population Size:**

Approximately 90,700 individuals in 8 wild populations includes 2 populations with unknown numbers of individuals. In addition, there are nine experimental populations with an unknown number of plants (USFWS, 2022)

**Population Narrative:**

Nine populations have been documented in Leon, Robertson, and Freestone counties; these include one each in Leon and Robertson counties that were both combined from two previously-recognized populations, based on genetic analyses and field surveys. All known populations are on privately-owned lands that were surveyed with landowner permissions. In addition, three small experimental populations have been successfully established on private land. The total known population has increased from about 35,250 in 1996 to 94,509 in 2008. This increase is due both to the discovery of new populations, and to growth of the known populations resulting from land use changes that are more favorable to conservation of the species (USFWS, 2010). It is important to note there are some discrepancies between the population estimates reported in the previous 5-year review (USFWS 2010) and in this current review. The 2010 5-year review, the population numbers listed for 2008 are interpreted as true population survey counts when in fact, these population estimates are based on visual surveys not quantitative count surveys (P. Williamson, pers. comm. 2022). The estimated population abundance of WP1-WP4, WP7, and WP8 are the same values in both the Williamson (2008, pp. 6-7) and the Services 5-year review (USFWS 2010) reports. Further communication with Dr. Williamson and other contractors indicates these populations are stable in recent surveys (see Table 1). In both the Service's (USFWS 2010, p. 13) and Williamson's report (2008, pp. 6-7), WP5 had an estimated population of 5,000 individuals. However, installation of a fence and development of a natural gas pipeline, both in November 2004, caused soil disturbance such that the population reduced in its abundance to only a few hundred individuals (Williamson 2008, pp. 6-7). Surveys conducted in 2022 by BRIT provided an updated population estimate for WP5 of approximately 61 individuals (see Table 1). Williamson surveyed WP6 in 2005 and discovered a newly established food plot that had caused disturbance to the population resulting in only two plants on-site (Williamson 2008, p. 7). In 2007, Williamson noted the abandonment of the food plot and a notable increase in LFSV flowering plants. Approximately 200 flowering plants were observed which when extrapolated to the full property area of the site (WP6 (10.6 ac)), is approximately 750 individuals (Williamson 2008, p. 7; USFWS 2010, p. 13). Most recently, a survey of WP6 conducted by TPWD in 2016 updated the population estimate to approximately 2,000 individuals (see Table 1). All updates about the species' abundance, status, and last observation date are provided above. Experimental Populations: The creation of reintroduction sites is essential to the recovery of the LFSV (USFWS 1992, pp. 32-33; recovery actions 62 and 23, respectively). The LFSV experimental populations (EPs) were created to determine the species potential success of reintroduction within suitable habitat (Williamson

2008, pp. 29-39). As of 2022, it is unknown how many of the 9 planted EPs remain because no surveys have been conducted on any EP since 2008(USFWS, 2022).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat could be lost through surface mining; petroleum exploration; highway, power line, and pipeline construction. The conversion of native grasslands to “improved pastures” of introduced grasses is an ongoing threat. Suppression of wildfire and poor rangeland management could lead to increased cover of woody vegetation, which could reduce habitat quality the degree of threat is difficult to assess. Some land uses, including OHV use, mowing, small-scale clearing, herbicide application, and annual wildlife food plots, can directly harm or destroy A. macrocarpa individuals, or reduce their reproductive potential (USFWS, 2010).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** All known A. macrocarpa populations occur on privately-owned land. Approximately 95 percent of Texas land area is privately owned. It is reasonable to assume that the vast majority, if not all existing A. macrocarpa habitat, including sites that have not been documented, occurs on private land. Therefore, the species’ populations and habitats are not subject to Federal or State protection unless there is a Federal nexus, such as provisions of the Clean Water Act or a federally-funded project (USFWS, 2010).

**Stressor:** Other natural or manmade factors affecting its continued existence (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Rising temperatures might enable the species to survive further north than at present, but might also reduce the southern limit of the range. Similarly, changes in the frequency and amount of precipitation could favor a shift in geographic range or habitat type. Changes in temperature and rainfall amounts and patterns could alter the species’ competitive advantage in the unique micro-habitats it now inhabits. At present, the Services cannot predict how the infinitely complex aggregation of climate change effects will affect the synecology of the species and its habitat (USFWS, 2010).

**Stressor:** Urban Residential Development (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Service is unaware of any large planned residential development projects at any of the WP or EPs. Site visits were not conducted between September 2015 and 2016, so any new disturbances could not be noted (P. Williamson, pers. comm. 2016). In 2022, part of WP6 was split and sold, and is now under multiple ownership (USFWS, 2022)

**Stressor:** Industrial Habitat Loss, Conversion, Fragmentation (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Two surface mines exist within the known range of the LFSV, the Jewett and Bremond Mines. Both are lignite mines (coal), operated by the Texas Westmoreland Coal Company and Luminant Mining Company, LLC, respectively. The Jewett mine is located approximately eight miles northwest of Jewett in Leon County. For this mine, the Service recommended that the applicant conduct habitat surveys for the LFSV; the applicant indicated that surveys for the LFSV were conducted and yielded negative results. The Bremond Mine is located six miles east of Bremond, Robertson County, and although within the range of the species, did not directly affect the plant. The Service provided recommendations for both applications under Section 7 of the Act and 404 of the Clean Water Act for each permit application. Mining operations can have impacts to the species habitat through removal, disturbance, and direct mortality of plants. Both of these mining facilities included other federally-listed species like the Navasota ladies'-tresses (NLT, Spiranthes parksii) and only NLT has been observed on these sites. It was estimated in 2014, that the total estimated impact acreage from mining projects within range of the NLT and LFSV was 50,600 acres (20,477 hectares (ha)) as of November 2013 (A. Vale, pers. comm. 2014). Lignite mining is the Railroad Commission of Texas (RCC) and our field office has not received any requests for the development of new lignite mines within the range of the LFSV. (USFWS, 2022)

**Stressor:** Linear Development (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Linear development projects, including transportation and oil and gas activities (i.e., liquid natural gas pipeline development and maintenance), has increased within the known range of the LFSV. Since 2010, the Service has formally consulted under Section 7(a)(1) of the Act (see Table 3) on four consultations that have included LFSV related to these activities, resulting in approximately 175 ac (70.8 hectares (ha)) of effects to suitable habitat (USFWS, 2022)

**Stressor:** Off Road Vehicle/ Off Highway Vehicle (ORV/OHV) use, Mowing, Clearing, Herbicides, and Wildlife Food Plots (USFWS, 2022).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Other threats noted to impact the LFSV include the loss and fragmentation of habitat from the use of ORV/OHVs, mowing, clearing of habitat, herbicide use, and the development of food plots. Habitat disturbance from ORV and OHV use has been frequently documented as a potential threat to the LFSV. Prior to 2010, vehicular disturbance activities have been documented at WP4. This type of disturbance may be continuing at WP4 as its effects were captured during site visits in 2019 and 2021 (USFWS, 2022).

**Stressor:** Mowing (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Mowing is a direct threat to LFSV, particularly during the blooming season (February through April). As discussed above mowing could be a potential threat for WP4 although the direct disturbance mechanism at that site isn't clear. As discussed in Williamson (2008, p. 5), and USFWS (2010, p. 25) to best preserve known populations it is recommended to LO's that mowing be done outside the flowering period of the plant (USFWS, 2022)

**Stressor:** Herbicide Use (USFWS, 2022).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbicide use is a direct threat to germinating seeds, seedlings, and flowering plants. It is recommended to LO's delay herbicide application until LFSV seeds have dispersed and plants have become dormant during June-September (Williamson 2008, p. 5; USFWS 2010, p. 25). We lack data about the use and/or effects of herbicide on populations as minimal surveys have been conducted (USFWS, 2022).

**Stressor:** Herbivory (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Minimal herbivory from deer, domesticated grazing animals, or insects have been noted in the past (USFWS 2010, p. 29) likely due to LFSV being psammophonious thus creating a sand armor to avoid herbivory (LoPresti 2018, p. 826). Experiments have been conducted to determine if levels of herbivory differed between psammophonious and non-psammophonious plants. LoPresti and Karbor (2016, pp. 826-832) compared yellow sand-verbena (A. latifolia), and honey-scented pincushion plant (Navarretia mellita, non-psammophonious) by removing sand from stems, petioles, and leaves of yellow sand-verbena and adding sand to soils of honeyscented pincushion plants, and then exposing both species to leaf-mining caterpillars (Lithariapteryx abroniaeella). Leaves with sand present resulted in less caterpillar herbivory, consistent with a physical defense function, than those without sand (LoPresti and Karbor 2016, p. 831). In a similar experiment, LoPresti (2018, p. 6) found that approximately 50 percent of plants with sand removed had feeding damage on leaves compared to intact (sand present) leaves which exhibited only 25 percent herbivory. Despite these results, the ecological function behind psammophony is not clear. LoPresti and Karbor (2016, pp. 826-827) postulated that plants exhibiting crypsis were also psammophonious. To test this hypothesis, sand was removed from 90 stems of the yellow sand-verbena; tan or green sand was added to 30 plants each to mimic the sand habitat or leaf color, and the remaining 30 plants had no sand added to act as controls (LoPresti 2018, pp. 829-830). Herbivory was highest on stems with no sand (15 percent) than those stems with sand. Overall, there was no difference in caterpillar herbivory due to sand color suggesting that sand armor functions as a defense mechanism is not a result of crypsis (USFWS, 2022).

**Stressor:** Climate Change (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change may be a factor affecting LFSV however, we do not know whether changes in climate that have already occurred have affected populations and/or its distribution.

While future climate projections indicate an increase in average annual temperature and decrease in average annual precipitation (Climate Mapper 2022; see Table 4), the Service is not able to predict how the species might be affected by the type (i.e., temperature or precipitation) and degree of future climate change under different greenhouse gas emission scenarios (representative concentration pathways (RCPs)) (USFWS, 2022).

***Recovery***

**Reclassification Criteria:**
At least 20 healthy, stable populations with a minimum of 600 plants in each should be located or established. A healthy population would be considered to be one with a habitat area of at least 25 acres, demographically stable, and genetically viable. These populations should be distributed throughout the natural, potential geographic range of the species, as determined by recovery research activities (USFWS, 2010).

Recovery Priority Number: 8

**Delisting Criteria:**
The 20 populations described for the reclassification criteria have maintained needed population structure and viability for at least 10 years. In addition, long-term agreements and management plans should be in place that will ensure their continued protection (USFWS, 2010).

**Recovery Actions:**
- Protect Abronia macrocarpa populations from existing and future threats and develop management plans (USFWS, 1992).
- Maintain a reserve germ bank/cultivated population with a responsible agency/Institution (USFWS, 1992).
- Study population biology. Initiate studies to gather information necessary for protective management and restoration. Study cultivation requirements (USFWS, 1992).
- Search/inventory potential habitat (USFWS, 1992).
- Assess restoration feasibility (USFWS, 1992).
- Develop and implement a reintroduction plan, if feasible (USFWS, 1992).
- Develop public concern and support for the preservation and study of Abronia macrocarpa (USFWS, 1992).
- Develop a post-recovery monitoring plan (USFWS, 1992).
- Revise the recovery plan and recovery criteria to reflect new information on the species' biology, ecology, and range, incorporating the most recent recovery planning guidance (National Marine Fisheries Service 2007). Specifically, the criterion of a minimum viable population area of 10.1 ha (25 ac) is unrealistic, since the known viable wild populations occupy much smaller areas. However, it is important to distinguish between the area requirements of both occupied and unoccupied potential habitat. Abronia macrocarpa inhabits sparsely-vegetated, unstable sandy soil formations; anecdotal observations indicate that the populations respond favorably to occasional light disturbance. Therefore, it is possible that this plant is narrowly adapted to a specific seral stage that continually shifts location as these inland sand dunes form and recede. If this is the case, the area requirement for unoccupied but intact potential habitat will be much greater than the area

occupied by the species at any given time; long-term survival would require landscape-scale conservation (USFWS, 2010).

- Increase the minimum viable population size of 600 individuals for the recovery criteria, as this appears to be too small (McGlaughlin et al. 2002, Williamson, pers. com. 2010) (USFWS, 2010).
- Continue to promote public support for conservation and recovery of the species through local schools and news media, non-governmental conservation organizations, and other forms of public outreach (USFWS, 2010).
- Continue periodic monitoring and surveys of the known populations to track demographic trends, and to detect and attempt to alleviate threats to these populations (USFWS, 2010).
- Support conservation of wild populations on private lands through the USFWS Partners for Fish and Wildlife Program and section 6-funded grants, and through cooperative efforts with Natural Resources Conservation Service and other state and federal agencies. Establish a private landowner support group, similar to the group now actively working to conserve Texas snowbells (Styrax platanifolius ssp. texanus) (USFWS, 2010).
- Continue to search for wild populations. Use GIS technology to identify areas of high potential habitat, and seek landowner permissions to survey those areas (USFWS, 2010).
- Conduct scientific investigation of the species' fire ecology. (USFWS, 2010).
- Continue to develop reintroduction techniques to improve establishment rates in the field and cost effectiveness. Once suitable techniques have been demonstrated through pilot reintroductions, implement a reintroduction program on a scale sufficient to recover the species. (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- Establish protected sites (recovery action 111; priority 1): Currently, no known occupied LFSV sites are protected by a conservation easement or other binding mechanism. Efforts between the Service, TNC, and LO to protect WP4 with a conservation easement began in 2019, however no such agreement has been secured. LO outreach and cooperation are vital to the success of these securements and should be a priority for future work with the species. Funding mechanisms should be developed and presented in concert with outreach efforts to the LO to implement protection and management of sites.
- Work with LO to manage sites for existing populations (recovery actions 112 and 113; priority actions 1 and 2, respectively): Both short-term and long-term reduction in threats and management should be explored for each known site once LO contact and coordination has been established and maintained. Once LO contact is established, management plans should be created and revised, as needed (recovery action 14, priority 2).
- Monitor known populations for general condition and reproductive success (recovery action 13; priority 2): Monitoring methods should be developed and used at all sites. Monitoring should occur annually at each known population (both WPs and EPs), where access is allowed, to track demographics and current threats.
- Maintain a reserve germ bank/seed bank and cultivated populations (recovery action 21 and 22; priority 1 and 2, respectively): Currently seeds are banked with CPC partners at Mercer and LBJWC. Seeds should also be banked at USDA's National Laboratory for Genetic Resources Preservation in Ft. Collins, Colorado. Additional seed banking could alleviate pressures should any stochastic event occur. Testing of seed viability needs to be conducted and seeds from current populations should be collected in the near future (to have preservation of current population genetics/flowering plant populations). Formal seed collection and management guidelines should be developed and

coordinated amongst the Service and partners that includes consideration of the species' needs, genetic representation of the species, and built-in redundancy for species/population preservation from stochastic events. Collection guidelines and purposes for reintroduction should be outlined in a species-specific plan and should adhere to the Service's 2000 Controlled Propagation and Reintroduction Policy (recovery action 62; priority 3).

- Continue with cultivation of LFSV for the purposes of restoration and reintroduction (recovery action 23; priority 2): Seed germination studies (Goodson 2007, p.15; Drennan 2008, p. 848; Williamson 2008, pp. 35-39; Goodson and Williamson 2011, p. 144) and early reintroduction experiments (Williamson 2008, pp. 29-39) have shown LFSV can be successfully cultivated in both the greenhouse and field. However, surveys of reintroduced LFSV have not been consistent and are needed for species recovery to determine the need for more restoration and reintroduction. Further research in species cultivation, restoration, and reintroduction would help determine the amount of successful germination/per seeds plants and how microhabitat plays a role in successful reintroduction. Continuing efforts to create and monitor additional reintroduced populations could help achieve the species recovery goal of downlisting as least 20 populations are needed.
- Determine habitat requirements (recovery actions 3111, 3112, and 3113; each priority 2): Species geology, soils, and microclimate should be investigated at a site-specific and landscape scale. Habitat mapping will help identify areas with suitable habitat to focus survey efforts for additional populations; and identify areas of suitable habitat to focus potential reintroduction efforts (recovery actions 41 and 42; priority 1 and 2, respectively).
- Assess the demographic needs and conditions for populations (recovery action 3211; priority 1): Analyses completed show variation among soil composition and characteristics across populations, although the plant species composition (i.e., associated species) at each population seem similar. Further analysis is necessary to monitor site condition changes (i.e., changes in soil composition, pH, etc.) and subsequent changes to LFSV populations (i.e., number of flowering plants).
- Characterize phenology (recovery action 322; priority 2): Investigate the phenological response to variations in timing and frequency of important climatic conditions (i.e., precipitation, temperature).
- Investigate the pollination biology (recovery action 3232; priority 2): Several pollinators have been identified in association with LFSV. While some experiments point to a selfincompatibility mating system (i.e., relying on pollinators for seed/fruit set), confirming if these are effective pollinators is important. Pollination biology research will improve management efforts of both LFSV and associated pollinators, and improve the overall long-term viability of the species.
- Investigate seed biology (recovery actions 331 and 332; each priority 2): Germination techniques have been investigated by Williamson and others using various germination methods including scarification, stratification, and mycorrhizal fungi inoculation. Best methodology, from current research knowledge, includes warm then cold seed stratification with the anthocarp removed. Further investigation is needed to understand the longevity and viability of stored seeds and the best germination methods for stored seed for later reintroduction.
- Conducting searches for existing populations (recovery action 41; priority 1): Efforts to search for additional LFSV populations should be coordinated between the Service, TPWD, and other partners. Working with other agencies, such as NRCS, the Service's Partner's for Fish and Wildlife (PFW) program, that conduct on-the-ground management and LO consultation is important to gaining LO trust and access to LFSV populations. Efforts will need to focus on educating LO's and partner organizations. Another important component of this recovery action should include the identification and refinement of suitable habitat requirements as outlined in recovery actions 3111, 3112, and 3113 above.

- Monitor existing reintroduction populations to understand effectiveness and feasibility of techniques (recovery action 51; priority 2): Several reintroduction efforts occurred by Williamson between 2006 and 2008, creating nine EPs. These efforts demonstrated that spring reintroductions are more successful than fall reintroductions however, this was ultimately dependent on site-specific characteristics (i.e., presence of cutter ants, soil characteristics, precipitation events). Since the initial creation of the EPs, sites have not been surveyed or monitored. Consistent monitoring of EPs is necessary to provide accurate reintroduction methods and management actions in the future. The genetic structure of LFSV has been observed to exhibit high heterozygosity in and among populations, and was used to improve genetic structure of EPs; however, no population genetic research has been conducted since the creation of EPs. Genetic structure research is needed to verify genetic variation was improved with created EPs, and ensure high heterozygosity among LFSV populations to protect the species from stochastic events.
- Continue to promote public support for the conservation and recovery of the species (recovery action 7; priority 2): Efforts should focus on providing the public with knowledge of the species needs and the importance of its conservation. In addition, the public should be made aware of potentially deleterious land management practices (i.e., mowing, ORV use, etc.); how to alter such land management practices so they provide dual benefits to the species and the LO/land manager (i.e., timing and frequency of mowing); other strategies to aid in species recovery (i.e., providing access for monitoring, allowing reintroductions, etc.); and necessary information about plant regulations under the Act.
- Determine response to disturbance, agricultural practices, and other land uses (recovery action 3133; priority 1): Efforts should focus on determining the impact of threats to LFSV including but not limited to ORV use, fire (prescribed burning), herbivory, and climate change. ORV use or mowing was observed at WP4, however, consistent surveys/observations are needed to better understand the types of disturbance occurring and their impact. Little to no information is known about the impacts of prescribed burning on LFSV. This needs to be investigated to determine if it could be a suitable restoration management strategy for the species. Herbivory by caterpillar was investigated by Dr. LoPresti, however LFSV exhibits psammophony (i.e., sand armor) which acts as defense against herbivory. Williamson observed population loss in an EP that was thought to be impacted by cutter ants however, these findings need further investigation.

# SPECIES ACCOUNT: *Aeschynomene virginica* (Sensitive joint-vetch)

***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** SJV

**Listing Status:** Threatened; 5/20/1992; Northeast Region (R5) (USFWS, 2016)

**Physical Description**

A robust annual legume that typically attains a height of 1.0-2.0 m in a single growing season, although it may grow as tall as 2.4 m. The stems are single, sometimes branching near the top, with stiff or bristly hairs. The leaves are even-pinnate, 2.0-12.0 cm long, with entire, gland-dotted leaflets. Each leaf consists of 30-56 leaflets. Leaflets are 0.8-2.5 cm long and 0.2-0.4 cm wide. The leaves fold slightly when touched. Pedicles are 3.0-8.0 mm long, bearing toothed bractlets about 4.0 mm long and 2.0-3.0 mm wide immediately below the flowers. The yellow, irregular, legume-type flowers are 1 .0-1 .5 cm across, streaked with red, and grow in racemes 2.0-6.0 cm long. The flowers have uniformly shaped anthers. The fruit is a loment with 4-10 one-seeded segments, the lowest 5.0-7.0 mm wide, turning dark brown when ripe. Fruits are 3.0-7.0 cm long, on a stipe 10.0-25.0 mm in length, and shallowly scalloped along one side (USFWS, 1995).

**Taxonomy**

In the pea family, Fabaceae (USFWS, 1995)

**Historical Range**

Tidal marshes of New Jersey, Pennsylvania, Delaware, Maryland, and Virginia, and ditches and agricultural fields in North Carolina (USFWS, 2013).

**Current Range**

Current range includes New Jersey, Maryland, Virginia, North Carolina. Delaware and Pennsylvania occurrences have not been observed since the 1800s (USFWS, 2013).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

<u>Adult:</u> Insect (USFWS, 2019)

**Breeding Season**

<u>Adult:</u> Germination begins late May to early June; flowers from July to September; fruits are produced simultaneously from July to late October (NatureServe, 2015).

**Key Resources Needed for Breeding**

<u>Adult:</u> Small bumblebees, some self-pollination (EPA, 2016)

**Reproduction Narrative**

Adult: Plants flower from July through September and occasionally into October. In autumn, senescence may be triggered by the drop in water temperature or by salinity intrusion due to a decrease in freshwater flow. Bumblebees have been observed pollinating the flowers. Fruits form shortly after the first signs of flowering in July. Although flowering continues until late fall, production of vigorous fruits appears to decline significantly by mid-October. Seed maturation begins in August and continues through October. Germination takes place from late May to early June. Seedlings grow quickly, approximately doubling in size every 2 weeks during the first 6 weeks (USFWS, 2019).

**Habitat Vegetation or Surface Water Classification**

Adult: Fresh to slightly brackish tidal river shores and estuarine-river marsh borders (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Majority are found in natural tidal marsh habitats, but also a few documented cases of a pocket marsh wetland, edge of a moist soybean field, and a mowed grassy strip between a manmade drainage channel and dirt road (EPA, 2016). Usually grows within 2 m of low water mark on raised banks in peaty, sandy or gravelly substrates. Salinity of one site in New Jersey ranges from 0.7 to 0.8 ppt with an average pH of 4.4. In North Carolina, A. virginica has been found in a few ditches and wet fields, but these are not considered stable populations. Associated species include Zizania aquatica, Petlandra virginica, Pontederia cordata, Bidens laevis, Polygonum arifolium, P. saggitatum, and Leersia oryzoides (NatureServe, 2015).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Decline of 50-70% (NatureServe, 2015)

**Species Trends:**

Decline of 10-30% (NatureServe, 2015)

**Number of Populations:**

Approximately 20 (NatureServe, 2015)

**Population Size:**

Approximately 7000 individuals (NatureServe, 2015)

**Adaptability:**

Sensitive to water pollution and marsh drainage; difficulty in controlling headwater pollution (NatureServe, 2015)

**Population Narrative:**

Species shows considerable annual fluctuations in population numbers. Over 3 years one population varied from approximately 50 to 2,000 individuals. Long-term trend is a decline of 50-70%; short-term trend is a decline of 10 - 30%. Many populations are no longer extant, or have not been relocated recently. New Jersey: 2,000 +/- 50; Maryland: several hundred individuals; Virginia: ca. 5,000 plants; North Carolina; all populations unstable in ditches. About twenty recently documented occurrences. New Jersey: 2 occurrences; Maryland: 5 occurrences; Virginia: 12 occurrences; North Carolina: 1 marginal occurrence (NatureServe, 2015).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 1995)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Aeschynomene virginica is susceptible to population and habitat destruction or degradation from a wide variety of anthropogenic sources, including: sedimentation, competition from exotic plant species, dams, dredging and filling activities, boating activities, shoreline stabilization and structural development, road and bridge construction, commercial and residential development, water withdrawal projects, changes in water quality, agricultural practices, introduced pest species, mining, timber harvest, over-visitation to sensitive joint-vetch sites, declines in muskrat populations, sea level changes (possibly in conjunction with natural cycles), plant collection (USFWS, 1995).

**Stressor:** Natural disturbances (USFWS, 1995)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Natural threats are often identified with disturbances, such as wave and ice action associated with severe storm events, competition, channel migration, sea level rise, and natural sedimentation processes. Healthy metapopulations of the sensitive joint-vetch are adapted to these stresses, and in some cases dependent upon them over time. Certain subpopulations may be locally extirpated, but others are able to establish and reproduce in newly opened habitat patches if seed viability and mobility are good and the frequency of disturbance events allows for biotic responses. Small populations are more vulnerable to these stresses than larger populations, especially if the disturbance event occurs during the growing season and plants are unable to compensate for high mortality rates within a particular year class. Severe hurricanes along the mid-Atlantic coast have the potential to temporarily or permanently destroy A. virginica habitat (USFWS, 1995).

***Recovery***

**Reclassification Criteria:**
Not available.

Recovery Priority Number: 2

**Delisting Criteria:**

1. The sensitive joint-vetch and the ecosystems upon which it depends are adequately protected within the following six watersheds: Manokin Creek in Maryland; Manumuskin River in New Jersey; and Rappahannock, Pamunkey, Mattaponi, and Chickahominy Rivers in Virginia (USFWS, 1995).

2. Annual monitoring over a 10-year period shows that the populations in these six river systems are stable or expanding (USFWS, 1995).

3. Life history and ecological requirements of the species are understood sufficiently to allow for effective protection, monitoring, and, as needed, management (USFWS, 1995).

**Recovery Actions:**

- Maintain the integrity of the tidal wetland systems upon which the sensitive joint-vetch depends (USFWS, 1995)
- Protect extant sensitive joint-vetch populations and sites (USFWS, 1995).
- Survey for additional populations (USFWS, 1995).
- Establish monitoring priorities, develop reliable monitoring techniques, and monitor populations accordingly (USFWS, 1995).
- Determine the ecological and distributional characteristics and requirements of the sensitive joint-vetch (USFWS, 1995).
- Develop an informational brochure on the importance of the sensitive joint-vetch and the tidal wetlands upon which it depends (USFWS< 1995).
- More consistent monitoring of all of the Virginia occurrences is needed to confirm the population trends in the portion of its range that has the greatest number of extant occurrences/subpopulations. This monitoring can also serve to detect current threats and identify areas where management actions such as Phragmites control may be needed in Virginia (USFWS, 2013).
- A review of the monitoring methodologies being used across the range of this species should be conducted with the purpose of increasing standardization. Monitoring protocols likely vary across the species range. Although long-standing monitoring programs may not want to abandon established methodology for fear of making their year-to-year data less comparable, a review could highlight where changes might be made and lead to increased standardization and therefore more comparable data rangewide (USFWS, 2013).
- Conduct genetic research to ensure that seeds representing the genetic diversity of SJV are in the collection of the National Center for Genetic Resources Preservation (Formerly National Seed Storage Laboratory) in Fort Collins, Colorado (USFWS, 2013).
- Investigations should continue into the effects of invasive plants such as Murdannia keisak and the introduced insect species, tobacco budworm (Heliothis virescens) and corn earworm (Helicoverpa zea) on SJV (USFWS, 2013).
- The role of muskrats in creating and maintaining SJV habitat needs to be investigated (USFWS, 2013).
- Consideration should be given to what role proactive measures such as habitat management, seed additions, and introductions in upstream habitat should play in a long term management strategy for SJV in light of dwindling populations in parts of its range, the serious threat from sea level rise, and questions about the ability of this species to migrate to upstream habitat. Recent publications mention the use of vegetation management and seed additions for the conservation and management of SJV or recommend directing

research efforts to introducing the species into new upstream sites. Guidelines should be developed in case more aggressive management strategies are warranted (USFWS, 2013).
- Surveys should be conducted in potential habitat throughout the range of the species (USFWS, 2013).
- Revise the recovery plan to update information and to consider the incorporation of the James River Basin in the Recovery Criteria (USFWS, 2013).

# SPECIES ACCOUNT: *Agalinis acuta* (Sandplain gerardia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/7/1988; Northeast Region (R5) (USFWS, 2016)

**Physical Description**

The sandplain gerardia is an annual light-green herb from 4 to 8 inches (1 to 2 decimeters) and occasionally up to 16 inches (four decimeters) tall. The stem is weakly angular and has few branches. The leaves are opposite, linear, and up to 1 inch (2.5 centimeters) long. The pink-purple, bell-shaped flowers appear from late August through September, are 0.4—0.5 inches (1 to 1.3 centimeters) long, and have two yellow lines and red or purple spots in the corolla throat. The corolla lobes are slightly notched at the tip. (USFWS, 1988)

**Taxonomy**

The sandplain gerardia is in the snapdragon family (Scrophulariaceae). (USFWS, 1988) In a 2019 document, the Service summarized more than 10 years of research and associated discourse regarding the phylogenetic studies that inform the Service's consideration of the taxonomic status of A. acuta.  Based on a detailed review of all the available scientific and commercial information, it was concluded that "the taxonomic entity known as A. acuta is not a distinct species (Neel and Pettengill 2009; Pettengill 2010; Pettengill and Neel 2011; Hays pers. comm. 2018a, 2018b). The Service therefore concurs with the taxonomic revision recommended by Pettengill and Neel (2011) and the FNA synonymizing A. acuta under A.decemloba."  (USFWS, 2019)

**Historical Range**

See current range/distribution.

**Current Range**

In 2017, known populations were present in the states of Connecticut, Rhode Island, Massachusetts, Maryland, and New York. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: < 1 year (inferred from USFWS, 1989)

**Dependency on Other Individuals or Species**

Adult: Insects for pollination (EPA, 2016)

**Breeding Season**

Adult: Flowers from mid-August to mid-October (USFWS, 1989)

**Reproduction Narrative**

Adult: Flowers from mid-August to mid-October. Life span is less than 1 year (USFWS, 1989).

**Habitat Type**

Adult: Terrestrial (USFWS, 1989)

**Habitat Vegetation or Surface Water Classification**

Adult: Dry, sandy, poor-nutrient soils of sparsely vegetated sandplain environments and serpentine barrens (USFWS, 1989)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: This species typically occurs on dry, sandy, poor-nutrient soils of sparsely vegetated sandplain environments and serpentine barrens, whose harshness may eliminate potentially competitive species (USFWS, 1989). It is dependent on periodic disturbance that maintains an open habitat. The soils are nutrient-poor, usually acidic, and excessively drained. An underlying factor common to all sites is the lack of competition from other species - a factor imposed by conditions that include extremely nutrient-poor, and sometimes minerally toxic, soils and regular or sporadic disturbance. Fire has played a role in maintaining open habitat at a number of Agalinis acuta sites (NatureServe, 2015).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Dispersal is possibly by wind or small animals (USFWS, 1989). If wind dispersed, seeds are not likely to travel far. Some dispersal may occur through ingestion by small animals such as meadow voles or cottontail rabbits (NatureServe, 2015).

***Population Information and Trends***

**Population Trends:**

Not available.

**Species Trends:**

Increase of > 10% (NatureServe, 2015)

**Number of Populations:**

22 - 23 (NatureServe, 2015)

**Population Size:**

100,000 - 1,000,000 individuals (NatureServe, 2015)

**Population Narrative:**

While there are about 6 sites with reasonably large, stable, well managed populations, few have good viability/integrity. "Large" represents a population that has maintained an average of 3000+ individuals over the past 5 years. Many populations are still very small or occur on marginal habitat such as small expanses of grassland surrounded by development or unsuitably dense vegetation (NatureServe, 2015).

### *Threats and Stressors*

**Stressor:** Habitat destruction or modification, or absence of disturbance within habitat (USFWS, 1989)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The most significant threat to A. acuta is the direct loss or degradation of its habitat. Residential, commercial, and recreational development has encroached on the species community. Shopping malls, condominiums and expanding highway systems have taken the place of much of the species natural habitat. Agricultural development and sand and gravel mining have destroyed large amounts of potential habitat (USFWS, 1989). The loss of grazing animals and the suppression of fires have allowed woody vegetation to claim many of its historical sites (NatureServe, 2015).

**Stressor:** Other factors with the potential to affect the species (USFWS, 1989)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Due to the relatively small population size of extant occurrences, It is likely that other factors may have the potential to affect the species. Natural disasters, reproductive failures and other influences on growth, reproduction and distribution have the potential to eliminate a site, if the effects are dramatic enough to prevent the plants from fully recovering (USFWS, 1989).

### *Recovery*

**Reclassification Criteria:**
1. There are 20 stable, wild populations located throughout the species historic range to ensure against any unpredictable events that could lead to reproductive failure and subsequent population decline. In order to be deemed “stable,” a population must maintain a 5-year running geometric average population size of at least 100 individuals. The geometric average is considered a better indicator of the stability of a population that exhibits wide year-to-year size fluctuations than is the arithmetic average (USFWS, 1989).

2. At least 15 of these populations are located on protected sites. Protection may be accomplished through: 1) ownership by government agency or a private organization that considers maintenance of the A. acute population to be the predominating management objective for the site; or, 2) a deeded easement or covenant that effectively commits present and future landowners to implementing any management activities needed to perpetuate the population. This high level of landowner commitment to site protection is necessary because of the species apparent need for active habitat manipulation to counteract the effects of removing natural sources of disturbance from the plants environment (USFWS, 1989).

3. There must be a proven technology for: 1) propagating the species in a cultivated setting; or, 2) storing seed in a seed bank and successfully sowing then on a wild site (USFWS, 1989).

Recovery Priority Number: 5C

**Delisting Criteria:**
Not available.

**Recovery Actions:**
- Protect known populations (USFWS, 1989).
- Investigate species and habitat characteristics necessary to maintain and establish populations throughout the range of the species (USFWS, 1989).
- Formulate and implement measures to maintain existing sites and locate, establish and maintain new sites (USFWS, 1989).
- Develop technology for cultivating plants and provide for long-term seed storage (USFWS, 1989).
- Periodically review progress towards species recovery and modify elements as appropriate (USFWS, 1989).
- Not available.

# SPECIES ACCOUNT: *Agalinis navasotensis* (Navasota False Foxglove)

***Species Taxonomic and Listing Information***

**Listing Status:** Proposed Endangered

**Physical Description**

The description provided by Canne-Hilliker & Dubrule 1993 (pg. 426-431) is as follows: Navasota false foxglove is an annual herb from a few fibrous roots, 2.8-9.0 decimeter (dm) tall, often tinged with purple, maroon, or bronze. Stem erect or sometimes declined, single from the base, divaricately branched above, terete to slightly angled below the branches. Leaves opposite, spreading to ascending or often recurved filiform, 0.5-1 millimeters (mm) broad, 1.2- 3 centimeters (cm) long, acute to acuminate. Pedicels slender, terete, spreading or ascending, glabrous to minutely scabridulous and always longer than the calyx. Calyx somewhat campanulate or funnelform, straight sided. Tube 2.2-3.7 mm long, 3-4 mm broad, unribbed, exterior glabrous, interior with a narrow band of capitate hairs below the sinuses and lobes; lobes triangular-subulate, 0.5-1.5 mm long, sinuses broad and straight to slightly concave. Corolla including lobes 16 – 25 millimeters (mm) long, lavender to rose-purple. Corolla paler in the larger blossoms and darker in the smaller, throat paler than lobes, with darker spots and two pale yellow lines abaxially. Tube 2-3 mm long, narrow, glabrous. Stamens didynamous, abaxial filaments 9-11 mm long, villous; adaxial filaments 5-6 mm long; sparingly villous. Anthers of abaxial stamens usually coherent by entangled hairs; thecae villous, 2- 3.2 mm long. Style 1.5 cm long, pubescent; stigma 2 - 4.5 mm long, densely yellow-papillate. Capsule 4-7 mm long, conspicuously longer than the calyx, 4- 4.5 mm broad, ovoid-or obovoid-oblong. Seeds 0.8-2.3 mm long, dark brown, irregularly trapezoidal, testa reticulate, radial walls of reticulae densely thickened, inner tangential walls with an irregular pattern of spinulose thickenings (USFWS, 2022).

**Taxonomy**

The currently accepted taxonomic classification of Agalinis navasotensis (Navasota false foxglove) is as follows: Order: Scrophulariales Family: Orobanchaceae (broomrape) (Pettengill and Neel 2008 & Flora of North America (c)) Genus: Agalinis Raf. (false foxglove) (Flora of North America (b) Species: Agalinis navasotensis (Canne-Hilliker & Dubrule 1993 & Flora of North America (USFWS, 2022).

**Historical Range**

Navasota false foxglove is a narrowly endemic, hemiparasitic, annual plant known in only two counties in southeast Texas, Grimes and Tyler counties (USFWS, 2022).

**Current Range**

Navasota false foxglove is a narrowly endemic, hemiparasitic, annual plant known in only two counties in southeast Texas, Grimes and Tyler counties (USFWS, 2022).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Food/Nutrient Narrative**

Adult: Navasota false foxglove have not been researched, but specialists hypothesize that little bluestem (Schizachyrium scoparium) is one of the main plants that it parasitizes (Reed, pers. comm. 2020). Little bluestem occurs in all three current source features for Navasota false foxglove. Also, the co569 occurring King Ranch bluestem (Bothriochloa ischaemum var. songarica), a non-native, invasive grass, could serve as a potential beneficial host but could also out-compete it for sunlight, if not managed (Strong and Williamson 2015, pg. 6). Currently, both species of host plants inhabit areas where Navasota false foxglove are found. These host plants provided needed nutrients for survival and reproduction of Navasota false foxglove, especially in drought years (USFWS, 2022).

**Breeding Season**

Adult: Blooms from mid-September to October, and seeds mature from October to early November (USFWS, 2022).

**Reproduction Narrative**

Adult: Little is known about specific reproductive biology for Navasota false foxglove, but inferences can be made from other Agalinis species. The reproductive age of false foxgloves is less than 1 year. False foxgloves need pollinators and are structured like typical bee-pollinated flowers with nectar guides and an open throat, but they can also self-pollinate. Corollas are present for one day only and drop by the end of the day. As a corolla falls, it drags the anthers and stigma together, effecting pollination (Pennell 1921, pgs. 515-525). Numerous dark brown seeds (0.8-2.3mm) are encapsulated within a 6-7 mm long (Canne-Hilliker & Dubrule 1993 p. 430), ovoid to obovoid-oblong fruit; not all seeds will germinate in a single year and not all seeds in a capsule are viable. Navasota false foxglove blooms from mid-September to October, and seeds mature from October to early November. Fruit maturation and seed dispersal occurs by November, with other Agalinis fruit typically containing between 50 and 180 seeds (USFWS, 2022).

**Habitat Type**

Adult: Terrestrial (USFWS, 2022)

**Habitat Vegetation or Surface Water Classification**

Adult: Remnant prairie (USFWS, 2022)

**Habitat Narrative**

Adult: The EO# 6674 (East) site is a remnant prairie on a rocky sandstone outcrop representing the easternmost escarpment of the Oakville formation. The soils consist of rock outcrop and sandy loam over sandstone. Plants occupy open areas of the outcrops where sun exposure is nearly constant. In 1967, Keeney presented his thesis on the “Flora and Ecological Relationships of the Easternmost Extension of the Oakville Formation of Texas.” Keeney’s study on the soil-plant relationships on the outcrop areas of the Oakville sandstones revealed several interesting findings, including that the soils are a major factor in determining flora distribution and that segregation of species exists when limiting factors (plant structure, soil types, adequate water, base rock material, etc.) within a particular area are complex. Plants inhabit soil types specific to their individual needs, therefore soil mapping can identify flora distribution based on specific soil types. Mapping these specific soils can provide information for species distribution, which can help narrow down survey areas specific to certain rare plant species. Isolation of species in the case of the Navasota false foxglove is limiting due to exposed rocky outcrops and well drained soils being a need for this species. Keeney described ten different factors in his thesis where soil-plane relationships can be used (Kenney 1967, pg. 5-6). At the EO# 6674 (East) site, most of the plants occur on exposed rock formations, similar to the habitat at EO# 6674 (West) site. The EO# 9000 site is an outcrop of the Catahoula Formation within a pine plantation and surrounding pine savannah. Soils consist of fine sandy loams and clay. The Catahoula formations are similar to the Oakville formations found in Grimes County, but many of the plants at this site were not near exposed rock like the ones in Grimes County. Soils at the EO# 9000 site tend to be hard when dry, and when wet the thick clay becomes sticky and slick (Reed et al 2005, pg. 3). Microhabitats The soils were analyzed at the current Navasota false foxglove locations to determine the habitat features of areas that are currently occupied. The Grimes County sites (EO# 6674 East and West) are within a formation described as renish-rock outcrop complex. Plants are located on 8 to 20 percent slope and Brenham clay loam. Grimes County is within the Catahoula formation that extends across most of the eastern and southern parts of Texas (Map 2 below). The EO# 9000 site has soils that are described as Colita fine sandy loam and are within the Browndell-Kittrell complex, stony. Individual plants occur on slopes of 1 to 3 percent in the former soil and 5 to 15 percent slopes on the latter soils. Navasota false foxglove has only been found in areas where these formations are exposed to the surface, producing shallow, well drained soils. Map 2 illustrates soil types that were selected for projecting soils and potential habitat features that are like currently occupied habitat conditions based on description and knowledge of soils in the areas of occupied sites. The description of these soil types varies across databases and counties, so it is difficult to determine which soil types are closely related across county lines. While developing and evaluating the soil and rock layers, it was determined that there is a lot of uncertainty between county boundaries and soil mapping. The soil mapping was helpful as a visual representation of the areas that could potentially be Navasota false foxglove habitat, but it was not ground-truthed and did not provide any increased probability that could be used to determine potential survey areas or critical habitat mapping (USFWS, 2022).

***Dispersal/Migration***

**Dispersal**

Adult: Fruit maturation and seed dispersal occurs by November, with other Agalinis fruit typically containing between 50 and 180 seeds (USFWS, 2022).

***Population Information and Trends***

***Threats and Stressors***

**Stressor:** very few 139 populations (low redundancy) (USFWS, 2022)

USFWS. 2022. Species Status Assessment Report for 32 Navasota False Foxglove (Agalinis navasotensis), Do Not Cite. Houston, TX.

# SPECIES ACCOUNT: *Amaranthus pumilus* (Seabeach amaranth)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 4/7/1993; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

An annual herb with reddish-colored, prostrate, highly branched stems that form clumps, often reaching 30 cm in diameter. Leaves are spinach-green, clustered towards the tips of the stems. Flowers and fruits are inconspicuous. (NatureServe, 2015)

**Historical Range**

Formerly occurred from vicinity of Charleston, SC north to islands south of Cape Cod, MA. Actual area formerly occupied was quite small; occurring only in a narrow band of suitable habitat. (NatureServe, 2015)

**Current Range**

Extant from vicinity of Cape Hatteras, NC, to vicinity of Cape Romain, SC, and at scattered sites on Long Island, NY, and in coastal Delaware, Maryland, Virginia, and New Jersey. (NatureServe, 2015) Populations in the latter four states were not known at the time of listing, but were subsequently rediscovered. (USFWS, 2007)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Annual seed production (USFWS, 1996)

**Lifespan**

Adult: Less than one year (USFWS, 1996)

**Breeding Season**

Adult: April to January (USFWS, 1996)

**Other Reproductive Information**

Adult: Probably wind pollinated (USFWS, 1996)

**Reproduction Narrative**

Adult: Flowering of the Seabeach Amaranth begins as soon as plants have reached sufficient size, typically commencing in July and continuing until their death in late fall or early winter. Seed production begins in July or August and reaches a peak in most years in September; also continuing until the plant dies. Seeds are regularly produced by nearly all adult plants; fertility is assumed to be high (Baskin and Baskin 1994). The relative roles of the fresh seed crop and banked seeds from previous years are unknown in seabeach amaranth. Weather events (including rainfall, hurricanes, and temperature extremes) and predation by webworms can significantly reduce the length of the reproductive season. Based on morphology of the flower and inflorescence, seabeach amaranth is probably wind-pollinated, as are most species of amaranth.  It is clear that seabeach amaranth is capable of self-pollination, and it is likely that self-pollination plays a large, probably dominant, role in seed production.Seeds may survive many years buried in the sand; they germinate when brought near the surface by severe storms. The seabeach amaranth is a classic example of a fugitive species--”an inferior competitor which is always excluded locally under interspecific competition, but which persists in newly disturbed habitats by virtue of its high dispersal ability; a species of temporary habitats” (Lincoln et al. 1982). (USFWS, 1996)

**Habitat Type**

Adult: Terrestrial (USFWS, 1996)

**Habitat Vegetation or Surface Water Classification**

Adult: Sparsely vegetated sand (USFWS, 1996)

**Dependencies on Specific Environmental Elements**

Adult: Requires tidal overwash (USFWS, 1996)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs 8 inches to 5 feet above mean high tide. (USFWS, 1996)

**Spatial Arrangements of the Population**

Adult: Sparse (USFWS, 2007)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 1996)

**Habitat Narrative**

Adult: The species occurs on barrier islands, mainly on coastal overwash flats at the accreting ends of the islands and lower foredunes and on ocean beaches above mean high tide (occasionally on sound-side beaches). It is intolerant of competition, not occurring on well-vegetated sites. According to Weakley and Bucher (1991), this species appears to need extensive, dynamic, natural areas of barrier island beaches and inlets, especially with fresh sand. Within this dynamic landscape, this amaranth functions as a fugitive species, occupying suitable habitat as it becomes available. (NatureServe, 2015)

***Dispersal/Migration***

**Motility/Mobility**

Adult: Moderate for seeds (USFWS, 2007)

**Dispersal**

Adult: Moderate for seeds (USFWS, 2007)

**Dispersal/Migration Narrative**

Adult: Seabeach amaranth produce numerous seeds. Seeds are blown along the surface of the sand to reach new habitat within an island. They also float in water. In addition to being washed inland by waves, the seeds can withstand the conditions necessary to move among islands. It is also likely that they have the ability to persist as seed banks in inlets and possibly offshore (Strand 2002). (USFWS, 2007)

**Additional Life History Information**

Adult: Seeds may survive many years buried in the sand; they germinate when brought near the surface by severe storms. (USFWS, 2007)

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2023)

**Species Trends:**

Declining (USFWS, 2023)

**Number of Populations:**

21 - 300 (NatureServe, 2015)

**Population Size:**

8,164 (latest population/observed number in 2021)

**Adaptability:**

Low (inferred from USFWS, 2007)

**Population Narrative:**

Given the fugitive nature of the species and the constantly changing environment where it occurs, it is difficult to make determinations about population size or trends based on limited data from annual surveys which had only been conducted for the last ten years (as of 2007). Northern populations are generally seen as declining, but southern populations fluctuate significantly, which is consistent with its occurrence in a geologically dynamic landscape. Total seabeach amaranth numbers reported in 2005 range-wide surveys were the lowest since 1999. Annual census data indicate up to 100,000 individuals, with up to 300 populations. However, in many cases, groups of existing mapped sites should be lumped to represent single, dynamic populations. Once the occurrences are re-mapped in this fashion, the range-wide number may be on the order of 30-50. (USFWS, 2007; NatureServe, 2015); USFWS provided detailed Census Data on the Seabeach amaranth in the addendum to the 2007 5-year review (USFWS, 2018). The nine historically occupied States identified in the plan are: Delaware (DE), Massachusetts (MA), Maryland (MD), North Carolina (NC), New Jersey (NJ), New York (NY), Rhode Island (RI), South Carolina (SC), and Virginia (VA). These recovery criteria have only been partially met. The natural range of seabeach amaranth includes Atlantic Coast barrier beaches, from Cape Cod, MA south to Charleston, SC, with the exception of CT where no plants have ever been reported (Figure 1.) Natural populations of seabeach amaranth currently persist in five states: NY, NJ, DE, MD and NC. The single population in SC persists mainly due to annual plantings. Seabeach amaranth is an annual species and therefore the number of individual plants observed at a population in any given year fluctuates greatly as the species goes through boom-and-bust years. Prior to 2000, surveys were inconsistent and focused mainly on NY, NC and SC beaches and total numbers were between 3,000 and 34,000. Since 2000, more consistent range-wide surveys have been conducted in NY, NJ, DE, MD, NC and SC. Limited surveys also occurred in MA and VA following the 2017 reintroductions, but plants have not been found there in recent years. Between 2000 and 2020, the range-wide numbers varied from a high of 249,261 in 2000 to a low of 1,323 in 2013. During the early 2000s (2000-2003), very large populations of seabeach amaranth (~200,000 plants) were found on Long Island, NY. Those numbers dropped off significantly in 2004 (~31,000 plants) and reached their lowest numbers in 2010 and gradually increased from 2014 to 2019. NJ populations reached a low in 2013, the year after hurricane Sandy decimated beaches there and in NY. The numbers in NY and NJ have rebounded some since the 2013. In NC, historically a stronghold for this species, numbers have declined since 2005 with only a few plants found state-wide in recent years. This reduction in resiliency and redundancy may be attributable to shorter hurricane return period in Carolinas compared to NJ and NY (NOAA 2023). The total number of plants, range-wide, is much less than it was in the early 2000s with only 6,964 plants found in 2020. The species was reintroduced to MA and VA in 2017, but those populations have not persisted. Unfortunately, 75% of the sites with suitable habitat within each state have not been occupied by seabeach amaranth for 10 consecutive years. Seabeach amaranth is an annual species and populations fluctuate from year to year. Some populations that occurred in excellent habitat and were considered stable in the past have not been seen for several years (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Beach hardening (sea walls, jetties, rip-rap, etc) (USFWS, 1996)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threat to the seabeach amaranth is from beach-hardening (sea walls, riprap, etc.) that prevents sand accretion. Dune fencing was thought to be a significant threat. Seabeach amaranth often occurs around sand fencing on newly created dunes. It doesn't appear that sand fencing is detrimental to the species, but the dune stabilization that they facilitate encourages other vegetation to colonize these areas and effectively reduces habitat for seabeach amaranth. USFWS, 2007)

**Stressor:** Development (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Development of barrier islands, especially by hotels and condominiums, threatens the seabeach amaranth by removing potential habitat, by stabilizing beaches, and by introducing non-native competing vegetation. Beach nourishment projects and beach raking are also associated with development. (USFWS, 2007)

**Stressor:** Pedestrians (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Pedestrian impacts are most common on beaches in resort towns and especially in close proximity to large hotels and condominiums. In populated areas, there is often an increase in human traffic on the sand. Beach chairs and umbrellas are frequently set up in the upper beach area near the edge of the dunes and informal sand volleyball courts are delineated on the upper beach. (USFWS, 2007)

**Stressor:** Off-road vehicles (USFWS, 1996)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** While seabeach amaranth populations are somewhat tolerant of ORV use from December until May, the brittle, fleshy stems are easily broken, and growing plants (May to December) do not generally survive a single pass by a truck tire. Thus, even minor beach traffic directly across the plants during the growing season is detrimental, causing mortality and reduced seed production. It appears that vehicles are most harmful to seabeach amaranth on beaches that are less accessible to pedestrians. Often, little to no seabeach amaranth is found in areas that receive high ORV use. (USFWS, 1996; USFWS, 2007)

**Stressor:** Beach raking. (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** On many beaches, especially those used recreationally, vehicles are regularly driven along the beach pulling various types of rakes in order to collect trash, seaweed, marsh grasses and other things that are considered undesirable to human beach visitors. This activity increases the potential of running over, or pulling up seabeach amaranth plants. Little vegetation occurs in the areas where beach raking occurs (Steve Sinkevich, USFWS, Long Island Field Office, pers. comm., 2006). (USFWS, 2007)

**Stressor:** Herbivory by webworms (USFWS, 1996)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At least 4 species of webworms, along with other larval insects are known to feed on seabeach amaranth, as well as other plant species. The insect threat is variable from year to year and is more important in southern seabeach amaranth populations. In addition, deer, feral horses, nutria, rabbits, and songbirds have been observed feeding on the seabeach amaranth. While impacts from predation are localized, poorly understood and mostly based on observations, it is generally believed that vertebrate predators may negatively affect seabeach amaranth growth and reproduction, while invertebrates do not. USFWS, 2007)

**Stressor:** Climate change (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** According to NOAA's Tides and Currents web page, the mid Atlantic coast is currently experiencing a rise in mean sea level of 0 to 2 feet per century. Given that Seabeach amaranth grows at very low elevations and is often the species found growing closest to the ocean, even a

minor rise in sea level could be detrimental to existing populations. (USFWS, 2018)

**Stressor:** Disease or predation (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of the listing, webworms were the only known predator of seabeach amaranth. Since that time, several species of animals have been identified as feeding on seabeach amaranth. While impacts from predation and disease on seabeach amaranth plants are localized, poorly understood, and mostly based on observations, it is generally believed that vertebrate predators may negatively affect seabeach amaranth growth and reproduction, while invertebrates do not. (USFWS, 2018)

***Recovery***

**Reclassification Criteria:**
Recovery Priority Number: 8C

**Delisting Criteria:**
Delisting will be considered when a minimum of 75 percent of the sites with suitable habitat within at least six of the nine historically occupied States are occupied by seabeach amaranth populations for 10 consecutive years. (USFWS, 1996)

**Recovery Actions:**
- Survey suitable habitat for additional populations. (USFWS, 1996)
- Monitor and protect existing populations including enforcement of laws protecting the species and/or its habitat. (USFWS, 1996; USFWS, 2015)
- Determine habitat protection priorities. (USFWS, 1996)
- Determine and implement the management necessary for long-term reproduction, establishment, maintenance, and vigor. (USFWS, 1996)
- Conduct research on the biology of the species including long-term demographic studies and determining the effects of past and ongoing habitat disturbance. (USFWS, 1996; USFWS, 2015)
- Develop techniques and reestablish populations in suitable habitat within the species' historic range. (USFWS, 1996)
- Develop a cultivated source of plants and provide for long-term seed storage. (USFWS, 1996)
- Establish new populations or rehabilitate marginal populations to the point where they are self-sustaining. (USFWS, 1996)
- Investigate and conduct necessary management activities at all key sites, and annually assess the success of recovery efforts. (USFWS, 1996; USFWS, 2015)
- Prepare articles for popular and scientific publications; prepare and distribute news releases and informational brochures. (USFWS, 2015)
- Revise or clarify sections of the Recovery Plan to determine when the recovery criteria have been met. The recovery plan does not define some terms used and other recovery criteria need to be clarified. Recovery criteria in future amendments or revisions need to include additional threats in the listing package that were not included in the 1996 Recovery Plan.

(USFWS, 2007)

- Define what constitutes "Likely to Adversely Affect" and "Jeopardy" for this species in order to improve consistency in USFWS consultations. (USFWS, 2007)
- Develop a list of list of conservation measures that Service biologists can use in formal consultations that address impacts to seabeach amaranth. (USFWS, 2007)
- Develop survey protocols, continue annual range-wide monitoring, and submit annual survey data to the lead recovery biologist for analysis. (USFWS, 2007)
- Develop management recommendations in accordance with USFWS policy. (USFWS, 2007)
- Develop guidelines for restoration, augmentation and transplantation. (USFWS, 2007)
- Discuss potential impacts of ORV use and beach raking with local governments. (USFWS, 2007)
- Ensure that seed collections and herbarium specimens represent a variety of populations from throughout the species range. (USFWS, 2007)
- Work with academic institutions to address the additional research needs. (USFWS, 2007)
- Work with partners to revise the photo identification cards, produce interpretive signs for beach access sites, encourage media coverage, and maintain an up-to-date web site. (USFWS, 2007)
- Develop guidelines or recommendations for restoration, augmentation and transplantation projects (USFWS, 2023).
- Develop criteria for consistently defining a “site” across the range, allowing for better tracking of progress toward the recovery objective (USFWS, 2023).
- Reintroduce populations to natural areas that may serve as refugia for the species. Example locations may include but are not limited to: Cape Romain NWR (SC), Huntington Beach State Park (SC), Hammocks Beach State Park (NC), Cape Lookout National Seashore (NC), Cape Hatteras National Seashore (NC), NC Coastal Reserve (NC), Volgenau Virginia Coast Reserve (VA), Chincoteague NWR (VA), Cape May NWR (NJ), E.B. Forsythe NWR (NJ), Nantucket NWR (MA), Monomoy NWR (MA) and other protected coastal reserves with associated habitat (USFWS, 2023).
- Continue working with coastal municipalities, parks and wildlife agencies to maintain protective fencing and restrict beach driving in areas with historically good populations of seabeach amaranth. Beach driving and raking should not be allowed at all during the growing season when seabeach amaranth plants are actively growing and/or producing seeds (April – December). If this is not possible, surveys should be conducted during the growing season prior to these activities and a wide protective buffer should be created around seabeach amaranth plants. Work with municipalities to designate Plant Protection Strips such as the ones that have been successful in NJ (USFWS, 2023).
- Ensure that seed collections for long term storage represent a variety of populations from throughout the species range. The North Carolina Botanical Garden has over 25 accessions of Seabeach amaranth seeds from populations across the range of the species (NJ, DE, MD, NC and SC) in long term protective storage to be used for future reintroduction and research. They should continue increasing the number of seeds in their collections through seed amplification projects (USFWS, 2023).
- Control invasive species on beaches and dunes and consider the potential negative impacts of native beach grasses sometimes planted after nourishment projects (USFWS, 2023).
- Monitoring and Research Activities Develop survey protocols and coordinate annual range-wide monitoring. Work with partners to fill in survey gaps as needed. Submit annual survey data to the lead recovery biologist. Conduct research on the effects of climate change,

beach driving, beach nourishment and inlet dredging/sand deposition projects (USFWS, 2023).

# SPECIES ACCOUNT: *Ambrosia cheiranthifolia* (South Texas ambrosia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 9/23/1994; Southwest Region (R2)

**Physical Description**

South Texas ambrosia is a herbaceous, ashy blue-gray, rhizomatous perennial in the Asteraceae Family (sunflowers) (Figure 4). Stems of the plant stand erect and are approximately10–60 cm (3.9– 23.6 in) tall. The number of individuals at any site is difficult to count due to rhizomatous growth habits that produce multiple stems from plants that are growing in closely-spaced colonies, thus inhibiting accurate stem number counts. The leaves are usually opposite at the base, and alternate above. The leaves are mostly oblanceolate or oblong-lanceolate, 2–7 cm (0.8–2.8 in) long, depending on the area of placement and the age of the stem, with the blade narrowing gradually at the base. Most leaves are unlobed and entire, although the lower and larger leaves of juvenile plants may be undulate or shallowly-pinnate. Both sides of the leaves appear whitened due to a fine and short appressed pubescence, giving the leaf an ashy, blue-gray color. The inflorescence is usually unbranched and composed of separate, inconspicuous male and female flowers. The male flowers occur in a terminal raceme 5–10 cm (2–4 in) long, composed of 10–12 small, light yellow, saucer-shaped flowers that are about 4 mm (0.16 in) broad with 4–6 acute, triangular lobes. The female flowers are in small clusters in the axils of the leaves. The fruit is an achene, somewhat angled and long with a stout beak. The fruit has 4- 5 blunt spines spread across the surface (Poole et al. 2007). (USFWS, 2018)

**Taxonomy**

In the Asteraceae (sunflower) family. The first ambrosia collection on record was taken by Luis Berlandier in 1835 in San Fernando, Tamaulipas, Mexico (USFWS 1993). In 1859, Asa Gray named the plant Ambrosia cheiranthifolia (Payne 1964). In 1932, the first collection of Ambrosia cheiranthifolia in the United States was taken from an area near Barreda (now Russelltown) in Cameron County, Texas, by Robert Runyon (Turner 1983). (USFWS, 2018)

**Historical Range**

Nueces County, Texas, on the north; as far south as San Fernando in Tamaulipas, Mexico, a distance of approximately 322 kilometers (USFWS, 2018).

**Current Range**

In Texas, north-central Kleberg County through north-central Nueces County. (USFWS, 2018)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Abiotic, Insect (EPA, 2016)

**Breeding Season**

Adult: Flowers and fruits in late summer and fall (USFWS, 2010)

**Key Resources Needed for Breeding**

Adult: Wind and possibily insects for pollination (USFWS, 2010)

**Reproduction Narrative**

Adult: Ambrosia cheiranthifolia’s primary reproductive period occurs in late summer/fall, dependent on rainfall, and lasts until the lack of water or cold temperatures curtails growth. At the Robstown site, most stems produced a terminal inflorescence of staminate (male) heads that released abundant winddispersed pollen. Below that, in the leaf axils of the upper 1/3rd to 2/3rds of the vegetative portion of the stem, a series of small, sessile pistillate (female) heads was normally produced throughout the reproductive season. It was noted that some stems produced only or predominately pistillate or staminate heads, but most stems produced both types of heads. A single achene was produced per pistillate head. The phyllaries (bracts surrounding the flower head on a composite plant) hardened around the single fruit as it matured, producing a somewhat star-shaped, bur with the "seed" embedded inside. Multiple female heads were produced in each axil throughout the reproductive period, so burs of varying maturity sometimes occurred at the same node simultaneously. Burs darkened, hardened, and most easily dehisced (dried, opened, and detached) at maturity, with most falling to the base of the plant. A number of burs remained on the stems as the leaves senesced and persisted for several weeks into the winter time. Plants at Robstown County Park produced a consistent average of 2.98 mature burs/cm (7.57 burs/in) the pistillate reproductive region of the stem (USFWS, 2010). More often than not ambrosia is seen reproducing vegetatively by rhizomatous regrowth in the upper portion of the soil. As a result, a single individual may be represented by several-tohundreds of stems, depending on the age of the plant (Turner 1983). The most current scientific information suggests that ambrosia patches represent several separate individual members of a larger metapopulation, as is thought to be the case on NASK. In 2010, Overath began work on NASK ambrosia to answer a number of genetics-related questions including variation within patches (whether dominated by one or a few clones) and relatedness among patches; as well as analysis of the genotypes within patches. Overath (pers. comm. 2012) found little genetic variation among ambrosia samples collected and compared to 13 genetic markers, implying that all the separate patches on NASK are likely part of one larger population (or metapopulation). Small patches of ambrosia may be part of the same clone, but larger patches are not composed of single clones (Overath 2013b). However, these genetic studies also suggested that some NASK ambrosia patches (2013b) were reproducing sexually or that they had in the relatively recent past. Overath’s genetic studies to determine the reproductive mode at other sites, including the St. James Cemetery (Nueces County), are incomplete at this time. (USFWS, 2018)

**Habitat Type**

Adult: Terrestrial (USFWS, 2018)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal grasslands and shrublands (USFWS, 2018)

**Geographic or Habitat Restraints or Barriers**

Adult: Low elevations; 26 to 66 ft

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2018)

**Habitat Narrative**

Adult: This plant grows in the Gulf coastal grasslands of southern Texas, and is found in grassland and mesquite shrubland habitat on various soils. It is associated with sites where native short-grass prairie species persist, and also on moderately disturbed sites such as cemeteries, right-of-ways, roadsides, parkfields, and eroded areas along creeks. Typically grows on well-drained, heavy soils associated with subtropical woodland communities. Found in various soils, both heavy clays to lighter-textured sandy loams, mostly of the Beaumont and Victoria Clay series (USFWS, 2018)).

***Dispersal/Migration***

**Motility/Mobility**

Adult: N/A

**Dispersal/Migration Narrative**

Adult: Thought to be dispersed by wind (USFWS, 2010).

***Population Information and Trends***

**Population Trends:**

Not available.

**Species Trends:**

Not available.

**Number of Populations:**

7 (USFWS, 2019)

**Population Size:**

Uncertain (USFWS, 2019)

**Population Narrative:**

As of 2014, there are seven extant, or presumed extant, ambrosia populations from north-central Kleberg County through north-central Nueces County. One site occurs on state land, on both the north and southbound ROWs of US Hwy 77. The largest population occurs on Federal land at the Naval Air Station Kingsville (NASK). There are two sites on city or county-owned lands; the Bishop City Park and the Nueces County Park in Robstown. Two sites are located on private land, including a large population at the St. James Cemetery in Bishop and a small group of plants on a lot in Kingsville (General Cavazos Boulevard). Additionally, a National Guard training area formerly leased from a private landowner, known as the KRTA, has several sites (Table 9). These KRTA populations became inaccessible and thus unverifiable after the lease expired in the mid-1990s. Observations using Google Earth show the habitat still exists and the ambrosia is assumed to be extant. All of these separate KRTA occurrences are less than 1.0 kilometer (km) (3, 280 feet (ft)) apart and may therefore be a single metapopulation. The same is true for the occurrences in the St. James Cemetery, Bishop City Park, and the US Hwy 77 ROW, as well as the separate patches of ambrosia on NASK (see paragraph below). If the ambrosia is sexually reproducing, the close proximity between occurrences allows for the genetic exchange between each occurrence, or sub-population, and may mean that these sub-populations constitute at least 3 different metapopulations based on these distances. The population at Robstown and the one in Kingsville would be considered separate populations. (USFWS, 2018)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasion of short-grass prairie by non-native grasses, conversion of native prairie to row crops and improved pasture, development in urban and rural areas, and restricted geographic distribution and abundance are historic, as well as ongoing, habitat-related threats (USFWS, 2010).

**Stressor:** Limited genetic diversity (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The current limited geographic distribution of A. cheiranthifolia may be expected to result in lower genetic diversity due to a lack of gene exchange through pollen, seed, or ramets between different sub-populations and populations. The existence of the species in fragmented, unconnected habitat patches can lead to restrictions in genetic variability, reducing the species' ability to overcome environmental stresses, especially during stochastic events or in response to climate change, and thereby render the populations vulnerable to extirpation and extinction (USFWS, 2010).

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Projected climate changes across the South Texas plains and the southern coastal region include higher temperatures, more frequent and prolonged droughts, and intensified rainfall events (Intergovernmental Panel on Climate Change 2007). These climatic conditions can cause or exacerbate direct stress to vegetation communities and individual plant species by decreasing water availability, altering temperature regimes to which the species has adapted, and subjecting the plants to flooding and potentially increased erosion from more severe storms (USFWS, 2010)

**Stressor:** Drainage improvements (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since most of the plants are located near or along drainage corridors and in close proximity to one another, improvements or diversion of water could perhaps impact the species.

These improvements could cause an increase/decrease in water amounts reaching natural drainages, cause a channelizing of natural drainage routes, and cause habitat fragmentation to an existing population or otherwise potential sites of A. cheiranthifolia (USFWS, 2010).

**Stressor:** Effects of pesticide drift (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Remaining areas of the native coastal prairie habitat of A. cheiranthifolia populations are surrounded by agricultural fields, pastures, and urban development, from which aerial drift of pesticides has potential to harm or kill individuals of the species. Insecticides could be considered a potential threat because they can directly or indirectly kill pollinators of A. cheiranthifolia (USFWS, 2010).

**Stressor:** Inadequacy of existing regulations (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Inadequacy of existing regulations (USFWS, 2022)

**Stressor:** small population size (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** small population size (USFWS, 2022)

**Stressor:** Climate change (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change (USFWS, 2022)

***Recovery***

**Reclassification Criteria:**
Downlisting Criteria 1: A recommended minimum of nine populations are necessary for downlisting and should have at least 7,500-15,000 mature stems per population. Each population should be stable or increasing over the next 20 years. The extant populations (seven total), as well as any that may be restored, augmented, or created, should be maintained with at least one natural population located in each of the drainage systems (Oso, Chililpitin Creek-San Fernando, Alazan Bay-Baffin Bay, and Santa Getrudis Creek basins) where the species is known to naturally occur to ensure genetic representation. (USFWS, 2018)

Downlisting Criteria 2: Each ambrosia site should be managed for and support high quality shortgrass prairie habitat. High quality shortgrass prairie habitat has these characteristics: 1) occurs in unplowed, relatively undisturbed soils; 2) has a high diversity and high vegetative cover of native grasses and forbs; 3) has a low vegetative cover of introduced grasses; and, 4) has a low vegetative cover of woody species (i.e. native brush). High quality shortgrass prairie habitat should contain species commonly associated with ambrosia (see Table 7 of 2018 Recovery Plan). Although ideal high quality shortgrass prairie habitat would be located in unplowed/undisturbed habitat areas, this scenario means only remnant pieces of land in Nueces County which has been largely converted to cropland, and is restricted in Kleberg County to areas that can be accessed for plant surveys. As a consequence, existing patches of shortgrass prairie may need intensive restoration or habitat may need to be created on areas that are currently devoid of vegetation due to previous land use. Unplowed/undisturbed habitats should be sought out and restored as a priority before attempting creation of new habitat amidst disturbed shortgrass prairie. Prolific and aggressive nonnative grasses and woody species should not constitute more than small patches within each high quality shortgrass prairie site and these undesirable species should not be spreading throughout the site or inhibiting growth and reproduction of ambrosia. Each ambrosia site should be managed and monitored appropriately to ensure the maintenance and restoration of high quality shortgrass prairie habitat and to minimize and control threats over a period of 20 years. (USFWS, 2018)

Recovery Priority Number: 8

**Delisting Criteria:**
Delisting Criteria 1: A minimum of 15 populations are necessary for delisting and should have at least 7,500-15,000 mature stems per population. Delisting may be possible if each of these populations remains stable or increasing over a period of 40 years. All extant populations, as well as any that are restored or created in the future, should remain secure. Also, a minimum of one natural population or genetically distinct population is extant within each drainage system (Oso, Chililpitin Creek-San Fernando, Alazan BayBaffin Bay, and Santa Getrudis Creek basins). (USFWS, 2018)

Delisting Criteria 2: At least seven of the populations that meet the delisting MVP minimum will be protected long-term (protection in perpetuity being optimum) via fee title acquisitions, conservation easements, or conservation agreements. These agreements will be between the USFWS, TPWD, or conservation organizations and landowners or land managers controlling areas with suitable habitat who carry out active management under USFWS-approved monitoring and management plans. See Downlisting Criteria 1 for a description of high-quality habitat. (USFWS, 2018)

**Recovery Actions:**
- 1. Habitat protection and management of all known population sites of South Texas Ambrosia in the United States. - Establish positive working relationships with landowners and land managers of all known sites. Maintain contact with all landowners or land managers each year. Educate landowners about the extreme rarity and significance of both the ecosystem and species on their property. Encourage the long-term stewardship of the shortgrass prairie at these sites through technical assistance to landowners; also potentially through long-term leases, conservation easements, and conservation agreements. - Cooperate with landowners and land managers to develop and implement management plans that address landowner and species goals. With willing landowners, determine short- and long-term land use goals and their effects on South Texas Ambrosia. With all cooperating landowners, develop and implement management plans that are beneficial to the species as well as acceptable to landowners and land managers. Develop a monitoring program that is reviewed by the USFWS and other interested parties, with voluntary

landowner assistance, to evaluate the effects of management practices on the species and ensure consistent and reliable monitoring of plant populations and management.  - Enforce applicable laws and regulations.  Work with regulatory agencies (DOD– NASK, TXDOT, TPWD, USDANRCS, and through internal USFWS coordination) to ensure that existing regulations are used to provide adequate protection of current habitat. (USFWS, 2018)

- 2. Monitor South Texas Ambrosia on an annual basis.  - Develop a monitoring plan for ambrosia. Monitoring plan will include population assessment and abundance measures to ascertain plant abundance and spread. Monitoring plan will include measurements of habitat conditions, ecological integrity, and conservation status of sites.  - Use the approved monitoring plans to annually monitor ambrosia, its habitat, management actions, and threats at extant sites.  - Monitor species and biotic communities and assess ecological integrity and conservation status of historic sites. (USFWS, 2018)
- 3. Initiate studies to gather biological information needed for effective management and recovery of ambrosia. - Determine specific habitat requirements (specifically limiting factors). Study soils and underlying geology. Determine the plant community structure for South Texas Ambrosia. Study community dynamics/ecology.  - Study population dynamics. Analyze the demographic structure of all populations. Characterize phenology and assess the most vulnerable stages of life cycle. Determine the primary means of reproduction in the wild. Study pollination biology and determine effective pollination requirements and effective pollinators. Study seed production and dispersal. Study seedling recruitment. Study population genetics to determine the genetic diversity within and among populations. (USFWS, 2018)
- 4. Survey for additional populations of ambrosia. As more information about the habitat and biology of the species becomes available, determining areas capable of supporting the species may be more predictable. Models, maps, and other tools will be developed showing the vegetative and edaphic characteristics of occupied sites. This information will help to determine where coastal shortgrass prairie habitats currently might remain intact and/or where the species could be located. These potential areas are a high priority to survey and engage in stewardship efforts. These surveys should be performed to locate existing and new populations and for use as potential reintroduction sites in Texas. (USFWS, 2018) (USFWS, 2018)
- 5. Cooperatively work with landowners and land managers to restore additional shortgrass prairie sites located in one or more of the drainage areas from which ambrosia is known to co-occur. (USFWS, 2018) (USFWS, 2018)
- 6. Establish seed or propagule banks and ex-situ (botanical garden, refugium, research institute, etc.) populations for the species. These banks and ex-situ populations will be established using approved reintroduction plans for South Texas Ambrosia (see Recovery Action 7 below). (USFWS, 2018)
- 7. Conduct a reintroduction program on public and private lands where there are willing partners. Evaluate and document the success of different cultivation techniques, site preparation, and other management techniques based on research, and assess any additional information necessary to attempt reintroduction. If reintroduction is feasible, a USFWS-approved Propagation and Reintroduction plan should be developed and implemented for ambrosia. This should provide for all phases of reintroduction, including site selection, site preparation, monitoring, and short- and long-term management strategies, particularly the effective management (eradication and prevention) of nonnative, invasive grass species. Reintroduced populations for South Texas Ambrosia should not be

considered successful until they are established, reproductively active, self-perpetuating, and demonstrated to be demographically and genetically viable. (USFWS, 2018)

- 8. Develop an education and outreach program. Develop any necessary educational or outreach materials. Provide educational and outreach materials to landowners and land managers. Provide educational and outreach materials to interested parties including agencies, engineering and consulting firms, developers, utilities, county road associations, and others.
- 9. Conduct Population Viability Analyses (PVA) and update the existing MVPs for the species based on current biological and ecological information. . Investigate South Texas Ambrosia' population genetics to ensure long-term persistence. Develop traditional MVP estimates for South Texas Ambrosia. Reassess the MVP size when new information is made available. (USFWS, 2018)
- 10. Review and track recovery. Maintain the STXPRT to help review the status of South Texas Ambrosia and assess the effectiveness of the management plans and other recovery tasks. Revise the Recovery Plan as appropriate. Develop a post-delisting monitoring plan when appropriate. (USFWS, 2018)
- The continued loss of habitat from invasive grasses exceeds impacts from all other currently known threats to A. cheiranthifolia in the extant populations in Nueces and Kleberg Counties. Evaluation of best management practices, including prescribed burns, grazing, and mowing, that will favor A. cheiranthifolia in these existing population sites is among the highest of priorities. Determining the best methods of controlling invasive plants, particularly introduced grasses, within A. cheiranthifolia populations is a critical need (USFWS, 2010).
- Further investigation of reproductive biology in wild populations is needed to ascertain if A. cheiranthifolia is reproducing sexually as well as vegetatively. Research is needed to describe pollination ecology and pollinator species of the plant. A thorough genetic analysis of A. cheiranthifolia, including a determination of the relatedness of subpopulations and populations, is needed to clarify the genetic diversity that exists within the species. New information collected on the genetics, pollinators, and dispersal of the species may help in understanding maximum or minimum distances between populations that would allow for transfer of genetic material (USFWS, 2010).
- Additional surveys for new populations of A. cheiranthifolia are needed in potential habitat areas in both counties, where permission to access land can be attained. Building good relationships with private landowners is a prerequisite to conducting these surveys. The Service, TPWD, and other partners should develop presentations and materials to share with landowners and their representatives that provide reassurance that threatened and endangered plants will not restrict land uses (USFWS, 2010).
- Soil analyses should be conducted at all known population sites. Soil analysis will help to elucidate the substrate that supports shortgrass prairie in the Texas Coastal Bend region. This would aid in focusing A. cheiranthifolia surveys as well as providing information needed to more fully understand habitat requirements for the shortgrass prairie species, including A. cheiranthifolia. A reintroduction plan for A. cheiranthifolia should be developed that identifies potential sites for both restoration and pilot introduction efforts (USFWS, 2010).
- Annual monitoring of existing populations should be undertaken to monitor status and trends and to evaluate condition of the plants and the habitat (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- The 2018 Recovery Plan includes actions that are needed to recover the South Texas ambrosia. The status of the species is still precarious, and we continue to recommend all the actions be implemented and that conservation partners actively seek funding to implement the actions

# SPECIES ACCOUNT: *Ambrosia pumila* (San Diego ambrosia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 7/2/2002; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

Ambrosia pumila is a clonal herbaceous perennial plant. Individual stems are generally 5 to 30 centimeters (cm) (2 to 12 inches (in)) tall, but may grow to 50 cm (20 in), and are densely covered with short hairs. The leaves are two to four times pinnately divided into many small segments and are covered with short, soft, gray-white, appressed (lying flat on surface) hairs. The species has separate male and female flowers on the same plant (monoecious). Male flowers have no petals, are yellow to translucent, and are borne in clusters on terminal flower stalks. Female flowers have no petals, are yellowish-white, and occur in clusters in the axils of the leaves below the male flower clusters (Nuttall 1840, pp. 344–345; Gray 1882, p. 217; Munz 1935, p. 544; Keck 1959, p. 1103; Ferris 1960, p. 148; Munz 1974, p. 112; Beauchamp 1986, p. 94; Payne 1993, p. 194) (USFWS, 2010).

**Taxonomy**

Ambrosia is a genus of 35 to 50 wind pollinated species of annuals and perennials in the Asteraceae (sunflower) family. The perennial taxa range from woody shrubs to herbaceous rhizomatous (possessing underground stems) taxa (USFWS, 1999).

**Historical Range**

Only known from southern San Diego County (Lake Hodges to the border) in the United States and from northern Baja California, Mexico (to Colonet acc. to Oberbauer or to El Arco acc. to Wiggins, or to 23 km south of Parador Catarina acc. to CNNDD), California. Also in Riverside County, California (Fish and Wildlife Service 1999) (NatureServe, 2015).

**Current Range**

Occurs in southern California from northwestern Riverside County, south through western San Diego County, to northwestern Baja California, Mexico (USFWS, 2010).

**Critical Habitat Designated**

Yes; 11/30/2010.

**Legal Description**

On November 30, 2010, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Ambrosia pumila (San Diego ambrosia) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in California (75 FR 74546-74604).

**Critical Habitat Designation**

The critical habitat designation for Ambrosia pumila includes six CHUs (including 12 sub-units) in Riverside and San Diego Counties, California. This species critical habitat encompasses approximately 783 acres (ac) (317 hectares (ha)) (75 FR 74546-74604).

Unit 1: Santa Ana River Watershed:  Unit 1 is located in western Riverside County and consists of two subunits totaling approximately, 26 ac (11 ha) of State or local government-owned land, and 85 ac (35 ha) of private land for a total of approximately 112 ac (45 ha) (values do not sum due to rounding). Subunit 1A: Alberhill Subunit 1A is located near Alberhill, north of Lake Elsinore and just west of Interstate Highway 15 in Riverside County, California. This subunit is near the northern base of Alberhill Mountain, and near the intersection of Lake Street and Temescal Canyon Road. Subunit 1A consists of approximately 23 ac (10 ha) of County-owned land, and 18 ac (7 ha) of privately owned land for a total of approximately 41 ac (17 ha). The approximately 23 ac (10 ha) of Countyowned land in Subunit 1A are conserved and currently managed by the Western Riverside County Regional Conservation Authority; transfer of ownership by the County of Riverside to the Western Riverside County Regional Conservation Authority is planned for the near future. This conserved area is not yet receiving active management. This subunit was occupied at the time of listing and remains occupied and, like all other extant occurrences, we also believe this subunit is essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 1A contains the physical and biological features essential to the conservation of Ambrosia pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and potentially periodic flooding presumed necessary for the plant’s persistence (PCE 1); and coastal sage scrub vegetation, which allows adequate sunlight and airflow for A. pumila (PCE 2). The PCEs in this subunit require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, and from human encroachment and development. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations. Subunit 1B: Nichols Road Subunit 1B is located about 2.1 mi (3.5 km) southeast of Subunit 1A (Alberhill), on the north and south sides of Nichols Road, in Riverside County, California. This subunit is near the southeastern base of Alberhill Mountain, just west of Durant Road and Temescal Creek. Subunit 1B consists of approximately 3 ac (1 ha) of State or local government-owned land, and 67 ac (27 ha) of privately owned land for a total of approximately 70 ac (29 ha) (values do not sum due to rounding). No lands in Subunit 1B are conserved or managed for biological resources. This subunit was occupied at the time of listing and remains occupied, and is essential to the conservation of this species because this subunit (along with Subunit 1A) represents the northernmost occurrences of this species, which is geographically situated to potentially assist this species expand its range northward. Like all other extant occurrences, this subunit is also essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). However, due to impacts from unauthorized grading and disking, and a permitted road realignment project, Ambrosia pumila within this subunit may be in imminent danger of extirpation. Subunit 1B contains physical and biological features that are essential to the conservation of A. pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant’s persistence (PCE 1), and ruderal habitat type, which allows adequate sunlight and airflow for A. pumila (PCE 2). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, and from activities (grading, construction, human encroachment) that occur in the area. Please see the Special Management Considerations or

Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations.

Unit 3: Santa Margarita River Watershed: Unit 3 is located in western Riverside County and consists of two subunits totaling approximately, 8 ac (3 ha) of State or local government-owned land, and 69 ac (28 ha) of private land for a total of 77 ac (31 ha). Subunit 3A: Santa Gertrudis Creek Subunit 3A is located about 1 mile (1.6 km) southwest of Unit 2, along the San Diego Aqueduct, south of the intersection of Chandler and Suzi Roads and north of Santa Gertrudis Creek in Riverside County. Subunit 3A consists of approximately 8 ac (3 ha) of Stateowned land and 25 ac (10 ha) of privately owned land for a total of approximately 33 ac (13 ha). No lands in Subunit 3A are conserved or managed for biological resources. This unit was occupied at the time of listing and remains occupied, and like all other extant occurrences, is essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 3A contains physical and biological features that are essential to the conservation of Ambrosia pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant’s persistence (PCE 1), and ruderal habitat type, which allows adequate sunlight and airflow for A. pumila (PCE 2). The physical and biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, human encroachment, and utility maintenance activities. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations. Subunit 3B: Murrieta Creek Subunit 3B is located in the City of Temecula in southwestern Riverside County, California. This subunit is near the western end of 1st Street, just west of Murrieta Creek. Subunit 3B consists of approximately 44 ac (18 ha) of privately owned land. No lands in Subunit 3B are conserved or managed for biological resources. This subunit meets the definition of critical habitat for this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 3B contains physical and biological features that are essential to the conservation of Ambrosia pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant’s persistence (PCE 1), and nonnative grassland habitat type, which allows adequate sunlight and airflow for A. pumila (PCE 2). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, from human foot and vehicle traffic that may occur in the area, and from development. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations.

Unit 4: San Luis Rey River Watershed: Unit 4 is located in northwestern San Diego County and consists of four subunits of approximately 17 ac (7 ha) of State or local government-owned land and approximately 74 ac (30 ha) of privately owned land, for a total of approximately 91 ac (37 ha). Subunit 4A: Calle de la Vuelta Subunit 4A is located near junction of State Route 76 and Calle de la Vuelta in unincorporated San Diego County. Subunit 4A consists of approximately 0.8 ac (0.3 ha) of State or local government-owned land and 14 ac (6 ha) of privately owned land, for a total of approximately 15 ac (6 ha). No lands in Subunit 4A are conserved or managed for biological resources. This subunit was occupied at the time of listing and, like all other extant occurrences, we also believe this subunit is essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 4A contains physical and biological features that are essential to the conservation of Ambrosia pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant's persistence (PCE 1), and ruderal vegetation, which allows adequate sunlight and airflow for A. pumila (PCE 2). The PCEs in this subunit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, human encroachment, road maintenance activities, and future widening of State Route 76. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations. Subunit 4B: Olive Hill Road Subunit 4B is located on the west side of State Route 76, south of Olive Hill Road in unincorporated San Diego County. Subunit 4B consists of approximately 16 ac (6 ha) of State or local government-owned land and approximately 8 ac (3 ha) of privately owned land, for a total of approximately 23 ac (9 ha) (values do not sum due to rounding). No lands in Subunit 4B are conserved (a portion of Subunit 4B is within the Groves mitigation preserve, managed by the California Department of Transportation (Caltrans); this area has not yet been conserved). The occurrence in this subunit was erroneously considered extirpated at the time of listing, but has since been found to be extant. Like all other extant occurrences, we also believe this subunit is essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 4B contains physical and biological features that are essential to the conservation of Ambrosia pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and flooding presumed necessary for the plant's persistence (PCE 1), and grassland vegetation which allow adequate sunlight and airflow for A. pumila (PCE 2). The PCEs in this subunit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, human encroachment, road maintenance activities, and future widening of State Route 76. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations. Subunit 4C: Jeffries Ranch Subunit 4C is located approximately 0.7 mi (1 km) southwest of Bonsall Bridge, adjacent to the south side of State Route 76 in the City of Oceanside, San Diego County. Subunit 4C consists of approximately 0.1 ac (0.05 ha) of State or local government-owned land and approximately 33 ac (13 ha) of privately owned land for a total of approximately 33 ac (13 ha). No lands in Subunit 4C are conserved. This subunit was occupied at the time of listing and, like all other extant occurrences, we believe this subunit is essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 4C contains physical and biological features that are essential to the conservation of Ambrosia pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant's persistence (PCE 1), and nonnative grassland vegetation, which allows adequate sunlight and airflow for A. pumila (PCE 2). The PCEs in this subunit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, human encroachment, road and utility maintenance activities, future widening of State Route 76, and potential development. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations. Subunit 4D: Gird/Monserate Hill Subunit 4D is located in the Fallbrook area of northern San Diego County, California. This subunit is adjacent to the north side of State Route 76, almost equidistant from Gird Road (to the west) and Monserate Hill Road (to the east). Subunit 4D consists of 0.7 ac (0.3 ha) of State-owned land and 20 ac (8 ha) of privately owned land, for a total of 21 ac (9 ha) (values do not sum due to rounding). No lands in Subunit 4D are conserved or managed for biological resources. This subunit was occupied at the time of listing and, like all other extant occurrences, we believe this subunit is also essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 4D contains physical and biological features that are essential to the conservation of A. pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant's persistence (PCE 1); and nonnative grassland vegetation, which allows adequate sunlight and airflow for A. pumila (PCE 2). The PCEs in this subunit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, from human encroachment that may occur in the area, and from development and road maintenance. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations.

Unit 5: San Dieguito River Watershed— Lake Hodges: Unit 5 is located in central San Diego County and consists of two subunits comprised of approximately 129 ac (52 ha) of State or local government-owned land and approximately 121 ac (49 ha) of privately owned land, for a total of approximately 249 ac (101 ha) (values do not sum due to rounding). This total does not include a portion of Subunit 5B (52 ac (21 ha)) that we have excluded from this designation under section 4(b)(2) of the Act (see the Exclusions under Section 4(b)(2) of the Act section of this rule). Subunit 5A: Lake Hodges East (Via Rancho Pkwy) Subunit 5A is located on the west side of Interstate 15, just north of Lake Hodges and south of Via Rancho Parkway in San Diego County. Subunit 5A consists of approximately 16 ac (6 ha) of State or local government owned land and approximately 5 ac (2 ha) of privately owned land, for a total of approximately 21 ac (9 ha) (values do not sum due to rounding). No lands in Subunit 5A are conserved or managed for biological resources. This subunit was occupied at the time of listing and, like all other extant occurrences, we also believe this subunit is essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 5A contains physical and biological features that are essential to the conservation of Ambrosia pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant's persistence (PCE 1), and nonnative grassland vegetation, which allows adequate sunlight and airflow for A. pumila (PCE 2). The PCEs in this unit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, human encroachment, utility maintenance activities, and potential development. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations. Subunit 5B: Lake Hodges West—Crosby Estates Subunit 5B is located just west of Lake Hodges in the western portion of central San Diego County, California. This subunit is on and adjacent to the west side of the Crosby National Golf Club. Subunit 5B consists of approximately 113 ac (46 ha) of State or local government owned land, 115 ac (47 ha) of privately owned land for a total of approximately 228 ac (92 ha) (values do not sum due to rounding). This subunit meets the definition of critical habitat for this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 5B contains physical and biological features that are essential to the conservation of Ambrosia pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant's persistence (PCE 1), and nonnative grassland habitat type, which allows adequate sunlight and airflow for A. pumila (PCE 2). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, from human encroachment that may occur in the area, and from golf course maintenance. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations.

Unit 6: San Diego River Watershed— Mission Trails Regional Park:  Unit 6 is located in Mission Trails Regional Park in the City of San Diego. Unit 6 consists of approximately 6 ac (3 ha) of State or local government owned land, and approximately 32 ac (13 ha) of privately owned land, for a total of 38 ac (15 ha) (values do not sum due to rounding). This total does not include a portion of Unit 6 (160 ac (65ha)) that we have excluded from this designation under section 4(b)(2) of the Act (see the Exclusions under Section 4(b)(2) of the Act section of this rule). This unit was occupied at the time of listing and remains occupied, and like all other extant occurrences, is essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Unit 6 contains physical and biological features that are essential to the conservation of A. pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant's persistence (PCE 1), and nonnative grassland habitat type, which allows adequate sunlight and airflow for A. pumila (PCE 2). The physical and biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, and human encroachment. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations.

Unit 7: Sweetwater River Watershed:  Unit 7 is located in southwestern San Diego County and consists of three subunits containing approximately 146 ac (60 ha) of federally owned land (San Diego National Wildlife Refuge), approximately 13 ac (5 ha) of State or local government owned land, and approximately 57 ac (23 ha) of privately owned land, for a total of approximately 215 ac (87 ha) (values do not sum due to rounding). Subunit 7A: Jamul Road Subunit 7A is located southeast of the City of El Cajon at and near junction of Jamul Road and Steele Canyon Road, on the north and south sides of Jamul Road. Subunit 7A consists of approximately 3 ac (1 ha) of State or local government owned land, and approximately 36 ac (15 ha) of privately owned land, for a total of approximately 39 ac (16 ha). No lands in Subunit 7A are conserved or managed for biological resources. This subunit was occupied at the time of listing and remains occupied. This subunit, like all other extant occurrences, is essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 7A contains physical and biological features that are essential to the conservation of A. pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant's persistence (PCE 1), and nonnative grassland habitat type, which allows adequate sunlight and airflow for A. pumila (PCE 2). The physical and biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, alterations of site hydrology, and offhighway vehicle use. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations. Subunit 7B: San Diego National Wildlife Refuge (SDNWR) Subunit 7B is located on the San Diego National Wildlife Refuge, south of Sweetwater River between Rancho San Diego Golf Course and the hills to the south, and on the north and south sides of a dirt trail adjoining the end of Par Four Drive in unincorporated San Diego County. Subunit 7B consists of approximately 118 ac (48 ha) of Federal land owned and managed by the Service, and approximately 15 ac (6 ha) of privately owned land, for a total of approximately 133 ac (54 ha). No private lands in Subunit 7B are conserved or managed for biological resources. This subunit was occupied at the time of listing and, like all other extant occurrences, we also believe this subunit is essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329 see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 7B contains physical and biological features that are essential to the conservation of A. pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and periodic flooding presumed necessary for the plant's persistence (PCE 1), and nonnative grassland vegetation, which allows adequate sunlight and airflow for A. pumila (PCE 2). The PCEs in this subunit may require continued management and protection on federally owned lands to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, and human encroachment. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations. Subunit 7C: Steele Canyon Bridge Subunit 7C is located mainly on the east side of State Route 94 on a slope between a concrete-lined ditch and a fence adjacent and parallel to State Route 94, approximately 0.7 mi (1.1 km) southeast of Subunit 7B, in unincorporated San Diego County. A small portion of the subunit is located on the opposite side of State Route 94 just south of Steele Canyon Bridge in a split-rail exclosure. Subunit 7C consists of approximately 28 ac (11 ha) of federally owned land managed by the Service, approximately 10 ac (4 ha) of State or local government owned land, and approximately 6 ac (2 ha) of privately owned land, for a total of approximately 44 ac (18 ha) (values do not sum due to rounding). No private or state/local government owned lands in Subunit 7C are conserved or managed for biological resources. This subunit was occupied at the time of listing and, like all other extant occurrences, we also believe this subunit is essential to the conservation of this species because of its contribution to the genetic diversity of the species (McGlaughlin and Friar 2007, p. 329; see Genetics section of the proposed rule (74 FR 44241, August 27, 2009)). Subunit 7C contains physical and biological features that are essential to the conservation of Ambrosia pumila, including sandy loam or clay soils located on an upper terrace of a water source, which provide nutrients, moisture, and flooding presumed necessary for the plant's persistence (PCE 1), and nonnative grassland vegetation, which allows adequate sunlight and airflow for A. pumila (PCE 2). The PCEs in this subunit may require continued management and protection on federally owned lands to address threats from nonnative plant species in situations where nonnative species are outcompeting A. pumila for resources, and human encroachment. Please see the Special Management Considerations or Protection section of this rule for a discussion of the threats to A. pumila habitat and potential management considerations.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Ambrosia pumila critical habitat consists of two components (75 FR 74546-74604):

(i) PCE 1—Sandy loam or clay soils (regardless of disturbance status), including (but not limited to) the Placentia (sandy loam), Diablo (clay), and Ramona (sandy loam) soil series that occur on or near (up to several hundred meters from but not directly adjacent to) a river, creek, or other drainage, or within the watershed of a vernal pool, and that occur on an upper terrace (flat or gently sloping areas of 0 to 42 percent slopes are typical for terraces on which Ambrosia pumila occurrences are found).

(ii) PCE 2—Grassland or ruderal habitat types, or openings within coastal sage scrub, on the soil types and topography described in PCE 1, that provide adequate sunlight, and airflow for wind pollination.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the occupied areas contain the physical and biological features that are essential to the conservation of the species, and whether these features may require special management considerations or protection. The area designated as critical habitat will require some level of management to address the current and future threats to the physical and biological features essential to the conservation of the species. In all units, special management will be required to ensure that the habitat is able to provide for the growth and reproduction of the species. Records indicate that Ambrosia pumila historically was known from over 50 locations in San Diego and Riverside counties, but the number of extant occurrences has been dramatically reduced because much of the species' habitat has been impacted by human activities (Burrascano and Hogan 1997, p. 7; Dudek 2000, p. 17; CNDDB 2010). A detailed discussion of threats to A. pumila and its habitat can be found in the final listing rule (67 FR 44372, July 2, 2002). The features essential to the conservation of A. pumila require special management considerations or protection to reduce the following threats, among others:
• Habitat destruction caused by urban development, including highway and utility corridor construction and maintenance, highway expansion, and development of recreational facilities (such as golf courses and campgrounds). These activities can destroy the PCEs by removing or compacting soil, making habitat unsuitable for Ambrosia pumila. • Soil compaction caused by the creation and use of trails by hikers, horses, and vehicles. Ambrosia pumila appears to be tolerant to some level of disturbance caused by trail creation and use; it is often found in the disturbed areas along margins of dirt trails. However, it is found less often in trailways, implying that although the appropriate soil type might be present, soil compaction can alter soil physical characteristics such that the soil can no longer support plant growth (PCE 1). • Habitat alteration caused by invasion of nonnative plant species that may, if present in large enough numbers,

change the plant assemblage or cover density to the extent that Ambrosia pumila plants can no longer receive adequate sunlight and airflow (PCE 2). • Alteration of hydrological and floodplain dynamics, such as channelization and water diversions, (an additional threat not discussed in the listing rule), which can change the frequency of flooding in occupied areas or eliminate natural periodic flooding presumed necessary for the plant's longterm persistence (PCE 1). Special management considerations or protection are required within critical habitat areas to address these threats. Management activities that could ameliorate these threats include fencing Ambrosia pumila occurrences and providing signage to discourage encroachment by hikers, horses, and offroad vehicle users; control of nonnative plants using methods shown to be effective (for examples, see CNLM 2008); guiding the design of development projects to avoid impacts to A. pumila habitat; and restoring and maintaining natural hydrology and floodplain dynamics of waterways associated with A. pumila occurrences where feasible. These management activities will help protect the PCEs for the species by reducing soil compaction (PCE 1), lowering the density of nonnative plants thereby maintaining the appropriate community structure (PCE 2), and maintain periodic flooding of A. pumila habitat where possible (PCE 1).

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Vegetative, presumed self-pollination, sexual (USFWS, 2010)

**Lifespan**

Adult: Unknown - presumed long-lived (USFWS, 2010)

**Breeding Season**

Adult: May - October (USFWS, 2010)

**Key Resources Needed for Breeding**

Adult: Winter rains, presumed wind-pollinated (USFWS, 2010)

**Reproduction Narrative**

Adult: Ambrosia pumila spreads vegetatively by means of slender, branched, underground root-like rhizomes from which new aboveground stems (aerial stems or ramets) arise each year (Nuttall 1840, p. 344; Munz 1974, p. 112; Payne 1993, p. 194). Aerial stems of Ambrosia pumila sprout from their underground rhizomes in early spring after winter rains, and flower between May and October (Keck 1959, p. 1103). However, aerial stems have been observed sprouting under dry conditions in late fall (A. Folarin, USFWS, 2008, pers. obs.). Ambrosia pumila is presumed to be wind-pollinated because most other species of Ambrosia are wind pollinated, and because biological pollinators have not been observed visiting A. pumila flowers (Johnson et al. 1999, p. 4; Dudek 2000, p. 16; Dudek 2003, p. P-331). Alternatively, pollinator(s) of A. pumila may have been extirpated (Dudek 2003, p. P-331). The species is presumed to be capable of self-pollination and of being self-fertile (i.e., self-compatible, where pollen from an individual plant can fertilize an ovule on the same plant, resulting in production of viable seed), because other species of Ambrosia are capable of self-pollination (Payne 1976, pp. 171–172). Ambrosia pumila is thought to have limited sexual reproductive output due to low production of viable seed

(Johnson et al. 1999, pp. 1–5; Dudek 2000, pp. 16–17; Dudek 2003, pp. P-331–P-332). Low seed production in this species is inferred by the lack of fertile fruits on all but a few preserved A. pumila museum specimens (G. Wallace, USFWS, 1999, pers. obs.), and field observers have found seed production in A. pumila to be low (Dudek 2000, p. 17; Dudek 2003, p. P-332). The longevity of individual plants is also unknown, although plants with clonal growth patterns tend to be long-lived (Watkinson and White 1985, pp. 44–45; Tanner 2001, p. 1980) (USFWS, 2010).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015); riparian (USFWS, 2010)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal scrub, grasslands, open floodplains (NatureServe, 2015); vernal pool (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs at ~600 ft. or ~1,600 ft. elevation (USFWS, 2010)

**Spatial Arrangements of the Population**

Adult: Colonial (USFWS, 2010)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2010)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from USFWS, 2010)

**Habitat Narrative**

Adult: Coastal scrub, grasslands, open floodplains and low valley bottoms below 150 m. Persists where disturbance has been superficial (NatureServe, 2015). The species is found primarily on upper terraces of rivers and drainages; however, several patches of the plant occur within the watershed of a large vernal (ephemeral) pool at the Barry Jones (Skunk Hollow) Wetland Mitigation Bank in Riverside County. It is generally found at or below elevations of 487 meters (m) (1,600 feet (ft.)) in Riverside County, and 183 m (600 ft.) in San Diego County (CNDDB 2010). Because of the clonal nature of Ambrosia pumila's growth, it is not possible to directly determine the number of genetically distinct plants (genets) present in an area simply by counting stems (McGlaughlin and Friar 2007, p. 320). The species is found primarily on sandy loam or clay soils (Johnson et al. 1999, p. 1; Dudek 2000, p. 18; CNDDB 2010; USDA 2008). The species may also be found in ruderal habitat types (disturbed communities containing a mixture of native and nonnative grasses and forbs) such as fire fuel breaks and edges of dirt roadways (Beauchamp 1986, p. 94; Payne 1993, p. 194; CNDDB 2010), however nonnative plants can out-compete A. pumila plants for resources in some situations. Ambrosia pumila consistently occurs in areas near waterways such as upper terraces of rivers or other water bodies. These areas do not necessarily provide high levels of soil moisture, and A. pumila is adapted to dry conditions (Keck 1959, p. 1103; Munz 1974, p. 112; Dudek 2000, Appendix A; CNLM 2008, p. 18) (USFWS, 2010).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: The dispersal strategy of Ambrosia pumila is unknown. Ambrosia pumila seeds lack structures that facilitate dispersal by wind or passing animals (Nuttall 1840, p. 344; Payne 1993, p. 194). The species may depend on periodic flooding of nearby waterways for dispersal of seeds and rhizomes that can produce new aerial stems (Dudek 2003, p. P- 332) (USFWS, 2010).

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

37 extant or presumed extant including translocations (USFWS, 2021)

**Population Size:**

Unknown (USFWS, 2010)

**Adaptability:**

Low (inferred from USFWS, 2010)

**Population Narrative:**

Reduced sexual reproduction may negatively impact the ability of the species to adapt to rapid environmental change or environmental change over the long term, which is especially deleterious to a rare species with disjunct occurrences such as A. pumila (Dudek 2000, p. 17; Dudek 2003, p. P-332). There are 16 extant native occurrences. Because of the clonal nature of Ambrosia pumila's growth, it is not possible to directly determine the number of genetically distinct plants (genets) present in an area simply by counting stems (McGlaughlin and Friar 2007, p. 320). Number of stems/patches visible each year may vary due to environmental factors (e.g., rainfall or temperature), and reliable, precise stem counts are not often available for occurrences (USFWS, 2010). Payne (1976) notes that self-pollination and self-fertility contribute strong inbreeding, as does seed longevity (USFWS, 1999).

***Threats and Stressors***

**Stressor:** Development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat loss associated with development is the result of destruction and modification of Ambrosia pumila habitat (associated soils and plant community) due to filling, grading, discing, construction, landscaping, and other activities. Urban development has displaced habitat supporting one occurrence of A. pumila since the species was listed in 2002, and will soon displace habitat supporting another. Of the 16 currently known extant occurrences of A. pumila, 7 are conserved or partially conserved. The remaining 9 of 16 occurrences are not conserved and are more vulnerable to habitat loss from urban development (USFWS, 2010).

**Stressor:** Nonnative plants (USFWS, 2010)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Nonnative plants continue to encroach upon Ambrosia pumila populations and pose a significant threat to the species throughout its range (CNDDB 2010; CNLM 2009, p. 3; Folarin, 2008, 2009, pers. obs.). Since listing, no research has been done to clarify the specific effects of nonnative plants on A. pumila. A recent study by CNLM demonstrated that reduction of nonnatives increases percent cover of A. pumila (CNLM 2008, p. 5; 2009, pp. 8 - 9) (USFWS, 2010).

**Stressor:** Fuel modification (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Weed abatement, fire suppression, and landscaping practices (including mowing, discing, and plowing) are fuel modification activities that were recognized as a threat to several occurrences of Ambrosia pumila in the listing rule. Mowing A. pumila plants, if done in midsummer to early fall, can remove flowering portions of the aerial stems, thus decreasing or preventing seed output. Mowing stems at other times may reduce the vegetative vigor of the plants. Discing, grading, or plowing occupied areas can break apart stems and rhizomes and leave rhizomes vulnerable to desiccation, potentially killing plants. Grading can also remove stems and rhizomes from a site completely (USFWS, 2010).

**Stressor:** Recreation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Human encroachment into Ambrosia pumila habitat on foot, bicycles, or horses can result in trampling of A. pumila stems along often-used trails (Dudek 2000, p. 20). Trampling and soil compaction were identified in the listing rule as a significant threat to A. pumila, affecting the species through direct destruction of stems and affecting its habitat by reducing percolation of water into the soil. The effects of soil compaction on A. pumila are not known (USFWS, 2010).

**Stressor:** Fragmentation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Most occurrences of Ambrosia pumila are patchy in nature, composed of a few to numerous smaller groups of aerial stems (McGlaughlin and Friars 2007, p. 319). While some of this patchiness may be inherent to the growth habit of the species, many occurrences are also fragmented by development activities, competition by nonnative plants, and human encroachment (CNDDB 2010). The creation and continued use of paths through occurrences of A. pumila has been a major source of fragmentation. Fragmentation of Ambrosia pumila occurrences could diminish the efficacy of wind pollination or biological pollinators by increasing the between-population distances (USFWS, 2010).

**Stressor:** Altered hydrology (USFWS, 2010)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Ambrosia pumila occurrences are almost always found on the upper terraces of rivers/streams or near the margins of vernal pools, where under natural conditions they would likely be subjected to inundation during large-scale flooding events (McGlaughlin and Friars 2007, p. 320). If A. pumila is dependent on these periodic flooding events for some aspect of its life history (e.g., seed germination, dispersal) or control of competing plants, altering the flooding regimes of associated waterways or vernal pools could have a significant impact on the species. However, since the Service is unsure if or to what degree A. pumila is dependent upon periodic flooding or other aspects of its proximity to waterways, it is unknown to what degree altering the hydrology of adjacent waterways would impact the species (USFWS, 2010).

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, it has become apparent that there is potential for threats to biota from ongoing accelerated climate change (IPCC 2007). The impacts of local climatic shifts on populations of native and nonnative plants that compete with Ambrosia pumila and the interaction of these shifts with other ongoing threats are as yet unmeasured. Habitat conditions altered as a result of climate change impacts could favor invasive nonnative plants, which could then out-compete A. pumila for resources. Climatic change could also impact hydrological systems on which the species may depend. While the Service recognizes that climate change is an important issue with potential effects to listed species and their habitats, the Service lacks adequate information at this time to make accurate predictions regarding its effects to particular species and habitats, including A. pumila (USFWS, 2010).

***Recovery***

**Reclassification Criteria:**
Not available - this species does not have a recovery plan

Recovery Priority Number: 11C

**Delisting Criteria:**
Not available - this species does not have a recovery plan

**Recovery Actions:**
- Not available - this species does not have a recovery plan
- Identify opportunities through the Service's Partners for Fish and Wildlife Program to seek habitat restoration and enhancement opportunities (USFWS, 2010).
- Work with partners to implement nonnative plant control methods such as those demonstrated effective by CNLM's 2008 study (USFWS, 2010).
- Work within the Service and with outside researchers to design studies aimed at gaining insight into sensitive aspects of the biology and life history of Ambrosia pumila (USFWS, 2010).
- Conduct field surveys to verify persistence of occurrences that are in question and accurately map extant occurrences (USFWS, 2010).

- Determine whether a program to propagate Ambrosia pumila in greenhouses and outplant the resulting plants in unoccupied areas would be biologically sound and feasible (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed below are to be completed over the next 5 years. Successful implementation of these actions will reduce threats to Ambrosia pumila. We recognize that conservation of this taxon will require cooperation and coordination with partners to minimize impacts from current threats and aid with future restoration efforts. 1. Develop a habitat suitability model and conduct surveys on potentially suitable habitat to inform our understanding of the species distribution, as new occurrences continue to be recorded in both the United States and Mexico. 2. Work with partners to secure conservation of the occurrences that currently receive no protection. 3. Work with partners to manage occurrences to support the long-term viability of the species including nonnative plant control and identifying opportunities through the Service's Partners for Fish and Wildlife Program to seek habitat restoration and enhancement opportunities. 4. Conduct research on the biology and life history of Ambrosia pumila to understand the factors that contribute to the production of viable seed and the role of sexual reproduction in maintaining resilient populations such as confirming the pollination mechanism, testing for self-compatibility, seed germination requirements, mechanism of seed dispersal, and seed viability. This will assist in identifying reasons for the persistence of certain occurrences and actions needed to help conserve others. 5. Develop a translocation program that details successful approaches, greenhouse techniques for propagation and identifies potential sites for translocation within a genetic framework. The plan should maximize redundancy in terms of the geographic locations and number of occurrences to be established. (USFWS, 2021)

# SPECIES ACCOUNT: *Amorpha crenulata* (Crenulate lead-plant)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 08/19/1985; Southeast Region (R4)

**Physical Description**

The crenulate lead-plant is a rhizomatous, perennial, deciduous shrub that grows to 1.5 m in height. The branches are red/purple, and contain 25 to 33 leaflets borne on leaves that are 0 to 15 centimeter (cm) long, with petioles 1 cm long or less. The crenulate leaflets are gray and green above, paler and glandular dotted below, and 5 to 11 cm long. The racemes are terminal, 15 to 20 cm long, solitary, or in clusters of two to three. The 8 millimeter (mm)-long flowers are held in loose clusters. The calyx is dark green or purplish, 3.2 to 4.0 mm long with the upper half glandular dotted. The showy white standard flower is 5.2 mm long and 4.2 mm wide with long exerted stamens. The fruit is 6 to11 mm long, laterally compressed, and glandular dotted on the upper two-thirds. The seeds produced in the fruit are 5 mm long and compressed. (USFWS, 1999)

**Taxonomy**

The crenulate lead-plant was described by Rydberg in 1919, citing his type specimen as J.K. Small and Percy Wilson #1898, May 9, 1904, In hammocks, between Coconut Grove and Cutler (New York Botanical Garden herbarium). Small (1933) followed this treatment. Isley (1986, 1990) argues that A. crenulata is an isolated variant of A. herbacea, distinguished only by the presence of crenulate leaf margins. He published the new combination as A. herbacea Walt. var. crenulata (Rydberg) Isley (Isley 1986). Synonyms: Amorpha crenulata Rydberg, A. herbacea auct. non. Walt. (USFWS, 1999)

**Historical Range**

The historical range of Amorpha crenulata encompasses only a 20 square-mile (52 km2) area from Coral Gables to Kendall (Service 1999) within Miami-Dade County, Florida. (USFWS, 2019)

**Current Range**

The current range of Amorpha crenulata encompasses only a 20 square-mile (52 km2) area from Coral Gables to Kendall (Service 1999) within Miami-Dade County. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Little is known of the life history of crenulate lead-plant. In two years of life history monitoring of one population, no seedlings were observed. Plants showed little to no growth and flowered primarily following human disturbance. Crenulate lead-plant is semi-deciduous, about 70 percent of plants losing most or all leaves between December and February. Pollinators or dispensers have not been observed (DERM 1993). New sprouts, when observed, have been identified as primarily adventitious roots (DOT 1997). In addition, the viability of germplasm is not known (DOT 1997). This species is relatively easy to cultivate, indicating that the lack of reproduction in the wild may not be due to a lack of viable seeds (A. Herndon, personal communication 1998). (USFWS, 1999)

**Habitat Type**

Adult: Pine rocklands

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 1999)

**Habitat Narrative**

Adult: The crenulate lead-plant occurs in plant communities that were historically associated with seasonally hydrated soils and frequent burning, including wet pinelands, transverse glades, and hammock edges. It can be found growing in poorly-drained Opalocka sands within pine rocklands or in wet prairies with Opalocka-rock outcrop complex soils. It requires open sun to partial shade. The type specimen (Small and Wilson #1898) cites the habitat as "In hammocks." No recent collections have been seen from within hardwood hammocks. Many of Small's specimen labels were pre-printed with habitat data and some species were collected and labeled as occurring in hammocks that were actually collected in habitats outside hammocks. It may be that crenulate lead-plant was never collected in hammocks. (USFWS, 1999)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

5 populations (USFWS, 2019)

**Population Size:**

~ 650 individuals (USFWS, 2019)

**Population Narrative:**

The current and historical range of Amorpha crenulata encompasses only a 20 square-mile (52 km2) area from Coral Gables to Kendall (Service 1999) within Miami-Dade County. Two of the four known historical A. crenulata populations (Matheson Hammock and Coral Pines Parks) are extirpated. Five A. crenulata populations, including three that are reintroduced, remain. The total population size of A. crenulata is approximately 649 individuals (Possley, Fairchild Tropical Botanic Gardens [FTBG], pers. comm. 2017a; Lange, FTBG, pers. comm. 2017; Lange et al. 2018). (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat loss and fragmentation
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** The pine rockland community of south Florida is critically imperiled globally (FNAI 2010b). In Miami-Dade County, development and agriculture have reduced pine rockland habitat by 90 percent. Continued habitat loss (Factor A) and fragmentation threaten the existence of this species, and less than 1 percent of the original acreage of pine rockland habitat remains outside of Everglades National Park (Herndon 1998). Populations on private sites remain threatened with destruction or habitat modification due to improper or lack of management (Factors A and E). (USFWS, 2019)

**Stressor:** Indequacy of existing regulatory mechanisms
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, regulatory mechanisms (Factor D) provide limited protections for this species. The Florida Department of Agriculture and Consumer Services designated these species as endangered under Chapter 5B-40, Florida Administrative Code. This law regulates the taking, transport, and sale of listed plants. This law does not prohibit private property owners from destroying listed plants, nor does it require them to manage habitats to maintain populations. The Natural Forest Communities (NFC) program was established by Miami-Dade County to encourage but not require private landowners to protect forested lands by making it necessary to apply for a permit with the County prior to working in designated NFCs (i.e., pinelands, hammocks). (USFWS, 2019)

**Stressor:** Inadequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire suppression continues to affect Amorpha crenulata(Factor E). Historically, frequent (approximately twice per decade), lightning-induced fires were a vital component in maintaining native vegetation and ecosystem functioning within south Florida pine rocklands. A period of just 10 years without fire may result in a marked decrease in the number of herbaceous species due to the effects of shading and litter accumulation (FNAI 2010b). The majority of extant populations of this species is affected by some degree of inadequate fire management, with the primary threat being shading by hardwoods (Bradley and Gann 1999; Bradley and Gann 2005). (USFWS, 2019)

**Stressor:** Nonnative invasive plants
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasion by exotic plant species continue to affect Amorpha crenulata (Factor E). Nonnative invasive plants compete with native plants for space, light, water, and nutrients, and make habitat conditions unsuitable for this species, which prefers open conditions (Factor E). Bradley and Gann (1999) indicated that the control of nonnative plants is one of the most important conservation actions for the pine rockland species and a critical part of habitat maintenance. Nonnative plants have significantly affected pine rocklands and negatively impacted all occurrences of this species to some degree (Bradley and Gann 1999; Bradley 2006; Bradley and Saha 2009; Bradley and van der Heiden 2013). (USFWS, 2019)

*Recovery*

**Reclassification Criteria:**
Not developed (USFWS, 1999; USFWS, 2010)

Recovery Priority Number: 5C

**Delisting Criteria:**
1. Existing natural populations achieve and maintain a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factors A and E) (USFWS, 2019)

2. A network of 5 new populations are either discovered or reintroduced that exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factors A and E) (USFWS, 2019)

3. All populations (criteria 1 and 2) are protected by a conservation mechanism. (addresses Factors A, D, and E) (USFWS, 2019)

4. Threats have been reduced or eliminated to the degree that this species will remain viable for the foreseeable future. (addresses Factors A, D, and E) (USFWS, 2019)

**Recovery Actions:**

- Conduct surveys to determine distribution of crenulate lead-plants. Crenulate lead-plants on county-owned pine rockland sites have been thoroughly surveyed in Miami-Dade County. However, other populations may be noted during pine rockland purchase and restoration program implementation. Fire may eliminate litter concealing listed species, or enable seeds in the seed bank to germinate. For that reason, pine rocklands that did not contain listed species when unmanaged should be resurveyed after fire events. (USFWS, 1999)
- Protect and enhance existing populations. It is imperative for the stabilization of crenulate leadplants that additional populations not be lost. The existing populations should be mapped, including obtaining GPS coordinates and developing GIS coverage. Herbarium voucher specimens should be collected and archived for all populations. (USFWS, 1999)
- Collect biological information important to species recovery. Additional information on the ecology and life history of pine rockland plants needs to be collected. Determine size and viability of all populations. Known populations of the listed pine rockland plants should be evaluated. Population viability needs to be investigated and determined for each listed plant species. (USFWS, 1999)
- Develop standardized monitoring. Standardized monitoring based upon the protocols developed by FNAI should be used for pine rockland species in order to determine the effect of management actions on these species and make the date compatible to existing databases. (USFWS, 1999)
- Continue to provide public information about pine rocklands and their unique flora. Public support will increase the chances of recovery for pine rockland species. Informational and educational materials have been produced. DERM and Miami-Dade County Parks and Recreation Department's Natural Areas Management have developed flyers, displays, newsletters, and press releases, and have held workshops with the general public. Organizations best able to carry out information and education programs include Metropolitan Miami-Dade County Parks and Recreation Department, the Florida Native

Plant Society, Everglades National Park, and Miami-Dade County DERM. Support of local press coverage should continue. DERM has developed a web page that will also aid in disseminating information about this endangered plant community to the public. (USFWS, 1999)

- Habitat-Level Recovery Actions: Develop a GIS database on all listed pine rockland species and their habitats, and distribute the database to researchers, land managers, and conservationists. Continue to protect and prevent degradation of pine rockland plant habitat. Restore areas to suitable habitat. Monitor habitat and ecological processes. Continue implementation of the fire education program and modify as necessary any fire management education program that has been developed. (USFWS, 1999)

# SPECIES ACCOUNT: *Amsinckia grandiflora* (Large-flowered fiddleneck)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 6/7/1985; Pacific Southwest (R8)

**Physical Description**

An annual dicot herb. Flowers are red-orange, 14-20mm. Fruit is smooth and shiny. (NatureServe, 2015). This annual species has bright, red-orange, trumpet-shaped flowers arranged in a fiddleneck-shaped inflorescence. Its bright green foliage is covered with coarse, stiff hairs (USFWS, 2009).

**Taxonomy**

Amsinckia grandiflora (large-flowered fiddleneck) is an herbaceous plant in the Boraginaceae (borage family) (USFWS, 2009).

**Historical Range**

Historically, A. grandiflora ranged from northern Contra Costa County, California, at the San Joaquin River Delta, south to Corral Hollow and adjacent areas in San Joaquin County (USFWS, 2009). The full range encompasses about 550 square miles, though much of that is either extirpated or poor introduction sites today (NatureServe, 2015).

**Current Range**

Currently, A. grandiflora is only found in two reintroduced locations, one at Site 300 in southwestern San Joaquin County and the second at Lougher Ridge in Contra Costa County (USFWS, 2009).

**Critical Habitat Designated**

Yes; 6/7/1985.

**Legal Description**

On May 8, 1985, the Service designated critical habitat (effective June 7, 1985) for Amsinckia grundiflora (large-flowered fiddleneck) (50 FR 19374 - 19378).

**Critical Habitat Designation**

The critical habitat designation for Amsinckia grandiflora includes one area of approximately 180 acres in San Joaquin County, California (50 FR 19374 – 19378). (USFWS, 1985)

California. San Joaquin County, Mount Diablo Meridian, T3S R4E Section 28 W1/2 NW1/4 and W1/2 SW1/4.

**Primary Constituent Elements/Physical or Biological Features**

This area includes the following known primary constituent elements (50 FR 19374 – 19378). (USFWS, 1985)

A steep, west- and south-facing slope with light textured but stable soils.

**Special Management Considerations or Protections**

Any activity that would result in a disturbance of the soil or the hydrological regime where the large-flowered fiddleneck occurs would probably adversely modify the critical habitat. Also, any activity that may increase the frequency of grass fires in the area may adversely affect the population and modify the critical habitat. Consturction activities, such as high explosives and controlled burns, could have an adverse impact on the large-flowered fiddleneck and its habitat unless they are undertaken carefully. (USFWS, 1985)

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Self-fertilization, vegetative (USFWS, 2009)

**Lifespan**

Adult: < 1 year (USFWS, 2009)

**Dependency on Other Individuals or Species**

Adult: Possibly A. edwardsii (USFWS, 1997)

**Breeding Season**

Adult: Spring (USFWS, 2009)

**Key Resources Needed for Breeding**

Adult: Fall/winter rain (USFWS, 2009)

**Reproduction Narrative**

Adult: This species has a low reproductive potential and a primitive reproductive system (NatureServe, 2015). Amsinckia grandiflora is an herbaceous annual that germinates with the onset of fall or early winter rain, grows vegetatively throughout the winter, flowers in the early spring, sets seeds and dies prior to the summer drought. Pollination studies by Carlsen (1996) and Carlsen et. al. (2002) indicate that A. grandiflora is not completely self-incompatible and, under greenhouse conditions, this species' nutlet output can approach that of A. tessellata, a common, self-compatible, homostylous species. Pollinators are needed for A. grandiflora to produce seeds (Carlsen et al. 2002) (USFWS, 2009). Bees, primarily Anthophora edwardsii (a solitary wood-boring bee in the family Megachilidae), were the most consistent visitors to A. grandiflora. However, there is no direct evidence of actual pollination by Anthophora (USFWS, 1997).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal grasslands (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Occupies inner coast range grasslands on steep slopes and sandy soil. The environmental specificity is very narrow; it is only known from a very narrow distribution (NatureServe, 2015).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Unavailable (USFWS, 2019)

**Species Trends:**

Stable (NatureServe, 2015)

**Number of Populations:**

2 extant natural populations; 9 extant introduced populations (USFWS, 2019)

**Population Size:**

~2500 or greater (natural and introduced sites) (USFWS, 2019)

**Population Narrative:**

At the time of listing, there was only one known population, which consisted of fewer than 50 plants. This population was located in southwestern San Joaquin County, California, at the Lawrence Livermore National Laboratory at the Droptower site at Site 300. In 2017, there were no plants at this site. There are two introduced populations adjacent to the Droptower site with a combined population of 132 plants in 2017 (Carlsen and Paterson 2018). The Draney Canyon site at the Lawrence Livermore National Laboratory at Site 300 was not visited in 2017 (Carlsen and Paterson 2018). There were 84 plants in the Carnegie Canyon site (formerly called the Etchelet site) in 2017 on Contra Costa Water District property (Carlsen and Paterson 2018), and a combined 2,559 plants at ten introduction sites in three counties in 2017 (Schweitzer, pers. comm. 2018). (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Invasive species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, the primary threat to Amsinckia grandiflora was the invasion of aggressive Amsinckia species and weedy nonnatives into the grassland habitat. This is still an ongoing threat (USFWS, 2009).

**Stressor:** Grazing (USFWS, 2009)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** At the time of listing it was thought that grazing may have been responsible, in part, for the extirpation of some populations of this species. The introduction of grazing animals to the Livermore area was thought to have degraded the native grasslands that once existed there. Since listing, a combination of either the change in the intensity of grazing or the change from cattle grazing to sheep grazing is thought to have possibly extirpated the natural population located at Carnegie Canyon (T. Carlsen, Lawrence Livermore National Laboratory, pers. comm. 2008). No plants were seen at this site in 2003 (T. Carlsen, pers. comm. 2008) (USFWS, 2009).

**Stressor:** Reproductive biology (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, the relatively primitive reproductive system of Amsinckia grandiflora was thought to put the species at a competitive disadvantage with its congeners and with nonnative plants. This factor continues to threaten A. grandiflora. Additionally, because of the small number of populations and their small sizes, stochastic (chance) extinction also threatens this species (USFWS, 2009).

**Stressor:** Small population size (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small population size increases the susceptibility of a population to extirpation from random demographic, environmental and/or genetic events (Shaffer 1981, 1987; Primack 2006; Groom et al. 2006). In this 5-year review populations of 200 growing plants (not counting ungerminated seeds) or less are considered to be small, in keeping with Menges' (1992) calculation that populations of this size are especially vulnerable to even moderate levels of environmental uncertainty. The combination of few populations, small range, and restricted habitat renders Amsinckia grandiflora susceptible to extinction or extirpation from a significant portion of its range due to random events, such as flood, drought, disease, or other factors (Shaffer 1981, 1987; Groom et al. 2006). Small populations may also be subject to increased genetic drift and inbreeding (Menges 1991; Ellstrand and Elam 1993). Populations that are continually small in size are particularly susceptible to adverse genetic changes due to drift. However, drift may also cause genetic changes with populations that occasionally fluctuate to small sizes (e.g., undergo population bottlenecks). Increased homozygosity resulting from genetic drift and inbreeding may lead to a loss of fitness (ability of individuals to survive and reproduce) in small populations. In addition, reduced genetic variation in small populations may make any species less able to successfully adapt to future environmental changes (Ellstrand and Elam 1993) (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate is predicted to change in California during the 21st century (Field et al. 1999; Cayan et al. 2005). Even modest changes in warming could result in a reduction of the spring snowpack, earlier snowmelt, and more runoff in winter with less runoff in spring and summer,

more winter flooding, and drier summer soils (Field et al. 1999; Cayan et al. 2005). The predicted impacts on California's ecosystems projected with a high certainty include higher sea level; decreased suitable habitat for many terrestrial species as climate change intensifies human impacts; and increased competition among urban, agricultural, and natural ecosystem uses (Field et al. 1999). Although the specific effects of climate change on Amsinckia grandiflora are unknown, the effects of increased winter flooding and drought conditions in the spring have the potential to adversely affect this species (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
1. A minimum of six management areas are secured and protected from the threats that caused listing initially, including urbanization, agricultural conversion, competition with invasive vegetation, and livestock overgrazing. (USFWS, 2019)

2. Sufficient information has been obtained to ensure the perpetuation of suitable habitat , and appropriate management, based on this information, is being implemented at each management area in perpetuity. (USFWS, 2019)

3. Each management area has an average of 3,000 individuals over two precipitation cycles or 10 years, whichever is longer, with sufficient acreage of suitable habitat to support an expanded population and provide an appropriate buffer. (USFWS, 2019)

4. The six management areas concurrently demonstrate self-maintenance without intensive management intervention (e.g. hand-pollination, seed collection, off-site propagation) needed to prevent population decline for two precipitation cycles or 10 years, whichever is longer. (USFWS, 2019)

**Delisting Criteria:**
A/1: A minimum of 12 management areas that encompass sufficient acreage with suitable habitat characteristics and an appropriate buffer area to conduct site specific management actions have been protected in perpetuity. Twelve areas will provide sufficient redundancy for the species to withstand potential catastrophic events. (USFWS, 2019)

C/1: Predation pressure by granivores and herbivores is at a level that does not result in a declining population trend for any of the management areas over four precipitation cycles or 20 years, whichever is longer. (USFWS, 2019)

E/1: Each management area has an average of 16,000 individuals over four precipitation cycles or 20 years, whichever is longer. (USFWS, 2019)

E/2: The twelve management areas concurrently demonstrate self-maintenance without intensive management intervention (e.g. hand-pollination, seed collection, off-site propagation) needed to prevent population decline for four precipitation cycles or 20 years, whichever is longer. (USFWS, 2019)

**Recovery Actions:**

- Conserve the genetic diversity of Amsinckia grandiflora. As added insurance against extinction, seeds shall be collected from all natural populations. This seed will be available to use for augmentation or reintroduction, if remaining natural populations decline or are extirpated. It is important to ensure that the collected seeds are representative of the entire range of the species' genetic variability, as indicated in Pavlik 1996. Because of the small number of natural populations known at this time, it is very important that propagules be taken in such a way that the donor plants or populations are not reduced. Possible impacts of seed collection or removal of plants from natural populations must be closely monitored to detect any effect harvest may have on source populations. (USFWS, 1997)
- Secure and protect the habitat for at least six management areas within the historical range. To meet the downlisting criteria, at least six management areas need to be established. At least two of these management areas shall comprise natural populations. Habitat also needs to be surveyed for reintroduction sites. If new populations are discovered and confirmed as A. grandflora, the areas where they occur should be protected and enhanced by appropriate means. (USFWS, 1997)
- Contact Landowners. To downlist to threatened status, at least six viable management areas must be protected by perpetual administrative agreements with the landowners on whose land A. grandflora or essential habitat for A. grandflora is found. Landowner contact constitutes the first step in this process.
- Establish six management areas and maintain or enhance populations of Amsinckia grandiflora that may occur within any area. Despite much ongoing habitat work, Amsinckia grandifiora management areas have not yet been designated. Until sites are selected, as many of the natural and reintroduced sites as possible shall be protected. Once the sites have been selected, management areas need to be established. Establishing management areas will include delineating boundaries of each area and securing and protecting habitat within the boundaries. At least two management areas shall contain natural populations. (USFWS, 1997)
- Characterize habitat and management requirements. An understanding of the population trends of each site, and interactions of key community members, including pollinators and dispersal vectors, is necessary to refine management plans and to revise management techniques. Many aspects of the basic life history and ecology of Amsinckia grandflora are not known. Factors that would be the most important for increasing the population size of each natural population need to be determined. Information gained from appropriate studies is needed to establish recovery goals, and to effectively and efficiently manage and protect natural and reintroduced populations of the species and its habitat. (USFWS, 1997)
- Develop and implement site-specific management plan for each management area . Management plans, which direct actions essential for preserving the populations as long as active management is deemed necessary, should be individually tailored to each management area. Because management actions, including habitat protection, monitoring, and population reintroduction are ongoing, these plans have, in practice, been partially completed. However, they should be written down, for the benefit of future managers and researchers, and to promote future management consistency. (USFWS, 1997)
- Reintroduce populations into management areas. Downlisting and recovery of Amsinckia grandflora require that additional populations be established and maintained. The interim goal, for downlisting, is to have at least six management areas with 1,500 reproductive plants each. To accomplish this goal, unless new populations are discovered, A. grandflora must have success in reintroductions on four management areas. The potential sites must

be identified and tested for suitability as reintroduction sites. Specific establishment test sites must be selected, secured, and managed. (USFWS, 1997)
- Determine delisting criteria . Information gathered needs to be analyzed to establish delisting criteria. Genetic factors also need to be studied to determine if they are limiting
- Secure the Carnegie Canyon population. The Carnegie Canyon population should be secured from a willing seller by fee title for the benefit of several listed species (USFWS, 2009).
- Conduct a management study whose first objective is the establishment of 6 to 10 acres of thriving Amsinckia grandiflora populations with the ultimate objective of determining what factors enable and prevent sufficient recruitment to sustain the populations. This study would be done in a completely controlled and intensively managed basis. Amsinckia grandiflora has been grown successfully in greenhouses, but we do not know why it is not thriving in the wild. Such a study would provide the information needed for recovery, while maintaining the seed stocks and as much genetic variability and adaptability as is needed to implement recovery. The expanded scale would also allow the study of more extensive techniques and the study of more kinds of management techniques simultaneously (USFWS, 2009).
- Maintain seed bank to have viable seeds for restoration (USFWS, 2009).
- Determine causes for the extirpations of the natural and reintroduced occurrences and remedy the decline of Amsinckia grandiflora (USFWS, 2009).
- Conduct a study to help determine the effect of grazing and other vegetation management on Amsinckia grandiflora populations and the restoration of perennial grasslands (USFWS, 2009).
- Conduct surveys to try to locate additional natural occurrences of Amsinckia grandiflora (USWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR ACTIONS OVER THE NEXT 5 YEARS 1. Continue to study the habitat requirements of the large-flowered fiddleneck to determine what factors enable sufficient recruitment to maintain population viability (i.e., selfmaintenance without augmentation) and to identify future recovery sites. 2. Continue working with the Natural Resources Conservation Service to develop guidance for grazing on properties where fiddleneck occurs and grazing is allowed. 3. Ensure self-perpetuating fiddleneck populations are protected in perpetuity. 4. Continue to maintain a seed bank to have viable seeds for restoration. 5. Conduct surveys to try to locate additional natural occurrences of the fiddleneck. 6. Continue to monitor the populations selected for Phase 2 of the reintroduction effort through the remainder of the precipitation cycle. (USFWS, 2021)

# SPECIES ACCOUNT: *Apios priceana* (Price's potato-bean)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 2/5/1990; Southeast Region (R4)

**Physical Description**

A twining, herbaceous, perennial vine that grows from a stout, thick, roundish tuber often 18 centimeters (cm) or 7.2 inches (in.) in diameter (Figure 1). The stem is round in cross section, somewhat twisted and slightly ridged. It is finely hairy early in its growth, but later becomes smooth and glabrous. Leaves of the main stem are 20 to 30 cm (8 to 12 in.) long, alternate, and pinnately compound with 7 (5 to 9) leaflets. The leaflets are 4 to 10 cm (1.6 to 4.0 in.) long and half as wide, ovate and obtuse or rounded at the base and on 3 to 5 millimeter (mm) (0.1 to 0.2 in.) hairy stalks. The upper leaflet surface is smooth at maturity, and the lower surface is pale, slightly hairy, and veiny. Leaves and leaflets of branches are smaller than those of the main stem. Racemes are 5 to 15 cm (2 to 6 in.) long, dense with flowers (50 to 70) and are usually in clusters of two and three in the axils of the leaves. Pedicels (flower stalks) are thin and 3 to 5 mm (0.1 to 0.2 in.) long; the bracts (small leaves at base of flowers) are longer than the pedicels and are ovate with a slender, tapering tip. The greenish-white or brownish pink flowers are 1 cm long (0.4 in.) and tinged with magenta at the apex. The standard (large, upper petal) is bi-auriculate (ear-shaped appendages) at the base with a fleshy beak-like apex, the wings (lateral petals) are shorter and narrowly oblong but rounded at the base, and the keel (bottom, ridged petals) are fleshy and curved upward. Pods are 12 to 15 cm (5 to 6 in.) long, 1 cm (0.4 in.) wide, and tapering at both ends. There are usually 4 to 10 seeds per pod. Seeds are 7 to 8 mm (0.3 in.) long and separated in the pod by a silvery white endocarp. The roots of A. priceana produce nodules 2 to 3.5 mm (0.1 in.) in diameter (Robinson 1898; Kral 1980; Woods 1988; Isely 1990; L. McCook, Missouri Botanical Garden, personal communication, 1992). (USFWS, 1993)

**Taxonomy**

A member of the pea family (Fabaceae). The genus Apios was described by Cornut in 1633; however, Linnaeus called the genus Glycine in 1753. In 1905, at the botanical congress in Vienna, Apios was conserved over Glvcine (pro parte). The genus consists of three Asian species and two North American species (Woods 1988). Common names for Apios oriceana include Price’s potato-bean, Sadie Price’s potato-bean, potato-bean, and Price’s ground nut. Type specimens are in the Gray Herbarium, Cambridge, Massachusetts. (USFWS, 1993). Woods (2005) revised the taxonomy of the North American species of Apios (Fabaceae). In doing so, he maintained recognition of Price’s potato-bean as Apios priceana Robinson, as originally published. A phylogenetic analysis indicated that the genus Apios originated in Southeast Asia, and that the North American species (A. americana and A. priceana) are more closely related to one another than to any of the Asian species (Li et al. 2014) (USFWS, 2016).

**Historical Range**

At time of Recovery Plan, found in 22 counties in five states: Alabama, Illinois, Kentucky, Mississippi, and Tennessee. Originally found in 1896 by Sadie Price in open woods near Bowling Green in Warren County, Kentucky. (USFWS, 1993)

**Current Range**

Mississippi (Clay, Oktibbeha and Lee counties); Alabama (Madison, Autsuga and Marshall counties); Kentucky (Lyon, Livingston and Trigg counties); Tennessee (Marion, Montgomery and Williamson counties) (NatureServe, 2015). The species is considered extirpated from the State of Illinois (Ebinger et al. 2010) (USFWS, 2016).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: primarily cross-pollination, self-pollination possible (USFWS, 2016)

**Dependency on Other Individuals or Species**

Adult: Multiple floral visitors/multiple effective pollinators (USFWS, 2022)

**Breeding Season**

Adult: June through September (NatureServe, 2015)

**Other Reproductive Information**

Adult: Various floral visitors (potential pollinators) have been identified, including Bombus spp. (bumble bees), Megachile sculpturalis (giant resin bee), M. campanulae (bellflower resin bee), and Hemaris thysbe (hummingbird clearwing) (Campbell et al. 2016). Of note is M. sculpturalis, which is non-native to the U.S., originating in eastern Asia, but may provide pollination services to dozens of plant species in the U.S. (including A. priceana) and is generally considered a benign introduced species (Campbell et al. 2016; Stevens et al. 2019). Paris and Boyd (2018) found multiple bee species were equally effective pollinators for Price’s potato-bean, indicating pollinator redundancy provides resilience from the species perspective (Senapathi et al. 2015). Considering reports of widespread declines in North American bumblebee populations (e.g., Cameron et al. 2011), reliance of Price’s potato-bean upon a suite of pollinating bees might buffer potential impacts of individual bumblebee population declines. However, the bee fauna Price’s potato-bean relies on may need additional conservation consideration to sustain adequate pollination services (Paris and Boyd 2018). Additionally, loss of pollination services by native bees may be offset somewhat by non-native bees, such as M. sculpturalis although the effectiveness of such non-native species as pollinators of Price's potato-bean is unknown (USFWS, 2022).

**Reproduction Narrative**

Adult: Flowers of A. priceana bloom from June through August, possibly as late as September (Kral 1983, Mahler 1970). Legumes mature in August to September (Kral 1983). Early reports by the discoverer of the species, Sadie Price, suggested that it does not frequently set fruit (Robinson 1898). Flowers of A. priceana bloom from June through August, possibly as late as September (Kral 1983, Mahler 1970). Legumes mature in August to September (Kral 1983). Early reports by the discoverer of the species, Sadie Price, suggested that it does not frequently set fruit (Robinson 1898). Potential pollinators include a butterfly (Eudamus tityrus), honey and bumble bees (Robinson 1898). Apparently the bees find the nectaries very difficult to access.

Apios priceana can be readily germinated by scarification of the seed coat through chipping (Seabrook 1973) or acid (Walter et al. 1986). Plants can grow 5-6 feet during the first summer, but do not flower. Flowering is apparently initiated only in plants that have over-wintered (Baskin pers. comm.). Tubers of A. priceana apparently require vernalization for growth (Bowden pers. comm.). Plants die back to the tuber in the mid-summer (NatureServe, 2015). Apios priceana plants produce very few seeds (Robinson 1898, Chester and Holt 1990). This low level of sexual reproduction may result in small population sizes and little dispersal of the species to new sites. It also is likely to result in low genetic diversity within populations (USFWS, 1993). During 2013, 10,752 flower buds were initiated, from which 2,550 flowers were produced, resulting in 97 mature fruits bearing a total of 234 seeds. Reproductive output was lower during 2010, when a sample of five plants that generated 4,299 flower buds ultimately produced only 7 mature fruits, yielding a total of 51 seeds. Results of a field-based study of the species' breeding system indicated that A. priceana is not self-compatible (Boyd 2014). However, production of viable seeds by a lone plant at Missouri Botanical Garden indicates that selfcompatibility is possible (M. Albrecht pers. comm. 2008). At least four species of medium (~1-1.5 cm length; Bombus pennsylvanicus, Bombus sp.) to large bees (>1.5 cm; Bombus bimaculatus, Megachile sculpturalis) were relatively efficient pollinators in the breeding system study (Boyd 2014) (USFWS, 2016).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Palustrine: forested wetland, riparian; Terrestrial: Cliff, Forest - Mixed, Forest/Woodland, Woodland - Mixed (NatureServe, 2015)

**Environmental Specificity**

Adult: Broad (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Open, rocky, wooded slopes and floodplain edges. Sites are usually under mixed hardwoods or in associated forest clearings, often where bluffs or ravine slopes meet creek or river bottoms. Soils are well-drained and loamy, formed on alluvium or over calcareous boulders. Several populations extend onto road or powerline rights-of-way. Price's potato-bean is an inhabitant of open, mixed-oak forests, forest edges and clearings on river bottoms and ravines, being unable to tolerate deep shade (USFWS 1989, Kral 1983). The species occurs on well-drained loams on old alluvium or over calcareous boulders (Kral 1983). According to the Missouri Botanical Garden, A. priceana prefers acidic, water retentive soils, requires no soil additives, can withstand winter temperatures below 5 degrees Celsius, shows no intolerance to supplemental feedings, and possesses no apparent pests (Bowden pers. comm.) (NatureServe, 2015).

***Dispersal/Migration***

**Dispersal**

Adult: Low (NatureServe, 2015)

**Dispersal/Migration Narrative**

Adult: Unlike its close relative, Apios americana, which produces numerous tubers, A. priceana produces only one. This fact may serve to severely limit natural dispersal of the species. Since A. priceana has just the single tuber, it is unable to be dispersed effectively along rivers by spring freshets as is A. americana (Seabrook and Dionne 1976) (NatureServe, 2015).

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Stable (USFWS, 2022)

**Number of Populations:**

57 (USFWS, 2022)

**Adaptability:**

Relatively resistant (NatureServe, 2015)

**Population Narrative:**

There are now 57 extant populations of Price's potato-bean distributed among 27 counties in 4 states (Table 1; Figure 1; ANHP 2022; KSNPC 2022; MNHP 2022; TDEC 2022). These populations are distributed across multiple U.S. Environmental Protection Agency (EPA) Level III ecoregions, which represent different ecological zones that share a characteristic set of natural communities, floral and faunal species, ecological dynamics, and environmental conditions (Figure 1; Omernik 1987). We are presuming the 15 populations that were not surveyed since the last 5-year review remain extant (Service 2016; ANHP 2022; KSNPC 2022; MNHP 2022; TDEC 2022). The general spatial extent of the species remains similar to what was reported in the last 5-year review. There is one new county included in the species distribution (e.g., adding Warren County, Kentucky), and the species remains extirpated from Illinois. A number of the populations are small and isolated from other known extant populations, limiting connectivity and potential gene flow. Because Price's potato-bean is known to periodically assume dormancy during the growing season until conditions are more suitable, numbers in this document should be considered best available estimates (Service 1993; Schotz 2018). Of the 59 total populations reported in the 2016 5-year review, 7 are presumed extirpated. However, an additional five populations have been identified since the last 5-year review (Service 2016). Four of the new populations were found in Alabama ranging in size from 12-24 plants and an additional new, very small population, i.e., 2 plants, was discovered in Kentucky. Of the extant populations, 13 in Alabama, 5 in Kentucky, 2 in Mississippi, and 6 in Tennessee are located on publicly owned lands or private conservation lands that are currently considered protected (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 1993)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Logging may threaten A. priceana populations. Selective removal of trees that shade plants can enhance growth and reproduction of A. priceana by increasing levels of light; however, clearcutting or heavy logging can eliminate populations (U.S. Fish and Wildlife Service 1989). It is unclear whether clearcutting will result in permanent destruction of populations. Populations of A. priceana are found in secondary-growth forest suggesting that the species may recover after heavy logging (Kral 1983). Landowners who do not know that the species is on their land or who are not interested in its continued survival may make land management decisions that are harmful to the species. The location of 11 populations on rights-of-way (road edges, powerlines, etc.) is also a potential threat to the species. Maintenance of these areas by herbicides, mowing, and clearing of trees could damage or extirpate these populations (U.S. Fish and Wildlife Service 1989, Chester and Holt 1990). Clearing trees may be harmful if the debris is piled on top of the populations. Widening of a road adjacent to an A. priceana population could easily wipe out an entire population. Mining for limestone is a potential threat to A. priceana populations found over limestone bedrock (Kral 1983). Grazing and trampling of plants by cattle can cause severe damage. The erosion of soil that results from heavy grazing and trampling also can harm the species (Medley 1980) (USFWS, 1993).

**Stressor:** Low reproductive potential (USFWS, 1993)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Apios priceana plants produce very few seeds (Robinson 1898, Chester and Holt 1990). This low level of sexual reproduction may result in small population sizes and little dispersal of the species to new sites. It also is likely to result in low genetic diversity within populations. It is not known whether A. priceana reproduces vegetatively; 1993).

**Stressor:** Pests and pathogens (USFWS, 1993; 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A variety of pests are reported to damage A. priceana plants, including spider mites (D. Wright, Missouri Botanical Garden, personal communication, 1991), a powdery mildew virus, and root-knot nematodes (Blackmon and Reynolds 1986). An unidentified insect has been observed to damage the flowers and fruits of A. priceana (E. Chester, personal communication, 1991). These pests may have a significant effect on A. priceana (USFWS, 1993). The bean leaf beetle (Certoma trifurcate) was observed eating leaves and flower buds, causing the formation of holes in the leaves and interrupting development of flowers and fruits. A second species of beetle, Chalepus scapularis, was collected from an A. priceana plant, but its feeding behavior was not observed. The extent to which these observations of insect herbivory indicate a threat to A. priceana is not known, but monitoring efforts for the species should include assessments of the extent of insect herbivory when observed and collection of specimens to identify potentially threatening species (USFWS, 2016).

**Stressor:** Invasive species (USFWS, 1993)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** An introduced, invasive plant, Coronilla varia (crown vetch), is threatening to outcompete one Kentucky population (Chester and Holt 1990). Other exotics, Ligustrum sinense and Rosa multiflora, are reported to be competing with populations in Mississippi (M. Morris, University of Florida, personal communication, 1992) (USFWS, 1993).

**Stressor:** Climate change (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Davenport (2007) included A. priceana in an analysis of potential effects of climate change on Alabama's plant life. The analysis was based on best professional judgment of how various habitat types and associated species would respond to climate changes that models predict Alabama will experience. Davenport (2007) concluded that "species demanding shady ravines and stream banks will constrict in distribution", including the hardwood forests inhabited by A. priceana. (USFWS, 2016).

**Stressor:** Feral hogs (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** we have identified feral hogs (Sus scrofa) as a potential new threat to the species. Noted to be among the most destructive exotic vertebrates established in the Southeast, feral hogs severely damage a variety of habitats and sensitive ecological communities, including those containing federally listed species (Lewis et al. 2019; Fern et al. 2020; Glow et al. 2020). Extensive feral hog damage has been observed across Bankhead National Forest, Alabama, where three protected Price's potato-bean sites occur (A. Cochran pers. comm. 2022). While there is no known record of direct damage to Price's potato-bean plants therein, as feral hog numbers increase, direct impacts to the species are anticipated, which necessitates additional research to assess their impacts on Price's potato-bean populations and habitats. (USFWS, 2022)

**Stressor:** Herbicide overspray (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In addition, we have identified herbicide overspray from agricultural fields as another emerging threat. Overspray has been observed near a protected population in Tennessee, but is most notable in Mississippi, where three of four known Price's potato-bean populations occur on property adjacent to cropland (MNHP 2022). Most recently, the Chickasaw Preserve (part of the larger Coonewah population and one of Mississippi's two protected populations) sustained substantial herbicide damage due to its proximity to neighboring soybean fields (J. Franklin pers. comm. 2022). While seed set is expected to be reduced or eliminated for the year because of exposure, uncertainty remains regarding the extent, severity, and precise impacts of how Price's potato-bean individuals will be affected by herbicide activity for agricultural purposes; therefore, more directed assessments are required (USFWS, 2022).

**Stressor:** Climate change (USFWS, 2022)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** First proposed as an emerging issue in the 2016 5-year review, the threat of climate change has been intensifying in recent years and is now considered a major driver limiting species viability (Service 2016). Climate change has the potential to affect distribution and abundance of plants by influencing seasonal weather patterns, frequency and timing of severe weather events, species interactions, and myriad plant physiological responses (Hawkins et al. 2008). The predicted increase in drought frequency, intensity, and duration could adversely affect the habitats inhabited by Price's potato-bean by reducing soil moisture and increasing plant mortality rates or reducing flowering and seed production rates. A positive effect of increased drought could result from increased mortality of woody vegetation and reduced rates of vegetation succession. Climate change may also disrupt plant-pollinator interactions via phenological shifts in flowering and/or pollinator activity (Hawkins et al. 2008; Hegland et al. 2009), which may thereby reduce sexual reproduction of Price's potato-bean. However, while climate has changed in recent decades in the region where Price's potato-bean occurs and the rate of change is expected to continue increasing for the foreseeable future, uncertainty remains regarding the extent, severity, and precise impacts of how Price's potato-bean's habitats and its interspecific interactions will be affected by these changes and how the species will respond to these changes (USFWS, 2022).

***Recovery***

**Reclassification Criteria:**
Not applicable.

Recovery Priority Number: 8

**Delisting Criteria:**
1. When there are at least 25 geographically distinct, self-sustaining, protected populations and they have been maintained for 10 years. A population will be considered self-sustaining if the population size is stable and there is evidence of successful reproduction. Protected populations will have appropriate legal protection and appropriate management. (USFWS, 1993).

**Recovery Actions:**

- Protect known populations. Twenty-one of the 25 known populations of A. priceana are on privately—owned land; the remaining four populations are on federally-owned land. One of the privately-owned populations is owned by The Nature Conservancy and is adequately protected. Four of the privately-owned populations are Registered Natural Areas. The remaining 16 privately-owned populations are unprotected. Legal protection of these areas is necessary to provide long—term security and prevent land use that is harmful to the species. Management plans should be developed for all populations that are protected, particularly those owned by the Federal government and conservation organizations. Management plans should be developed for the remaining populations once some sort of protection is achieved. Without this protection, A. priceana habitat will continue to be destroyed, and the species may become extinct. (USFWS, 1993)
- Investigate effects of potential management techniques. Potential management techniques for A. priceana should be tested to determine their effectiveness. Because there are few populations of A. priceana and population sizes are small, it is essential that work begins to

enhance growth and reproduction of plants and to reestablish populations (if found necessary). Without this active management, the species is likely to become extinct. The selection of populations used for these experiments should be based on their need for this type of management and the size and vigor of the population. The experimental treatment should be applied within replicated plots. The number and size of the plots should be determined by the size of the population and the density of the plants. An equal number of unmanipulated plots should be established as controls. (USFWS, 1993)

- Search for new populations. The search for new populations of A. priceana must continue. The most accurate information on the number and distribution of populations is necessary to make appropriate decisions about management of the species.(USFWS, 1993)
- Study biology of Apios priceana. An increased understanding of the biology of A. priceana is necessary to develop appropriate management practices for the species. (USFWS, 1993)
- Maintain plants and seeds ex situ. Plant material should be preserved in artificial conditions in case catastrophes destroy all or most populations of the species. This stored material also could be used to establish new populations if natural populations become depleted. The Center for Plant Conservation (Center) has extensive experience in this area and should be involved in the planning and implementation of these tasks. (USFWS, 1993)
- Provide public information . Priority should be given to providing landowners with information about the species. Apios priceana is already on display at the Missouri Botanical Garden (a member botanical garden of the Center for Plant Conservation) and is used to educate the public about rare plants and conservation needs. The artificial population at Land Between the Lakes should be maintained and similarly used to educate the public. Providing the public with information about the species could also encourage amateur and professional naturalists to search for new A. priceana populations. (USFWS, 1993)
- Apios priceana plants are being grown artificially in several locations. These plants will provide seeds and tubers for further studies of the species. Seeds from these plants also may be used in the future to reestablish extirpated populations (USFWS, 1993).
- Work is also being done to protect several naturally occurring populations of A. priceana. Four populations are Registered Natural Areas. Although this is not legally binding protection, it does indicate that the owners of the property are showing an active interest in the survival of the species. A population in Tennessee has been purchased by The Nature Conservancy (USFWS, 1993).
- Four populations are on federally-owned land. These populations are legally protected by the Endangered Species Act. Two populations in Kentucky are on land owned by the Tennessee Valley Authority within an area designated as a Conservation Education Center (Table 1, number 7 and number 8) (U.S. Fish and Wildlife Service 1990). TVA has shown active involvement in the protection of the species. Two populations in Alabama are owned by the U.S. Army Corps of Engineers (U.S. Fish and Wildlife Service 1990) (USFWS, 1993).
- Searches for new populations of A. priceana were carried out in Tennessee and Illinois during the 1990 growing season. The search in Tennessee resulted in the discovery of four new occurrences of the species (Tennessee Department of Conservation 1991). The Illinois search did not result in the discovery of new sites or the relocation of the two populations previously known from the State (Hutchinson 1990). A search for the species in Tennessee in 1991 resulted in the discovery of five new populations (Tennessee Department of Conservation 1991) (USFWS, 1993).
- Continue efforts to work with local governments and highway officials to reduce threats associated with roadside maintenance, including establishing cooperative agreements when

possible (USFWS, 2016).

- Continue management at LBL and Sauta Cave NWR to reduce canopy cover and invasive species encroachment and promote flowering, seed production, and population growth. Encourage similar management efforts at other protected sites (USFWS, 2016).
- Work with Natural Heritage Programs, NPS, USFS, and others to establish consistent range wide monitoring program (USFWS, 2016).
- Work cooperatively with Redstone Arsenal, Alabama, to manage and monitor population on Department of Defense lands (USFWS, 2016).
- Work cooperatively with ADCNR to manage and monitor population at Old Cahawba Forever Wild Tract in Alabama (USFWS, 2016).
- Work cooperatively with NPS to develop conservation strategies for populations at Fort Donelson National Battlefield, in Tennessee, and Natchez Trace Parkway, in Mississippi (USFWS, 2016).
- Work with landowners of protected sites to develop conservation agreements that establish biological goals for A. priceana, identify management strategies to achieve those goals, and include a monitoring plan for measuring effectiveness of conservation efforts as relates to the species' status (USFWS, 2016).
- Ensure that ex situ accession information and propagation protocols are maintained and curated in the Center for Plant Conservation National Collection of Endangered Plants centralized database (USFWS, 2016).
- Conduct experimental studies that examine the species' habitat needs in order to develop management protocols that bolster population size and fitness. While it has been assumed that A. priceana will respond favorably to opening forest canopies, current monitoring protocols are not adequately designed to compare population responses across light gradients. Future work should include design of experiments to examine the response of natural or experimental populations to fire, canopy thinning, and other management tools. Greenhouse studies to explore effects of varying levels of shade, soil moisture, and soil fertility could also improve understanding of factors that regulate growth of A. priceana individuals and populations (USFWS, 2016).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES A detailed discussion of recovery criteria and actions is presented in the species' recovery plan (Service 1993). In conducting this status review new and/or targeted potential recovery activities were identified and are included below. These actions are recommended to support and promote recovery of Price's potato-bean. Use of a numbered list for these recommendations is for convenient reference only and does not necessarily imply prioritization of any activity over others. Recovery Activities 1. Continue efforts to work with local governments and highway officials to reduce threats associated with roadside maintenance, including installing signage, training staff and contractors on appropriate management techniques and avoidance measures, and establishing cooperative agreements, when possible. 2. Continue management at Land Between the Lakes National Recreation Area and Sauta Cave National Wildlife Refuge to reduce canopy cover and invasive species encroachment and promote flowering, seed production, and population growth. Encourage similar management efforts at other protected sites. 3. Work cooperatively with the National Park Service and U.S. Forest Service to develop conservation strategies for populations at Fort Donelson National Battlefield in Tennessee, Natchez Trace National Parkway in Mississippi, and Bankhead National Forest in Alabama. 4. Collaborate with State and Federal agencies to initiate and perform feral hog eradication and control efforts across the range of Price’s potato-bean. 5. Work with landowners of protected sites to develop conservation agreements that establish biological goals for Price’s potato-bean, identify management strategies to achieve those goals, and include a monitoring plan for measuring effectiveness of conservation efforts as related to the species’ status. 6. Work cooperatively with the Chickasaw Nation to develop strategies for expanding populations at Chickasaw Preserve in Mississippi, while also increasing protections for the existing population. 7. Ensure that ex situ accession information and propagation protocols are maintained and curated in the Center for Plant Conservation National Collection of Endangered Plants centralized database. Monitoring and Research Activities 1. Work with state Natural Heritage Programs, National Park Service, U.S. Forest Service, National Wildlife Refuges, and other partners to establish a consistent range wide monitoring program. 2. Coordinate with the National Park Service, Mississippi Natural Heritage Program, and other partners to identify suitable outplanting strategies and locations at Natchez Trace Parkway in Mississippi. 3. Build on earlier experimental studies that examine the species habitat needs to develop/improve management protocols that bolster population size and fitness. Future work should include design of experiments to examine the response of natural or experimental populations to fire, canopy thinning, herbicide application, and other management tools, as well as to emerging threats.

# SPECIES ACCOUNT: *Arabis georgiana* (Georgia rockcress)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/14/2014; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

A slender, erect biennial, with white flowers produced on a leafy stem to 9 dm in height. Leaves disposed at the base and along the stem, are alternate, lanceolate to narrowly elliptic, 1-5 cm long, and slightly clasp the stem. The flowers are produced in a terminal inflorescence that is sometimes loosely branched; 4-merous with petals 6-9 mm long. The fruit is an erect pod roughly 1 mm wide and 5-7 cm long. Flowering season: late March to early May. (NatureServe, 2015)

**Taxonomy**

Georgia rockcress was first collected in 1841, by Boykin from the vicinity of the Chattahoochee River in Georgia. Several other collections of this species were made in the late 1800s; however, Harper was the first to document its distinctiveness, after seeing it in fruit in 1901, on the bank of the Chattahoochee River in Stewart County, Georgia. Harper later described it as a distinct species in 1903 (Allison 1995, p. 4). Georgia rockcress was maintained as a distinct species (Arabis georgiana) in Hopkins’s 1937 monograph of Arabis in the eastern United States (Allison 1995, p. 3) (USFWS, 2013).

**Historical Range**

Georgia rockcress is known from the Lower Gulf Coastal Plain, Upper Gulf Coastal Plain, Red Hills, Black Belt, Piedmont, and the Ridge and Valley Physiographic Provinces (Schotz 2010, p. 6; Allison 1995, p. 6) (USFWS, 2014).

**Current Range**

Despite fairly extensive searches, this species is currently known from fewer than 25 populations in Alabama and western Georgia. (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 9/12/2014.

**Legal Description**

On September 12, 2014, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Arabis georgiana (Georgia rockcress) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 17 critical habitat units (CHUs), in Alabama and Georgia (79 FR 54635-54667).

**Critical Habitat Designation**

The critical habitat designation for Arabis georgiana includes 17 CHUs in Gordon, Floyd, Harris, Muscogee, and Clay Counties Georgia and Bibb, Dallas, Elmore, Monroe, Sumter, and Wilcox Counties, Alabama. This species critical habitat encompasses approximately 732 acres (ac) (297 hectares (ha)) (79 FR 54635-54667).

Unit 1. Fort Tombecbee, Sumter County, Alabama: The 6-ha (14-ac) Fort Tombecbee unit is approximately 0.5 kilometers (km) (0.3 miles (mi)) northeast of the city of Epes, Alabama, and is owned by the University of West Alabama. This Georgia rockcress occurrence inhabits the crest and steep slopes of a deeply incised stream bank overlooking a small intermittent creek approximately 91 m (300 ft) upstream from its confluence with the Tombigbee River. Livestock grazing was observed during a visit made in May 2010, in a portion of the site where the species was previously observed; it is conceivable that livestock may have further impacted the occurrence. Only four plants were found in 2010 (Schotz 2010, p. 51). The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with road crossings, development and potentially grazing.

Unit 2. Marshalls Bluff, Monroe County, Alabama: The 11-ha (27-ac) Marshall Bluff unit is a privately owned tract 9.6 km (6 mi) southwest of Perdue Hill, Alabama, on the eastern bank of the Alabama River on a high bluff (Marshalls Bluff) overlooking the Alabama River. An abandoned quarry exists approximately 150 m (500 ft) distant to the east, and while the quarry may have destroyed bluff habitat, the quarry currently poses no threat to the occurrence, and there are no plans to expand the quarry (Schotz 2010, p. 22). More than 400 plants were found in 2010. The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with mining.

Unit 3. Prairie Bluff, Wilcox County, Alabama: Privately owned, the 13-ha (32-ac) Prairie Bluff unit is located along the banks of the Millers Ferry (William ‘‘Bill’’ Dannelly) Reservoir, approximately 1.6 km (1 mi) north of the Lee Long Bridge on State Route 28. Georgia rockcress is scattered along the bluffs and ravines associated with the Alabama River. Nonnative species, most notably Ligustrum sinense (Chinese privet) and Lonicera japonica (Japanese honeysuckle), threaten this site (Allison 1999, p. 2; Schotz 2010, pp. 54–55). More than 500 plants were found in this unit in 2010; however, some habitat was likely inundated by the reservoir. This site is slated for residential development with lakeside lots, and the infestation of nonnatives will likely become worse. The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with roads, development, hydropower, and nonnative species.

Unit 4. Portland Landing River Slopes, Dallas County, Alabama: Privately owned, the 12-ha (31-ac) Portland Landing River Slopes unit is located 18 km (11.5 mi) south of Orrville, Alabama, on the south side of the Alabama River at Portland Landing. This occurrence of Georgia rockcress is restricted to the unstable, highly erodible, sandy soils along the bank of the Alabama River. Nonnatives, most notably Melia azedarach (Chinaberry or bead-tree), Japanese honeysuckle, and Pueraria montana var. lobata (kudzu), are present, and although not severe, these nonnatives will persist without active management (Schotz 2010, p. 40). In 2010, 498 Georgia rockcress plants were recorded (Schotz 2010, p. 40). The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with timber harvest, hydropower, and nonnative species.

Unit 5. Durant Bend, Dallas County, Alabama: Privately owned, the 12-ha (28-ac) Durant Bend unit occurs 16 km (10 mi.) east of Selma in a sharp bend on the Alabama River. Fewer than 50 plants were reported in sandy alluvium along the Alabama River under a partially open to filtered canopy in 2010 (Schotz 2010, p. 37). While the majority of plants occur in forested conditions, a small number of plants were observed in relatively open and exposed soils of actively eroding sections of the riverbank. Nonnatives, including Chinese privet and Japanese honeysuckle, are present but not severe. Timber harvesting has recently taken place approximately 46 m (150 ft) north of the site, but it currently has not impacted species' viability or habitat integrity (Schotz 2010, p. 37). The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with timber harvest and nonnative species.

Unit 6. Murphys Bluff Bridge Cahaba River, Bibb County, Alabama: Privately owned, the 11-ha (26-ac) Murphys Bluff Bridge Cahaba River unit is 11.4 km (7 mi) southwest of Centreville, Alabama, and located along the west bank of the Cahaba River downstream (southwest) of the Murphy Road Bridge. Chinese privet, Japanese honeysuckle, and other nonnatives are present, but are relatively sparse. Infestation of nonnative plants could worsen. Timber harvesting has been observed nearby and may pose a potential concern (Schotz 2010, p. 22). Sixteen Georgia rockcress plants were found at this location during the 2010 survey. The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with road crossings and nonnative species.

Unit 7A. Creekside Glades, Bibb County, Alabama: Privately owned, the 11-ha (26-ac) Creekside Glades subunit is located 9.6 km (6 mi) north-northeast of Centreville, Alabama, along the banks of Little Schultz Creek. Georgia rockcress occurs in association with a small dolomite glades complex on either side of Little Schultz Creek. The plants (mostly rosettes, i.e., non-reproductive) predominantly occur in the ecotone of the glades and the encompassing woodland, in association with a mix of shrubs and low-growing trees. A smaller number of individuals (mostly mature) can be found in the glades and surrounding woodlands (Allison 1999, p. 2; Schotz 2010, p. 30). This subunit contained 42 plants in 2010. A utility line right-of-way passes through this subunit, and while there is no canopy on the right-of-way, it provides essential supporting habitat such that the right-ofway has not been excluded from critical habitat. The physical or biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats associated with development and utility right-ofway maintenance. Unit 7B. Little Schulz Creek, Bibb County, Alabama Privately owned, the 12-ha (28-ac) Little Schulz Creek subunit is located 8.9 km (5.5 mi) north-northeast of Centreville, Alabama. In 2010, 29 plants occurred on limestone outcrops along the west bank of the Cahaba River. The site is characterized as a bouldery limestone woodland situated along a low bluff overlooking the Cahaba River. Georgia rockcress inhabits shallow soils associated with the bluff, occurring under an open to lightly shaded canopy (Schotz 2010, p. 32). This subunit consisted of 29 plants in 2010. The physical or biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats associated with development and utility right-ofway maintenance.

Unit 8A. Cottingham Creek Bluff and Unit 8B. Pratts Ferry, Bibb County, Alabama: Privately owned, the Cottingham Creek Bluff subunit is located on the east side of the Cahaba River, upstream of Pratts Ferry Bridge, 10 km (6.2 mi) northeast of Centreville, Alabama. The Pratts Ferry subunit is located on the west side of the Cahaba River, downstream of Pratts Ferry Bridge, 10 km (6.2 mi) northeast of Centreville, Alabama. A small portion (26 percent (5.88 ha (14.5 ac)) of the Cottingham Creek Bluff subunit is owned by The Nature Conservancy (TNC). A small number of plants are confined to an abandoned limestone quarry several hundred feet back from the southeastern side of the river's edge. Chinese privet and Japanese honeysuckle impact this site, particularly in the vicinity of the abandoned quarry. Nonnatives could become worse. Timber harvesting is of potential concern in an area adjacent to the population on the west side of the Cahaba River, which was selectively logged in the 1990s (Allison 1999, p. 3; Schotz 2010, pp. 34–35). Subunit 8A is 22 ha (55 ac), and subunit 8B is 11 ha (28 ac). In 2010, these two subunits together contained 299 Georgia rockcress plants. The physical or biological features essential to the conservation of the species in these subunits may require special management considerations or protection to address threats associated with road crossings, timber harvest, and nonnative species.

Unit 9A. Fern Glade, Bibb County Alabama: The 14-ha (34-ac) Fern Glade subunit is centered near the confluence of the Little Cahaba River and Sixmile Creek approximately 14.2 km (8.9 mi) northeast of Centreville, Alabama. Twelve percent of the Fern Glade subunit (4.2 ha (1.7 ac)) is owned by TNC, and 79 percent (10.9 ha (27 ac)) of this subunit is part of the Cahaba National Wildlife Refuge. A moderate incursion of invasive Chinese privet and Japanese honeysuckle occurs at this site. Nonnatives will likely become worse (Allison 1999, p. 3; Schotz 2010, p. 26). A small glade on the north side of the Little Cahaba River had 81 Georgia rockcress plants in 2010. The physical or biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats associated with timber harvest and nonnative species. Unit 9B. Sixmile Creek, Bibb County, Alabama Privately owned, the Sixmile Creek subunit is located 13.7 km (8.5 mi) northeast of Centreville, 0.8 km (0.5 mi) upstream on Sixmile Creek from its confluence with the Little Cahaba River. The majority of this subunit (96.6 percent or 8.2 ha (20.3 ac)) was acquired by TNC in 2013. This population of Georgia rockcress is on the west side of Sixmile Creek. In a relatively isolated site, Georgia rockcress occupies the upper slope and summit of a steep forested bluff overlooking Sixmile Creek. This 13-ha (31-ac) subunit had 59 Georgia rockcress plants in 2010. The physical or biological features essential to the conservation of the species in this subunit may require special management considerations or protection to address threats associated with timber harvest and nonnative species.

Unit 10A. Browns Dam Glade North and Unit 10B. Browns Dam Glade South, Bibb County, Alabama: Privately owned, the Browns Dam Glade subunits are located 15.8 km (9.8 mi) northeast of Centreville, Alabama, on both sides of the Little Cahaba River. Subunit 10A is on the north side of the river, and subunit 10B is in a sharp bend on the south side of the River. More than 96 percent of subunit 10A (13.7 ha (33.8 ac)) and all of subunit 10B are owned by TNC. A combination of open woodland and dolomitic glades characterize the site. An infestation of nonnatives, most notably Chinese privet, occurs at this unit. This site serves as a primitive recreation area for local residents, resulting in some trash disposal and the construction of fire pits (Allison 1999, p. 5; Schotz 2010, pp. 24– 25). Subunits 10A and 10B are 14 ha (35 ac) and 15 ha (37 ac), respectively. A complex of dolomitic glades and associated woodlands along both sides of the Little Cahaba River contained 71 Georgia rockcress plants in 2010. The physical or biological features essential to the conservation of the species in these subunits may require special management considerations or protection to address threats associated with nonnative species.

Unit 11. McGuire Ford/Limestone Park, Bibb County, Alabama: Privately owned, the McGuire Ford/ Limestone Park unit is located 18.7 km (11.6 mi) northeast of Centreville, Alabama, on the southeast side of the Little Cahaba River. A small number of plants occupy shallow soils of low, rocky limestone outcrops along the Little Cahaba River under a lightly shaded canopy of eastern red cedar, chinquapin oak, white ash, Southern sugar maple, and redbud, among others (Allison 1999, p. 5; Schotz 2010, p. 20). This 6-ha (15-ac) unit contained 50 Georgia rockcress plants during the 2010 survey. The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with roads, development, and maintenance of a pasture.

Unit 12. Fort Toulouse State Park, Elmore County, Alabama:  State-owned, the Fort Toulouse State Park unit is located 16 km (10 mi) north of Montgomery, Alabama, on the south side of the Coosa River. Georgia rockcress is widely scattered along the bluffs overlooking the Coosa River, primarily occupying mesic, sandy soils of upper slopes and crest. Japanese honeysuckle is beginning to severely impact many areas of the site (Allison 1999, p. 2; Schotz 2010, p. 42). This 7- ha (17-ac) unit contained 47 Georgia rockcress plants during the 2010 survey. The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with maintenance of a recreational field and nonnative species.

Unit 13. Fort Gaines Bluff, Clay County, Georgia:  Privately owned, the Fort Gaines Bluff unit is located 1.5 km (0.9 mi) south of Fort Gaines, Georgia, on the Chattahoochee River. This high, steep, eroding river bank has sandy loam soils and an intact hardwood overstory. Japanese honeysuckle has become severe over much of area (Allison 1995, pp. 18–29; Moffett 2007, p. 9). This 17- ha (43-ac) unit contained 84 Georgia rockcress plants in 2010. The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with timber harvest and nonnative species.

Unit 14A. Goat Rock North and Unit 14B. Goat Rock South, Harris and Muscogee Counties, Georgia:  Privately owned, the Goat Rock Dam is 18.5 km (11.5 mi) north of Columbus Georgia. The Goat Rock North subunit is immediately north of Goat Rock Dam on the banks of Goat Rock impoundment, while the Goat Rock South subunit is immediately downstream of Goat Rock Dam along the high bluffs overlooking the Chattahoochee River. All of Goat Rock North subunit and the majority of the Goat Rock South subunit are owned by a corporation that supports conservation efforts for Georgia rockcress. The corporately owned property is provided modest protection in the shoreline management plan, which was developed during Federal Energy Regulatory Commission (FERC) licensing (FERC 2004, pp. 29–30). However, the southernmost portion of the Goat Rock South subunit is privately owned. This high rocky bluff is mostly covered by a mature canopy of trees. A narrow portion of this habitat has a transmission line passing over the top where all woody species have been removed; however, Georgia rockcress plants are scattered in the transmission line right-of-way. This area contains PCEs 1 and 2; therefore, it is included in the final designation. Nonnative species, including Chinese privet and Japanese honeysuckle, have severely impacted this site (Allison 1995, pp. 24– 27; Moffett 2007, pp. 6–9). Conservation actions here have included invasive species/woody competition removal (both manually and chemically) to benefit existing Georgia rockcress plants, and prescribed burning to open up new adjacent sites for outplanting enhancement. The Chattahoochee Nature Center (CNC) outplanted approximately 300 Georgia rockcress plants of the Goat Rock genotype at this site in 2008. The local office of TNC has also expressed interest in possibly including this site in their long-range ecosystem planning (Elmore 2010, pp. 1–3). Subunits 14A and 14B are 7 ha (19 ac) and 24 ha (59 ac), respectively, and contain two or more of the PCEs throughout the subunits. In 2007, approximately 1,000 Georgia rockcress plants were found scattered across these subunits. The physical or biological features essential to the conservation of the species in these subunits may require special management considerations or protection to address threats associated with hydropower, utility line maintenance, and nonnative species.

Unit 15. Blacks Bluff Preserve, Floyd County, Georgia: Privately owned, the 37-ha (92-ac) Blacks Bluff Preserve unit is located 6.5 km (4.0 mi) southwest of Rome, Georgia, on the Coosa River. Blacks Bluff is in private ownership with a conservation easement on the property. There were 27 Georgia rockcress plants reported on this site in 1995; however, the presence of nonnative species has since extirpated all Georgia rockcress from this site. The Georgia Plant Conservation Alliance (GPCA) and TNC agreed to bolster the existing population with plants grown from seed collected at the two nearby (Ridge and Valley physiographic province) populations, Whitmore Bluff, and Resaca Bluffs. The CNC collected seed and grew 35 plants from Whitmore Bluff and 65 plants from Resaca Bluffs. In 2008, 100 Georgia rockcress plants were planted in this unit, with 84 Georgia rockcress surveyed on this site in 2011 (Goldstrohm 2011, p. 1). This steep bluff with limestone ledges and boulders has a mature deciduous canopy. Multiple sources of disturbance, including an abandoned quarry, have impacted this site and resulted in the establishment of many nonnative species, including Japanese honeysuckle and Nepalese browntop (Allison 1995, pp. 19–20; Moffett 2007, pp. 5–9; Elmore 2010, pp. 1–3). The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with roads, mining, and nonnative species.

Unit 16. Whitmore Bluff, Floyd County, Georgia: Privately owned, the Whitmore Bluff unit is located 6.5 km (4 mi) northeast of Rome, Georgia, on the east bank of the Oostanaula River. This steep bluff with limestone boulders has a mature canopy with Ulmus alata (winged elm), Quercus montana (chestnut oak), and Fraxinus americana (white ash), and an understory including Hydrangea arborescens (wild hydrangea), Toxicodendron radicans (poison ivy), and Sedum ternatum (woodland stonecrop). Japanese honeysuckle has severely impacted this site (Allison 1995, p. 21; Moffett 2007, pp. 6–9; Elmore 2010, pp. 1–3). This 17-ha (43- ac) unit contained 63 Georgia rockcress plants in 1995, but only 12 in 2010. The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with timber harvest and nonnative species.

Unit 17. Resaca Bluffs, Gordon County, Georgia: Privately owned, the Resaca Bluffs unit is located 0.8 km (0.5 mi) southwest of Resaca, Georgia, immediately east of I–75 along the northern bank of the Oostanaula River. This unit includes a rocky limestone bluff with a mature canopy, including eastern red cedar, Quercus nigra (water oak), Quercus velutina (black oak), winged elm, white ash, southern sugar maple, and redbud. Nonnative species, including Chinese privet and Japanese honeysuckle, have severely impacted this site (Allison 1995, pp. 22–23; Moffett 2007, pp. 5–9; Elmore 2010, pp. 1–3). This 5-ha (13-ac) unit contained 51 plants in 1995, and 42 in 2010. The physical or biological features essential to the conservation of the species in this unit may require special management considerations or protection to address threats associated with road crossings, development, and nonnative species.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Arabis georgiana critical habitat consists of four components (79 FR 54635-54667):

(i) Large river bluffs with steep and/ or shallow soils that are subject to localized disturbances that limit the accumulation of leaf litter and competition within the Lower Gulf Coastal Plain, Upper Gulf Coastal Plain, Red Hills, Black Belt, Piedmont, and Ridge and Valley Physiographic Provinces of Georgia and Alabama.

(ii) Well-drained soils that are buffered or circumneutral generally within regions underlain or otherwise influenced by granite, sandstone, or limestone.

(iii) A mature, mixed-level canopy with spatial heterogeneity, providing mottled shade and often including species such as Juniperus virginiana (eastern red cedar), Ostrya virginiana (American hophornbeam), Quercus muehlenbergii (chinquapin oak), Fraxinus americana (white ash), Acer barbatum (southern sugar maple), and Cercis canadensis (eastern redbud) with a rich diversity of grasses and forbs characterizing the herb layer.

(iv) Intact habitat that is fully functional (i.e., with mature canopy and discrete disturbances) and buffered by surrounding habitat to impede the invasion of competitors.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographic area occupied by the species at the time of listing contain features which are essential to the conservation of the species and which may require special management considerations or protection. A fully functioning bluff habitat (i.e., with mature canopy and discrete disturbances) is required to provide the features essential to the conservation of this species and may require special management considerations or protection to reduce the following threats: Land-clearing activities that alter the canopy, including silvicultural management, building of utility lines, structures, roads, or bridges; construction of reservoirs that inundate habitat; mining activities; or introduction of invasive species that compete directly with Georgia rockcress. Large-scale disturbances, such as fire or soil-disturbing activities, should be minimized. A mature canopy with spatial heterogeneity should be maintained to impede invasive species while providing an opportunity for localized disturbances as canopy-gap dynamics develop. Invasive species should be eliminated from the critical habitat units. A mature canopy on the bluffs and a surrounding buffer area will help to exclude nonnatives.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2013)

**Dependency on Other Individuals or Species**

Adult: Pollinators (inferred from USFWS, 2013)

**Breeding Season**

Adult: March - April

**Reproduction Narrative**

Adult: Flowering occurs from March to April, with fruiting beginning in May and into early July (Allison 1995, p. 4; Patrick et al. 1995, pp. 17–18; Chafin 2007, pp. 47–48; Schotz 2010, p. 3) (USFWS, 2013).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Palustrine: herbaceous wetland, riparian; Terrestrial: bare rock/talus/scree, barrens, cliff, mixed forest (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: High to moderate light conditions (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Heavy shade, acidic soils (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Shallow soil accumulations on rocky bluffs, ecotones of gently sloping rock outcrops, outcrops along rivers, and sandy loam along eroding riverbanks. It is occasionally found in adjacent mesic woods but it will not persist in heavily shaded conditions. Requires high to moderate light conditions, occurs on soils which are circumneutral to slightly basic (Norquist 2000). Ketona Glades and other locations in Bibb County, AL (Allison and Stevens 2001). The environmental specificity is narrow as this species is a specialist with key requirements common (NatureServe, 2015). This species requires large river bluffs with steep slopes and/ or shallow soils that are subject to localized disturbances (USFWS, 2014).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Unknown (NatureServe, 2015)

**Species Trends:**

10 - 30% decline (NatureServe, 2015)

**Resiliency:**

Currently there are three populations with excellent resilience, six populations with good resilience, five populations with fair resilience, three populations with poor resilience, five historical populations, and two extirpated populations. (USFWS, 2021a)

**Representation:**

Representative units for this species correspond to a North Georgia, South Georgia, and Alabama group according to genetic analysis. (USFWS< 2021a)

**Redundancy:**

Georgia rockcress is endemic to Alabama and Georgia. Populations of Georgia rockcress are restricted to small patches of suitable habitat associated with large river bluffs with steep and/or shallow soils that are subject to localized disturbances that limit the accumulation of leaf litter and competition, underlain with granite, sandstone, or limestone. The habitat specificity for this species has resulted in limited and fragmented suitable habitat resulting in low redundancy; therefore, Georgia rockcress may be at a higher risk for extinction from habitat loss or degradation associated with localized events (manmade or natural). (USFWS, 2021a)

**Population Growth Rate:**

Unknown (NatureServe, 2015)

**Number of Populations:**

17 (USFWS, 2021)

**Population Size:**

~ 5,000 plants (USFWS, 2013)

**Adaptability:**

Low (inferred from USFWS, 2013)

**Population Narrative:**

No studies have been conducted on population dynamics and reproduction biology. However, based on field inspections, recruitment appears low. Most occurrences are small, containing only a few plants. This species has experienced a short-term decline of 10 - 30%; although many occurrences have remained relatively stable over the past 10-20 years, some have decreased in size primarily as a result of invasive species, logging, and succession. (NatureServe, 2015). Currently, 18 populations are documented to occur across Alabama and Georgia. Georgia rockcress is rare throughout its range. Moffett (2007, p. 8) found approximately 2,140 plants from all known sites in Georgia. Moffett (2007, pp. 1–2) indicated that the overall status of the three populations in the Ridge and Valley ecoregion (Floyd and Gordon Counties, Georgia) was poor, as these populations tended to be small, and declining in size and vigor. Schotz (2010, p. 8) documented fewer than 3,000 plants from all known sites in Alabama. Only the Goat Rock Dam and Fort Benning populations are sufficiently large (greater than 1,000 individuals) to preclude a genetic bottleneck (Schotz 2010, pp. 13–57; Moffett 2007, p. 8) (USFWS, 2013). Georgia rockcress continues to be threatened with extinction throughout its range. Only about half (9 of 17) of the extant Georgia rockcress populations are currently resilient (good to excellent resiliency) and more than 75 percent of the populations are threatened by habitat degradation from invasive plant species. In the future under "Status Quo" conditions, only four to two populations are expected to be resilient in 20 to 40 years, respectively, without additional conservation efforts which may be facilitated by the ESA and prioritized with ESA protections and recovery programs. (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, habitat degradation, more than its outright destruction, is the most serious threat to this species' continued existence. Most of the Coastal Plain rivers surveyed by Allison (1995, p. 11) were considered unsuitable for Georgia rockcress because their banks had been disturbed to the point where there was no remaining vegetative buffer. Recent habitat degradation (i.e., vegetation denuded and replaced by hard-packed, exposed mineral soil) has occurred at several Georgia sites in association with residential development and campsites atop the bluffs (Moffett 2007, pp. 3–4). Disturbance associated with timber harvesting, road building, and grazing in areas where the plant exists has created favorable conditions for the invasion of nonnative weeds in this species' habitat (Factor E) (Schotz 2010, p. 10). Timber operations that remove the forest canopy promote early successional species and result in the decline of Georgia rockcress (Schotz 2010, p. 10). Encroachment of development in the form of bridges, roads, houses, commercial buildings, or utility lines allowing for the introduction of nonnative species (Factor E) also result in the decline of Georgia rockcress (Schotz 2010, pp. 9–10; Moffett 2007, pp. 2–7; Alison 1995, pp. 7–18). Quarrying destroys the bluff habitat by removing the canopy and soil. Rock bluffs along rivers have also been favored sites for hydropower dam construction. Historically, suitable habitat was destroyed or degraded due to quarrying, residential development, timber harvesting, road building, recreation, and hydropower dam construction. Severe impacts continue to occur across the range of this species, from quarrying, residential development, timber harvesting, road building, recreation, and hydropower dam construction, and one or more of these activities pose ongoing threats to all known populations (USFWS, 2013)

**Stressor:** Small population size (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Given the extremely small size of Georgia rockcress populations, projects that destroy even a small amount of habitat can have a serious impact on this species, including existing genetic diversity of the species. Given the extremely small number of total plants (fewer than 5,000 in a given year; 12 of the 18 populations have fewer than 50 plants (Schotz 2010, p. iii; Elmore 2010, pp. 1–4; Moffett 2007, pp. 2–7; Alison 1999, pp. 1–5; Alison 1995, pp. 7–18)), and that the species is distributed as disjunct populations across five physiographic provinces (Schotz 2010, pp. 9–10; Moffett 2007, pp. 2–7; Alison 1995, pp. 7–18) in three major river systems, each population is important to the conservation of genetics for the species (Garcia 2012, pp. 30–36). Any threats that remove or further deteriorate populations can also have a detrimental effect on the existing genetic diversity of the species (USFWS, 2013)

**Stressor:** Climate change (USFWS, 2013)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change will be a particular challenge for biodiversity because the interaction of additional stressors associated with climate change and current stressors may push species beyond their ability to survive (Lovejoy 2005, pp. 325–326). The synergistic implications of climate change and habitat fragmentation are the most threatening facet of climate change for biodiversity (Hannah and Lovejoy 2005, p. 4). Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, pp. 1–3; Hayhoe et al. 2004, p. 12422; Cayan et al. 2005, p. 6; Intergovernmental Panel on Climate Change (IPCC) 2007, p. 1181). Climate change may lead to increased frequency and duration of severe storms and droughts (Golladay et al. 2004, p. 504; McLaughlin et al. 2002, p. 6074; Cook et al. 2004, p. 1015).). While severe drought would be expected to have an effect on the plant community, including the mature canopy and canopy gap dynamic, and increased storm intensity could accelerate erosion-related disturbances, the information currently available on the effects of global climate change and increasing temperatures does not make sufficiently precise estimates of the location and magnitude of the effects. In addition, we are not currently aware of any climate change information specific to the habitat of the Georgia rockcress that would indicate which areas may become important to the species in the future (USFWS, 2013).

**Stressor:** Nonnative species (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threat to extant populations of Georgia rockcress is the ongoing invasion of nonnative species due to the degradation of its habitat. Encroachment from timber management and development in the form of bridges, roads, houses, commercial buildings, or utility lines allowing for the introduction of nonnative species has resulted in the decline of Georgia rockcress (Schotz 2010, pp. 9–10; Moffett 2007, pp. 2–7; Alison 1995, pp. Human-induced disturbance (quarrying, residential development, timber harvesting, road building, recreation and hydropower dam construction) has fragmented river bluff habitats and created conditions so that these bluff habitats are receptive to invasion of nonnative species (Honu and Gibson 2006, pp. 263–264). Disturbance of 17 of the 18 known sites occupied by this species has provided opportunities for the invasion of aggressive, nonnative weeds, especially Lonicera japonica (Japanese honeysuckle).

### *Recovery*

**Reclassification Criteria:**
Not available - this species does not have a recovery plan.

**Delisting Criteria:**
Not available - this species does not have a recovery plan.

**Recovery Actions:**
- Not available - this species does not have a recovery plan.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Finalize the recovery plan. • Conduct regular monitoring or resurvey all known accessible populations. • Conduct studies to determine the number and distribution of populations required to maintain the species' genetic diversity and long-term viability. • Continue and expand work with federal and state conservation agencies, nongovernmental organizations, and private individuals and organizations to protect and manage existing habitats and populations, including the development and implementation of management plans, as needed. • Identify, implement, and assess management actions to sustain extant populations, including but not limited to invasive species management and forest management practices that set back succession. • Establish methods to effectively reintroduce and monitor Georgia rockcress. • Develop a captive propagation and reintroduction plan. • Conserve germplasm (genetic material; e.g. seed) and promote genetic diversity. • Conduct studies of genetic variation within and between known sites. • Investigate potential pest and disease threats for Georgia rockcress. • Conduct studies into the species' life history, biology, and ecology to improve management of the species and its habitat. • Look for opportunities to protect existing populations through acquisition, easements and/or management agreements. • Develop and implement management strategies for the Georgia rockcress, initially with the two State parks in Alabama. • Search for new populations within suitable habitat. (USFWS, 2021)
- Conservation Scenario 1: Status Quo Maintaining the current level of management and conservation in an effort to offset habitat degradation and canopy closure resulted the extirpation of three populations by 2040 and six in 2060 (Table 6-15; Figure 6-2). Of nine currently resilient populations, only four are expected to be resilient by 2040, and only two will remain so in 2060. Of 24 known populations, 20 populations will be either not resilient or extirpated by 2040 and 22 will be either not resilient or extirpated by 2060. Three populations change from fair (C) to extirpated between 2040 and 2060, as their current population size made persistence unlikely (Table 6-9). Over half (16 of 24; 67 percent) of the populations are extirpated in the 2060 projection. Extirpated populations occur on private lands subject to canopy closure and/or the spread of invasive species, and on protected state lands that do not utilize management to limit the impacts of these threats. (USFWS, 2021a)
- The loss of resilient populations within representative units in the Status Quo Scenario indicates a potential decline in the species' adaptive capacity that can be offset through increased conservation and management. Under the Status Quo there is a great loss of resilient populations from representative units resulting in a loss of species level adaptive capacity. Given the reductions in resiliency and the extirpation of populations at 2040 and 2060, the species' representation is predicted to be greatly reduced from current levels in this scenario. However, these losses are offset under the Focused Scenario where resilient populations are maintained in all representative units, with the Expansion Scenario maintaining or increasing representation in all units with the potential to expand the species range. (USFWS, 2021a)

# SPECIES ACCOUNT: *Arabis macdonaldiana* (McDonald's rock-cress)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/28/1978; Pacific Southwest (R8)

**Physical Description**

A perennial species having relatively large, conspicuous lavender to purplish flowers and a rosette, usually flattened, of obovate to broadly oblanceoate leaves from which the flowering stems arise (Rollins 1973). Seeds are winged at the distal end and have trichomes (hairs) on the leaves which are simple. Arabis mcdonaldiana is glabrous (without hairs) except for a few marginal trichomes on the basal leaves; is less than 1.5 decimeters high, and has truncate petals . (USFWS, 1990)

**Taxonomy**

Arabis mcdonaldiana was first described by Alice Eastwood (1903). In her original description, Eastwood (1903) employed the spelling used in this recovery plan, naming the species in honor of Captain James M. McDonald. Critchfield (1977) altered the spelling to "macdonaldiana" following Recommendation 73C.4 of the International Code of Botanical Nomenclature (Latest edition: Stafleu 1978). Critchfield considered the Eastwood spelling to be an orthographic error. Since, however, the spelling change is based on a recommendation of the Code, not a rule, and because it is unclear whether this recommendation applies to previously published names, the original spelling "mcdonaldiana" is retained. (USFWS, 1990) Genetics research summarized in the USFWS 2013 Five-Year Review reported that Harbaugh-Reynaud and Vorobik sampled 42 specimens within the purple-flowered Arabis group. Their results indicated that Arabis macdonaldiana is represented by two distinct lineages: (1) Red Mountain, Mendocino County, California; and (2) Siskiyou and Del Norte counties, California, and Curry and Josephine counties, Oregon. In their summary report of the 2012 research, Harbaugh-Reynaud and Vorobik recommended that Arabis macdonaldiana specimens from Red Mountain retain the name Arabis macdonaldiana, while the other lineage be revised to be a distinct species (yet to be named), or a subspecies of Arabis aculeolata. Furthermore, Harbaugh-Reynaud and Vorobik determined that Arabis macdonaldiana on Red Mountain is clearly distinct from any other taxon (Harbaugh-Reynaud and Vorobik 2012). Therefore, although there has been much confusion and uncertainty related to the taxonomy genetics of the purple-flowered Arabis group, the most recent genetic work indicates that Arabis macdonaldiana on Red Mountain is distinct from any other taxon. (USFWS, 2013)

**Historical Range**

At the time it was listed, Arabis macdonaldiana was considered to be restricted to a single population at Red Mountain, Mendocino County. However, in 1993, the taxonomic treatment of the species was revised to include populations of purple-flowered rock-cress located near the Oregon border. Since 1993, the species was thought to occur in Mendocino, Del Norte, and the very western portion of Siskiyou counties in California, and the very southern portion of Curry County in Oregon (USFWS, 2013).

**Current Range**

Recent genetic work indicates that Arabis macdonaldiana is confined to Red Mountain, Mendocino County, California (USFWS, 2013).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Vegetative (USFWS, 2013; see habitat narrative)

**Breeding Season**

Adult: April - May (USFWS, 2013)

**Reproduction Narrative**

Adult: Flowering typically occurs between April and May (USFWS, 2013).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Barrens, forest, shrubland (NatureServe, 2015); open scrub (USFWS, 2013)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire (USFWS, 2013)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs ~1,200 m elevation (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 2013)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Occurs in rocky serpentine areas or reddish soils derived from serpentinite, in dry open woods or brushy steep slopes or ledges; usually at elevations of about 1200 m. The environmental specificity is narrow; it is known from 2 or 3 specific areas on serpentine on the north coast of California and in Oregon (NatureServe, 2015). Arabis macdonaldiana occurs in soils derived from ultramafic parent material, containing high levels of heavy metals and low levels of nutrients. Its habitat ranges from barren gravel slopes to open scrub and pine woodlands. Arabis macdonaldiana is highly rhizomatous and clonal, making the determination of an individual difficult. Fire is an important factor affecting vegetation patterns in general across the Klamath Bioregion, including the Red Mountain area where Arabis macdonaldiana occurs, and appears particularly important in maintaining many open habitats (Skinner et al. 2006; U.S. Forest Service [USFS] 1995; Baad 2002) (USFWS, 2013).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Decline of 30-50% (NatureServe, 2015)

**Species Trends:**

10 - 30% decline (NatureServe, 2015)

**Number of Populations:**

34 (NatureServe, 2015)

**Population Size:**

> 10,000 (USFWS, 2013); 17,500 (NatureServe, 2015)

**Population Narrative:**

This species has experienced a long-term decline of 30-50%. The total number of known plants is about 17,500. CNDDB currently has 29 EO's, 9 of which are historic. 10 additional field forms remain unprocessed. California has 29 occurrences, 4 of which are historic. Oregon has 10 occurrences but one is historic. The short term trend is estimated to be slightly declining (10 - 30%) due to mining activities (NatureServe, 2015). Taken together, population survey data suggest the overall population size probably exceeds 10,000 plants (USFWS, 2013).

***Threats and Stressors***

**Stressor:** Mining (USFWS, 2013; USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mining continues to pose a threat to Arabis macdonaldiana at Red Mountain, because the entire distribution of Arabis macdonaldiana continues to be held under unpatented lode and/or placer mining claims. However, the degree of threat is less than when the species was listed, due to Red Mountain Wilderness designation, which has reduced the vulnerability of Arabis macdonaldiana to impacts from new mining claims. Any mining operation on Red Mountain would most likely be an open-face bench type that would involve removal and processing of the mineral-bearing ore containing nickel, chromium, and cobalt (Service 1984). All vegetation and habitat for Arabis macdonaldiana would be removed in the affected area. Although the operations plan would require restoration of the affected areas, plant species composition would undoubtedly be altered. There is no evidence in the literature indicating Arabis macdonaldiana is able to recolonize disturbed soils. Regardless of existing mining claims, Arabis macdonaldiana habitat and serpentine soils in general contain an attractive source of heavy metals, particularly nickel, subject to technological improvements and market fluctuations. Therefore, future pressure to open these lands to mining is possible (USFWS, 2013). The 2019 Amended Recovery Plan reported that new information regarding threats has been obtained that

suggest the threat of mining has been greatly reduced, but not entirely eliminated based on the expiration of several previously valid mining claims near the populations. Several of the mining claims in the Red Mountain Unit of the South Fork Eel River Wilderness Area (Red Mountain Wilderness) have been forfeited. These forfeited claims cannot be relocated, which reduces the threat of mining in the area. However, there are areas occupied by McDonald's rock-cress outside of the Red Mountain Wilderness that are still open for mineral entry. (USFWS, 2019)

**Stressor:** Fire suppression (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A potential threat not identified when the species was listed, and not yet well characterized, is the progressive encroachment into Arabis macdonaldiana habitat by woody species in the absence of fire. Fire suppression efforts can cause adverse effects on Arabis macdonaldiana as a result of fire breaks constructed with heavy equipment or hand crews. Fire breaks are often placed along ridge lines, potential suitable habitat for Arabis macdonaldiana. The heavy equipment generally scrapes a layer of earth, eliminating all vegetation and permanently altering the soils. Fire suppression would also maintain existing scrub and forested habitat, allowing progressive encroachment on the species. At the same time, fire control measures could be beneficial by reducing fire intensity in situations where Arabis macdonaldiana is vulnerable to incineration. Without fire to periodically restore early successional conditions and an open canopy, Arabis macdonaldiana would likely decline in a portion of its range (USFWS, 2013).

**Stressor:** Genetic diversity (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The genetic implications of habitat fragmentation, genetic isolation and declining effective population size are threats common to rare species (Saunders et al. 1991; Meffe and Carroll 1997). At Red Mountain, small breeding populations and the potential loss of genetic diversity from inbreeding and/or random genetic drift could be a problem, given the limited population size and limited range of the species, particularly if the decline observed at Red Mountain continues in future years (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Global climate change likely constitutes a new threat for the species. Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999; Cayan et al. 2005; IPCC 2007). However, predictions of climatic conditions for smaller subregions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. Arabis macdonaldiana at Red Mountain may not have access to environmental heterogeneity, due in part to its more limited extent (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
1. At least ten viable subpopulations are protected and managed to assure their continued existence. Subpopulations include at least 1,000 reproductive individuals (have flowered at least once or are capable of flowering), and a population structure indicating stable or increasing reproductive plant numbers. Subpopulations are polygons or clusters of individuals that are separated by >100 meters. (USFWS, 2019)

2. The ten viable subpopulations must be distributed between both soil types that currently support McDonald’s rock-cress (Littlered and Hiltebiden/Dann soils), with at least two viable subpopulations in each of the two soil types from which the species is currently known to occur. For the purposes of this plan, a subpopulation includes at least 1,000 reproductive individuals, and a population structure indicating stable or increasing reproductive plant numbers. (USFWS, 2019)

Recovery Priority Number: 14C

**Delisting Criteria:**
1. Over a 20-year survey period, monitoring demonstrates a stable or increasing trend in abundance and distribution over the entire Red Mountain population (or across the minimum ten subpopulations). During a minimum of 80 percent of the survey period (i.e., 16 years), an estimated population of 10,000 reproductive individuals will remain extant across all subpopulations. Monitoring will demonstrate a minimum average patch occupancy rate (number of subpopulations with occupied habitat divided by total number of subpopulations) of 60 percent. (USFWS, 2019)

2. At least 10 subpopulations of 1,000 or more reproductive individuals should be protected and managed in perpetuity to reduce or eliminate threats to the species, or perpetual endowments are secured for management necessary to maintain the continued existence of the species. Agreements for the protection and appropriate management of the selfsustaining subpopulations should be in place. Perpetual protection on public land will be assured via management plans. Formal stewardship agreements (e.g., conservation easements or similar instruments) should be in place to ensure perpetual long-term, species-appropriate management on privately owned land. (USFWS, 2019)

3. Lands in public ownership (federal lands) should consider land use allocations compatible with managing habitats to maintain or enhance McDonald’s rock-cress occupied habitat. Habitat management plans (HMPs) should be developed and implemented that include restoration opportunities, use restrictions, and/or management actions for the conservation of sensitive, threatened, and endangered plants and wildlife resources. Approved HMPs should include a minimum of a 100-meter (300-foot) surface disturbance buffer around occupied McDonald’s rock-cress habitat, and would prioritize avoidance of occupied habitat and assist in connectivity for pollination between subpopulations. (USFWS, 2019)

4. An ex situ collection of plant material is established in a Center for Plant Conservationaffiliated botanic garden. A soil seedbank would typically provide a strategy for a species to regenerate populations in the face of stochastic events as well as natural senescence;

however, this species is known to be susceptible to high rates of seed predation. (USFWS, 2019)

5. A monitoring plan to cover a minimum of 10 years post-delisting of McDonald's rockcress has been approved by the Pacific Southwest Regional Director and is ready to be implemented at the time of delisting. (USFWS, 2019)

**Recovery Actions:**

- Enforce laws and regulations that may affect conservation of the species. To accomplish the primary objective of this recovery plan it is necessary for the appropriate Federal and State agencies to rigorously enforce all laws and regulations which may affect conservation of Arabis mcdonaldiana. Foremost among these laws and regulations is the Endangered Species Act of 1973, as amended, and its associated regulations. Other relevant laws and regulations include the California Native Plant Protection Act, applicable to those areas within the range of A. mcdonaldiana that are privately owned; the Federal Land Policy and Management Act, under which the Bureau administers lands under its jurisdiction; the National Environmental Policy Act and California Environmental Quality Act; the Wilderness Act and Bureau regulations and policies applying to lands under wilderness review for those applicable portions of the species' range; the Bureau regulations governing the surface management of Federal lands under the U.S. Mining Laws; the State of California Surface Mining and Reclamation Act of 1975; the Clean Water Act of 1977 as it applies to the regulation of surface disturbing activities such as mining which pollute waterways; and the Clean Air Act as applicable to air pollution associated with the processing of minerals. (USFWS, 1990).
- Protect essential habitat. Sufficient habitat must be protected to insure the well-being of Arabis mcdonaldiana. This will require identification and precise mapping of the essential habitat as well as determining and selecting the appropriate means to do so. Much of the opportunity to protect A. mcdonaldiana will depend upon the authority of the State and Bureau to regulate surface mining. (USFWS, 1990).
- Monitor agency compliance with the recovery plan. To assure that all aspects of the recovery program are proceeding in an effective and timely manner, a compliance monitoring effort should be initiated. (USFWS, 1990).
- Enhance public awareness of Arabis mcdonaldiana recovery effort through informational and educational programs. Although an awareness program does not contribute direct benefits to the recovery effort, it can provide important long-term benefits. Audio-visual programs, a small brochure on the unique resources of Red Mountain, and a pamphlet on Arabis mcdonaldiana could help foster respect for the values addressed in this plan. In addition, scientific study of the soils, vegetation, and fauna of Red Mountain should be encouraged. Additional studies could provide as yet unknown benefits to future generations. (USFWS, 1990).
- A field study of A. macdonaliana should be conducted to determine the degree to which shrub and tree encroachment may be impacting the population (USFWS, 2013).
- A field study of A. macdonaliana should be conducted to determine the continued presence of Arabis macdonaldiana in previously mapped habitat polygons, or other locations at Red Mountain (USFWS, 2013).
- A field study of A. macdonaliana should be conducted to determine the cause for the observed decline in Arabis macdonaldiana in the vicinity of the study sites used by Baad (2002) (USFWS, 2013).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Because there is some evidence to suggest that the population may have declined since listing (Service 2013, entire), a field study of McDonald's rock-cress should be conducted to determine: (1) The degree to which shrub and tree encroachment may be impacting the population; (2) The continued presence of McDonald's rock-cress in previously mapped habitat polygons, or other locations at Red Mountain; (3) The cause for the observed decline in McDonald's rock-cress in the vicinity of the study sites used by Baad (2002). (USFWS, 2020)

# SPECIES ACCOUNT: *Arabis serotina* (Shale barren rock cress)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 7/13/1989; Northeast Region (R5) (USFWS, 2016)

**Physical Description**

A facultative biennial herb characterized in its nonreproductive stage by an inconspicuous basal rosette of lobed leaves. Average rosette size ranged from 1.6—3.5 cm. In its reproductive stage, the basal leaves shrivel as the slender stem grows, or "bolts," and the inflorescence develops (USFWS, 1991).

**Taxonomy**

A member of the mustard family, Brassicaceae. There has been some debate over the taxonomy of the species: A. serotina is not mentioned in some floras and is treated as synonymous with Arabis laevigata var. burkii in others (USFWS, 1991).

**Historical Range**

First observed in Virginia; extent of historical range is not reported (USFWS, 1991).

**Current Range**

Ten counties in Virginia and West Virginia (USFWS, 1991).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect (EPA, 2016)

**Breeding Season**

Adult: Flowers from mid-July through September (USFWS, 1991)

**Key Resources Needed for Breeding**

Adult: Flower flies (USFWS, 1991); possibly bees (NatureServe, 2015).

**Reproduction Narrative**

Adult: Flowers from mid-July through September (USFWS, 1991); Pollinated by insects (flower flies and butterflies, possibly bees (NatureServe, 2015).

**Habitat Type**

Adult: Terrestrial (USFWS, 1991)

**Habitat Vegetation or Surface Water Classification**

Adult: Shale barrens of the Ridge and Valley Province of the Appalachian Highlands (USFWS, 1991)

**Geographic or Habitat Restraints or Barriers**

Adult: Elevation from 400 to 600 m (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Habitat is shale barrens of the Ridge and Valley Province of the Appalachian Highlands (USFWS, 1991), occurring only on sparsely-vegetated xeric, south or west-facing shale slopes (barrens) at elevations from 400 to 600 meters (NatureServe, 2015). Populations are known from both the shale openings and shale woodlands adjacent to the shale openings. The term "shale barren" is a general reference to certain mid-Appalachian slopes that possess the following features: 1) southern exposures, 2) slopes of 20-70 degrees and 3) a covering of lithologically hard and weather-resistant shale or siltstone fragments (NatureServe, 2015).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Increasing (USFWS, 2023)

**Number of Populations:**

62 (USFWS, 2023)

**Population Narrative:**

Since the 2010 status review, VDCR-DNH conducted shale barren rock cress surveys in 2013 (Van Alstine and Heffernan 2013, entire), 2017 (Van Alstine 2017, entire), 2018 (Van Alstine 2019, entire), 2019 (Stanley 2019, entire), and 2020 (Stanley 2021, entire). At the time of the 2010 status review, more than half of the known occurrences in VA had not been revisited since the 1990s. As of this review, approximately 30 (of 34) previously known EOs in VA have been revisited/monitored, and several new EOs and SFs within existing EOs have been identified. Of the 30 EOs that were revisited, 4 were downranked, and the remainder had no change in rank. The four downrankings were a result of either finding lower numbers of SFs than previous counts or finding other site conditions or reproductive conditions that lowered the EO rank. For this status review, VDCR-DNH staff botanist John Townsend reviewed the VA reports written since the 2010 status review to clarify the findings in terms of EOs and SFs. A total of 3 new EOs (comprising a total of 7 new SFs) were recorded during the 2017-2020 surveys, as well as a total of 31 new SFs that were grouped into existing EOs due to proximity to known SFs (J. Townsend, VDCR-DNH, email to S. Hoskin, Service, August 27, 2021). In 2011, WVDNR botanists reduced shale barren rock cress monitoring frequency to every 5 years due to concerns that shale barrens might be negatively impacted by people traversing the barrens during surveys. Depending on funding and staffing, EOs are monitored every 5 years. In 2017, WVDNR botanists clarified that a plant identified as shale barren rock cress was smooth rock cress (Arabis laevigata var. burkii) (WVDNR 2018, unpaginated). In 2019, WVDNR staff assisted in investigating a report of a new occurrence of shale barren rock cress in the path of a proposed Federal highway. After examining seeds under a dissecting microscope, sharing plant photos and a summary of characteristics with experts in VA and WV, and examining known shale barren rock cress plants, they determined the plants in question were a different species (WVDNR 2019). Overall, the status and trends in WV have been stable, but many of the EOs have fair or worse viability, which increases their risk to stochastic events (A. Silvis, WVDNR, letter to S. Hoskin, Service, January 25, 2021). In summary, the number of known EOs throughout the species range has increased from 34 to 62 in the 34 years since the time of listing, with 1 EO in WV not relocated and 4 EOs in VA not revisited since the 1990s. Twenty-nine EOs in VA and 22 EOs in WV have been assessed since 2010. Of these 51 EOs, 4 have been downranked and 47 have had no change in status since their original discovery (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat degradation or modification (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Road, dam, and railroad construction have resulted in the partial destruction and disturbance of shale barrens containing A. serotina (USFWS, 1991).

**Stressor:** Drought (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Increased reproductive failure was observed among populations in one West Virginia valley that suffered a severe drought in 1987. Additional West Virginia data from 1988 and 1989 -- years of drought and normal rainfall, respectively -- suggested significant negative effects from drought on reproduction in the A. serotina populations studied, including dead terminal and lateral shoot tips and decreased fruit production (USFWS, 1991).

**Stressor:** Herbivory (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory by deer has been suggested by some investigators as a significant threat to A. serotina, although the data are mainly circumstantial. Most grazing activity appears to occur in spring, when (if a plant is not otherwise stressed) loss of the terminal bud could increase branching and, possibly, flower and seed production; this makes it difficult to ascertain the degree of threat grazing represents (USFWS, 1991).

**Stressor:** Other factors that can affect species populations (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since most of the 34 extant populations consist of less than 100 plants (many with fewer than ten individuals), this rare species may be particularly vulnerable to local extirpation. In general, any other threat that acts on the species is more likely to destroy a small population

than a large one. These small populations may also be susceptible to catastrophic loss by a stochastic event causing reproductive failure such as a tree falling or seed dispersal into an unsuitable habitat (USFWS, 1991).

**Stressor:** Insects and insect-control measures (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** There has been some concern about possible impacts on A. serotina from gypsy moth (Lymantria dispar) infestation. Escaping in New England, the gypsy moth has moved south, defoliating large forest tracts and causing substantial mortality of trees in some forest types. The moth has entered the northern portion of A. serotina's range and may cover the entire range in the next one to four years. Of more immediate concern are the possible effects on A. serotina caused by treatments to control gypsy moths, which may cause high mortality in certain non-target organisms. These organisms include pollinators of A. serotina such as two rare butterflies (Pvrcrus wyandot and Euchloe olympia), which inhabit shale barrens and adjacent woodlands (USFWS, 1991).

**Stressor:** Overcollection (USFWS, 1991)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Overcollection of this species by botanists may also pose a threat to some populations of A. serotina, particularly at the more accessible shale barrens (USFWS, 1991).

**Stressor:** Fire suppression (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** There has been little research conducted on the role of fire in shale barrens. In Illinois, Heikens et al. (1994, p. 279) found no increase in herbaceous understory plants at a shale barren in the short term, 7 months after a prescribed burn. The authors note that more research is necessary to understand the best ways to restore and maintain shale barren habitats. WVDNR reported that prescribed fire may pose a threat to populations, but the impacts of prescribed fire currently are poorly understood, and it is possible that prescribed fire, under certain management prescriptions and implementations, may be beneficial for the species (WVDNR email to Sumalee Hoskin, Service, January 25, 2021). Stanley (2021, p. 7) noted that lack of fire is likely a potential threat to B. serotina, although again noting the role of fire historically in shale barrens is poorly understood. One source indicates that shale barrens were historically prone to regular burning (Aldrich et al. 2010, p. 36). A prescribed burn of a shale barren adjacent to a population of B. serotina resulted in the species occurring in the burned area where it was not previously known to occur (Fred Huber, pers. comm.). Although the 2010 status review referred to prescribed fires as "a newly identified threat to this species" it further stated that there is "limited information in the scientific literature about the impact of fire and/or prescribed burns to shale barrens and specifically to A. serotina." To date there has not been targeted research to understand whether fire is ultimately beneficial or harmful to shale barren rock cress. However, as stated earlier, this species occurs in fire-prone areas that may have a history of fire, which is indicative that it has adapted to periodic fire. Without fire, the woodland landscapes surrounding

the barrens may begin to encroach. While fire may have short-term negative impacts to individuals, it is unclear whether a frequent fire regime may have long-term beneficial impacts to the species (USFWS, 2023).

**Stressor:** Climate change (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Shale barrens and their associated species have a naturally patchy distribution as they occur in spatially isolated outcroppings across the landscape. Shale barrens are also considered xeric (low moisture) habitats, and the species that occur there are adapted to those conditions. There is little available information specific to the potential impacts of climate change to shale barren habitats or associated species. Anderson et al. (1999, p. 95) made the assumption that shale barren endemics are likely to have the capacity to tolerate temperature extremes given the high summer temperatures often experienced on shale barrens. Damschen et al. (2012) conducted a literature review of the responses of plant communities on “special soils,” specifically serpentine communities, and found that the limited amount of research available seems to indicate that these communities may be less sensitive to climatic changes than their “normal soil” counterparts (p. 1127); however, they noted that application to other “special soil” communities like shale barrens can be challenging given the differences in specific stressful conditions, functional traits, and stress-tolerance adaptations of the different plant communities (i.e., low moisture vs. acidic soils vs. nutrient limited, etc.; p. 1127). In summary there is high uncertainty associated with the potential effects of future climatic changes to shale barrens in general and B. serotina specifically. However, the currently available information, albeit limited, does not indicate a mechanism for impacts to the species from changing climate (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
1. Twenty demonstrably self-maintaining populations are distributed throughout the species' range (USFWS, 1991).

2. The habitat of these 20 populations is permanently protected (USFWS, 1991).

3. Seeds are stored to prevent extinction in case of disastrous loss of natural populations (USFWS, 1991).

Recovery Priority Number: 11

**Delisting Criteria:**
1. Twenty demonstrably self-maintaining populations are distributed throughout the species' range (USFWS, 1991).

2. The habitat of these 20 populations is permanently protected (USFWS, 1991).

3. Seeds are stored to prevent extinction in case of disastrous loss of natural populations (USFWS, 1991).

4. Fifteen additional self-maintaining populations and their habitat are permanently protected (USFWS, 1991).

**Recovery Actions:**

- Seek protection of all extant populations, and secure permanent protection for demonstrably self-maintaining populations and their habitat (USFWS, 1991).
- Monitor extant populations and their habitat on a regular basis (USFWS, 1991).
- Search for additional populations (USFWS, 1991).
- Study life history, ecological, and population parameters and establish guidelines for determining what constitutes a self-maintaining population (USFWS, 1991).
- Store seeds off-site in case of loss of extant populations (USFWS, 1991).
- As needed, manage populations for the maintenance of each population and its habitat (USFWS, 1991).
- Not available.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS x Complete process for removal of ESA protections x Develop post-delisting monitoring plan in collaboration with state agencies While not a requirement for delisting the species, research using prescribed fire to restore the historical fire regime of shale barrens would ascertain its impact on native species including B. serotina. This activity would address an area of uncertainty that has been frequently noted by state biologists and the results would be informative for habitat restoration purposes for species associated with rare and unique shale barren habitats (USFWS, 2023).

# SPECIES ACCOUNT: *Arctomecon humilis* (Dwarf Bear-poppy)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 12/06/1979; Mountain-Prairie Region (Region 6) (USFWS, 2015)

**Physical Description**

perennial herb with long taproots, woody caudices, and tufts of basal leaves. Short leafy peduncles are only 12-15 cm tall. Due to the short leafy stems, the white flowers appear to float above the cluster of leaves, accentuating the plant's low stature. The flower of A. humilis usually has 4 petals. The genus name is based on the bear paw-like appearance of the shaggy villous leaves while the leaves of are only slightly lannate with deeply 3-toothed leaves at the apex. The abundant white flowers that bloom mid-April through May are showy next to the red soils in which the plant grows. (USFWS, 2015; NatureServe, 2015)

**Taxonomy**

While three species of bear-poppy share common morphological features, the combination of features is distinctive in each one. The dwarf bear-poppy exhibits similar stamen and pistil structure to A. merriamii and the racemose inflorescence of A. californica rather than the solitary inflorescence of A. merriamii. The clustered pure white flowers of the dwarf bear-poppy and the bright yellow-flowered A. californica make them quite attractive in their arid environment. The dwarf bear-poppy is characterized by several unique features including stature, leaf morphology, and floral parts. Its short leafy peduncles are only 12-15 cm tall. Both other species have tall naked peduncles: A. merriamii, 20-35 cm, and A. californica, up to 60 cm. Due to the short leafy stems, the white flowers appear to float above the clusters of leaves, accentuating the plant's low stature. Although each species may have from 4-6 petals, the dwarf bear-poppy usually have 4 petals (Atwood 1977). (USFWS, 1985); Dwarf bear-poppy (Arctomecon humilis Coville), is one of three species in the genus Arctomecon of the poppy (Papaveraceae) family. The other two species are A. californica and A. merriamii. The dwarf bear-poppy is the only Arctomecon species found in Utah. There are no taxonomic issues with its status as a distinct and clear species (Nelson and Welsh 1993, Welsh et al. 2003). (USFWS, 2016)

**Current Range**

Endemic to the Dixie Corridor; extant in Washington Co., Utah on the eastern edge of the Mohave desert. (USFWS, 1985); Dwarf bear-poppy is restricted to approximately 9,000 acres (3,642 ha) of habitat in the vicinity of St. George in Washington County, Utah (see Figure 2). The elevation range the species occupies is 823 to 1,006 m (2,700 to 3,300 ft). Approximately 30 percent of the habitat is located on state, private or municipally administered lands; the remaining 70 percent occurs on federal lands managed by the Bureau of Land Management (BLM) (see Table 1) (BLM 2008, Nelson 1989). (USFWS, 2016)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Dwarf bear-poppy reproduces sexually by seeds. The species has a mixed mating system and is thus capable of producing seeds through self-fertilization or crosspollination by pollinators (Tepedino et al. 2014). However, the highest number of seeds and fruits are produced when flowers are cross-pollinated (Tepedino et al. 2014). (USFWS, 2016)

**Breeding Season**

Adult: Seedling recruitment is episodic and occurs en masse when rainfall is sufficient during the late winter and spring. (USFWS, 2016); Mid-April through May (NatureServe, 2015)

**Key Resources Needed for Breeding**

Adult: Seeds are primarily dispersed by wind and animals, mainly ants and rodents, which are also seed predators (Harper and Van Buren 2004; Farrall and Mull 2012; Mull 2012). Seeds are dispersed before they are mature and they need several years to complete development before they germinate (Nelson 1989b; Allphin et al. 1998; Allphin pers. comm. 2014). (USFWS, 2016)

**Reproduction Narrative**

Adult: The abundant white flowers that bloom mid-April through May are showy next to the red soils in which the plant grows. Seeds are dispersed by ants. (NatureServe, 2015). The dwarf bear-poppy is pollinated by many native bees and the non-native European and Africanized honeybee (Apis mellifera). Floral visitors have included at least nineteen different species from six families (Tepedino et al. 2014). Pollinator diversity has declined over the past decade with the loss of two specialist pollinators, the native solitary bees, Perdita meconis and Eucera quadricincta (Tepedino et al. 2014). The loss of specialist pollinators may be the result of the recent invasion of Africanized honeybees to Washington County, Utah (Portman et al. 2017, 2018; Tripodi et al. 2019). One of the primary pollinators is now the Africanized honeybee which appears to be adequately meeting the dwarf bear-poppy's pollination needs in recent years, but the long-term stability of this new mutualism is not yet known (USFWS, 2022).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Desert (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations between 700 and 1402 m. (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (Natureserve, 2015)

**Dependency on Other Individuals or Species for Habitat**

Adult: The dwarf bear-poppy grows sympatrically with the Moenkopi endemic Eriogonum thompsonae var. albiflorum. (USFWS, 1985)

**Habitat Narrative**

Adult: Dwarf bear-poppy habitat is sparsely vegetated, and consists of highly weathered rounded hill and dome formations. Roughly half of the soil surface is bare of vegetation, and the majority of the living cover in the habitat is biological soil crust1 (Nelson 1989a; Nelson and Harper 1991; Simpson 2014). Associated native plants include shadscale (Atriplex confertifolia), Torrey's ephedera (Ephedra torreyana), nodding buckwheat (Eriogonum cernum), desert trumpet (E. inflatum), desert pepperweed (Lepidium fremontii) and burrobush (Ambrosia salsola). Invasive species include red brome (Bromus rubens), cheatgrass (Bromus tectorum), barb-wire Russian thistle (Salsola paulsenii), and African mustard (Malcomia africana) (Harper and Van Buren 2004; Simpson 2014). (USFWS, 2016); Dwarf bear-poppy is found on gypsiferous clay soils derived from the Moenkopi Formation, sometimes on cryptogamic crust. Occurs on rolling low hills and ridge tops, often on barren, open sites in warm desert shrub communities. Found at elevations between 700 and 1402 m. The dwarf bear-poppy grows sympatrically with the Moenkopi endemic Eriogonum thompsonae var. albiflorum. (USFWS, 1985; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds are dispersed by ants. (NatureServe, 2015)

***Population Information and Trends***

**Population Trends:**

A Population Viability Analysis (PVA) for the species indicates a downward population trend within the past 21 years (Meyer et al. 2015) (UWFWS, 2016); Short-term trends indicate a decline of 10 to 30% (NatureServe, 2015)

**Number of Populations:**

9 (USFWS, 2022)

**Population Size:**

We now cautiously estimate that 25,129 adult plants occur range-wide, with 71 percent occurring in the two largest fully censused populations, White Dome and Webb Hill (USFWS, 2022)

**Population Narrative:**

Because of its restricted habitat, it probably never was common. Population numbers fluctuate widely from year to year, based on precipitation, and a large seed bank with long lived seeds is a requirement for the maintenance of this species (Harper and Van Buren 2004). Short-term population trends indicate a decline of 10 to 30%. (NatureServe, 2015). We now know of nine dwarf bear-poppy populations on Federal (Bureau of Land Management (BLM)), Tribal, State of Utah, and private lands (Table 1). We re-evaluated and merged the original 11 population boundaries into seven populations using Nature Serve criteria (Nature Serve 2020). Two additional populations (Warner Valley Springs and Purgatory Flats) were discovered since 2009 (Washington County Water Conservancy District 2009; USFWS 2019). In our last status review, we reported the acreage of suitable habitat because comprehensive survey and census information was not available (USFWS 2016a). We now cautiously estimate that 25,129 adult plants occur range-wide, with 71 percent occurring in the two largest fully censused populations, White Dome and Webb Hill (Table 1). This population estimate is based on a recent census of five populations (Webb Hill, White Dome, Beehive Dome, Shinob Kibe, and Val Springs) using drone (unmanned aerial vehicle) imagery, a partial survey of the Red Bluffs population using drones, and recent site visits to two populations (Warner Valley Springs, Purgatory Flats). Census surveys were timed to occur during peak detection years following recruitment events. The uncertainty of our total population estimate is associated with the large, annual fluctuations in plant abundance, the low detectability in average or poor detection years when the species resides as a dormant seedbank, the low detection of seedlings from drone imagery, and lack of a complete census at the Red Bluffs and North Warner Ridge populations. We will update our range-wide estimate as new drone census data become available for the Red Bluffs and North Warner Ridge populations. (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Recreation (including OHV use, hiking, mountain biking, horseback riding, unauthorized recreational use, and vandalism) (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** damage and mortality of individuals, destruction and fragmentation of habitat, soil compaction and erosion, destruction of biocrusts, and degradation of vegetative community (Harper et al. 1998; Brooks and Lair 2005; Ouren et al. 2007; Roth 2012). (USFWS, 2016)
**Narrative:** While OHV use in the habitat has declined significantly since 1999, the impact to the habitat and the species continues into the future. Old OHV trails continue to be used by non-motorized users and the majority of this use is unauthorized. Since enforcement is sporadic, we do not have good reporting of the current level of unauthorized recreational use in the majority of the populations. We anticipate the level of recreational use will increase in poppy habitat with an increase in local population growth, with smaller buffers between residential development and poppy habitat, and with fewer options for recreation as open space is developed in and immediately surrounding the St. George city limits. Therefore, we designated the threat level from recreation as high for dwarf bear poppy. (USFWS, 2016

**Stressor:** Land development (including residential and industrial development, utility projects, and road development) (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:** Potential impacts to dwarf bear-poppy from land development include mortality of individuals, habitat loss, degradation and fragmentation, increased soil erosion, increased dust generation, reductions in pollinator populations, reductions in plant reproductive potential, reductions in seed bank quantity and quality, and increasing invasive plant occurrences (Brock and Green 2003). (USFWS, 2016)
**Narrative:** Land development was considered a threat to dwarf bear-poppy at the time of listing (USFWS 1979). All known populations occur in Washington County, UT, in and around the city of St. George, which is currently one of the fastest growing metro areas in the country (U.S. Census Bureau 2000, 2010, 2014). Projections indicate that the population of Washington County will likely increase by 243 percent by the year 2050 from recorded 2010 levels (Utah Foundation 2014). Todate approximately 50 percent of the dwarf bear-poppy's historic habitat has been lost to urbanization and degradation from off-road vehicles (Harper and Van Buren pers. comm. 2004). Currently, the poppy no longer occurs on private lands in Washington County except for

habitat protected by The Nature Conservancy (TNC) (TNC 2015). Roughly 22 percent of known poppy habitat remains under state ownership by Utah School and Institutional Trust Lands Administration (SITLA). The loss of poppy habitat is highly likely in the next twenty years on the majority of State lands. A priority for recovery is the protection of poppy habitat on State and private lands. Protection options include land exchanges between the BLM and the State of Utah, land acquisition by TNC, a conservation agreement with the State of Utah, or additional protections afforded by the State of Utah and private landowners. Due to the high exposure and intensity of development in and around dwarf bearpoppy habitat, the continued and increasing levels of development in Washington County and around St. George, and the severity of the direct and indirect impacts to the species resulting from development, we assign development a high threat level for dwarf bear-poppy. (USFWS, 2016)

**Stressor:** Livestock Grazing (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** We determine that livestock grazing is a potential threat to dwarf bear-poppy because we do not have evidence of a population level impact to the species. We will continue to assess the potential of livestock grazing to pose a threat to the species. Regular monitoring of livestock grazing in poppy habitat is recommended and research on the direct and indirect impact of livestock grazing to the species is needed. (USFWS, 2016)

**Stressor:** Invasive Species (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive plants can exclude native plants and alter pollinator behaviors (D'Antonio and Vitousek 1992; DiTomaso 2009; Mooney and Cleland 2001; Levine et al. 2003; Traveset and Richardson 2006). Red brome, an invasive annual grass, was the only non-native plant specifically noted in the species' habitat from the earliest plant community assessment (Nelson and Harper 1991). We determine invasive species are a potential threat to dwarf bear-poppy because they are present at a low level in the habitat and we do not have evidence of a population level impact to the species. We will continue to assess the potential of invasive species to pose a threat to the species. Regular monitoring of invasive species in poppy habitat is recommended and research on the direct and indirect impact of invasive species to the species is needed.

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the absence of the Act's protection, we believe the existing regulatory mechanisms would not provide dwarf bear-poppy with adequate protection from threats. Under the Act's protection, a review of Federal actions potentially impacting the species can be performed. Because the species occurs on Federal land, threats to the species can be addressed by regulatory mechanisms, and some threats (development, recreation) have been addressed. Enforcement of unauthorized recreation is not being addressed on Federal land, but that is not a result of lacking regulatory mechanisms. A newly identified threat to the species, the loss of specialist pollinators, is also not being addressed on Federal land but we need more information

about this threat in order to identify adequate regulatory mechanisms. There are no regulatory mechanisms on State and private lands to protect the species from these threats. We assign an overall threat level of high because development and recreation are high threats to the species and are not adequately being addressed by existing State regulatory mechanisms. (USFWS, 2016)

**Stressor:** Loss of Pollinators and Pollinator Diversity (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In summary, we have evidence that primary pollinators of dwarf bear-poppy no longer occur within the species' range and that the pollinator assemblage has simplified to generalist pollinators that can only be relied upon to provide adequate pollination services in areas of high plant density. The species' new primary pollinator, the honey bee, is in decline and may not be a reliable pollinator in the future. We also have documented impacts to reproduction that are likely due in part to pollinator limitation. We anticipate the level of development and habitat fragmentation to increase in poppy habitat with an increase in local population growth and it already appears that the species' important specialist pollinators are not able to tolerate and adapt to the current level of development and habitat fragmentation within the species' range. Given these considerations and the critical importance of seed production for the dwarf bear-poppy, we now determine the loss of specialist pollinators is a threat to the species now and in the foreseeable future, and we assign a high threat level. We strongly encourage the synergistic feedback of this threat and other stressors be evaluated and mitigated to prevent extinction (see Brooks et al. 2008 on synergies among extinction drivers).

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 5C

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**
- 1. Protect occupied and suitable habitat from urban development. (USFWS, 2016)
- 2. Protect occupied and suitable habitat from degradation and additional fragmentation. (USFWS, 2016)
- 3. Support and monitor pollinators in occupied and suitable habitat as well as in adjacent habitat. (USFWS, 2016)
- 4. Perform research on suitable microsites for seedling establishment. (USFWS, 2016)
- 5. Perform propagation research using seeds and plant tissue. (USFWS, 2016)
- 6. Perform a comprehensive census of the medium and large dwarf bear-poppy populations (Red Bluff, Warner Ridge, Webb Hill, White Dome, and Beehive Dome). (USFWS, 2016)
- 7. Update the Recovery Plan. (USFWS, 2016)
- 8. Conduct Census and Monitoring Studies:Comprehensively census all known populations on a regular basis in order to produce an accurate picture of population number and

distribution to adequately characterize the species' status. In addition to the populations identified in #6, above: a) Locate and survey the Warner Valley Springs population on foot. b) Survey the Shinob Kibe population on foot. c) Based on census results, develop and implement a range-wide monitoring plan to determine population trends and select monitoring plot locations to regularly monitor recruitment, plant reproduction, and pollinator assemblage. Evaluate population breeding system. d) Monitor crust recovery of land scars periodically. BLM and TNC assistance with this action is essential. e) Regularly monitor and assess recreational use within plant populations. BLM, TNC, and State assistance with this action is essential. (USFWS, 2016)

- 9. Abate Heavy Land Use:a) Identify with GIS all land scars and degradation of habitat within populations and evaluate every 5 years. BLM and State assistance with this action is essential. b) Utilize technical expertise (USGS Las Vegas and Moab or universities) for habitat restoration, trail planning, and assessment of vehicular routes including mountain bikes trails in dwarf bear-poppy habitat. c) Assess and if necessary remove or redirect activities that negatively impact dwarf bear-poppy habitat. d) The Service should be a cooperator on the Washington County Comprehensive Travel and Transportation Management Plan. e) Update ACEC management prescriptions at Red Bluff and Warner Ridge/Fort Pierce to reflect current levels of impact on dwarf bear-poppy: Provide regular, adequate, and responsive monitoring and management at ACECs; Update Implementation Schedule of needed activities; Update ACEC Activity Plans. f) Provide ACEC management protections for the remaining dwarf bear-poppy populations on BLM lands. g) Provide consistent, scientifically based, range-wide management plans for the species. h) Engage and educate recreational user groups that are creating heavy use impacts. (USFWS, 2016)
- 10. Provide Adequate Law Enforcement to address unauthorized recreation use: a) Support law enforcement officials in promoting compliance with off-highway vehicle laws (and regulations) and effective deterrents of abuses of public land. b) Increase patrol of BLM lands to reduce non-compliant land use. c) Seek support and help from the Cities of St. George, Santa Clara, and Washington to manage use within poppy habitat. d) Prioritize and schedule regular land use patrol at high use areas (suggested Red Bluff near Bloomington, Red Bluff near Boomer Hill, Webb Hills at Brigham Road, White Dome at River Run Road, and North Warner Ridge). (USFWS, 2016)
- 11. Conduct Research to Better Understand Species and Species Response to Stressors and Threats: a) Repeat Population Viability modeling using new census and monitoring data on a regular basis. b) Evaluate the synergistic effect or feedback of multiple threats and stressors on the landscape and design a mitigation strategy to prevent extinction. c) Evaluate and implement a human-assisted gene flow pilot study. d) Evaluate and implement a pollinator rearing or transplant pilot study. (USFWS, 2016)
- 12. Coordinate with State, County, City Officials and Developers: a) Coordinate advance planning of development and infrastructure to avoid, minimize, and mitigate impacts to dwarf bear-poppy habitat. Conservation measures include permanent habitat protections with pollinator buffers to offset impacts, and seed and soil salvage operations to preserve the seedbank and genetic diversity when habitat is lost. b) Evaluate, address and offset habitat impacts from increased land use due to easier access provided by highways. (USFWS, 2016)
- Conservation measures are not available.

***Conservation Measures and Best Management Practices:***

- Recommended future actions: Based on recent discussions with conservation partners, we recommend the following future actions: 1. Work with partners to protect as much occupied and potential habitat as possible and improve habitat conditions for plants and pollinators by providing intact or restored habitat conditions, nesting sites and additional pollen and nectar sources; 2. Work with partners to restrict recreational use and restore degraded habitat areas to support the species and its pollinators in the Red Bluffs, Webb Hill, White Dome, and Shinob Kibe populations; 3. Work with partners to collect seeds prior to development and periodically from all populations to provide a genetically representative, off-site seed collection; 4. Continue range-wide monitoring efforts at the four populations (Red Bluffs (Tonaquint Block), White Dome, Beehive Dome, and Shinob Kibe) and expand to additional populations on protected lands; 5. Work with researchers to develop a fine-scale species distribution model using census imagery to identify favorable seedling microsites for seed additions and support future population augmentation efforts on BLM and TNC lands; 6. Work with partners and researchers to perform pilot seedings on BLM and TNC lands in favorable seedling microsites; 7. Continue to investigate propagation methods for the species to reduce plant and population losses and preserve genetic diversity; and 8. Work with researchers to develop an annual detectability estimate for the species based on population monitoring data to calculate the percentage of the population above ground and detectible for section 7 consultation effects analyses and population estimates. (USFWS, 2022)

# SPECIES ACCOUNT: *Arctostaphylos confertiflora* (Santa Rosa Island manzanita)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 7/31/1997; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

aperennial shrub in the heath (Ericaceae) family that grows 0.1 to 2.0 meters (4 inches to 6.5 feet) high, sometimes reaching as high as 6 meters (20 feet) (Wells 1993; Parker and Vassey in titt. 1998) (Figure 7). Santa Rosa Island manzanita occurs in prostrate and upright forms, the former most likely due to climatic influences and herbivory (McMmnn 1951). The plant has smooth, dark red-purplebark and densely hairy-glandularbranchlets and flower stalks. The leaves are light green, round-ovatewith cupped margins. The flowers occur in dense clusters that mature into flattenedreddish-brownfruits (McMinn 1951). Another manzanita on Santa Rosa Island, Arctostapliytos tomentosa, has three subspecies. These are differentiated from A. confertflora and eachother by variously having long, stiffhairs or no glandularity(A. t. ssp. crustacea - long, nonglandular hairs; A. t. ssp. insuticola - pubescent, nonglandular hairs; A. t. ssp. subcordata - long, glandular hairs) (USFWS, 2000).

**Taxonomy**

Belongs to the heath family (Ericaceae) (USFWS, 2014). Santa Rosa Island manzanita was described as Arctostaphytos confertflora by Eastwood in 1934 from a collection made by Hoffinann 4 years earlier “in a sheltered dell south of Black Mountain” on Santa Rosa Island (Eastwood 1934). Munz (1958) published the new combination Arctostaphytos subcordata var. confertflora. However, in subsequent treatments of the genus, Wells (1968, 1993) has continued to use the original taxonomy (USFWS, 2000).

**Historical Range**

See current range.

**Current Range**

Known from three areas on Santa Rosa Island; the north-east side of Black Mountain (less than 300 plants) combined with the Torrey Pine vicinity (less than 100 plants), the canyons on the south-east side of the island (less than 1,000 plants), and in the vicinity of South Point (approximately 200 plants) (USFWS, 2000).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Possibly sexual and self-pollination, based on closely related species (USFWS, 2014)

**Lifespan**

Adult: 100+ years (USFWS, 2014)

**Key Resources Needed for Breeding**

Adult: Fire; insect pollinators, based on closely related species (USFWS, 2014)

**Reproduction Narrative**

Adult: It has lost this ability to resprout and, as such, reproduce only by seed (obligate seeder) (Tyler and Odion 1996). Obligate seeders produce seeds annually, and a small proportion of the seeds may germinate each year. Dormant seeds are long-lived and accumulate in leaf litter and soil over time creating a long-term seed bank. Often in chaparral, the trigger is a fire; although the Service does not know the exact germination triggers for A. confertiflora, there is no reason to think it is different for this species of Arctostaphylos. Pollination and seed production in Arctostaphylos confertiflora are not well understood. Researchers studying A. pringlei (a closely related obligate seeder) observed that the species was pollinated by solitary bees, bumblebees (Bombus spp.), and syrphid flies (family Syrphidae); and the heaviest visitation was from honey bees (Apis spp.). They also observed successful self-pollination in A. pringlei (Fulton and Carpenter 1979). Arctostaphylos confertiflora is a long-lived perennial (individuals of the species may live 100 years or longer (Schreiner et al. 2006; D. Rodriguez, NPS, in litt. 2013)). Recruitment has been nearly zero at all three population locations for as long as monitoring has occurred (USFWS, 2014).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Chaparral, mixed woodland, pine woodland (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Scattered (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Scattered on sedimentary substrates (shales, volcanoclastic sediments, and sandstone) in chaparral, mixed woodland, and pine woodland communities. Extant plants are mostly on very steep slopes (NatureServe, 2015). Arctostaphylos confertiflora occurs as a component of mixed chaparral, mixed woodland, and island pine (Pinus torreyana, P. muricata) woodland vegetation types (Service 2000) (USFWS, 2014).

***Dispersal/Migration***

**Dependency on Other Individuals or Species for Dispersal**

Adult: Possibly U. l. santarosae (inferred from USFWS, 2014)

**Dispersal/Migration Narrative**

Adult: The NPS has observed the Santa Rosa Island fox (Urocyon littoralis santarosae) consuming Arctostaphylos confertiflora seeds, although the seeds appear to pass through the fox digestive system intact (Rodriguez, in litt. 2007). Seed viability testing was conducted on seeds contained in island fox scat; results indicate that there was no loss of viability in these seeds compared to the viability of undigested seeds (Ransom Seed Lab 2007) (USFWS, 2014).

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2014)

**Redundancy:**

There is a lack of redundancy for Santa Rosa Island manzanita because the species is likely restricted to a single island, and most of the individuals of the species are in the Black Mountain occurrence, with relatively small numbers of plants at South Point or Sierra Pablo. This has not changed since listing, and is unlikely to change. The restricted range and few occurrences, coupled with possibly depleted seed banks, means that stochastic extirpation of small populations leading to species extinction remains a threat (USFWS, 2024).

**Number of Populations:**

3 (USFWS, 2014)

**Population Size:**

6,500 - 8,500 (USFWS, 2014)

**Adaptability:**

Low (inferred from USFWS, 2014)

**Population Narrative:**

It is found in only three populations. It is not possible to determine population trends (based on recruitment and mortality rates) at this time for Arctostaphylos confertiflora. There are 6,500 to 8,500 individuals on Santa Rosa Island (USFWS, 2014).

***Threats and Stressors***

**Stressor:** Erosion (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The listing rule for Arctostaphylos confertiflora identified soil loss (via erosion) and habitat alteration by non-native mammal species as Factor A threats to the species. All non-native ungulates excepting a few deer were removed from Santa Rosa Island in 2011 (Rodriguez pers. comm. 2012), and direct habitat destruction and curtailment by these animals is no longer a threat. However, because the ungulates were removed only recently, their impacts on A. confertiflora have not yet been reversed. Remaining indirect effects of ungulates on A. confertiflora habitat include edge effects from game trails, as well as wind and water erosion continuing to affect the seed bank, seed bed, and leaf litter. Although small increases in litter cover have occurred in some areas since monitoring started in 2001 (Schreiner et al. 2006), the

ground underneath arborescent A. confertiflora individuals is exposed and accumulated leaf litter tends to be removed by wind (Rodriguez pers. comm. 2012) (USFWS, 2014).

**Stressor:** Insect damage (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The 2007 5-year review reported insect damage to individuals of Arctostaphylos confertiflora in all three populations. Damage included fruit and seed predation (Rodriguez, pers. comm. 2006a, 2012) and leaf damage (Dale-Cesmat, in litt. 2005; Rodriguez, pers. comm. 2006b, 2012). The NPS correlated apparently higher levels of “die-back” with insect damage at Black Mountain (Rodriguez, in litt. 2006c). In late 2007, the NPS and USGS observed defoliation of A. confertiflora individuals by tussock moth caterpillars. In the following spring, at least seven individuals appeared to have died as a result (McEachern and Rodriguez 2008). The individual plants killed by the moths were already stressed by other factors, and it is likely that healthy A. confertiflora would be resilient to defoliation by tussock moths (Rodriguez pers. comm. 2012). Tussock moths appear on A. confertiflora in an irregular, multi-annual cycle. The Service is uncertain regarding the extent to which insect damage represents a threat to the species; however, tussock moths can rapidly defoliate plants (Brubaker 1978, Harrison and Maron 1995) and could pose a threat to species such as A. confertiflora that have a restricted range and low reproductive success (USFWS, 2014).

**Stressor:** Low reproductive success (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In some locations, the past browsing pressure resulted in plants that never had the opportunity to fruit, flower, and produce seed. In other locations, plants had become arborescent through browsing of the lower portions of the plant; in this case, even if the plants produced seed, the increased erosion under and around stands did not provide suitable conditions for seed retention and germination. These effects compromised the seed bank and reduced the quality of germination sites. The Ransom Seed Lab (2007) found that the germination rate during standard lab testing was zero. These results are not uncommon for Arctostaphylos species (Rodriguez pers. comm. 2012), because members of this genus typically require a specific trigger (such as scarification from a fire event) to break seed dormancy and allow germination to occur (USFWS, 2014).

**Stressor:** Stochastic events (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although the extant populations of Arctostaphylos confertiflora are not particularly small, there are only three. Rarity, including a small number of populations, makes a species vulnerable to stochastic events. Arctostaphylos confertiflora is a long-lived species and there are 6,500 to 8,500 individuals on Santa Rosa Island. Therefore, most natural stochastic events are unlikely to extirpate all three populations. One exception is fire. Although the species is an obligate seeder and likely requires fire for large-scale germination, mature plants of this species do not regenerate when damaged by fire as do burl-forming species of Arctostaphylos. In

addition, the species' depleted seed bank may preclude large-scale germination required to replace destroyed mature plants. Therefore, a large enough fire could extirpate one or more of the three known A. confertiflora populations (USFWS, 2014).

**Stressor:** Climate change (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the northern hemisphere indicate warmer air temperatures, more intense precipitation events, increased summer continental drying, and increased fire frequency (Field et al. 1999; Cayan et al. 2005; Westerling et al. 2006; IPCC 2007). Increased fire frequency could have positive or negative impacts on Arctostaphylos confertiflora. Recently, Loarie et al. (2008) modeled the potential impacts of climate change on the flora of California. They predicted that species' distributions will shift in response to climate-driven habitat changes. Specifically, they predicted that, in general, species will shift northward and to higher elevations, and may experience a reduction in the extent of available habitat. Species will redistribute with shifting habitat, depending on the ability of each species to do so. Species diversity will also shift with a general trend of diversity increasing towards the coast and northwards, with these areas becoming de facto future refugia. Given the narrow geographic range of A. confertiflora, the species will have limited ability to disperse in response to climate change (USFWS, 2014).

***Recovery***

**Reclassification Criteria:**
Maintain three stable or increasing populations on Santa Rosa Island with evidence of natural recruitment for a 30-year period including the normal precipitation cycle (USFWS, 2000).

Recovery Priority Number: 2

Other Actions 2. Seed stored in CPC (Center for Plant Conservation) cooperating facilities. • Seeds banked for conservation are from relatively few maternal individuals and not all populations are represented. Conservation seed banks are not funded in perpetuity. This criterion has not been met. 3. Seed germination, propagation techniques, and fire ecology understood. • There have been studies of the soil seed bank and seed germination, and there has also been propagation from cuttings and then successful outplanting both seed and cutting derived plants. This criterion has been met. 4. Natural seed bank developed and maintained. • Soils continue to improve following ungulate removal. There is evidence that the soil seed bank is increasing, and natural seedlings are becoming more frequent, also indicating the presence and function of a soil seedbank. However, both the soil seed bank and numbers of seedlings have not been rigorously documented. The status of this criterion is uncertain. 5. Fire management plan developed. • CINP completed a draft fire management plant (CINP 2023). The plan recognizes that threatened and endangered species need to be protected from adverse effects of wildfire (p. 17). This criterion has been met. 6. Protected from browsing to allow reproduction. • No non-native ungulates remain on Santa Rosa Island. This criterion has been met. 7. Life history research conducted and incorporated into recovery criteria. • Many facets of the species biology, including reproductive output, the soil seed bank, seed viability, seed germination, and seedling requirements have been investigated. This criterion has largely been met. 8. If declining, determine cause and reverse trend. • While the natural populations appear to be stable or increasing, because of infrequent censuses and irregular monitoring this is not well documented. A robust census and population monitoring protocol needs to be developed. This criterion has not been adequately met (USFWS, 2024).

**Delisting Criteria:**
1. No decline in populations for 10 years after downlisting (USFWS, 2000).

2. All potential habitat surveyed. Santa Rosa Island has been extensively surveyed during vegetation surveys (Reyes et al. 2017 entire), and the distribution of the species on Santa Rosa Island is well understood. This criterion has been met. (USFWS, 2021)

**Recovery Actions:**
- Support and intensify active control programs where herbivory or habitat alteration by alien animals exists (USFWS, 2000).
- Develop and implement a plan to achieve the goals and standards of the Conservation Strategy. The Conservation Strategy is a draft strategy for conservation of island resources prepared by biologists from the National Park Service, U.S. Fish and Wildlife Service, and the U.S. Geological Survey, Biological Resources Division. This Strategy is essentially a primer or guide that provides the basis for the recovery of the species in this recovery plan and should be referred to as a supporting document (USFWS, 2000).
- Restore habitats and control competitive weeds for long-term management of the listed species and their habitats (USFWS, 2000).
- Conduct thorough surveys for all species in the recovery plan (USFWS, 2000).
- Conduct research that aids in the conservation and recovery of the species in the recovery plan (USFWS, 2000).
- Store seeds at facilities certified by the Center for Plant Conservation and develop successful seed germination and propagation techniques (USFWS, 2000).
- Develop successful outplanting techniques (USFWS, 2000).
- The Service recommends that the NPS conduct a threats assessment for insect damage to Arctostaphylos confertiflora. If the assessment indicates insect damage is a concern, the NPS could consider a trial insect control program and additional monitoring to track the extent of insect damage (USFWS, 2014).
- Arctostaphylos confertiflora seeds may require episodic disturbances to stimulate seed germination. These conditions are critical for the establishment and survival of new generations and recovery of the species. Additional research should be done to identify germination cues using methods that are more appropriate for fire-adapted seeds. Once germination cues are better understood, the NPS could explore ways to enhance these conditions in the field through activities such as controlled burns and erosion control (USFWS, 2014).
- Because this species is an obligate seeder and regeneration is sporadic without the presence of disturbance such as fire, an important measure of recovery is the size and viability of the seed bank. The seed bank should be monitored at regular intervals (such as every 3 years) by surveying the amount of seeds in the soil seed bank and conducting seed viability analysis on the seed samples collected during the surveys (USFWS, 2014).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Develop a monitoring plan to track population sizes and distribution. 2. Bolster conservation seed banks with additional maternal lines from all populations. 3. Research seed germination and seedling recruitment requirements. 4. Monitor soil seed bank seed abundance, and develop methods to enhance the soil seed bank. (USFWS, 2021)
- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Develop census and monitoring plans to better track occurrence sizes and of Santa Rosa Island manzanita, especially of seedlings. 2. Continue to develop methods to assess and enhance the soil seed bank. 3. Continue research on seed germination and seedling recruitment requirements, particularly under natural conditions. 4. Bolster conservation seed banks with additional maternal lines from all occurrences. 5. Search the Dick's Harbor area on Santa Cruz Island for the species (USFWS, 2024).

# SPECIES ACCOUNT: *Arctostaphylos glandulosa ssp. crassifolia* (Del Mar manzanita)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/7/1996; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A perennial burl-forming shrub; plant height ranges from 1 to 1.2 meters (3.3 to 4 feet) tall. It has thick, leathery leaves that are dark grey-green and a characteristic smooth red bark. It has clusters of urn-shaped flowers (white to pink). The twigs and young stems characteristically lack glandular hairs, but rather are either densely covered with short fine hairs or have scattered longer hairs. The leaves are dark grey-green, sometimes with a reddish margin. The flowers are small, urn-shaped, white to pink in color, and appear between late winter and early spring. Compared to other subspecies, the globose fruits are small and markedly depressed and the twigs lack glandular hairs. The fruits of A. glandulosa produce an average of six seeds embedded in a hard resinous endocarp surrounded by a pulpy pericarp (USFWS, 2010).

**Taxonomy**

A member of the Ericaceae (heath family). In a recent taxonomic treatment for the species A. glandulosa, a new, narrower distribution for A. g. subsp. crassifolia was proposed. Based on morphologic traits, researchers restricted the distribution to within 3, or possibly 6 miles (mi) (5 to 10 kilometers (km)) from the coast, from Encinitas in San Diego County, south to Baja California (Keeley et al. 2007, p. 57). Carlsbad was not included in this distribution because the research suggests that while some of the plants in Carlsbad are A. g. subsp. crassifolia, many are a different subspecies (A. g. subsp. glandulosa) and that these northern populations comprise a mixture of the two subspecies (Keeley et al. 2007, p. 57). Based on this new treatment, surveys for A. g. subsp. crassifolia by land managers at the Rancho La Costa Habitat Conservation Area in Carlsbad, yielded nine individuals in a population previously thought to be over 1000. The majority of the plants at this site are now considered A. g. subsp. glandulosa (CNLM, unpubl. data 2009) (USFWS, 2010). Also known as Eastwood's Manzanita (NatureServe, 2015).

**Historical Range**

Historically, Arctostaphylos glandulosa subsp. crassifolia was believed to be restricted to sandstone terraces and bluffs along the immediate coast in San Diego County, California, from Carlsbad south to Torrey Pines State Reserve (USFWS, 2010).

**Current Range**

Endemic to San Diego County, California and northwestern Baja California, Mexico (USFWS, 2010).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Vegetative, sexual (USFWS, 2010)

**Breeding Season**

Adult: December - April (NatureServe, 2015)

**Key Resources Needed for Breeding**

Adult: Insect pollinators, fire (USFWS, 2010)

**Reproduction Narrative**

Adult: Blooms December-April (NatureServe, 2015). The fruits of A. glandulosa produce an average of six seeds. The flowers of Arctostaphylos glandulosa are self-incompatible and are visited by flies, bees, and bee-flies (Keeley 1977, p. 821; Moldenke 1976, pp. 318-353). Arctostaphylos glandulosa seeds are dependent on fire to germinate. Typically, seedlings are only established in the first year after a fire (Keeley 1991, p. 96). Arctostaphylos glandulosa subsp. crassifolia plants are woody shrubs, which, when mature, can regenerate from burls (lignotubers) and from seeds. The burl at the base of the stem is covered with undeveloped branch buds. Typically, these buds will sprout after the stems are removed or damaged by fire or other means. Occasionally some of these buds will sprout in the absence of fire (Keeley 1992a, p. 1196) (USFWS, 2010).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Maritime chaparral (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Coastal fog (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs < 100 m elevation (NatureServe, 2015); canopy-forming vegetation - shade intolerant; generally occurs within 5 mi of the coast (USFWS, 2010)

**Spatial Arrangements of the Population**

Adult: Linear (inferred from USFWS, 2010)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Sandstone terraces and bluffs at < 100 m elevation in low, fairly open southern maritime chaparral communities. (NatureServe, 2015). A. glandulosa is shade intolerant and can be replaced by taller stature species (Howard 1992, p. 5). Southern maritime chaparral can be described as a chamise-black sage chaparral that includes rare species such as A. g. subsp. crassifolia and is associated with coastal fog from Carlsbad south to Point Loma. It occurs on weathered sandstone soils including the Carlsbad series, Cesterton series, and Corralitos sandy loam. It can also be found on loamy alluvium, rough broken land, and terrace escarpments. Southern maritime chaparral is typically found within 5 mi (8 km) of the coast (USFWS, 2010).

### *Dispersal/Migration*

**Dispersal**

Adult: Low to moderate (USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: There does not appear to be any specialized seed dispersal mechanism and the fruits generally fall close to the parent plant in late summer where they may be consumed by rodents (Keeley 1977, pp. 821-826). Some are eaten by foxes or coyotes and may be transported some distance away (Keeley 1977, p. 826; J. Keeley, U.S. Geological Survey, pers. comm. 2009) (USFWS, 2010).

### *Population Information and Trends*

**Population Trends:**

Not available

**Number of Populations:**

56 Extant EO's (USFWS, 2023)

**Population Narrative:**

At the time of the 2010 5-year review for Arctostaphylos glandulosa subsp. crassifolia, there were 51 known occurrences [including 1 relocation and restoration site (EO 15) and 1 transplanted occurrence at San Diego Botanic Garden in Encinitas, California (EO 59)] that were extant or presumed extant (Service 2010, pp. 5, 7) (Appendix A). Six of the 51 occurrences were yet to be included as Element Occurrences (EO) in CNDDB, the database maintained by California Department of Fish and Wildlife (CDFW) (Appendix A). Since then, all occurrences identified in the 2010 5-year review have been assigned EO numbers in CNDDB, EO 53 was subsumed into the nearby EO 47, and 6 new EOs (EOs 61–62, 65–67, and 73; Figure 1; Table 1) have been described (CDFW 2023, database). Thus, there are 56 extant (or presumed extant) EOs that are currently known (CDFW 2023, database). However, the subspecies identity of plants at inland locations such as MCAS Miramar has been questioned; some experts have suggested that plants at these locations are hybrids or belong to a different subspecies of A. glandulosa (USFWS, 2023).

### *Threats and Stressors*

**Stressor:** Development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** According to the listing rule, the majority of extant populations had been greatly reduced and significantly fragmented due to urban and agricultural development mostly prior to listing (USFWS 1996, p. 52378). The majority of these populations were distributed in highly fragmented habitat along the margins of residential development. At listing, four of the six

largest populations were threatened by proposed or approved development projects. Since listing, completion of these projects resulted in an additional 35 percent being eliminated through direct impacts and 20 percent through indirect impacts to these four populations. In addition, several of the smaller populations were impacted by development (USFWS 1996, pp. 52377- 52378). Impacts of development are rangewide (USFWS, 2010).

**Stressor:** Fire management (USFWS, 2010).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fuel modification activities can result in the damaging or removal of plants and their habitats. In addition, these activities can increase the fragmentation of habitat and increase the rate and extent of introduction of nonnative species which could in turn increase both erosion and fire frequency, all of which pose threats to A. g. subsp. crassifolia (see discussion of nonnatives and altered fire regime below) (Longcore 2003, p. 116). Fire history data shows that the majority of Arctostaphylos glandulosa subsp. crassifolia occurrences (mainly located directly adjacent to residential development) have not burned in the last 100 years. Fire suppression activities may have prevented these areas from burning given their proximity to residential development, however, their proximity to residential development also puts them more at risk to be subjected to fire. Given this last assumption, the Service believes that fire suppression activities alone in the order of 100 years may not pose a threat to the habitat of A. g. subsp. crassifolia. However, more information is needed to determine what, if any, the impacts are of fire suppression in cycles greater than 100 years. Fires that occur too frequently may threaten the species because if resprouting plants are burned again before they are able to adequately replenish stores in the burls or sufficient seeds for their seed bank leaving the long term persistence of the plants in doubt. When fires are too frequent, nonnatives (especially grasses) can invade frequently burned areas and outcompete natives. In addition, they can modify the environment in their favor by creating a mass of highly flammable fuels which not only can extend the length of the fire season, but alter the types of fires that occur (USFWS, 2010).

**Stressor:** Invasive species (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some invasive nonnative plants can become well established locally and may have profound impacts to the habitat. For example, land managers at the Rancho La Costa Habitat Conservation Area (EO 1) in the City of Carlsbad have noted a nonnative grass, Ehrharta calycina, as a serious problem for the reserve (Appendix 1). This grass is invasive, can cover the ground like a mat, and potentially increase the flammability of the area (J. Vinje, CNLM, pers. comm. 2009). According to the California Invasive Plant Inventory, Ehrharta calycina is considered to have a severe ecological impact on plant and animal communities and are considered to be severely invasive (Cal-IPC 2006, pp. 3-11). Another example is the presence of a woodland Eucalyptus spp. at San Dieguito County Park (EO 17). The canopy is relatively open over the Arctostaphylos glandulosa subsp. crassifolia occurrence but there is a layer of dead, high oil content leaves augmented by park personnel who spread additional leaf litter and wood chips from maintenance operations in the area (Luciani, pers. obs. 2009). If, and when a fire starts at this site, it will likely be intense enough to kill at least some of the burls. In addition, Eucalyptus spp. can have an allelopathic effect on other plants from the compounds found in its bark and leaf

litter. These compounds have been shown to inhibit germination, seedling length, vigor, and nitrogen fixation of certain plant species (Sasikumar et al. 2001, pp. 135-137). Currently, nonnative species likely continue to be a threat to A. g. subsp. crassifolia and its habitat at most occurrences (USFWS, 2010).

**Stressor:** Residential development
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Most A. g. subsp. crassifolia occurrences are directly adjacent to residential development. Use of these lands, whether or not public access is allowed, has proven to be problematic. For example, unwanted public use of lands supporting A. g. subsp. crassifolia have resulted in trail creation, disposal of green waste, dumping of trash, vandalism, and itinerant encampments on the Kelly Ranch and Rancho La Costa Preserves in the City of Carlsbad (CNLM 2008a, p. 22; CNML 2008b, p. 28). The Service has no evidence of direct impacts to A. g. subsp. glandulosa or its habitat; however, these activities generally lead to habitat degradation (USFWS, 2010).

**Stressor:** Small population size (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some of the occurrences of Arctostaphylos glandulosa subsp. crassifolia are potentially threatened by having a small population size. The listing rule estimated a 50 percent decline in the number of stands and individuals since 1982. In addition, the rule stated that over 75 percent of the remaining individuals occurred at 6 of the 25 locations. Four of those populations have been further reduced by development. At one occurrence (the portion of EO 1 at the Rancho La Costa Habitat Conservation Area) there are only nine individuals of A. g. subsp. crassifolia. A commonly accepted principal in conservation biology is that small populations have higher probabilities of extinction than larger populations. Populations with small numbers of individuals are more susceptible to genetic drift, losing variation more readily making them more prone to local extinction. In addition, species whose numbers have been significantly reduced due to habitat destruction may be more susceptible to genetic stresses imposed by small population size (Barrett and Kohn 1991, p. 7). Other factors that can make small populations more susceptible to extinctions than large populations are demographic stochasticity and naturally occurring events such as wildfires, floods, droughts, and disease (Shaffer 1981, p. 131). Because the majority of A. g. subsp. crassifolia occurrences are small, it is reasonable to consider these smaller populations at risk due to these effects of small population size (USFWS, 2010).

**Stressor:** Military training (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, populations of A. g. subsp. crassifolia have been found on MCAS Miramar (EO 47, 50, 51, 52, 54, 55, and MCAS Miramar training areas). Potential threats to the plant on MCAS Miramar range from ground training activities including foot traffic, motor vehicle operations, combat engineering support operations, temporary encampments, and fixed or rotary wing aviation operations (MCAS Miramar 2006, p. 2-6). Impacts from these training

activities can result in trampling and destruction of seedlings and plants. However, threats associated with these training activities are thought to be minimal and potentially offset by management considerations described in MCAS Miramar's INRMP (USFWS, 2010).

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, p. 1; Cayan et al. 2006, pp. 1, 7-8; IPCC 2007, pp. 8-9). However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. One study has predicted that 5 to 10 percent of California's native plant species would no longer find suitable habitat within the state, and thus be vulnerable to extinction, if average temperatures warmed 5 to 6° F (2.7 to 3.3° C) (Morse et al. 1995, p. 393). Whether or not this would include Arctostaphylos glandulosa subsp. crassifolia is unknown (USFWS, 2010).

**Stressor:** Herbivory and Disease (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** While the health of the Arctostaphylos glandulosa subsp. crassifolia population in the MCAS Miramar post-fire monitoring plots has increased, surveyors also observed signs of herbivory and disease. While monitoring 253 tagged individuals, MCAS Miramar surveyors observed nectarrobbing (i.e., when insects access floral resources from the outside of the flower opening without touching the flowers anthers or stigma) on "many individuals," signs of insect herbivory of leaves on 14 percent of individuals, and black leaf spots (which could be a sign of sun damage or fungal growth) on 32 percent of individuals (Tetra Tech, Inc 2012, p. 15). The report recommended that disease and herbivory continue to be monitored to determine if these factors negatively impact A. g. subsp. crassifolia growth and reproduction over time (Tetra Tech, Inc 2012, p. 18). The Center for Natural Lands Management also mentioned disease as a potential threat to Arctostaphylos glandulosa subsp. crassifolia. In a letter to the U.S. Fish and Wildlife Service, the Center for Natural Lands Management stated that powdery mildew (Podosphaera xanthii), a fungal disease, had been observed affecting the leaves of A. g. subsp. crassifolia at preserves they managed in Carlsbad, California (Center for Natural Lands Management 2021, in litt., p. 2). In 2017, they initiated monitoring to determine presence of powdery mildew on A. g. subsp. crassifolia at the La Costa Glen Habitat Conservation Area, but did not find any (Center for Natural Lands Management 2021, in litt., p. 2–3). (USFWS, 2023)

**Stressor:** Hybridization (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A report from MCAS Miramar suggested that hybridization could be a threat to the subspecies, in addition to altered fire regime (including plant canopy encroachment), nonnative invasive plants, erosion with high rainfall events, nectar-robbing and herbivory, and potential

disease (USFWS, 2023)

***Recovery***

**Reclassification Criteria:**
Not available - this species does not have a final recovery plan.

Recovery Priority Number: 6C

**Delisting Criteria:**
Not available - this species does not have a final recovery plan.

**Recovery Actions:**

- Not available - this species does not have a final recovery plan.
- Determine subspecific identity and densities of plants at occurrences peripheral to the core coastal portion of the range (USFWS, 2010).
- Assess the reproductive output of Arctostaphylos glandulosa subsp. crassifolia occurrences, including seed production and viability (USFWS, 2010).
- Determine causes and likely remedies for apparent low rate of establishment of new plants. This should include establishing the role of fire in the species biology and exploration of an acceptable alternative (USFWS, 2010).
- Evaluate the status of Arctostaphylos glandulosa subsp. crassifolia in Mexico (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed below are to be initiated over the next 5–10 years. Successful implementation of these actions will provide a better understanding of Arctostaphylos glandulosa subsp. crassifolia population health, reproductive output, and factors affecting the low rate of establishment. Additional genetic information will also help to better understand relatedness between the listed entity and the other six subspecies and provide more clarity of the geographic distribution of the listed entity. We recognize that conservation of this taxon will require cooperation and coordination with partners to minimize impacts from current threats and aid future restoration efforts. 1. Work with partners to identify opportunities for conservation or preservation of Arctostaphylos glandulosa subsp. crassifolia occurrences on private lands. Support land acquisition to meet Habitat Conservation Plan goals. Work with local, State, and Federal partners to identify and leverage funding (i.e., section 6) to acquire A. g. subsp. crassifolia habitat. 2. Assess the taxonomic status of Arctostaphylos glandulosa subspecies (and similar species) in California and Mexico such that the endangered entity (A. g. subsp. crassifolia) can be clearly identified. a. Determine the geographic distribution of the endangered entity and hybridization zones. b. If necessary, revise circumscriptions for Arctostaphylos glandulosa subspecies and related taxa. 3. Evaluate the status of Arctostaphylos glandulosa subsp. crassifolia in Mexico. 4. Assess the reproductive output of Arctostaphylos glandulosa subsp. crassifolia occurrences, including seed production and viability. 5. Determine causes and likely remedies for apparent low rate of establishment of new plants. This should include establishing the role of fire in the subspecies’ biology and exploration of an acceptable alternative. 6. Determine the extent to which herbivory or disease may be affecting survival, reproduction, or recruitment of Arctostaphylos glandulosa subsp. crassifolia. (USFWS, 2023).

# SPECIES ACCOUNT: *Arctostaphylos morroensis* (Morro manzanita)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 1/17/1995; Pacific Southwest (R8)

**Physical Description**

This shrub reaches a height of 1.5 to 4.0 meters (5 to 13 feet) and has crowded oblong to ovate grey-green to olive-green leaves, 2.5 to 4.0 centimeters (1 to 1.5 inches) long, with petioles 2 to 6 millimeters (0.08 to 0.20 inch) long. The white to pinkish flowers are 5 to 8 millimeters (0.2 to 0.3 inch) long, and form orange-brown fruits 8 to 13 millimeters (0.3 to 0.5 inch) in diameter with 8 to 10 stones per fruit that are fused but separable. The bark ofthe trunk is a shaggy grey to brown; the leafblades range from wedge-shaped (cuneate) to rounded ornearly straight (truncate) at the base, with the lower surface paler and usually somewhat tomentose (short woolly hairs). Occasional specimens have small projecting lobes at bases of the leaf blades and a short leafstalk or none at all (USFWS, 1998).

**Taxonomy**

Member of the heath (Ericaceae) family. Morro manzanita (Aretostaphylos morroensis) (Figure 3) was first described by Albert E. Wieslander and Beryl 0. Schreiber in 1939 (Wieslander and Schreiber 1939) based on a specimen collected in Hazard Canyon, south ofMorro Bay, which is now within the boundaries ofMontai'ia de Oro State Park. The species has continued to be recognized by McMmnn (1939), Abrams (1944), Munz(1959), Hoover (1970), and Wells (1993) (USFWS, 1998).

**Historical Range**

Endemic to San Luis Obispo County, California. The distribution of A. morroensis is correlated with the distribution of Baywood fine sands. Based on the distribution of these sands, the historical distribution of A. morroensis is estimated to have comprised between 2,000 and 2,700 acres (809 and 1,092 hectares (ha)) (USFWS, 2013).

**Current Range**

Arctostaphylos morroensis ranges from the northeast side of Morro Bay to the southern end of Montaña de Oro State Park, a distance of less than 10 miles (16.1 kilometers) (USFWS, 2013).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2013)

**Lifespan**

Adult: 47+ years (USFWS, 1998)

**Dependency on Other Individuals or Species**

Adult: Bombus vosnesenskii (USFWS, 2013)

**Breeding Season**

Adult: Winter (USFWS, 2013)

**Key Resources Needed for Breeding**

Adult: Insect pollinators, > 40 year fire intervals (USFWS, 2013)

**Reproduction Narrative**

Adult: Arctostaphylos morroensis flowers in the winter, with fruit maturation and seed dispersal occurring in the fall. Unlike other species of manzanita, A. morroensis is an obligate seeder, lacking a woody burl from which it can resprout post-fire. Fruits contain 8 to 10 seeds each. Although it is unknown whether the flowers are self-compatible, extensive research revealed that pollination is required for reproduction. In 1998 and 1999, Tyler and Odion found that bumblebees (Bombus vosnesenskii) are the dominant pollinators, though anthophorid bees (Anthophora urbana), several bee flies (Bombylius spp.), and syrphid flies (family Syrphidae) are also known pollinators. The authors also noted surprisingly low pollinator activity for both years surveyed (Tyler et al. 1998 and 2000). Only 10 percent of flowers examined in 1998 produced fruits. For Arctostaphylos morroensis and other obligate-seeding species of manzanita, maintenance and regeneration are dependent upon mass germination triggered by fire (Tyler and Odion 1996). Fire breaks seed dormancy and also creates open areas where seedlings can germinate and individuals establish. Due to very low seed viability in Arctostaphylos morroensis, in combination with high seed mortality in response to fire, Tyler and Odion (1996) suggest that stands burned at cycles greater than 40 years would have sufficient time to accumulate an adequate seed bank (USFWS, 2013). Morro manzanita is a long-lived shrub; studies of stand age based on trunk ring counts and aerial photos of previous disturbance events, including fire and possibly clearing, indicate that the youngest intact stands are some of those south of Highland Drive, which are about 37 years old. Stands west of Pecho Drive are about 47 years old. The remainder are older than 47 years, with stands in the Elfin forest estimated to be the oldest (Tyler and Odion 1996) (USFWS, 1998).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal dune scrub, maritime chaparral, coast live oak woodland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire (USFWS, 2013; see reproduction narrative)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs < 200 m elevation (NatureServe, 2015); closed-canopy (USFWS, 2013)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2013)

**Habitat Narrative**

Adult: Inhabits soils derived from ancient sand dunes. Found in nearly pure stands on steep slopes, especially on north exposures. On low-moderate slopes, found in association with coastal dune scrub, maritime chaparral, and coast live oak woodland communities; < 200 m elevation. (NatureServe, 2015). Development of climax, closed-canopy chaparral stands has an adverse effect on populations of A. morroensis by precluding expansion into otherwise suitable habitat. Arctostaphylos morroensis is primarily found on Baywood fine sand soils (ancient wind-blown beach sands), though small stands have also been documented on Santa Lucia shaley clay loam (Soil Conservation Service 1958, McGraw 2005) (USFWS, 2013).

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 2013)

**Dispersal/Migration Narrative**

Adult: Birds and large mammals (coyote (Canis latrans) and mule deer (Odocoileus hemionus)) are thought to aid Arctostaphylos morroensis in seed dispersal (Keeley and Hays 1976). This secondary dispersal (which occurs after the parent plant initially sets seed) is limited, however, as evidenced by 90 percent fewer seeds present in soil cores 5 feet (1.5 meters) away from A. morroensis compared to samples taken from beneath the canopy (Tyler and Odion 1996) (USFWS, 2013).

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Stable (inferred from USFWS, 2013)

**Number of Populations:**

18 (NatureServe, 2015); Unknown (USFWS, 2013)

**Population Size:**

Currently unknown; previously 86,500 - 153,000 (USFWS, 2013)

**Adaptability:**

Low (inferred from USFWS, 2013)

**Population Narrative:**

It is unknown precisely how many populations occur across the range of the species. LSA estimated approximately 153,000 Arctostaphylos morroensis plants occurred across the species' range at the time of listing. McGuire and Morey produced a lower estimate than LSA (using a 15-foot diameter per individual), estimating that the total species population would be closer to 86,500 individuals (McGuire and Morey 1992). An accurate estimate of Arctostaphylos morroensis abundance throughout its range was unavailable at the time of the 5 year review. Tyler and Odion (1996) hypothesized that the low viability may be due to inbreeding as a consequence of small effective population sizes. The current status of Arctostaphylos morroensis is not markedly different than what was summarized in the final listing rule published in 1994, the final recovery plan completed in 1998, or the most recent 5-year review, released in 2008 (USFWS, 2013). There are 18 occurrences (NatureServe, 2015)

***Threats and Stressors***

**Stressor:** Habitat destruction and alteration (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Areas of habitat with high cover of Arctostaphylos morroensis are still at risk on private lands that could be developed in the future. For example, in 2010, a privately owned parcel containing this species in Cabrillo Estates was developed for a private residence. The spread of nonnative species, particularly veldt grass, has altered the composition of the plant communities associated with Arctostaphylos morroensis habitat. This in turn is likely altering the fire cycle, potentially increasing the frequency of fires, and decreasing the viability of existing seed banks. the acquisition of lands reduces the threat of destruction of habitat from development. However, the continued spread of nonnative species throughout Arctostaphylos morroensis' range and the fire cycle needs particular to the species (discussed below in Factor E) necessitate land management that is not currently in place; alteration of habitat from nonnative species is increasing (USFWS, 2013).

**Stressor:** Altered fire cycles (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Land managers have not planned any prescribed burns for Arctostaphylos morroensis habitat. The U.S. Army Corps of Engineers burned and cleared shrubs in Montaña de Oro State Park in 1958; however, the Service has no knowledge or evidence of prior burns (Odion and Tyler 2003). Montaña de Oro State Park performs controlled burns as needed and when possible, but burning A. morroensis habitat is inhibited by the nature of the landscape. The fuel requirements, steepness of the slopes, limited accessibility, and proximity to residential areas make a prescribed burn for A. morroensis difficult to perform (V. Cicero, California State Parks, in litt. 2012)). The most recent wildfire within the State Park occurred in 1997, but did not burn A. morroensis stands. Wildfires for this maritime chaparral habitat are estimated to occur about every 50 to 200 years (Cicero in litt. 2012). For these reasons, the limited ability to manage fire cycles hinders efforts to reduce the threat of altered fire cycles to A. morroensis (USFWS, 2013).

**Stressor:** Invasive species (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The nonnative veldt grass (Ehrharta calycina) has spread to the Los Osos and Morro Bay region. This species has not only invaded disturbed areas, such as vacant lots, road cuts, and utility corridors, but is becoming naturalized in native plant communities, including conserved lands owned and/or managed by the CDFW and CDPR for Arctostaphylos morroensis (J. Vanderwier, U.S. Fish and Wildlife Service, pers. obs., 2006). Members and volunteers associated with Small Wilderness Area Preservation use manual removal to fight veldt grass in the Elfin

Forest and continue to make progress (Sarafian 2011). Although veldt grass more likely competes for resources with herbaceous species than with established perennials, its presence may also increase the frequency and risk of fire that would negatively affect A. morroensis by reducing the abundance and viability of its seed bank. Veldt grass is not currently invading established A. morroensis stands in Montaña de Oro State Park, although it may prevent recruitment in areas where it has already invaded the habitat (Cicero in litt. 2012). In the final listing rule, the Service recognized that stands of Arctostaphylos morroensis in Montaña de Oro State Park were being overtopped by spreading eucalyptus (Eucalyptus spp.) planted in the early 1900s. The Service noted that A. morroensis is not able to survive such encroachment due to reduction in available soil moisture, increased shading, and the effects of growth-inhibiting terpenes that are released from eucalyptus (California Invasive Plant Council 2006-2011). Although the general plan for Montaña de Oro State Park calls for the removal of exotic species, including eucalyptus, this program has only been partially implemented. In past years, eucalyptus removal efforts generally focused on removing seedlings from outside the bounds of the original groves and not specifically from habitat that supports A. morroensis (Service 1998). Recently, efforts to control eucalyptus have been undertaken and have been successful in preventing further recruitment. However, fluctuations in the park’s budget in coming years may hinder these efforts; therefore, the Service still considers competition with eucalyptus to be a threat (Cicero in litt. 2012). Other invasives not mentioned at the time of listing, including narrow-leafed iceplant (Conicosia pugioniformis), are encroaching upon Elfin Forest populations of Arctostaphylos morroensis. Bridal creeper (Asparagus asparagoides) is also posing a threat in the Elfin Forest (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the northern hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, Intergovernmental Panel on Climate Change 2007). Arctostaphylos morroensis’ small and isolated range increases its vulnerability to random fluctuations in annual weather patterns and environmental disturbances such as those that may result from climate change. Recently, Loarie et al. (2008) discussed the potential impacts of climate change on the flora of California. Based on climate modeling, they predicted that species’ distributions will shift in response to climate change and that species will “move” to higher elevations and northward, depending on the ability of each species to do so. Broadly, indirect ecological impacts caused by fog and variation in humidity could alter pollinator activity, soil moisture, and phenology of the species. In general, the scientific community lacks adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors such as limited geographical distribution, will affect federally listed species. Small-ranged species, such as A. morroensis, are more vulnerable to extinction due to these changing conditions (Loarie et al. 2008) (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
Not applicable.

Recovery Priority Number: 8

**Delisting Criteria:**
1. Ninety percent of existing acreage supporting high (75-100 percent) and medium (25-75 percent) cover of Morro manzanita and 85-90 percent of low (1-24 percent) cover supporting Morro manzanita are secured from human-induced threats in preserves in the Northeast Los Osos, South Los Osos and West Pecho Conservation Planning Areas with no greater fragmentation by roads, residences, or other areas of human use than currently exists. (USFWS, 1998)

2. Evidence that the acreage and approximate cover classes of Morro manzanita in preserves can be maintained over time and that preserves are not made unmanageable by small size, proximity to urban development, or fragmentation. (USFWS, 1998)

3. Site-specific management plans have been successfully implemented for the preserves. Because habitat in the Conservation Planning Areas must remain unfragmented to recover this species, habitat attrition must be restricted to isolated or remnant patches of Morro manzanita that are unlikely to be viable over the long term. Highest priority for securing sites should be given to stands where Morro manzanita is the dominant in terms of cover, where large blocks of occupied habitat are still present, and where Morro manzanita habitat can be secured that abuts other protected lands, as in the South Los Osos Conservation Planning Area. (USFWS, 1998)

**Recovery Actions:**
- Secure populations and habitat on unprotected lands. Methods for securing lands include in-fee purchase, gifts of easement or fee interest by the property owner, deed restrictions (provided restrictions cannot be changed privately without the knowledge of Federal, State and County agencies), acquisition of property rights (e.g., development rights) or permanent conservation easements. (USFWS, 1998)
- Manage secured lands to control or eliminate other known threats. Although habitat alteration through development is currently the most substantial and irreversible threat facing all of the species in this plan, the management of lands secured from development will remain a formidable task, made more so in those cases where the secured habitats are adjacent to high density residential and urban development. (USFWS, 1998)
- Evaluate potential threats and conduct management-oriented research. Conduct habitat-oriented research for Morro Bay species. Conduct species-specific research. Evaluate research results and use in future management. (USFWS, 1998)
- Determine population dynamics and effects of recovery efforts. Studies should be conducted to learn the number and size of successful self sustaining populations for the species to establish criteria for its reclassification. (USFWS, 1998)
- Develop and implement an education/information program. The benefits of protecting native species and their habitats and maintaining native biological communities should be explained clearly to all concerned parties. (USFWS, 1998)
- Reevaluate recovery criteria and revise recovery plan based on expanded knowledge from research, monitoring, and management. The scientific validity of the recovery criteria and recovery plan should be reviewed and revised as more information becomes available. The criterion of maintaining sufficient numbers of populations or conservation areas should be assessed, and the success or failure of management actions should be evaluated. (USFWS,

1998)

- Recommendation from 2013 5-Year Review: 1. Additional lands with high densities of Arctostaphylos morroensis should be secured from the threat of development in Northeast Los Osos, West Pecho, and South Los Osos conservation planning areas. (USFWS, 2013)
- Recommendation from 2013 5-Year Review: 2. All secured lands should be managed to ensure ecosystem function. Active management is needed to maintain and enhance populations of Arctostaphylos morroensis; therefore, the development and implementation of management plans that identify specific actions for the species are critical to its recovery. At a minimum, these plans need to address: (a) regeneration requirements for the species; and (b) an assessment of the extent of the threat of competition from nonnative invasive plant species. The Service should work with CDPR, CDFW, and other relevant partners to encourage the development and implementation of these management plans. (USFWS, 2013)
- Recommendation from 2013 5-Year Review: 3. Ensure that management actions are implemented and ongoing by securing and using funding sources. Engage partners (State Parks and/or the County of San Luis Obispo) in an effort to work with them toward the common goal of securing the long-term persistence of Arctostaphylos morroensis.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Coordinated conservation and research are needed to better understand the biology and ecology of Morro manzanita, in particular to restore and maintain the existing stands and facilitate recruitment. These efforts should include: • Conduct a more-detailed analysis of the distribution and abundance of and threats to Morro manzanita, with a coordinated team effort including site visits by USFWS and partners. • Conserve and protect habitat in vicinity of and near existing stands of Morro manzanita • Develop and implement site-specific management plans for Morro manzanita habitat within preserves including success criteria for evaluating effectiveness of management. • Conduct modelling to anticipate the effects of climate change on distribution and abundance of Morro manzanita, including changes in temperature, precipitation, extent of marine fog layer, and sea level rise. • Develop protocols for long-term restoration success. 1. Consider using method with seedlings of Sarafian (2011, p. 5), and suggested method for collecting and sowing seeds of Tyler and Odion (2020, p. 164). 2. In light of the threat of climate change with severe drought and increased temperatures, consider using methods for cultivating seeds for propagation and outplanting in arid lands used by Abella et al. (2012, entire), Abella et al. (2015, entire), Abella (2017, entire) and Abella et al. (2020, entire). • Continue studies of the species' relationship with fire. • Collect seeds for conservation seed banking. • Introduce Morro manzanita into living collections at several botanic gardens (USFWS, 2022).

# SPECIES ACCOUNT: *Arctostaphylos myrtifolia* (Ione manzanita)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened: listed in 1999 (64 FR 28403)

**Physical Description**

Ione manzanita is an evergreen shrub of the heath family (Ericaceae). Reaching a height of generally less than about 4 feet (1.2 meters) and commonly only 2 feet (0.6 meter) tall, plants appear low and spreading. Its bark is red, smooth, and waxy. Olive-green leaves are small 1/4 to 1/2 inch (0.6 to 1.3 centimeters), oval in shape, pointed at the tip, and often pointed at the base as well. The white to pinkish urn-shaped flowers are also small, averaging 1/8 inch (0.3 centimeters) across, and appear from January to February. Its small, rounded, greenish fruits are 1/8 inch (0.3 centimeters) long and 1/16 inch (0.15 centimeter) wide. This manzanita species lacks a basal burl (a basal burl is a swelling at the junction of roots and stems that allows many chaparral shrub species to sprout from the base, and vegetatively regenerate after a fire). After a fire, Ione manzanita must regenerate from seed. Ione manzanita can be distinguished from other species in the same genus by its smaller stature and the color of its leaves (NatureServe 2014; USFWS 2009; USFWS 2010).

**Historical Range**

Ione manzanita occurs throughout all of its presumed historical range in Amador County, though many populations have been reduced in size due to mining, road construction, development, and diseases. The distribution of Ione manzanita was believed to extend as far east as the Town of San Andreas in Calaveras County. However, efforts to locate and identify the San Andreas populations of Ione manzanita have not been successful. Because of the discontinuous nature of the Ione Formation on which it grows, Ione manzanita was always patchily distributed with other chaparral and oak forest types (USFWS 2010; NatureServe 2014).

**Current Range**

Ione manzanita occurs in about 100 individual stands, which cover a total of about 1,000 acres (4 square kilometers). It is narrowly endemic to a habitat found only in the central Sierra Nevada foothills of California. At the time of listing, Ione manzanita was known from 17 occurrences covering approximately 1,000 acres (4 square kilometers); currently, the Calflora Occurrence Database (Calflora 2014) contains 94 records for Ione manzanita from Amador and Calaveras Counties, and the CNDDB (2014) recognizes 15 occurrences for this species. Most of the occurrences are on private lands. One occurrence on U.S. Bureau of Land Management (BLM) land is within the Ione Manzanita Area of Critical Environmental Concern. Two additional occurrences are partially on BLM lands. Four small, pure (containing only Ione manzanita) populations and several smaller, mixed populations also occur on the State-owned Apricum Hill Ecological Reserve managed, by the California Department of Fish and Wildlife (USFWS 2010; CNDDB 2014; NatureServe 2014).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Food Source**
Adult: sunlight

**Food/Nutrient Narrative**
Adult: This species is a plant that aquires its energy from sunlight via photosynthesis.

**Reproductive Strategy**
Adult: Flowering plant

**Lifespan**
Adult: unknown

**Dependency on Other Individuals or Species**
Adult: unknown

**Breeding Season**
Adult: January and February (Calflora 2014; CNPS 2014).

**Key Resources Needed for Breeding**
Adult: unknown

**Reproduction Narrative**
Adult: Flowering occurs from mid-January to early March and fruits are fully developed by late spring or early summer (Gankin and Major 1964, p. 796). Arctostaphylos myrtifolia is an obligate seeder that can be killed by fire and therefore depends entirely on seeds stored in the soil or dispersed to the site for stand regeneration (Gankin and Major 1964, p. 795).

**Habitat Type**
Adult: barrens, shrubland/chaparral

**Dependencies on Specific Environmental Elements**
Adult: 190 to 1,900 feet (60 to 580 meters) (CNPS 2014) with soils that are highly acidic, and high levels of aluminum

**Geographic or Habitat Restraints or Barriers**
Adult: restricted to Ione Formation

**Spatial Arrangements of the Population**
Adult: clumped according to suitable resources

**Environmental Specificity**
Adult: special habitat requirements, but not special feeding requirements

**Tolerance Ranges/Thresholds**
Adult: low

**Site Fidelity**

Adult: high; plants do not move once they become established

**Habitat Narrative**

Adult: Ione manzanita occurs on outcrops of the Ione Formation (a remnant Eocence, hard white sandstone formation) in an area of about 22,500 acres (91 square kilometers) in Amador County. A few separate populations occur in Calaveras County. The populations range in elevation from 190 to 1,900 feet (60 to 580 meters) (CNPS 2014), with the largest populations occurring at elevations between 295 and 900 feet (90 and 275 meters) (USFWS 2009; USFWS 2010). Ione manzanita is mostly confined to the unusual soils of the Ione formation. These soils are highly acidic, and contain high levels of aluminum. This soil environment is extremely hostile to the growth of most plants (aluminum in high concentrations can be toxic to plants). Organic matter and nutrient availability is low. Ione manzanita only occupies sites where the extreme conditions described above persist. It commonly grows in pure stands; at the edge of these stands, there may be a transition zone where Ione manzanita and whiteleaf manzanita coexist. It also occurs in transitional zones with surrounding taller chaparral types, but it does not persist if it is shaded (USFWS 2009; USFWS 2010; NatureServe 2014).Some manzanita species have basal burls that can resprout after a fire burns the canopy; Ione manzanita does not have a burl. It is an obligate seeder that can be killed by fire. It depends entirely on seeds stored in the soil or dispersed to the site; seed germination may be promoted by periodic fire (USFWS 2010).

***Dispersal/Migration***

**Motility/Mobility**

Adult: not moble

**Dispersal**

Adult: unknown

**Dependency on Other Individuals or Species for Dispersal**

Adult: unknown

**Dispersal/Migration Narrative**

Adult: There is not much information available regarding the dispersal of this species

***Population Information and Trends***

**Population Trends:**

Unknown

**Species Trends:**

Declining

**Population Growth Rate:**

unknown

**Number of Populations:**

17

**Population Size:**
unknown, but likely greater than 100 individuals

**Minimum Viable Population Size:**
unknown

**Resistance to Disease:**
low

**Adaptability:**
low

**Population Narrative:**
Current status and number of individuals is unknown. At the time of listing Arctostaphylos myrtifolia was known from 17 occurrences covering approximately 404.7 ha (1,000 ac)Individuals occur in stands, with approximately 100 stands documented as still existing. Populations exist in a narrow geographic range that contains the required soil conditions; they occur primarily on private or non-Federal lands. The amount of Ione manzanita habitat lost to mining and has not been quantified, because information regarding the total acreage of land newly disturbed by mining operations is proprietary. However, the loss is believed to be significant. Populations are restricted to a very limited habitat, with much of that population suffering from disease. The ability of populations to recover is limited by poor health and reduction of habitat. There are only about 100 stands, with an unknown number of individuals in a limited area of habitat. A significant portion of those populations are suffering from disease. Populations are restricted to habitat in the Ione Formation soil conditions. Loss of habitat due to mining and other development removes potential area for regrowth.

***Threats and Stressors***

**Stressor:** Mining
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nearly all populations of this species occur on private or non-Federal land. The primary threat facing this species is the ongoing and threatened destruction and modification of its habitat by mining for silica sand, clay, lignite, common sand and gravel; and reclamation of mined lands involving establishment of vegetation with which this species cannot co-exist. A lesser degree of threat is posed by commercial or residential development, clearing for agriculture and fire protection, and continued erosion due to previous fireline construction and driver training for California Department of Forestry and Fire Protection (CDFFP) employees. Commercial and residential development also threatens the habitat of Arctostaphylos myrtifolia. In 1993, a 43 ha (106 ac) parcel in the city of Ione reported to have A. myrtifolia was cleared, presumably to facilitate future development (Randy L. Johnsen, Ione City Administrator, in litt. 1994). The Amador County master plan has zoned an area in the northern Ione chaparral near Carbondale for industrial uses. Its habitat occurs in areas that contain valuable minerals. Clay mining began in the Ione area around 1860. Since that time, the Ione area has produced about a third of the fire clay in California (Chapman and Bishop 1975). Lignite, a low-grade coal, also has

been mined in the Ione area since the early 1860s, initially for fuel, but more recently for wax used for industrial purposes. Chapman and Bishop (1975) reported the Ione lignites were the only lignites used commercially in the United States in the production of a specialized wax (montan wax). Quartz sand used in making glass containers, and laterite used for making cement also are commercially mined in the Ione area (Chapman and Bishop 1975). Common sands and gravels are also mined for various uses. Mining of all of these deposits has resulted in the direct removal of habitat for this plant species (Wood and Parker 1988; V. Thomas Parker, Professor of Biology, San Francisco State University, in litt. 1994; M. Wood, in litt. 1994). Strip mining of silica for glass and clay for ceramics and industrial filters has extirpated (caused extinction of) populations of A. myrtifolia north and south of Highway 88 (Roof 1982). mining results in conversion of former habitat to rangeland, pasture, and other agricultural uses; landowners do not restore the original plant community that was lost when the area was mined. Additionally, once the area is mined, the specialized substrate required by the plants may no longer be present. This type of disturbance permanently precludes restoration of habitat suitable for Arctostaphylos myrtifolia. To a lesser extent, land conversion to grazing and agriculture also has degraded or destroyed the habitat for these plants (Wood and Parker 1988; V.T. Parker, in litt. 1994; M. Wood, in litt. 1994). Both activities continue to pose threats to its habitat.

**Stressor:** Disease
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Recent studies by Swiecki and Bernhardt (2003, pp. 1–49) and Swiecki et al. (2005, pp. 1–38) determined that at least three different diseases are affecting the health of Arctostaphylos myrtifolia in the Ione area. First, a branch canker disease caused by a species of Fusicoccum that had previously been identified, and two newly identified pathogens, Phytophthora cinnamomi and P. cambivora. Progressive dieback associated with Fusicoccum spp. cankers likely contributes to and may sometimes cause the death of A. myrtifolia plants. Phytophthora spp. were found to cause contiguous patches of mortality in stands of A. myrtifolia due to root and crown rot (Swiecki and Bernhardt 2003, p. 4; Swiecki et al. 2005, p. 22). While mortality associated with Phytophthora spp. appears to have been noted since the 1980’s, Swiecki and Bernhardt (2003, p. 41) believe it was at least partially confused with the branch canker disease because both diseases can occur together in the same area. However, mortality associated with Fusicoccum spp. tends to be patchily distributed within a stand and mortality caused by Phytophthora spp. is continuous. Swiecki and Bernhardt (2003, pp. 41–43) determined that two species of Fusicoccum affect Arctostaphylos myrtifolia plants by killing off branch tips or infecting larger diameter stems where the infection may expand and girdle the stem. The girdling of the stem may result in the death of large portions of the plant or the plant in its entirety. Swiecki and Bernhardt (2003, p. 41) observed that stem cankers associated with Fusicoccum spp. may expand slowly during the months from March to October; however, if the die-back associated with Fusicoccum spp. exceeds new growth, individual plants may eventually be killed. Although advancement of the disease appears to be reduced during the drier months, stem canker severity, and subsequent dieback, appears to be related to plant water stress (Swiecki and Bernhardt 2003, p. 43). Arctostaphylos myrtifolia is highly susceptible to the pathogen Phytophthora cinnamomi. The P. cinnamomi pathogen was first identified as affecting A. myrtifolia by Swiecki and Bernhardt (2003, p. 5). Phytophthora cinnamomi is considered to be a serious pathogen of agricultural crops and native plant communities. In California, it is known to infect avocado trees, orchard trees, ornamental plants and Christmas tree farms (Swiecki and Bernhardt 2003, p. 44). More

recently P. cinnamomi was identified to be partially responsible for mortality in Quercus agrifolia (coast live oak) (Garbelotto et al. 2006, p. 1). Phytophthora cinnamomi is a disease that causes root and crown rot and is responsible for killing off large patches of A. myrtifolia in the Ione area. Once infected by this pathogen, the root system of the plant begins to decay until the loss of roots and/or water-conducting tissues causes the plant to desiccate (Swiecki and Bernhardt 2003, p. 43). Additionally, P. cinnamomi can also infect the leaves and stems of the plant, providing the same symptoms as Fusicoccum infections, making it difficult to determine which disease is affecting a particular plant (Swiecki and Bernhardt 2003, p. 45). Introduction of Phytophthora cinnamomi into Arctostaphylos myrtifolia habitat represents longterm, if not permanent, destruction of habitat due to its long persistence in the soil (Swiecki and Bernhardt 2003, p. 43). Phytophthora cinnamomi can persist in the environment in the absence of susceptible hosts. This pathogen survives in the soil in infected roots, or as long-lived resident spores (Swiecki and Bernhardt 2003, p. 44). There is no known cure or prevention for this A. myrtifolia disease (Swiecki and Bernhardt 2003, pp. 45–47). Swiecki and Bernhardt (2003, pp. 26–27) found that A. myrtifolia regeneration within an older portion of a mortality center was killed off by P. cinnamomi, while Swiecki et al. (2005, p. 25) discovered healthy A. myrtifolia regeneration in other older portions of mortality centers. However, subsequent investigation in 2009 discovered regeneration in these mortality centers displayed extreme dieback, or complete mortality (Karuzas, in litt. 2009, p. 1). Swiecki et al. (2005, p. 330 further noted that although reductions in pathogen populations may occur over time, it is unclear what period of time is needed to allow successful reestablishment of A. myrtifolia. The pathogenic activity of Phytophthora cinnamomi is favored by free moisture and under wet conditions, multiple infection cycles are likely to occur. Phytophthora cinnamomi is primarily spread to new areas through the movement of infested soil by humans, particularly through the use of vehicles (Swiecki and Bernhardt 2003, p. 45). Once the disease has been introduced into an area, the movement of the pathogen is facilitated by water flow. Swiecki et al. (2005, p. 33) noted that the local spread of P. cinnamomi occurs during the wet season at a cross slope and upslope rate of approximately 0.25 m (0.8 ft) per year. Down slope spread has been calculated at 2 m (6.5 ft) per year, presumably due to transport via flowing water, and under stagnant stream conditions P. cinnamomi has been located 10 m (33 ft) from disease-associated mortality centers (Swiecki et al. 2005, p. 34). While it is more likely for P. cinnamomi infected soil to be spread over larger distances during the wet season, movement of infected soils can readily occur during dry months as the result of mining operations and excavation (Swiecki et al. 2005, p. 35). An investigation of the distribution of the Phytophthora cinnamomi pathogen throughout the range of Arctostaphylos myrtifolia found that P. cinnamomi infection is widespread throughout the Ione and Buena Vista area, with a second disease center in the Carbondale area (Swiecki et al. 2005, pp. 1–38). Of the populations located in and around Ione and Buena Vista, over 50 percent have been killed by disease or are at risk of being infected (Swiecki, in litt. 2008, p. 1). DNA microsatellite analysis of P. cinnamomi isolates from Apricum Hill Preserve identified four genetically distinct variants, suggesting multiple introductions of the pathogen at this location. Additionally, two of the four genotypes have been identified elsewhere in California (Swiecki et al. 2005, pp. 28–29). Investigation of the A. myrtifolia mortality on BLM land in the Carbondale area resulted in the discovery of a second soil-borne Phytophthora species, P. cambivora (Swiecki et al. 2005, p. 36). While it is not known what effect P. cambivora has on A. myrtifolia, P. cambivora is closely related to P. cinnamomi and is also an aggressive root pathogen (Swiecki et al. 2005, p. 36). Phytophthora cinnamomi is currently considered to be the greatest threat to Arctostaphylos myrtifolia. As of 2005, P.cinnamomi was documented as occurring in two of the five large A. myrtifolia populations. However, because P. cinnamomi is causing mortality in a number of native forests and chaparral communities in northern California (Swiecki, in litt. 2008, p. 2), and contaminated soil is readily transported on vehicles and in nursery stock, it is likely that P. cinnamomi will spread throughout the range of A. myrtifolia in the foreseeable future.

**Stressor:** Inadequate regulations
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Regulatory mechanisms thought to be inadequate to protect Arctostaphylos myrtifolia included: (1) the CEQA; (2) the SMARA; and (3) local regulations (see five year review for more information).

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 5C

**Delisting Criteria:**
Not available

**Recovery Actions:**

- Currently there is no approved final or draft recovery plan for Eriogonum apricum (inclusive of vars. apricum and prostratum) or Arctostaphylos myrtifolia, therefore a high priority action should be finalizing a recovery plan for these species. Disease is currently the greatest threat to A. myrtifolia, and as such, a high priority should be placed on identification of the current extent of this pathogen within the range of A. myrtifolia and implementing measures to restrict the movement of infested soil and plant materials from areas affected by Phytophthora cinnamomi. Additional emphasis should be placed on conducting research into how to eliminate this disease from the ecosystem and identify other methods to prevent disease transmission. As part of this effort, the symptomatology, etiology, and impact of P. cambivora on A. myrtifolia and other species should be studied. Additionally, priority should be placed on identifying the status of E. apricum populations and obtaining an accurate representation of the area occupied by this species and the availability of habitat for restoration purposes. These tasks would aid us in better understanding the threats facing these species and to develop methods to help reduce the threats.

Nature Serve

five year review 2010

final listing rule

# SPECIES ACCOUNT: *Arctostaphylos pallida* (Pallid manzanita)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened

**Physical Description**

Pallid manzanita is an upright, evergreen shrub, usually 1.5 to 13 feet (2 to 4 meters) tall, but occasionally much taller. The bark on the main branches is gray to reddish. The leaf blades are 0.75 to 1 inch (2.5 to 4.5 centimeters), and a pale, dull-green color. Flowers are white and urn-shaped, 0.23 to 0.27 inch (6 to 7 millimeters) long, in dense clusters (USFWS 2014; Jepson 2013). Additional detail from 2015b: Arctostaphylos pallida is an upright, evergreen, non-burl-forming, obligate-seeding shrub. It grows up to 4 meters (13 feet) in height, with rough, gray, or reddish bark. The twigs (terminal branches) are bristly and canescent (covered with whitish fine hairs). The pale green leaves surround the stem and are attached by a petiole less than 2 millimeters (0.08 inch). The leaves are closely imbricated (overlap), and are cordate (heart-shaped) and glabrous (hairless). The leaf blade is 2.5 to 4.5 centimeters (1.0 to 1.8 inches) long, 2 to 3 centimeters (0.8 to 1.2 inches) wide, ovate or oblong-ovate, glaucous (covered with a whitish waxy covering), dull, and smooth (Wells 1993). The inflorescences (cluster of flowers) are dense, 3 to 5 per branch; the bracts (leaflike organ subtending an inflorescence) are 5 to 9 millimeters (0.2 to 0.35 inch), widely lanceolate (narrow and tapering at both ends), and acute (sharply pointed) (Wells 1993). The flowers are white, rose, or white-rose in color, urn-shaped, and 6 to 7 millimeters (0.2 to 0.3 inch) long; and flowering occurs from December to March. Fruits are 8 to 10 millimeters (0.3 to 0.4 inch), globe-shaped, and sticky (Wells 1993). (USFWS, 2015b).

**Taxonomy**

Arctostaphylos pallida was first described by Eastwood (1933), based on a specimen collected by W. W. Carruth in 1902 from the “East Oakland Hills.” Prior to Eastwood (1933), the specimen was included in Arctostaphylos andersonii. Jepson (1922; 1939) did not recognize A. pallida as a separate species and continued to include it in Arctostaphylos andersonii. McMinn (1939) published the combination A. andersonii var. pallida, apparently agreeing with J. E. Adams’ conclusions (first presented in his 1935 dissertation at the University of California at Berkeley) that the Oakland specimen was distinct but related to A. andersonii. This combination was not published until several years later (Adams 1940). In their floristic treatment of California, Munz and Keck (1959) followed McMinn’s treatment. Wells (1969) recognized A. pallida as a species separate from A. andersonii and retained this treatment in the Jepson Manual (Wells 1993). The phylogenetic analysis and relationships outlined in Boykin et al. (2005) do not support A. pallida as being a variety of A. andersonii. Although Parker et al. (2012) revised the taxonomy of several Arctostaphylos species for the second edition of the Jepson Manual; no taxonomic revisions were made to A. pallida. Arctostaphylos pallida is recognized as a full species (Parker et al. 2012).

**Historical Range**

Pallid manzanita has a historical range in the Contra Costa Hills in the northern Diablo Range in Alameda and Contra Costa counties, California (NatureServe 2014). It was collected on the summit of East Oakland Hills in January of 1902. A second population, which was believed to have been reported in the 1940s or 1950s, was on Sobrante Ridge in Contra Costa County (USFWS 2014). Added in 2015: Based on a personal communication with the late James Roof, the founding director of East Bay Regional Parks District's (EBRPD) Tilden Regional Park Botanical Garden (Tilden Park; Amme et al. (1987) noted that Mr. Roof planted several dozen A. pallida, in the period between 1939-1940, along Shasta Road and Golf Course Drive in Tilden Park. (USFWS, 2015b).

**Current Range**

There are 13 documented occurrences where pallid Manzanita currently exists. All extant, naturally occurring populations are in two geographic regions: Huckleberry Ridge in Alameda County, and Sobrante Ridge in Contra Costa County. There are likely dormant seed banks of pallid manzanita in the range of the species, as indicated by the presence of germinated seeds at several sites in Joaquin Miller Park following soil disturbance and/or burning (USFWS 2014). The largest concentration of pallid manzanita occurs on Huckleberry Ridge, with many stands distributed across connected and adjacent ridge tops. The largest stands by number and size occur along the boundary between East Bay Regional Park District's (EBRPD) Huckleberry Botanic Regional Preserve, and private properties to the west, primarily on northeast-facing slopes and extending southwest over the top of the ridge into the urban development of Skyline Boulevard. The second-largest concentration of pallid manzanita occurs at Sobrante Ridge in EBRPD's Sobrante Ridge Ecological Preserve. A 2004 survey indicated the population existed within 1.33 acres at Sobrante Ridge. There also exists a small, naturalized population at Tilden Park that is divided into two stands. One is scattered along the roadside of Wildcat Canyon Road, and the other is along the Selby Trail north of Shasta Road (CNPS 2014, USFWS 2014).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Food Source**

Adult: sunlight

**Competition**

Adult: yes (see threats section)

**Food/Nutrient Narrative**

Adult: This species acquires its energy from sunlight via photosynthesis.

**Reproductive Strategy**

Adult: diploid, obligate seeding; also capable of reproducing vegetatively by layering

**Dependency on Other Individuals or Species**

Adult: Depends on bees for pollination; seed caching by seed predators may be important for surviving fires

**Key Resources Needed for Breeding**

Adult: fire

**Reproduction Narrative**

Adult: Arctostaphylos pallida is diploid, obligate seeding, and shade-intolerant (Amme and Havlik 1987). Bees and other insects in the superfamily Apoidea, in particular European honeybees (Apis melifera), appear to be important pollinators (Amme and Havlik 1987, B. Solvesky, Service, pers. obs. 2010). Two basic life history patterns are found among species within the genus Arctostaphylos with respect to wildfire; Arctostaphylos plants either survive wildfire and resprout from a basal burl (sprouter) or Arctostaphylos plants are killed by fire and regenerate from seeds stored in the soil (obligate seeder). Obligate seeding Arctostaphylos species, like A. pallida, may require 5 to 25 years before substantial seed crops are produced (Keeley 1986). Seeds typically suffer high rates of predation (Kelly and Parker 1990); however, seed caching by seed predators may be an important mechanism by which seeds are buried to a sufficient depth at which they may survive high-intensity wildfires. Parker (2010) found that while overall seedling density declined with fire intensity, the proportion of seedlings emerging from rodent caches increased. Seeds that are not depredated on are slowly added to the soil seed bank, eventually reaching depths at which they can survive fire (Parker 2007). Obligate seeding Arctostaphylos species tend to have fire-dependent seedling recruitment; and mature stands tend to be even-aged, exhibiting little to no regeneration during fire-free intervals (Safford and Harrison 2004). Mechanical disturbance may be an alternative to fire under certain conditions. The regeneration of seedlings at stands where vegetation management activities disturbed the soil and increased light levels, in the absence of fire, indicates fire is not required for seed germination to occur. However, based on the large number of seedlings that occur at Huckleberry Preserve as the result of a pile burn, compared to other stands with seedlings where fire has not occurred, fire is likely a more effective means of stimulating germination. In addition to being an obligate seeder, A. pallida can reproduce vegetatively by layering. Layering occurs when branches become partially or fully buried in soil or litter and produce roots. Some extensive clones of A. pallida have developed in this manner within the Sobrante Ridge population (Amme and Havlik 1987).The understory of mature Arctostaphylos pallida stands and chaparral vegetation in general is typically free of vegetation, including regeneration. The cause of the lack of vegetation beneath chaparral species has been attributed to allelopathy (inhibitory biochemical interactions between plants), small mammal herbivory, and/or fire dependant seed banks. Keeley and Keeley (1989) concluded that in nature, a substantial proportion of the seed pool of some chaparral species is unlikely to germinate in the absence of fire and that dormancy mechanisms minimize seed germination during periods of low-survival probability. However, they also note that a portion of the seed pool is potentially capable of germinating in the absence of fire. A study comparing the regeneration and recolonization of obligate-seeding to sprouting Arctostaphylos after fire found that the seedlings of obligate seeders did not compete well against sprouters post-fire; thus, seedlings are adapted to openings in chaparral after fire (Keeley and Zelder 1978). Based on this observation, Keeley and Zelder (1978) hypothesized that longer fire-free periods favor obligate seeders by creating more and larger openings in chaparral post-fire, because: (1) longer fire-free periods result in higher fuel loads and more intense fires, thereby reducing the number of sprouters that survive fire; and (2) long fire-free periods allow for increased stem-exclusion, thereby reducing the density of potential sprouters after a fire. In support of this hypothesis, Odion and Davis (2000) found that chaparral with dense canopy cover prior to fire tended to be barren after fire, where heating was relatively high, except for the occasional obligate seeding Arctostaphylos and obligate seeding Ceanothus. The authors also noted that obligate seeders tended to have deeply buried seeds, allowing them to withstand prolonged soil heating. A study of the effects of prescribed fire on A. morroensis (Morro manzanita), a closely related species to A. pallida (Boykin et al. 2005) and a federally endangered obligate-seeding species from Morro Bay, California, found that A. morroensis may require considerably longer than 40 years between fires to establish a deeply buried seed bank with enough viable seed to adequately compensate for mortality and prevent population decrease or local extinction (Odion and Tyler 2002). However, it is not clear how long it takes to produce a persistent soil seed bank in which seeds are buried deep enough to withstand fire (Parker 2007).

**Habitat Type**

Adult: maritime chaparral vegetation type and appears to be co-dominant with other woody shrubs and shrub-form trees

**Dependencies on Specific Environmental Elements**

Adult: cool air temperatures that experience maritime fog

**Geographic or Habitat Restraints or Barriers**

Adult: likely restricted to the northwestern extremity of the Diablo Range (see Misc. Section)

**Spatial Arrangements of the Population**

Adult: clumped according to suitable resources

**Environmental Specificity**

Adult: Narrow; special habitat requirements

**Tolerance Ranges/Thresholds**

Adult: shade intolerant

**Site Fidelity**

Adult: very high

**Habitat Narrative**

Adult: The primary soil series Arctostaphylos pallida occurs on, including the large stands and satellite stands along Huckleberry Ridge and portions of Sobrante Ridge and Tilden Park, is Millsholm loam (NRCS 2013). The Millsholm soil series consists of shallow, well-drained soils that formed in material weathered from sandstone, mudstone, and shale. In addition to Millsholm loam, A. pallida occurs on other shallow well-drained soils series, rock formations, and soil complexes with parent materials that include shale, schist, greenstone, sandstone, silty clay loam, or conglomerate. The Huckleberry Preserve and the Sobrante Ridge stands grow on soil composed of Middle Miocene cherts and shales of the Monterey Group (Amme and Havlik 1987). These soils are thin, well drained at the surface, and deficient in many essential plant nutrients. However, the fractured and bedded rocks below hold water that is accessible to deep roots. Satellite stands along Skyline Boulevard occur on Pinehurst Shale and the Joaquin Miller Formation; both substrates are mixtures of shale, sandstone, and minor conglomerate. The stand along Exeter Drive occurs on soft sandstone. Arctostaphylos pallida appears to only grow on these soils in areas that experience maritime summer fog, and have not been found on the same substrates where summer air and soil temperatures are higher (Johnson 1983). Arctostaphylos pallida is a component of the maritime chaparral vegetation type and appears to be co-dominant with other woody shrubs and shrub-form trees, including A. crustacea subsp. crustacea (brittle leaf manzanita), Vaccinium ovatum (California huckleberry), Chrysolepis chrysophylla var. minor (golden chinquapin), and several shrub-form Quercus species. Maritime chaparral represents a plant community of special concern because of the high density of narrowly distributed endemic species, its patchy distribution, and its association with forest edges or odd soils (Parker 2007). Arctostaphylos pallida is shade intolerant and will slowly die when shaded by larger trees and shrubs. However, based on the results of vegetation management activities conducted in the mid-1980s at Huckleberry Preserve, Chabot, and Big Trees Trail and in the mid-2000s at Redwood Regional Park and Big Trees Trail, A. pallida responds positively to activities that reduce light competition and disturb the soil. Four vegetation types exist on Sobrante Ridge: maritime chaparral, oak woodland, coastal scrub, and grassland (Amme and Havlik 1987). The area outside of the shale soil formation is dominated by open park-like coast live oak woodland, interspersed with grassland and coastal scrub; while the area within the shale soil formation is dominated by maritime chaparral, including A. pallida and A. crustacea subsp. crustacea. Within the approximately 3.6-hectare (9-acre) shale soil formation, primarily along the edges, are A. custacea subsp. crustacea; within the center of the formation is the largest concentration of A. pallida, occurring on both east- and southwest-facing slopes. There are two vegetation types within the Huckleberry Preserve stand: maritime chaparral and oak/California bay laurel (Quercus species/Umbellularia californica) woodland. As is the case at Sobrante Ridge, the most barren soils at Huckleberry Preserve are occupied by the largest concentrations of Arctostaphylos pallida. Unlike the large stand at Huckleberry Preserve and the Sobrante Ridge, the soils of the satellite stands of the Huckleberry Ridge population are more developed and less nutrient deficient, capable of supporting redwood and coast live oak vegetation types. As such, the A. pallida at these sites occur mainly on roadcuts and within forest gaps.

***Dispersal/Migration***

**Motility/Mobility**

Adult: not mobile

**Dispersal**

Adult: only the seeds can disperse

**Dispersal/Migration Narrative**

Adult: There is not a lot of available dispersal information on this species.

***Population Information and Trends***

**Population Trends:**

some declining and some with unknown status

**Species Trends:**

unknown

**Population Growth Rate:**

unknown

**Number of Populations:**

3 (2 Naturally occurring. 1 Naturalized) (USFWS, 2023)

**Population Size:**

The most recent counts have estimated the population to be 2,444 mature plants and 133 seedlings (USFWS, 2023).

**Minimum Viable Population Size:**

unknown

**Resistance to Disease:**

low

**Adaptability:**

low

**Population Narrative:**

Distribution: At the time of listing, the pallid manzanita was known to be distributed between two naturally occurring populations and a single naturalized population. The distribution of the three populations have not significantly changed. The Huckleberry Ridge population is the largest known population and exists as a large colony with several satellite colonies. The population at Huckleberry Ridge occurs within East Bay Regional Park District's (EBRPD) Huckleberry Botanic Regional Preserve (Huckleberry Preserve), East Bay Municipal Utility District (EBMUD) managed areas, City of Oakland owned land, Pacific Gas and Electric power line easements, and on private property. Since listing, two colonies have been extirpated (Table 1). The second population occurs at Sobrante Ridge, within EBRPD's Sobrante Ridge Ecological Preserve. The third population was planted in the 1930s–1940s and occurs near the Tilden Park Botanical Garden (Tilden Park) in Contra Costa County (USFWS, 2023). Abundance: At the time of listing, the total population size was determined to be around 4,385 plants (Service 2011, p. 3). During the 2011 status review, the total population size was determined to be around 1,350 mature plants and 295 seedlings (Service 2011, p. 3). The most recent counts have estimated the population to be 2,444 mature plants and 133 seedlings. Table 1 below details most recent survey years for the different colonies within the three populations, and their most recent counts. Some of the increases may be explained by habitat management; at Chabot in Joaquin Miller Park, 125 seedlings germinated following extensive tree removal – with scarification from raking suspected to have assisted seed germination (Ella Matsuda, Friends of Sausal Creek, pers. comm. 2023). Similarly, on EBMUD managed lands, the number of pallid manzanitas more than tripled after the removal of over-shading trees (East Bay Municipal Utility District 2020, p. 12). Other increases can be linked to the discovery of new individuals and potential differences in counting of individuals from previous survey years; at the Huckleberry Preserve, surveys were completed in previously unmonitored areas where new mature plants were discovered (Californian Environmental Services 2018, p. 196). Lastly, a small colony of 10 outplanted individuals was propagated from cuttings taken by Friends of Sausal Creek between 2018 – 2023 (Ella Matsuda, Friends of Sausal Creek, pers. comm. 2023); limited information is available on the outplanted colony (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Disease
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Recently, Phytophthora cinnamomi has been confirmed infecting and killing A. pallida plants at Huckleberry Preserve and the Big Trees Trail stands. In contrast to the unidentified fungal pathogen, A. pallida infected with P cinnamomi die within several months of signs of infection and do not experience branch or stem dieback while maintaining healthy branches and meristems. To our knowledge, the extent of the infestation within stands of A. pallida has not been quantified and the potential for widespread population decline is still unknown. The pathogenic activity of Phytophthora cinnamomi is favored by free moisture, and under wet conditions multiple infection cycles are likely to occur. Phytophthora cinnamomi is primarily spread to new areas through the movement of infested soil by humans, particularly on vehicle tires, but also on shoes, tools and equipment that become contaminated with infested soil (Swiecki and Bernhardt 2003). In addition, P. cinnamomi has been isolated from container stock purchased from several native plant nurseries, suggesting nursery stock used for restoration projects or planted within the Wildland Urban-Interface (WUI) can provide a vector for this disease (Swiecki et al. 2011). In addition, a high percentage of woody plant materials from commercial nurseries are infested with various root-rotting Phytophthora species, including P. cinnamomi. This not only increases the likelihood that remnant plants in landscapes will be killed by this pathogen, but further increases the risk to stands in the vicinity of landscaped parcels, especially where landscaped parcels are located upslope of A. pallida stands (e.g., Manzanita Drive area) (T. Swiecki pers. comm. 2012).Human transport of contaminated soil is the primary vector for introducing Phytophthora cinnamomi into new areas. Most Arctostaphylos pallida stands occur along ridge tops, adjacent to unpaved maintenance roads and trails, increasing the likelihood contaminated soils will be spread throughout the East Bay Hills on shoes, bicycles, and vehicles. Once Phytophthora cinnamomi has been introduced into an area, its movement is facilitated by water flow, especially downhill. Swiecki et al. (2005) noted that the local spread of P. cinnamomi in A. myrtifolia occurs during the wet season at a cross-slope and upslope rate of approximately 0.25 meter (0.8 foot) per year. Down slope spread has been calculated at 2 meters (6.5 feet) per year, presumably due to transport via flowing water (Swiecki et al. 2005). Over a longer time interval, Swiecki and Bernhardt (2012) have documented that P. cinnamomi has spread at average rates about 1 meter (3.3 feet) per year in relatively level sites within A. myrtifolia stands.Introduction of Phytophthora cinnamomi into Arctostaphylos pallida habitat represents a long-term and substantial threat. Phytophthora cinnamomi can persist in the environment in the absence of susceptible hosts, surviving in the soil in infected roots, or as long-lived resident spores (Swiecki and Bernhardt 2003). There is no known cure for plants that have been infected. Prevention of this disease depends on the exclusion of the pathogen from areas that contain host plants.

**Stressor:** Fire frequency
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A lack of frequent small fires to stimulate regeneration and reduce fuel loads within stands of chaparral represented one of the greatest threats to the species. There has been considerable debate about the effects of decades of fire suppression on chaparral ecosystems (Moritz 2003). One side of the debate argues that fire suppression has increased fuel loads which lead to fewer, but larger wildlfires. This theory is supported by studies contrasting shrubland fire regimes north and south of the U.S.-Mexican border (Minnich 1983, 1995, 2001), suggesting that

the pattern of frequent small fires south of the boarder is a model of what fire regimes were like north of the boarder prior to fire suppression policy. Based on this assumption, proponents of this theory suggested that California-shrubland WUI management should de-emphasize fire suppression and reestablish an age mosaic of shrublands to return the landscape to a condition in which fire size is constrained by discontinuities in fuels due to smaller, more frequent fires.In contrast, others contend that relatively large stand-replacing crown fires are a natural part of these ecosystems and that urban expansion into these ecosystems has increased the rate of fire incidence through human ignition sources, resulting in more destructive (that is, expensive due loss the of human structures) fires. This is supported by research that has shown that frequency and area burned have not declined as a result of fire suppression (Keeley 1999), extremely large, stand replacing crown fires in California shrubland ecosystems predate fire suppression policy (Keeley and Fotheringham 2001, Keeley and Zedler 2009); over the last 130 years there has been no significant change in the incidence of large fires greater than 10,000 hectares (24,710 acres); fire suppression has not reduced the area burned (Conrad and Weise 1998, Keeley et al. 1999); large extensive fires are not dependent on stand age (Keeley et al. 1999, Moritz 2003); and when wildfires occur under severe fire conditions they burn through all but the youngest age-class of chaparral and coastal scrub (Keeley et al. 1999, Keeley 2002). Keeley and Fotheringham (2001) question the use of current fire regimes south of the border as a model of what fire regimes were like north of the border prior to fire suppression for the following reasons: (1) fire frequency from human ignition sources is five times greater south of the boarder; (2) most fires in northern Baja California, Mexico are driven by on-shore northwestern breezes, which have a different capacity for fire spread than fires driven by foëhn winds; (3) areas south of the border tend to receive less precipitation and soils tend to be less fertile, both of which affect fuel production; (4) much of the chaparral-dominated landscape south of the boarder is a plateau, lacking topographic heterogeneity, which affects the rate of fire spread and increases solar evaporation and reduced fuel production; and (5) few, if any, contiguous chaparral stands south of the boarder reach the sizes of those north of boarder. In a study of relative frequency of human-caused and lightning-caused fires in the coast range east of San Francisco Bay, Keeley (2005) found that most years were without any lightning-ignited fires: in Contra Costa County 86 percent of the years had no lightning-ignited fires and in Alameda County the figure was 74 percent. Wildfire in Alameda and Contra Costa counties is most often human caused; thus, the fire return interval is likely no longer within the evolutionary bounds of the species. Odion and Tyler’s (2002) study of Arctostaphylos morroensis indicates that a fire return interval of 40 years or less would likely result in the extirpation of the species, and other studies on obligate seeding Arctostaphylos similarly found that long fire-free intervals (with an interval greater than one fire every 100 years) likely do not represent a significant threat (Keeley and Zelder 1978, Odion and Davis 2000). Consequently, a relatively short fire-return interval, one that depletes the soil seed bank before it can be replenished, is likely a greater threat to A. pallida than a relatively long fire-return interval.Still, because fire is essential to the natural regeneration of Arctostaphylos pallida and regeneration can be difficult in the absence of fire, fire suppression remains a threat. The Huckleberry Preserve site has likely not experienced a stand-replacing fire for more than 80 years and would benefit from fire or other management activities that stimulated regeneration and reduced competition with native and non-native species. The Sobrante Ridge site likely experienced a stand-replacing fire 30 to 40 years ago (Service 1998) and appears to be healthy and vigorous. EBRPD does not typically conduct broadcast burning in the WUI due to the threat of fire escape and liability; however, EBRPD is proposing to burn slash piles at Huckleberry Preserve as part of their Wildfire Hazard Reduction and Resource Management Plan (LSA Associates, Inc. 2009) (WHRRMP). The limited opportunities to use fire to stimulate regeneration of A. pallida represents a threat to the species, because the effectiveness of mechanical soil disturbance to stimulate regeneration has not been proven to provide adequate regeneration.

**Stressor:** Goat grazing
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Both EBRPD and the City of Oakland have used domestic goat (Capra aegagrus) grazing as a tool to reduce fuel loads and wildfire hazard within the WUI of the East Bay Hills. Due to the relatively indiscriminant food selection preferences of the domestic goat, this practice poses a serious, yet easily avoidable, threat to Arctostaphylos pallida. According to Kanz (2004) goat grazing by the City of Oakland is responsible for the extirpation of the Manzanita Flat stand and has caused damage to A. pallida plants at the Big Trees Trail site. The WHRRMP specifically excludes the use of goat grazing near stands of A. pallida. Goat grazing is a minor threat in areas other than City of Oakland properties, but is a significant threat to A. pallida occurring on City of Oakland properties.

**Stressor:** Succession and invasive species
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Succession of maritime chaparral to oak/California bay laurel (Quercus species/Umbellularia californica) woodland and shading by non-native invasive species such as Eucalyptus species and Pinus radiata were cited as significant threats to Arctostaphylos pallida at the time of listing and continue to represent one of the most significant threats to the species. Mosaics of grassland, oak woodland, coastal scrub, and chaparral, in some locations, have been reported to correlate with geological substrate (Cole 1980, Davis et al. 1988) and soil characteristics (Harrison et al. 1971). However, Callaway and Davis (1993) found each of these vegetation types represented abundantly on most soil depths, slope aspects, and all geological substrates. Cyclical changes between chaparral, oak woodland, grassland, and coastal scrub do occur. However, the interactions between variables responsible for vegetation type conversion and the rate of conversion are complex and site-specific. Callaway and Davis (1993) found that transition rates varied with substrate and topographic position, indicating fire, grazing, and the physical environment interacted to determine direction and rate of conversion. Variation in transition on different substrates suggests that only portions of the vegetation on the landscape may be dynamic, with some patches in certain combinations of environment and disturbance that change rapidly, and other patches that remain static as edaphic or topographic climax communities. As a broad generalization, in the absence of disturbance and on sites with environmental factors that allow for transition from one vegetation type to another, grasslands tend to transition to coastal scrub, coastal scrub to chaparral or oak woodland, chaparral to oak woodland, and oak woodland to grassland (Callaway and Davis 1993). Arctostaphylos pallida is highly shade intolerant and the invasion of tree-form plant species creates shade that causes A. pallida shrubs to slowly die over several years if management action is not taken. All of the stands of A. pallida, to some degree, show signs of succession to oak/ California bay laurel woodland and/or are being shaded by non-native trees. The Huckleberry Preserve stands and all of the satellite stands of the Huckleberry Ridge population are in severe decline due to shading via native species and non-native invasive species. For example, the Chabot stand will likely be extirpated within a decade if action is not taken that addresses this issue. Shading lowers seed

production, reduces vegetative growth, causes branch dieback and ultimately results in plant death. However, A. pallida stands that experience 100 percent mortality will likely have a viable, although declining, seed bank for many decades.

**Stressor:** Nitrogen Deposition
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Atmospheric nitrogen deposition is a complex process by which reactive chemical species of nitrogen (N), nitrogen oxides (NOX), ammonia (NH3), and their reaction products are deposited onto surfaces and enter ecosystems as N-fertilizer. As a consequence of anthropogenic inputs, the global nitrogen cycle has been significantly altered over the past century (Weiss 2006). The added N has been shown to allow nutrient-deficient soils, such as serpentine, to be invaded by both native and non-native species that require added nutrients to survive (Weiss 2006). Although it has been posited that the succession of maritime chaparral to oak/bay (Quercus species/Umbellularia californica) woodland in the East San Francisco Bay is due to fire exclusion or is a natural process, it is also possible N-deposition has created conditions that have allowed vegetation-type conversion, from maritime chaparral to oak-bay woodland, to occur on the nutrient deficient soils that are typical of Arctostaphylos pallida.

**Stressor:** Hybridization
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Hybridization between Arctostaphylos pallida and other Arctostaphylos species was cited as a threat at the time of listing and continues to threaten the species today. Hybridization is known to occur naturally between A. pallida and A. crustacean. However, several species of Arctostaphylos not known to co-occur with A. pallida have been used for landscaping on private lands within the urban development adjacent to Huckleberry Preserve and threaten nearby A. pallida individuals through pollen swamping and hybridization leading to genetic assimilation. While most Arctostaphylos are diploid, about 30 percent are tetraploid. Differences in ploidy level are not a complete barrier to hybridization, and several diploid-tetraploid crosses have been observed in the field (e.g., A. crustacea X A. pallida) (Wahlert et al. 2006). From examination of populations of co-occurring diploid Arctostaphylos species in the field, in which the co-occurring Arctostaphylos species are from different genetic clades as defined in Boykin et al. (2005), there is very little or no hybridization (V.T. Parker and M.C. Vasey, unpublished data). However, A. glauca, A. pajaroensis and A. pallida are from the same genetic clade (Boykin et al. 2005) and are all diploid (Parker et al. 2012). Furthermore, hybrids have been observed between A. pallida and A. glauca (bigberry manzanita) and hybridization may be occurring in areas where residents have planted A. pajaroensis (Pajaro manzanita). This calls into question the genetic integrity of the seed bank within the City of Oakland residential development along Huckleberry Ridge and, to some extent, within the adjacent Huckleberry Preserve stands. If the seed bank in this area, including that of the Huckleberry Preserve stands, has been genetically compromised though hybridization with non-native Arctostaphylos species, regeneration in the area could result in a hybrid swarm and a blurring of the genetic integrity of all future stands of A. pallida in the area. At this time, the extent to which hybridization has occurred and the extent to which hybridization threatens A. pallida is not known.

**Stressor:** Landscaping
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Arctostaphylos pallida plants that occur within the yards of private residences (less than 57 plants) in City of Oakland residential neighborhoods are highly susceptible to mortality from landscaping activities. The majority of these plants will likely be lost in the foreseeable future due to these activities and a lack of regeneration. In addition, the genetic integrity of the soil seed bank is questionable due to hybridization with non-native Arctostaphylos species (see Factor D, Hybridization above). Due to the susceptibility of these plants to mortality from landscaping and home improvement projects, and ongoing hybridization with non-native Arctostaphylos species, these plants and the associated seed bank will not contribute to meeting any of the recovery criteria for this species.

**Stressor:** Herbicide Use
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, herbicide use for the purpose of controlling roadside vegetation in the residential development adjacent Huckleberry Preserve was cited as a threat to Arctostaphylos pallida. Kanz (2004) indicated that A. pallida plants below the Pacific Gas and Electric Company power lines, between Manzanita Drive and Skyline Boulevard, exhibited evidence of herbicide use. Herbicide use continues to be a minor threat to A. pallida, particularly within the urban development and associated A. pallida stands adjacent to Huckleberry Preserve.

**Stressor:** Small Population Size and Stochasticity
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Because Arctostaphylos pallida exists as three populations with only two large stands and several small satellite stands, inbreeding depression and stochastic events represent significant threats to the species. Inbreeding depression can result in reduced fitness, which, coupled with small population size may result in a higher susceptibility to stochastic events, such as excessive rain, drought, and landslides, that further increase the likelihood of loss of genetic variability. Stochastic events, such as prolonged rainy periods, can also increase susceptibility to other threats, such as fungal pathogens and Phytophthora cinnamomi.

**Stressor:** Climate Change
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Effects to this species as a result of climate change are unclear. A trend of warming in the mountains of western North America is expected to decrease snowpack, hasten spring runoff, and reduce summer stream flows, and increased summer heat may increase the frequency and intensity of wildfires (IPCC 2007). While it appears reasonable to assume that the species may be affected, we lack sufficient certainty on knowing how and to what degree climate change will affect the species, the extent of average temperature increases in California/Nevada, or potential changes to the level of threat posed by drought, fire, etc. The most recent literature

on climate change includes predictions of hydrological changes, higher temperatures, and expansion of drought areas, resulting in a northward and/or upward elevation shift in range for many species (IPCC 2007).A modeling study by Loarie et al. (2008) provides an evaluation of potential trends to California’s floristic communities under climate change scenarios. In general, large numbers of plant species will tend to move to higher elevations, towards the coast, or northwards. The models suggest that climate change has the potential to break up local floras, resulting in new species combinations, with new patterns of competition and biotic interactions (Loarie et al. 2008). Based on these models, Arctostaphylos pallida plants would likely be unable to shift their range naturally because of their dependence on specific soil types and a maritime climate and due to the presumably low dispersal potential of the species. Climate change may also affect summer fog frequency and have a substantial impact on Arctostaphylos pallida, which is dependent on a fog-influenced maritime climate. According to M. Vasey (personal communication 2010), coastal endemic Arctostaphylos species are more vulnerable to summer drought stress than interior species, and if the frequency of coastal fog declines, the hydrologic regime of coastal Arctostaphylos species will likely become more challenging as they are not well-adapted to water stress. In addition, summer fog increases plant, soil, and atmospheric moisture, which decreases fire hazard and decreases the threat of too-frequent fire. Based on observational (Bakun 1990, Lebassi et al. 2009) and modeling studies (Diffenbaugh et al. 2004, Snyder et al. 2003) climate change may intensify upwelling, an important process in fog production off the coast of California, suggesting increases in fog in response to increased carbon emissions. However, Johnstone and Dawson (2010) found empirical evidence for moderate fog reductions since 1951, with interannual and multidecadal variations governed largely by ocean-atmosphere circulation and temperature anomalies.

***Recovery***

**Reclassification Criteria:**
Not applicable

Recovery Priority Number: 5

**Delisting Criteria:**
To delist Arctostaphylos pallida, threats to the species habitat must be reduced. This will be accomplished when the following has occurred: The 6,700 mature Arctostaphylos pallida plants counted toward recovery in delisting criterion E/2 are protected from incompatible uses through long-term conservation agreements with landowners. To delist A. pallida, the threat of disease must be controlled or eliminated. This will be accomplished when the following have occurred: Tools or treatments have been developed and are effectively being utilized that have stopped the spread of Phytophthora cinnamomi and any individual mortality. Treatments have been developed that allow Arctostaphylos pallida plants infected with Phytophthora cinnamomi to produce viable seed during or after treatment in quantities similar to uninfected healthy A. pallida plants. A Phytophthora cinnamomi monitoring plan has been developed and implemented for all Arctostaphylos pallida stands and areas within watersheds of stands, to determine if stands are infected, the extent of infection, and to identify potential sources of future infection. Other natural or manmade factors believed to affect the continued existence of Arctostaphylos pallida include: fire frequency, wildfire fuel reduction treatments, succession and non-native invasive species, and small population size and stochasticity. To delist A. pallida, these threats must be reduced. This will have been accomplished when the following have

occurred: There are at least three separate populations of mature Arctostaphylos pallida plants: at least one population south of California State Route 24 (SR24) and at least two populations north of SR24, each with at least 1,700 genetically pure mature A. pallida plants.1 For the purpose of recovery, a population is considered to be separate as long as it is more than 3.0 kilometers (1.9 miles) from the nearest A. pallida stand, and a mature plant is defined as being 25 years of age or greater. There are at least 6,700 genetically pure mature Arctostaphylos pallida plants. Competing native and non-native vegetation is controlled to a level whereby Arctostaphylos pallida vigor is not negatively affected and landowners have committed to provide long-term vegetation control that will conserve resident A. pallida. Stand regeneration methods (mechanical or fire) result in an increasing trend in the number of mature Arctostaphylos pallida over a 25-year period. Seed, representative of the breadth of the species' genetic diversity, is stored at a seed storage facility.

**Recovery Actions:**

- In 2009, as part of a Low Effect Habitat Conservation Plan for EBMUD lands in the San Francisco East Bay, a large Pinus radiata that shaded the Pinehurst Road stand was removed. Prior to the removal of this tree, the stand had declined from 25 to 11 mature Arctostaphylos pallida plants. Apparently, the increased light not only invigorated the plants that had been shaded, but the mild disturbance to the site, caused by horse logging activities, stimulated a portion of the soil seed bank and over 52 A. pallida seedlings germinated. EBMUD continues to survey the Pinehurst Road stand on an annual basis.
- In the summers of 2004 and 2005, approximately 500 square feet (152 square meters) were cleared by EBRPD at Huckleberry Preserve, leaving only Arctostaphylos pallida plants. Cut material and dead wood were placed into piles. In late February and early March of 2007, the piles were burned. In 2008, 176 seedlings had sprouted within the burned area.
- The Big Trees Trail stand is likely to have sustained greater mortality if not for vegetation management activities conducted by a local volunteer watershed restoration organization, the Friends of Sausal Creek (FOSC). The FOSC conducts surveys of the site and occasionally removes both native and non-native plants that shade Arctostaphylos pallida plants. The management of the Big Trees Trail stand was included in the Chabot management plan to allow for a memorandum of understanding between FOSC and CDFG to permit FOSC to conduct restoration activities at both sites. A small number of A. pallida seeds have again germinated at the Big Trees Trail site in the absence of fire. Seed germination is likely due to soil disturbance caused by vegetation removal activities that scarified the seed coats.
- A 1995 Environmental Impact Report (EIR) prepared for the construction of the Science Center in Oakland California required that an A. pallida management plan be created and implemented. The plan was finalized in September 2009, and proposes to restore habitat and maintain a minimum of 21 plants at the site (Nomad Ecology 2009). According to the management plan, restoration activities were to begin in October 2009; however, the A. pallid at the Science Center have continued to decline and management activities did not begin until 2013.
- Recovery Strategy: Because Arctostaphylos pallida is an obligate-seeding species naturally occurring as even-aged stands with a long-lived soil seed bank, the primary management goal, at the stand level, should be to maximize seed production and to ensure the soil seed bank is adequate to replace all mature plants within a stand in the event of fire. At this time, the most significant long-term threats to seed production and stand regeneration, and in effect, the continued existence of the species, are: 1) the fungal pathogen Phytophthora cinnamomi which directly kills A. pallida plants and results in perpetual soil contamination;

2) competition, via succession, with native and non-native vegetation for light and space; 3) an altered fire regime that may prematurely deplete soil seed banks; 4) fire fuels management; and 5) small population and stand sizes that increase the likelihood stochastic events will extirpate a stand or population. In addition to ensuring habitat loss does not occur as a result of development, these threats can be minimized or ameliorated through the implementation of management plans that include and prioritize the control of P. cinnamomi at the stand level, P. cinnamomi spread abatement at the landscape level, management of competing native and non-native vegetation, perpetual stand regeneration, maintenance of genetic diversity, stand expansion, establishment of additional stands, and compatible fuel reduction treatments and methods.

- Phosphite (neutralized phosphorous acid), is a biodegradable systemic fungicide that, in part, potentiates plant defense mechanisms so that there is a more rapid and robust response to the pathogen. Phosphite stresses Phytophthora cinnamomi, causing it to release chemical signals that trigger the natural defense mechanisms of the host plant, thereby reducing the ability of P. cinnamomi to colonize and reproduce within the host (Suddaby and Liew 2008). Phosphite can be applied as a low volume aerial spray, high volume foliar spray, or by trunk injection of individual plants. The dosage of phosphite required to protect individual plant species is not universal. Applications that are too high for a particular plant species will have side-effects, such as leaf burning and a reduction in pollen viability, however, these effects may be temporary (Suddaby and Liew 2008). The efficacy of phosphite is not permanent and reapplication is required. The appropriate treatment regime (including an understanding of season, dose, application type, frequency, etc.) for Arctostaphylos pallida is not known at this time, but treatment frequency could be as often as once every 2 years. Low volume aerial application rates in Western Australia have ranged from 12 to 24 kilograms per hectare (11 to 21 pounds per acre) with disease control anticipated for approximately 2 years post-spray (Barrett et al. 2001). A study is currently underway to assess the efficacy of phosphite for limiting the spread of root disease caused by P. cinnamomi in native A. myrtifolia stands (Swiecki and Bernhardt, 2012).
- EBRPD's Wildfire Hazard Reduction and Resource Management Plan: According to EBRPD's Wildfire Hazard Reduction and Resource Management Plan (WHRRMP) the maritime chaparral vegetation type represents an extreme wildfire hazard. To reduce the hazard, the WHRRMP aims to focus mechanical fuel treatment efforts on key locations, including almost all stands of Arctostaphylos pallida. To minimize the effects of the WHRRMP, the Service is working with the Federal Emergency Management Agency and EBRPD to complete a long-term A. pallida management plan. Although the WHRRMP threatens A. pallida, the WHRRMP includes the removal of both native and non-native vegetation that grows within and adjacent to stands of A. pallida to reduce wildfire hazard. Shading by native and non-native species poses a significant threat to the existence of A. pallida (see Factor E section on Succession and Non-native Invasive Species); thus, the WHRRMP, if implemented in conjunction with an A. pallida management plan, may benefit the species.

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Conduct frequent surveys for Phytophthora cinnamomi infection to understand risk of infection and rate of mortality once infected. 2. Develop tools and treatments to control the spread and impact of Phytophthora cinnamomi. 3. Continue to use mechanical methods to clear over-shading trees, especially at the Big Trees Trail in Joaquin Miller Park colony and the Sobrante Ridge population. 4. Collect and store seeds from Tilden Park and Huckleberry Ridge populations, including accessions from each colony in the Huckleberry population. 5. At the Tilden Park, outplant seedling pallid manzanitas and scarify the ground to increase germination of latent seeds. 6. Partners and stakeholders should continue to promote Phytophthora cinnamomi education to the public to promote reduction of disease spread within and among the colonies (USFWS, 2023).

# SPECIES ACCOUNT: *Arenaria paludicola* (Marsh Sandwort)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/3/1993; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A herbaceous green perennial often supported by surrounding vegetation, with angled or grooved stems, which are glabrous (without hair) except at the nodes (points of leaf attachment) (Figure 1, Figure 3). The trailing stems often root at the nodes, and can be up to 1 meter (3 feet) long. The opposite leaves of the plant are lanceolate (lance-shaped) and narrowly acute (sharp-pointed), with a solitary mid-vein. The species blooms from May to August. At Oso Flaco Lake, it was flowering with some green fruit in early June (John Chesnut, in litt. 1998). Flowers are small, white, and borne singly on long stalks arising from the leaf axils (point of leaf attachment to the stem); capsules (fruits) contain 15 to 20 seeds. The solitary axillary flower and smooth, angled stem distinguish this species from others in the genus. Hitchcock (1964) speculated that this plant was “very seldom collected, possibly because it is mistaken for sterile plants of Galium aparine,” a common species. As reported by Bonilla (1992, in litt. 1998) from Zempoala Lakes in the state of Morelos in central Mexico, this species is an annual, flowering April to September and producing seeds from June to October. (USFWS, 1998)

**Taxonomy**

Marsh sandwort (Arenariapaludicola) is a dicotyledonous plant belonging to the pink family (Caryophyllaceae). Pertinent synonyms for the scientific name are Minuartia paludicola House; Alsinopsispaludicola A. Heller; Arenariapalustris S. Watson not of Gay 1845; and Alsine palustre Kellogg. The species first was described as Alsine palustre by Albert Kellogg in 1863, from specimens collected by Bolander near Fort Point (now within Golden Gate National Recreation Area), San Francisco, California. The plant was then “very abundant in swamps” in the area (Kellogg 1863). In 1876, Sereno Watson reassigned the species to the genus Arenaria. The resulting name, Arenaria palustris, inadvertently duplicated the name that Gay had published earlier, in 1845, for another species. This duplication of names was corrected by B.L. Robinson (1894), who substituted the currently used scientific name, Arenaria paludicola. (USFWS,1998)

**Historical Range**

Historically collected by botanists from scattered locations near the Pacific coast in southern and central California and Washington. California locations were recorded in 1899 in San Francisco and San Bernardino counties, in 1947 in Santa Cruz and San Luis Obispo counties, and in 1950 and 1964 in San Luis Obispo County. The southern range limit is given as Los Angeles County by Hitchcock (1964), and as the Santa Ana River (Orange County) by Hartman (1993). In a sequence of regional floras starting with Abrams and Ferris (1944), and continuing through Mason (1957), Munz and Keck (1968), Hoover (1970), Munz (1974), Smith (1976), and Hartman (1993), the earlier floras report the species as widespread within its historical range. Later floras report it as more localized and restricted, becoming “occasional,” “scarce” in swamps and marshes, and most recently, “rare.” (USFWS, 1998)

**Current Range**

In California, in San Luis Obispo County. One extant wild population at Oso Flaco Lake; one introduced population at Sweet Springs Marsh on the southern edge of Morro Bay. (USFWS,

2008)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual, vegetative (USFWS, 2008)

**Breeding Season**

Adult: May - August (USFWS, 2008)

**Reproduction Narrative**

Adult: It generally blooms from May to August. This plant can also reproduce asexually. It can produce adventitious roots on the trailing stems that come in contact with suitable conditions (USFWS, 2008).

**Habitat Type**

Adult: Wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Freshwater marshes (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 0 - 450 m elevation (NatureServe, 2015); possibly shade (USFWS, 1998)

**Environmental Specificity**

Adult: Very Narrow (inferred from USFWS, 1998)

**Habitat Narrative**

Adult: Inhabits freshwater marshes from close to sea level to 450 m elevation. Plants have been found in areas with shallow standing water and with no standing water. Substrates are saturated, acidic, organic bog soils. Sensitive to disturbance; specialized habitat and wetlands are vanishing (NatureServe, 2015). Shady or filtered light conditions may inhibit the growth of Arenaria paludicola (USFWS, 1998).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Declining (most populations extirpated) (USFWS, 2008)

**Species Trends:**

Declining (USFWS, 2008)

**Number of Populations:**

2 (USFWS, 2020)

**Population Size:**

1 - 1000 individuals (NatureServe, 2015)

**Population Narrative:**

Marsh sandwort was once a wide ranging species with a historic range that extended along the west coast from Washington State to Mexico (Service 2008, p. 5-6). The species distribution is now reduced to three isolated occurrences, with two populations at GGNRA in Marin County and two populations in San Luis Obispo County; at the Sweet Springs Nature Preserve on Morro Bay and Oso Flaco Lake on ODSVRA (Figure 1). Threats identified at the time of listing, in the 1998 Recovery Plan, and in the 2008 5-year review remain largely unchanged (Service 1993, 58 FR 41378; Service 1998, p. 8 and 18-21; Service 2008, p. 10-13). Climate change effects, especially those resulting in hydrological changes to marsh and other wetland habitats, are a new primary threat to the species. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Habitat destruction and degradation (USFWS, 2008).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** There continues to be both a loss and degradation of habitat due to development/urbanization and a conversion of marsh habitat due to the collateral, but indirect, effects from development/urbanization. Some of this habitat loss occurs in watersheds that are classified as impaired by the Regional Water Quality Control Board for excessive amounts of nitrogen and other nutrients (California State Water Resources Control Board 2006a). The vegetation in these watersheds exhibits excessive growth that is consistent with biostimulation and eutrophication (a state in which the total nitrogen is >1.5 milligrams/liter and/or the total phosphorus is >0.075 milligrams/liter within an aquatic system) (California State Water Resources Control Board 2006a, California State Water Resources Control Board 2006b, Central Coast Ambient Monitoring Program 2002, Dodds et. al. 1998) (USFWS, 2008).

**Stressor:** Herbivory (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory has been documented in some locations. While this plant may be able to withstand some herbivory, herbivory may cause a reduction in its reproductive success due to the loss of flowers and the correlated reduction in the production of seeds. The extent of this threat is not known, but the herbivory of even a few flowers may have a significant effect on the long-term survival of Arenaria paludicola because there are so few individuals and only one known population remaining in the wild (USFWS, 2008).

**Stressor:** Small population size (USFWS, 2008)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small populations are threatened by inbreeding depression (Ellstrand and Elam 1993). Small populations can have significantly lower germination rates than larger populations of the same species due to high levels of homozygosity (Menges 1991). An increase in urban development has reduced the range of this species considerably. Increasing development in the area will likely increase threats from stochastic events. Indirect effects from urbanization in the watershed include changes in hydrology, changes in vegetation, and an increase in nonnative species. The effects of competition with nonnative species is most problematic immediately adjacent to urban areas and in habitat that has been isolated or fragmented by development (Alberts et al. 1993). These factors may not be enough to threaten the survival of A. paludicola independently, but taking into account its limited range, the cumulative and synergistic effects of all of these factors combined could be a threat to the survival and recovery of A. paludicola (USFWS, 2008).

***Recovery***

**Reclassification Criteria:**
1. When new plants are established so that there are at least 5 populations of at least 500 individuals each (USFWS, 1998)

2. When some of the populations occur in permanently protected habitats within the Black Lake Canyon and the dune lakes area (USFWS, 1998)

3. When some of the populations are in other areas of suitable habitat with the species' historical range in the United States (USFWS, 1998)

4. When the populations remain viable for at least 5 years. Viable populations are defined as those that are showing natural reproduction and either stable or increasing in size over time, without artificial augmentation(USFWS, 1998)

**Delisting Criteria:**
1. If threats are reduced or eliminated so that protected populations are capable of persisting without significant human intervention or perpetual endowments are secured for management 5 necessary to maintain the continued existence of the species. The most outstanding management needs currently are: a) controlling competition with nonnative species, and b) managing water conditions, particularly flow and salinity, that the species depends on. (USFWS, 2019)

2. If protected populations are established across the species ecological settings (in addition to Black Lake Canyon and the Dune Lakes area), including San Mateo Creek in San Onofre State Park in Orange County or comparable site(s) in that region; the San Antonio Creek drainage on Vandenberg Air Force Base in Santa Barbara County or comparable site(s) in that region; and wetlands in Golden Gate National Recreation Area in San Francisco County or comparable site(s) in that region. (USFWS, 2019)

3) the populations remain viable for at least 10 years. Because this species has narrow microhabitat conditions that it will tolerate, particularly with respect to soil moisture and salinity, and in light of fluctuations that can occur with climatic conditions, local groundwater table levels, and saltwater intrusion events, the persistence of populations with these varying conditions over time needs to be confirmed. (USFWS, 2019)

**Recovery Actions:**

- 1. Protect, maintain, and enhance species habitats. The most important immediate objective in the recovery plan for and Marsh sandwort is the protection of its habitat. - Coordinate among agencies involved in recovery activities. - Define and maintain the sensitive Resource Area boundary and restrictions at Black Lake Canyon. - . Establish protection agreements. - Acquire key land parcels and conservation easements. Enhance existing habitat at Black Lake Canyon. - Continue to protect, maintain, and enhance habitat in the Dune Lakes area. - . Communicate species and habitat protection information to all concerned parties. (USFWS, 1998)
- 2. Document and monitor population and habitat characteristics. - Conduct plant surveys. - Protect newly discovered populations. - Monitor all populations and habitats. (USFWS, 1998)
- 3. Conduct research on the ecology and biology of the species. - Identify potential impacts of conducting research. - Determine population characteristics and life history of the species. - valuate species' tolerances. - Investigate the effects of genetic diversity. (USFWS, 1998)
- 4. Augment existing populations. In addition to protecting existing and newly discovered habitats of Marsh sandwort , monitoring these populations and their habitats, and conducting research on the biology and ecology of the species, attempts should be made to augment existing populations. (USFWS, 1998)
- 5. Establish new populations. Because Marsh sandwort currently has very restricted distribution in California, establishment of new populations within the historic range of the species at potentially suitable sites other than at historic sites should be attempted. If new populations are successfully established, it will reduce the likelihood that a catastrophic event could result in the extinction of the species with its current restricted distribution. (USFWS, 1998)
- 6. Evaluate Progress and Update Management and Recovery Guidelines. Results of all recovery activities should be evaluated and incorporated into updated management and recovery guidelines for the species. All relevant information should be distributed. (USFWS, 1998)
- Work with the California Department of Parks and Recreation and other stakeholders to implement site-specific management activities in the immediate future to alleviate threats and prevent the loss of the last, known remaining wild population (at Oso Flaco Lake) (USFWS, 2008).
- Work with others to establish several new populations in the near future to reduce the risk of extinction to Arenaria paludicola and maintain ex situ stock at two or more institutions (USFWS, 2008).
- Assemble a scientific recovery implementation team to assist us in determining a scientifically sound plan to reintroduce and introduce Arenaria paludicola to sites within its historical range in California (USFWS, 2008).

- Work with the Regional Water Quality Control Board to determine nutrient levels in the watersheds which have supported Arenaria paludicola in the recent past (particularly Black Lake Canyon and Oso Flaco), and work with local landowners and stakeholders to alleviate (and remove) any threats to A. paludicola that are associated with water quality (USFWS, 2008).
- Conduct a genetic analysis to determine the extent of variation within and between Arenaria paludicola populations to help determine an appropriate recovery and reintroduction strategy (USFWS, 2008).
- Survey historical Arenaria paludicola sites for potential extant occurrences and to identify suitable sites for reintroductions and survey areas in southern and central California and near Tacoma in Washington State for potential new A. paludicola occurrences and to identify suitable sites for introductions (USFWS, 2008).
- Modify downlisting criterion number 4 ("[T]he [introduced] populations remain viable for at least 5 years") to viable onsite reproduction for more than one generation (i.e., a second, or "f2" generation) has been confirmed (USFWS, 2008).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The following actions are recommended based on the current 5-year review: 1. Implement annual monitoring programs and develop comprehensive management plans to ameliorate the threats at extant populations. 2. Conduct surveys within suitable marsh habitats throughout the historic range and in extirpated sites previously known to have supported the species. 3. Conduct introductions at suitable sites that include long-term management strategies to ensure success and persistence of the species at introduced locations. 4. Continue to collect seed to expand the ex situ conservation seed bank collection. 5. Conduct research to evaluate site-specific effects of climate change, the role of sexual reproduction, the seed bank, and genetics of the species to inform management and introduction efforts. (USFWS, 2020)

# SPECIES ACCOUNT: *Argemone pleiacantha* (Sacramento prickly poppy)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 08/24/1989; Southwest Region (Region 2) (USFWS, 2016)

**Physical Description**

Sacramento prickly poppy is a robust, short-lived perennial, 0.5-1.5 m (1.5-5.0 ft) tall with 3-12 branching stems and striking, blue-green colored leaves. The leaves are about 10.0-15.0 cm (4.0-6.0 in) long, with rectangular sinuses and spine-tipped lobes extending almost to the midrib. The veins and midrib are armored with stout, yellow spines. The large and showy white flowers have 6 petals 3.0-4.0 cm (1.2—1.6 in) long and 8.0-9.0 cm (3.5 in) wide, with numerous orange stamens and a purple stigma. Capsule spines are simple. The small, round, black seeds are 2.5 mm (0.1 in) in diameter and dispersed by wind, water and possibly animals (R. Galeano-Popp, U.S. Forest Service (USFS), pers. comm., 1992; R. Sivinski, New Mexico Energy Minerals and Natural Resources Department (NMEMNRD), in litt., 1992). In addition to the deeply divided leaves and simple capsule spines, Sacramento prickly poppy has white—colored stem sap. (USFWS, 1994)

**Taxonomy**

Recent molecular and geographic data (Cervantes et al., 2010) support a scientific name change for the Sacramento prickly poppy from Argemone pleiacantha spp. pinnatisecta to Argemone pinnatisecta, which was documented in the previous 5-year review for the poppy (USFWS, 2013). However, the scientific name has yet to be changed in the List of Endangered and Threatened Wildlife and Plants (50 CFR 17.12) and associated recovery documents (USFWS, 2022).

**Historical Range**

The species' known historical range covered 13 canyons in 8 canyon systems of the Lincoln National Forest (LNF). Populations existed in Fresnal Canyon, including Salado and La Luz canyons; Dry Canyon; Marble Canyon; Alamo Canyon, including Caballero, Gordon, and Deadman canyons; Mule Canyon; San Andres Canyon; Dog Canyon; and Escondido Canyon (USFWS, 2022).

**Current Range**

Currently, poppies are known to be extant in 11 of these canyons. The species is also known to occur on Bureau of Land Management lands, private lands, Oliver Lee State Park, and on State of New Mexico and City of Alamogordo rights-of-way (USFWS, 2022).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Dependency on Other Individuals or Species**

Adult: The flowers have a variety of pollinators that include carpenter bees (Xylocopa californica arizonensis), honey bees (Apis mellifera), bumblebees (Bombus ssp.), soldier beetles (Cantharidae), lizard beetles (Liguriidae), flies (Diptera), and butterflies (Lepidoptera) (U.S. Forest Service 2004). (USFWS, 2013)

**Breeding Season**

Adult: May through summer (USFWS, 2013)

**Key Resources Needed for Breeding**

Adult: Germination can only occur after cold stratification and is further enhanced if the seed coat is also scarified. (USFWS, 1994)

**Reproduction Narrative**

Adult: Generally, plants bloom during the second year, if moisture availability has allowed for sufficient growth. Flowering begins in May and continues throughout the summer depending on elevation and moisture conditions. The flowers have a variety of pollinators that include carpenter bees (Xylocopa californica arizonensis), honey bees (Apis mellifera), bumblebees (Bombus ssp.), soldier beetles (Cantharidae), lizard beetles (Liguriidae), flies (Diptera), and butterflies (Lepidoptera) (U.S. Forest Service 2004). Studies of pollination biology and subsequent fruit set and seed production show that prickly poppy will set little or no fruit unless visited by pollinators. Self pollination, either within one flower or among flowers of the same plant, results in significantly fewer fruits and fewer seeds per fruit (Tepedino 1992). Seed output for mid- sized plants in Alamo and Dog canyons averaged about 2,000 seeds per plant (Malaby 1988). However, based on nursery results, seed germination is low (approximately 3 percent in 1989) and seedling mortality is high (Malaby 1988). Germination can only occur after cold stratification and is further enhanced if the seed coat is also scarified. (USFWS, 1994; USFWS, 2013)

**Habitat Type**

Adult: Terrestrial and palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Riparian, desert, forest/woodland, woodland- conifer (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations between 4,200 and 7,120 feet (USFWS, 1994)

**Environmental Specificity**

Adult: Medium, with some key requirements (USFWS, 1994)

**Tolerance Ranges/Thresholds**

Adult: High (USFWS, 1994)

**Habitat Narrative**

Adult: Sacramento prickly poppy is found in the dry hills, pinyon-juniper zone (Flora of North America Editorial Committee 1997) on loose, gravelly soils of open disturbed sites, canyon bottoms and slopes (McDonald 2010). Usually in areas of enhanced soil moisture such as north-facing slopes, canyon bottoms, along drainages, and near leaks in water pipelines. Sacramento prickly poppy occurs in rocky canyons on the western slope of the Sacramento Mountains. It ranges from 4,200 feet elevation in the lower Dog Canyon area to 7,120 feet elevation in upper Alamo Canyon area (Malaby 1987). The topography of the area is characterized by steep, rocky hillsides. Soils are primarily derived from limestone and may also contain sandstone and gypsum (USFS 1992). Numerous large canyons and arroyos drain westward into the Tularosa Basin. Annual precipitation in the Sacramento Mountains averages about 38 cm (15 in) per year, most of which occurs from July through October, during brief but heavy thundershowers (U.S. Soil Conservation Service (SCS) 1981). All canyons on the west side of the Sacramento Mountains experience periodic and severe flash floods (USFS 1992). Wide fluctuation in diurnal and seasonal temperatures is characteristic of the western slope of the Sacramento Mountains. Temperatures average above 90 degrees Fahrenheit from mid—May to mid— September and may go as low as 16 degrees Fahrenheit during the winter (SCS 1981). High temperatures combined with high insolation and high evaporation rates create xeric conditions in the western foothills of the Sacramento Mountains (NMNP PAC 1984). Unlike seedlings, established poppy plants appear to be capable of weathering periods of drought by becoming dormant. (USFWS, 1994; USFWS, 2013)

***Dispersal/Migration***

**Dispersal**

Adult: Medium (USFWS, 1994)

**Dispersal/Migration Narrative**

Adult: The small, round, black seeds are 2.5 mm (0.1 in) in diameter and dispersed by wind, water and possibly animals (R. Galeano—Popp, U.S. Forest Service (USFS), pers. comm., 1992; R. Sivinski, New Mexico Energy Minerals and Natural Resources Department (NMEMNRD), in litt., 1992). The majority of Sacramento prickly poppy seeds do not travel far from the parent plant and would remain there if flash floods did not move these large and heavy seeds downslope through the canyon drainage channels. This large endosperm could be a potential source of food for various rodents, birds, and insects. Dispersal by animals to upland sites may account for the occasional presence of prickly poppy plants in areas away from drainages. Soreng (1982) observed ants transporting seeds. (USFWS, 1994)

***Population Information and Trends***

**Population Trends:**

Decline of 62% over 23 years (USFWS, 2022)

**Number of Populations:**

9 (NatureServe, 2015)

**Population Size:**

~1,000 (NatureServe, 2015)

**Population Narrative:**

Long-term population trends suggest a decline of 30 to 50%. Approximately 1,286 total plants of Sacramento prickly poppy occupy 10 canyons on the western slope of the Sacramento Mountains in south—central New Mexico. In the late 1980's, there were approximately 1300 plants (McDonald 2010). More recently, the total number of plants is estimated to be below 1000 (Sivinski 1999; Tonne 2008 cited by Cervantes et al. 2010). (USFWS, 1994; NatureServe, 2015) Little new information is available on this species' population trend since the previous 5-year review was completed in 2013 (USFWS, 2013). New data on the poppy was provided by the LNF and included survey data that were collected from 2013 to 2019. These data show that counts of adult prickly poppy in Alamo and Caballero canyons have fluctuated each year but remained relatively static between 2016 and 2019. While the most current survey data do not show as steep of a decline as was documented in the last 5-year review (62 percent over 23 years; USFWS, 2013), the species still appears to be declining in the number of adults at sites that were surveyed. The surveys conducted did not document many seedling or sub-adult poppies, which may indicate that recruitment is not occurring or some unknown threat is affecting adult poppy reproduction ability. Alternatively, the apparent lack of recruitment could be associated with difficulties in locating seedlings, especially in areas that other vegetation is dense, resulting in under reporting of seedling and sub-adult poppies. Since the last 5-year review, survey efforts have occurred sporadically and advantageously across known poppy sites rather than systematically across all poppy sites. Inconsistent survey of poppy sites makes it difficult to determine if poppies are persisting at all previously known sites, if these populations are remaining relatively static as seen in Alamo and Caballero canyons, or if a population may have been extirpated from some sites. In 2018, data were collected in 6 canyons, indicating that the species continues to persist at these locations, though two sites had less than 5 individuals and no documentation of recruitment. Only Alamo and Caballero canyons were re-surveyed in 2019 (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Flooding (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Flooding and erosion are known threats to the poppy (Soreng 1982; U.S. Fish and Wildlife Service 1989, 1994, 2004, 2012; Sivinski 1992; Forest Service 2004; Tonne 2008). In 1977, severe floods were observed to remove up to 100 plants from lower Alamo Canyon (Fletcher 1978; Soreng 1982). Two years later, when Fletcher found only six plants in this location in 1979, he speculated that the population might be in jeopardy of extirpation. Observations since this time have shown that plants in and along arroyos are subject to periodic damage and loss of mature plants from floods, and numbers fluctuate considerably in response to flooding. Some plants are completely removed or buried by floods, and others re-sprout from roots (Tonne 2008). Recent floods have had severe, damaging effects to individual poppy plants, but long-term impacts to populations are unknown (U.S. Forest Service 2008). (USFWS, 2013)

**Stressor:** Livestock (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Grazing and trampling by livestock can destroy young seedlings and can potentially degrade the quality of poppy habitat. Livestock grazing can affect vegetation species composition, plant density, and plant vigor. Cattle tend to occupy canyon bottoms, where poppy seedlings are most likely to occur, because the steep sides of the canyon render most of the

acreage in the pasture inaccessible. Out of the approximately 11,000 acres on the Alamo winter pasture, only about 3,000 acres are usable and accessible to livestock. Livestock may avoid eating most mature poppy plants due to their bitter-tasting latex; however, early season basal rosettes with spines have been grazed to the ground (Forest Service 2005). Detrimental effects to the poppy depend on the timing, intensity, and duration of livestock use. Trampling by cattle has been more frequently observed than herbivory, especially of adult plants. Herbivory by livestock appears to occur mostly during periods of drought, but trampling by livestock can impact the poppy at any time (Salas and Barker 2003; Tonne 2008). Healthy mature plants appear to be capable of re-sprouting after livestock tread on them, but mortality appears likely to occur in young plants or in stressed mature plants suffering from drought or disease. At higher stocking rates, the threat of seedling mortality is greatly increased because livestock have a direct negative impact on the poppy when their presence coincides with the emergence of seedlings (Soreng 1982; Wagner and Sabo 1982; U.S. Fish and Wildlife Service 1989, 1994, 2005, 2008, 2012; Wood 1992; Salas 2003). The period between germination and establishment of the mature poppy is the most vulnerable time in this plant’s life cycle. This developmental stage is the main impediment to increased abundance in any colony or population of this taxon. Germination has been documented throughout the range of the poppy, sometimes in great abundance. However, as with many plants, few of these seedlings survive to become reproductive adults. Some are killed almost immediately through trampling by livestock, while others face periods of dry weather, flooding, or other disturbance. Rotation dates have sometimes been violated, and cattle have remained in poppy habitat year-round, causing damage to poppy seedlings and likely contributing to poor watershed condition through the reduction of herbaceous and riparian vegetation (Tonne 2008, U.S. Forest Service 2008). (USFWS, 2013)

**Stressor:** Herbicide spraying (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In 2007, herbicide was sprayed by the New Mexico Department of Transportation on U.S. Highway 82 near High Rolls, New Mexico, to reduce vegetation in the right-of-way. The herbicide was applied directly to at least five adult poppies, killing three of these. The Forest Service flagged areas that should not be sprayed, but this did not successfully protect the plants. The use of flagging does not appear to be adequate because, at best, it protects only adults known to the Forest Service employee deploying the flagging. It does not protect seedlings or young plants, or adults that are hidden from view (Tonne 2008). Due to this event, the New Mexico Department of Transportation has not sprayed herbicide in poppy habitat again. An agreement to improve protection of poppies from this activity has been discussed among the New Mexico Department of Transportation, U.S. Forest Service, and U.S. Fish and Wildlife Service. (USFWS, 2013)

**Stressor:** Road maintenance (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** During spring 2008, the City of Alamogordo cleared a maintenance road in upper Alamo Canyon, destroying many mature poppies (U.S. Forest Service 2008). During a survey in June 2008, only a few poppies had re-sprouted in this area. Some poppies that were previously

located in or adjacent to the roadway were missing and presumed dead, but a few had re-sprouted in the road (U.S. Fish and Wildlife Service 2008). (USFWS, 2013)

**Stressor:** Water extraction (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The City of Alamogordo captures water at the head of Alamo, Caballero, Fresnal, and La Luz canyons, potentially reducing the amount of water available to the poppy. Because poppy seedlings are delicate and sensitive to drying until they establish their taproot, any factor that increases soil dryness is likely to affect seedling establishment and recruitment. This permanent removal of water at headwater springs under State water rights by local communities, combined with livestock presence, drought, and climatic fluctuations have degraded riparian and spring habitat (U.S. Forest Service 2003, 2008; Tonne 2008). These relatively mesic areas within the range of the poppy may have historically served as important reserves during periods of drought. (USFWS, 2013)

**Stressor:** Road and pipeline construction, maintenance (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Road and pipeline construction and maintenance activities sometimes destroy poppy plants. The Lincoln National Forest performs road maintenance on approximately 523 km (325 mi) of roads per year. Additional maintenance is conducted on Federal, State, and county non-National Forest System roads (U.S. Forest Service 2004). In Fresnal Canyon, road maintenance by the Otero County Road Maintenance Department resulted in the loss of poppy plants along an unpaved National Forest System road. In Fresnal Canyon, road maintenance by the Otero County Road Maintenance Department resulted in the loss of poppy plants along an unpaved National Forest System road. During spring 2008, the City of Alamogordo cleared a maintenance road in upper Alamo Canyon, destroying many mature poppies (U.S. Forest Service 2008). Surveys in June 2008, reported that only a few poppies had re-sprouted. Many poppies that were previously located in or adjacent to the road were missing and presumed dead (U.S. Forest Service 2008). The loss of plants in the upper reaches of occupied habitat leads to reductions in seed dispersal from this area to existing colonies and potential new habitat downstream. The City of Alamogordo maintains water pipelines that tap large springs on the upper western slope of the Sacramento Mountains. These pipelines occur in La Luz, Fresnal, Alamo, and Caballero Canyons. The water rights for these systems pre-date the Lincoln National Forest. The pipelines in Alamo, Caballero, and Fresnal Canyons, canyons occupied by poppy, have been replaced over time as the pipes become cemented in with calcium carbonate. The new pipelines no longer leak water along their route through the canyon bottoms, as they historically have, and, consequently, no longer provide water to limited areas that may have supported poppies in the past (U.S. Forest Service 2004). Municipal use of canyon water has changed the natural hydrology, making upland areas and canyons much drier, perhaps reducing poppy habitat. Pipeline repair, replacement, and maintenance are ongoing in four canyons. These pipelines and associated activities continue to impact the suitability of poppy habitat. Heavy equipment used to transport, excavate, position, and remove large sections of steel pipe may damage or destroy plants if not carefully controlled and monitored. The Forest Service has surveyed, consulted upon, and monitored these activities when informed of them in advance (U.S. Fish and Wildlife

Service 2008). (USFWS, 2013)

**Stressor:** Mowing and herbicide application along roadways (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Roadway maintenance, including herbicide use and mowing, may threaten the poppy. Although the poppy is adapted to disturbed habitats, and, therefore, could benefit from some ground-disturbing activities, blading along drainage ditches and the shoulders of unpaved roads has destroyed some poppy plants (U.S. Forest Service 2004). Invasive plants such as Russian thistle, tamarisk, spotted knapweed, and Russian knapweed occur in poppy habitat. At present, the Forest Service and New Mexico State Highway and Transportation Department coordinate efforts at weed control and implement spraying of infested sites along the highways. Because plant competition may be a limiting factor to the distribution of the poppy based on the poppy's preference for sites that are more open and less densely vegetated, eliminating invasive plants may be beneficial for the poppy (U.S. Fish and Wildlife Service 1994). However, any spraying performed near poppy individuals still may pose a threat to the survival of this species. Direct and indirect application of herbicides on poppies in 2007 resulted in loss of plants occurring along the Highway 82 corridor (Tonne 2008). Since this occurrence, the New Mexico State Highway and Transportation Department has ceased spraying herbicides in proximity to poppy plants. In addition, the Lincoln National Forest has completed consultation on their Noxious Weed Control Plan for treatments of noxious weeds in the vicinity of the poppy. (USFWS, 2013)

**Stressor:** Off-highway vehicles (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Off-highway vehicles are recognized to be a potential threat to the poppy. Off-highway use of motorized vehicles on established trails is permitted in Alamo, Caballero, and Dry canyons on the Lincoln National Forest. Dry Canyon is not currently occupied by the poppy, and the mouth and only western access route into Alamo and Caballero canyons through City of Alamogordo land is closed to motorized traffic. Unauthorized off-highway vehicles can crush individual poppy plants and threaten the health of poppy habitat. Off-highway vehicles can destabilize or compact soils, which affect seed germination and plant growth. Motorized travel is prohibited on the Forest beyond 91 meters (m) (300 feet [ft]) from a road, except for purposes of camping or parking. This excludes use in the channels of Fresnal and La Luz canyons on National Forest System lands. Offhighway vehicles can crush or disturb poppy individuals and may modify the soils, local hydrology, and microclimates associated with seed germination and plant growth (U.S. Forest Service 2004). Furthermore, the creation of trails through poppy habitat can promote the spread of noxious weeds already present in the area (U.S. Forest Service 2004) into these areas which may threaten the poppy's establishment through competition. As an indication of increased interest in off-road riding in poppy habitat, a website exists that provides advice on how to circumvent Lincoln National Forest closures and lists detours to take in the vicinity of Alamo Canyon. Off-highway vehicles present a moderate threat to the poppy at this time. (USFWS, 2013)

**Stressor:** Fungal mold (USFWS, 2013)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** The presence of Alternaria sp., a fungal mold that can be a plant pathogen, has been observed to be an intermittent problem throughout the distribution of the poppy (Tonne 2005). For example, this fungal stem canker caused 7 of 18 plants to fail to set fruit and subsequently die in Dog Canyon (Sivinski 1999). It appears to be most common and damaging in drought years (Tonne 2008). A link between decreased water availability and increased cases of disease may exist, as drying may weaken a plant's resistance to disease. (USFWS, 2013)

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Global climate change may be a threat to the poppy in the foreseeable future. The global average temperature has risen by approximately 0.6 degrees Celsius during the 20th Century, according to the Intergovernmental Panel on Climate Change (Intergovernmental Panel on Climate Change 2001, 2007). Warming temperatures have been documented in recent decades in the southwestern United States. In New Mexico, mean annual temperature has increased by 0.6 degree per decade beginning in 1970, and warming is greatest in spring (Lenart 2005). Higher temperatures lead to higher evaporation rates which may reduce the amount of runoff, groundwater recharge, and consequently spring discharge (Stewart et al. 2004). Temperature changes and seasonal shifts may stimulate earlier growth in the spring or extend the growing season into the fall that is out of phase with available moisture, possibly leading to increased water stress and decreased survival for the poppy. Flowering phenology may also be affected by temperature shifts, potentially causing asynchronous relationships with pollinators and reducing chances of sexual reproduction for the plant. In recent years, the area occupied by the poppy has been under severe drought. These precipitation levels led to low soil moisture conditions that severely curtailed recruitment of poppies into the population (U.S. Fish and Wildlife Service 2004a; Tonne 2008). From 2008 continuing through to the present, the Palmer long-term drought severity index for Otero County has been primarily in the severe to extreme range (National Oceanographic and Atmospheric Administration 2008-2013). Thus climate change presents a significant threat to the poppy, with impacts likely from not only precipitation and temperature changes, but also from possible interactive effects with grazing, water extraction, and disease. (USFWS, 2013)

**Stressor:** Small population size and low genetic diversity (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Decreasing genetic diversity is an indirect threat capable of extirpating the limited populations of poppies. Populations composed of smaller numbers of plants with narrow distributions are more susceptible to elimination from stochastic events, such as flooding or drought, or demographic fluctuations, such as reduced numbers of adults or diminished seed banks, than are larger, more widely distributed populations. A loss of populations or individuals may contribute significantly to a reduction in the gene pool and the ability of the species to adapt to environmental changes. With fewer, more widely spaced plants, out-crossing may become more difficult, which Tepedino (1992) has shown reduces fruit and seed set and could preclude population recovery. At this time, the small population size and limited genetic diversity present

a minor threat to the Sacramento prickly poppy. (USFWS, 2013)

***Recovery***

**Reclassification Criteria:**

The Sacramento prickly poppy will be considered for downlisting when: 1. The Alamo-Caballero Canyon population is shown to be stable or improving over a 20- year period with at least 1,000 individuals (flowering adults) according to the following measures: a) The Alamo-Caballero Canyon population has been designated as the core recovery population. The Alamo-Caballero Canyon population includes all individuals (flowering adults) located with these two canyon systems. This core population will be monitored yearly using annual demographic trend monitoring at representative sites to provide a population estimate based on methodology peer-reviewed by species experts and approved by the Service. The 20-year monitoring period will accommodate for periods of fluctuation in population size or years when monitoring may not be possible. b) Approximately every 5 years, range wide and peripheral counts within Alamo and Caballero Canyons will be conducted using standardized methods peer-reviewed by species experts and approved by the Service. c) Species presence and abundance is maintained at the aforementioned level within the core Alamo-Caballero Canyon population. The population shall be considered stable when a linear regression analysis (or other method which has been peer-reviewed by species experts and approved by the Service) of the population numbers estimated from the results of annual demographic monitoring reveals no significant decline in numbers. d) A population viability analysis (PVA) (or other appropriate method which has been peer-reviewed by species experts and approved by the Service) will be conducted to determine the demographic parameters necessary to maintain a resilient population. A resilient population is one that is able to maintain approximately a 95% likelihood of persistence over a 100-year period (or other appropriate period of time which has been peer-reviewed by species experts and approved by the Service). Based on the PVA, the recovery criteria would be reassessed or adjusted to establish an accurate population number to achieve a resilient population, if necessary. (USFWS, 2019)

2. The 7 additional canyon systems (outside of Alamo-Caballero Canyon), which represent the currently-known occupied habitat for the Sacramento prickly poppy, are shown to maintain stable or improving occupancy over a 20-year period with at least 50% of the canyons demonstrating an average of 75% probability of occupancy over this time frame, according to the following measures: a) Maintain or increase occupied and high probability of occupancy habitat within these canyon systems. b) These additional canyon systems will be surveyed at least once every 2 years utilizing annual occupancy monitoring at representative sites within each canyon to provide a probability of occupancy for the canyon based on methodology peer-reviewed by species experts and approved by the Service. The 20-year monitoring period will accommodate for periods of fluctuation in population size or years when monitoring may not be possible. c) Occupancy is maintained at 75% probability of occupancy within at least 50% of the additional canyon systems. The canyon systems shall be considered stable when occupancy analysis based on methodology peer-reviewed by species experts and approved by the Service reveals no significant decline in occupancy. d) As well as demonstrating no significant decline in occupancy, each canyon system should maintain functionality over the 20-year period with appropriate demonstrated population dynamics as defined by methodology peer-reviewed by species experts and approved by the Service. e) Approximately every 5 years, efforts to characterize occupied and high probability of occupancy habitat throughout the canyon systems

should be conducted based on methodology peer-reviewed by species experts and approved by the Service. f) A population viability analysis (PVA) (or other appropriate method which has been peer-reviewed by species experts and approved by the Service) will be conducted to determine the demographic parameters necessary to maintain resiliency across these additional populations. A resilient population is one that is able to maintain approximately a 95% likelihood of persistence over a 100-year period (or other appropriate period of time which has been peer-reviewed by species experts and approved by the Service). Based on the PVA, the recovery criteria would be reassessed or adjusted to establish an accurate population number to achieve a resilient population, if necessary. (USFWS, 2019)

3. The genetic corridors between populations are maintained through patterns of occupancy within different canyon systems to promote gene transfer as defined by methodology peer-reviewed by species experts and approved by the Service. (USFWS, 2019)

4. The Alamo/Caballero Canyon populations, as well as populations within additional canyon systems considered occupied habitat, must be protected through the development and implementation of species-specific management recommendations that protect the species from identified threats (e.g., livestock grazing and water extraction). a. These management recommendations should be developed in coordination with the Service and implemented by the appropriate land management entity (entities). b. These management recommendations should be periodically evaluated (i.e., at least every 2 years) to ensure effectiveness and success in protecting the species from identified threats. (USFWS, 2019)

Recovery Priority Number: 5C

**Delisting Criteria:**
1. The Alamo-Caballero Canyon population is shown to be stable or improving over a 20- year period with at least 1,500 individuals (flowering adults) according to the following measures: a) The Alamo-Caballero Canyon population has been designated as the core recovery population. The Alamo-Caballero Canyon population includes all individuals (flowering adults) located with these two canyon systems. This core population will be monitored yearly using annual demographic trend monitoring at representative sites to provide a population estimate based on methodology peer-reviewed by species experts and approved by the Service. The 20-year monitoring period will accommodate for periods of fluctuation in population size or years when monitoring may not be possible. b) Approximately every 5 years, range wide and peripheral counts within Alamo and Caballero Canyons will be conducted using standardized methods peer-reviewed by species experts and approved by the Service. c) Species presence and abundance is maintained at the aforementioned level within the core Alamo-Caballero Canyon population. The population shall be considered stable when a linear regression analysis (or other method which has been peerreviewed by species experts and approved by the Service) of the population numbers estimated from the results of annual demographic monitoring reveals no significant decline in numbers. d) A population viability analysis (PVA) (or other appropriate method which has been peer-reviewed by species experts and approved by the Service) will be conducted to determine the demographic parameters necessary to maintain a resilient population. A resilient population is one that is able to maintain approximately a 95% likelihood of persistence over a 100-year period (or other appropriate period of time which has been peer-reviewed by species experts and approved by the Service). Based on the PVA, the recovery criteria would be reassessed or adjusted to establish an accurate population number to achieve

a resilient population, if necessary. The recovery criteria would be reassessed to establish more appropriate population numbers, if necessary. (USFWS, 2019)

2. The 7 additional canyon systems (outside of Alamo-Caballero canyon) which represent occupied habitat for the Sacramento prickly poppy are shown to maintain stable or improving occupancy over a 20-year period with at least 75% of the canyons demonstrating an average of 75% probability of occupancy over this time frame, according to the following measures: a) Maintain or increase occupied and high probability of occupancy habitat within these canyon systems. b) These additional canyon systems will be surveyed at least once every 2 years utilizing annual occupancy monitoring at representative sites within each canyon to provide a probability of occupancy for the canyon based on methodology peer-reviewed by species experts and approved by the Service. The 20-year monitoring period will accommodate for periods of fluctuation in population size or years when monitoring may not be possible. c) Occupancy is maintained at the aforementioned levels within the additional canyon systems. The canyon system shall be considered stable when occupancy analysis based on methodology peer-reviewed by species experts and approved by the Service reveals no significant decline in occupancy. d) As well as demonstrating no significant decline in occupancy, each canyon system should maintain functionality over the 20-year period with appropriate demonstrated population dynamics as defined by methodology peer-reviewed by species experts and approved by the Service. e) Approximately every 5 years, efforts to characterize occupied and high probability of occupancy habitat throughout the canyon systems should be conducted based on methodology peer-reviewed by species experts and approved by the Service. f) A population viability analysis (PVA) (or other appropriate method which has been peer-reviewed by species experts and approved by the Service) will be conducted to determine the demographic parameters necessary to maintain resiliency across these populations. A resilient population is one that is able to maintain approximately a 95% likelihood of persistence over a 100-year period (or other appropriate period of time which has been peer-reviewed by species experts and approved by the Service). Based on the PVA, the recovery criteria would be reassessed or adjusted to establish an accurate population number to achieve a resilient population, if necessary. (USFWS, 2019)

3. Genetic diversity is maintained within the core Alamo/Caballero canyon population, and throughout populations within canyon systems which are considered occupied habitat, according to the following measures: a) The weak genetic divergence that has been observed between populations found in different canyon systems is maintained at a sufficient level to avoid any potential outbreeding depression as defined by methodology peer-reviewed by species experts and approved by the Service. b) The genetic corridors between populations are maintained through patterns of occupancy within different canyon systems to promote gene transfer as defined by methodology peer-reviewed by species experts and approved by the Service. (USFWS, 2019)

4. The existing species-specific management recommendations (developed in coordination with the Service and implemented by the appropriate land management entity/entities) have been effective and successful in protecting the species over the 20-year period required to reach the delisting criteria described above. In addition, all land managing agencies have developed a Post-Delisting Monitoring Plan (which has been approved by the Service's Southwest Regional Director) to cover a minimum of 5 years post-delisting of the species and are prepared to implement this plan prior to delisting to ensure the ongoing conservation of the listed species

and the continuing effectiveness of management actions. a) In addition to this criterion, monitoring and research have been completed to conclude with a high degree of certainty that population sizes, quality, configuration, and management are adequate to provide a high probability of species survival (greater than 90 percent over 100 years). (USFWS, 2019)

**Recovery Actions:**

- Study biological and habitat requirements of the species. (USFWS, 1994)
- Develop a management plan for the City of Alamogordo's water pipeline project in the Alamo and Fresnal Canyon systems with measures to avoid or reduce impacts to populations. (USFWS, 1994)
- Develop a management plan with the Lincoln National Forest and the Bureau of Land Management for Sacramento prickly poppy plants located on lands under their jurisdiction. Conduct long-term monitoring studies to evaluate the impacts of livestock grazing and trampling, and off-road vehicles on these populations. (USFWS, 1994)
- Develop a management plan with the New Mexico State Highways and Transportation Department for populations occurring in the Highway 82 right-of-way and any other plants affected by their management. (USFWS, 1994)
- Develop a conservation agreement with private landowners to protect plants on private property. (USFWS, 1994)
- Conduct surveys in potential habitat. (USFWS, 1994)
- Study biological and habitat requirements of the species. (USFWS, 2013)
- Develop a management plan for the City of Alamogordo's water pipeline project in the Alamo and Fresnal Canyon systems with measures to avoid or reduce impacts to populations. (USFWS, 2013)
- Develop a management plan with the Lincoln National Forest and the Bureau of Land Management for Sacramento prickly poppy plants located on lands under their jurisdiction. Conduct long-term monitoring studies to evaluate the impacts of livestock grazing and trampling, and off-road vehicles on these populations. (USFWS, 2013)
- Develop a management plan with the New Mexico State Highways and Transportation Department for populations occurring in the Highway 82 right-of-way and any other plants affected by their management. (USFWS, 2013)
- Develop a conservation agreement with private landowners to protect plants on private property. (USFWS, 2013)
- Conduct surveys in potential habitat. (USFWS, 2013)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Establishing a specific survey protocol, methodology, and monitoring schedule to document population trends and gain an accurate assessment of population size and extent would be beneficial for the poppy. Additionally, threats that could be managed through landowner action such as livestock herbivory and water development/diversion should be reduced to the maximum extent practical and monitored to determine existing and on-going impacts to the Sacramento prickly poppy and its habitat. A species status assessment to inform a recovery plan revision should, when workload permits, be conducted to incorporate new information on the species. Research is needed to better understand best practices that would support restoring the poppy throughout its range and to identify habitat requirements of the species. This research should include analyzing the long-term viability of the poppy to determine if inbreeding depression or other factors may exist that are limiting poppy fecundity and recruitment and develop management recommendations that could prevent the continued decline in poppy population size and resilience. Investigation is also needed to determine if the acquisition of water rights under the existing water rights law established by the state of New Mexico is possible to protect habitat for the Sacramento prickly poppy (USFWS, 2022).

# SPECIES ACCOUNT: *Argythamnia blodgettii* (Blodgett's silverbush)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/31/2016; Southeast Region (R4)

**Physical Description**

Argythamnia blodgettii, in the Euphorbia family, is an erect, perennial shrub or herb, 10 to 60 cm (4 to 24 in) tall, with a woody base and small, green flowers. The stems and leaves are covered with small hairs. The leaves, arranged alternately along the stems, are 1.5 to 4.0 cm (0.6 to 1.6 in) long, have smooth (or rarely toothed) edges, are oval or elliptic in shape, and often are colored a distinctive, metallic bluish green. The plants have separate male and female flowers. Staminate (male) flowers have a calyx 7 to 8 mm (0.27 to 0.31 in) wide, consisting of 4 to 5 lanceshaped sepals that are larger than the petals. The petals are broadly elliptic and shorter than the sepals. There are 10 stamens. Pistillate (female) flowers have 4 to 5 sepals that are 5 to 6 mm (0.19 to 0.24 in) long, lance-shaped, and often more narrow than those of male flowers. The petals are broadly elliptic, shorter than the sepals. The fruit is a woody capsule 4 to 5 mm (0.16 to 0.19 in) wide, which contains the seeds (Adapted from Small 1933, pp. 784–785; Bradley and Gann 1999, p. 2). (USFWS, 2015)

**Taxonomy**

Botanist John Torrey first described the species in Chapman (1884, p. 100) as Aphora blodgettii, reporting it for South Florida. In an 1896 (p. 100) revision of the genus, Pax placed it in the genus Ditaxis. In 1897 (p. 100), Chapman placed it in the genus Argythamnia. In 1903, Small placed it again in the genus Ditaxis. In 1914, Pax (p. 100) placed it in synonymy under Ditaxis fendleri, a plant of Colombia, Venezuela, Curacao, and Trinidad. Small (1933, pp. 784–785) retained it as Ditaxis blodgettii, treating it as a southern Florida endemic. Subsequent authors (Webster 1967, p. 100; Long and Lakela 1971, p. 558; Wunderlin 1998, p. 100; Wunderlin and Hansen 2003, p. 100) have retained it as a southern Florida endemic Argythamnia blodgettii (from Hodges and Bradley 2006, p. 10). The Integrated Taxonomic Information System (2015, p. 1) uses the name Argythamnia blodgettii and indicates that this species' taxonomic standing is accepted. The online Atlas of Florida Vascular Plants (Wunderlin and Hansen 2008, p. 1) uses the name A. blodgettii. In summary, there is consensus that A. blodgettii is a distinct taxon. We have carefully reviewed the available taxonomic information to r each the conclusion that the species is a valid taxon. Synonyms include Aphora blodgettii Torr. ex Chapm.; Ditaxis blodgettii (Torr. ex Chapm.) Pax; Argyrothamnia blodgettii (Torr. ex Chapm.) Chapm.; and Ditaxis fendleri Pax, not (Mull. Arg.) Pax and K. Hoof. (USFWS, 2015)

**Historical Range**

U.S., Florida, Miami-Dade and Monroe counties. Argythamnia blodgettii historically occurred from central and southern Miami-Dade County from Brickell Hammock to Long Pine Key in Everglades National Park, and in Monroe County throughout the Florida Keys from Totten Key south to Key West (Bradley and Gann 1999, p. 2) (USFWS, 2015).

**Current Range**

U.S., Florida, Miami-Dade County. Argythamnia blodgettii is currently known from central Miami-Dade County from Coral Gables and southern MiamiDade County to Long Pine Key in Everglades National Park, and the Florida Keys from nine islands, from Windley Key (Bradley and

Gann 1999, p. 3) southwest to Boca Chica Key (Hodges and Bradley 2006, pp. 10, 43) (USFWS, 2015).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2015)

**Breeding Season**

Adult: Flowering and fruiting take place throughout the year (USFWS, 2015).

**Other Reproductive Information**

Adult: Perennial (USFWS, 2015)

**Reproduction Narrative**

Adult: Reproduction is sexual; flowering and fruiting apparently takes place throughout the year (Bradley and Gann 1999, p. 3) (USFWS, 2015).

**Habitat Type**

Adult: Low, moist limestone areas near margins of pine rocklands. Sunny edges and gaps in pine rocklands, rockland hammocks, and coastal berm (USFWS, 2013).

**Habitat Vegetation or Surface Water Classification**

Adult: Forest/Woodland, Woodland - Conifer (USFWS, 2013)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 2015)

**Habitat Narrative**

Adult: Argythamnia blodgettii grows in pine rocklands, in sunny gaps or edges of rockland hammock and coastal berm, and on roadsides (Bradley and Gann 1999, p. 3). It grows from crevices on oolitic limestone or on sand. The pine rocklands habitat where it occurs requires periodic fire to maintain an open, sunny understory with a minimum amount of hardwoods. Bradley and Gann (1999, p. 3) indicated that this species does tolerate some degree of human-induced disturbance. It can often be found along disturbed edges of pine rocklands, rockland hammock, and coastal berm, or in completely scarified pine rocklands (Bradley and Gann, 1999, p. 3) (USFWS, 2015).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2023)

**Number of Populations:**

55 Populations (26 extant, 15 uncertain, and 14 extirpated) (USFWS, 2023)

**Population Size:**

~21,000 total (USFWS, 2023)

**Population Narrative:**

At the time of listing, Blodgett's silverbush had been documented in 50 populations (20 extant, 15 uncertain, and 15 extirpated) in Miami-Dade and Monroe Counties (Service 2016). However, several of these populations are near each other, within NatureServe's (2020) 0.62-mile (1.0-kilometer [km]) distance to differentiate populations but occur on separate parcels or lands with different ownership and were thus treated as separate populations in the listing rule. The Service now uses NatureServe's (2020) 0.62-mile (1.0-km) distance to delineate populations. Therefore, populations in the listing rule (Service 2016) that are within 0.62 miles (1.0 km) of each other are now combined into single populations with subpopulations (Appendix A). Also, the Big Pine Key/National Key Deer Refuge population reported in the listing rule (Service 2016) has been split into three separate populations based on their distances of over 0.62 miles (1.0 km) apart. In the listing rule (Service 2016), we considered a population to have an uncertain status if it had not been surveyed in 15 or more years and extirpated if the plants were not seen during a survey or if the habitat had been destroyed. However, we have no quantitative information on how long Blodgett's silverbush seeds may persist in the soil seed bank (Service 2015), and observations from Fairchild botanists indicate they may form persistent soil seed banks (Wintergerst 2023). Therefore, in this review, we are considering a population or subpopulation extirpated if the habitat is developed or there is a negative survey more than five years old with a small (>100) or unreported number plants in the previous survey. A population or subpopulation is considered to have uncertain status if it has a negative survey within five years with presence recorded previously and habitat remaining or has not been observed in more than 15 years with presence recorded previously and habitat remaining. A population or subpopulation is considered extant if it has been observed on site in the previous 15 years. Using this new population delineation and updated status categorization, we recognize 55 populations (26 extant, 15 uncertain, and 14 extirpated) in MiamiDade and Monroe Counties (Table 1; Appendix A). This difference in population delineation reflects a reduction in the number of populations due to combining several from the listing rule, but also an increase from splitting the Big Pine Key/National Key Deer Refuge population into three separate populations. In addition to these delineation changes, the number of populations has increased due to five newly discovered populations, five population introductions, and four populations that were not reported in the listing rule (Appendix A). Additionally, the status of some populations has changed since the listing rule with six populations declining and one improving in status (USFWS, 2023). The current population size of extant Blodgett's silverbush populations in MiamiDade County is approximately 9,152 plants, which is close to the estimated population size at the time of listing (8,985 plants; Service 2016). Notably, 8 of the 11 extant populations consist of fewer than 100 plants and only 3 (Larry and Penny Thompson Memorial Park, Camp Owaissa Bauer Area, and Long Pine Key in Everglades National Park) have over 1,000 plants. The current population size of extant Blodgett's silverbush populations in Monroe County is approximately 11,885 plants, which is approximately 1,300 fewer plants than the estimated population size reported at the time of listing (13,200 plants; Service 2015 based on the Hodges and Bradley

2006 report). The difference is mostly attributed to the decline in the species at the two Naval Air Station Key West populations, between which over 1,400 plants were estimated to occur at the time of listing (Bradley and Hodges 2006; FNAI 2011, 2022; Service 2016), but only 106 plants were documented in early 2022 (Texas A & M University [TAMU] 2022). However, since the population on Big Munson Island is by far the largest with 8,000 to 9,000 plants according to Hodges and Bradley (2006) and there is no recent population estimate, the total number of plants in Monroe County could change considerably depending on the current size of the Big Munson Island population. Additionally, many of the populations in Monroe County may have experienced impacts from Hurricane Ian in October of 2022, which passed over the Keys with tropical storm force winds after the most recent surveys occurred for this review. Notably, as of April 2022, 12 of the 15 extant populations consist of fewer than 100 plants and only 3 (Lignumvitae Key Botanical State Park - Island, Cactus Hammock/Long Beach Area in National Key Deer Refuge, and Big Munson Island) have over 1,000 plants (USFWS, 2023)

***Threats and Stressors***

**Stressor:** Agricultural and residential development (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Pine rocklands in Miami-Dade and Monroe Counties have lost nearly 90 percent of their area due to agricultural and residential development (OBrien 1998, p. 208). Development has reduced the coverage of pine rocklands from 130,358 acres (52,754 ha) to 15,256 acres (6,174 ha) (OBrien 1998, p. 208). Most of the ecosystems on the Keys have been impacted by humans, through widespread clearing of rockland hammocks in the 19th century for farming, or building of homes and businesses (Hodges and Bradley 2006, p. 6). Habitat loss continues to occur in its range, and most remaining suitable habitat has been negatively altered by human activity. Outside of ENP, only about one percent of the Miami Rock Ridge pinelands have escaped clearing, and much of what is left is in small remnant blocks isolated from other natural areas (Herndon 1998, p. 1) (USFWS, 2016).

**Stressor:** Habitat Fragmentation/Fire suppression (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat fragmentation leads to the possibility of fire suppression in and around these isolated fragments. While this plant is not entirely limited to fire-maintained pine rocklands, fire suppression threatens the survival of Blodgett's silverbush. Pine rocklands need regular fires to prevent hardwood encroachment and excessive accumulations of litter. Under natural conditions, lightning fires typically occurred at 3- to 7-year intervals. With fire suppression, hardwoods eventually invade pine rocklands and shade out understory species like Blodgett's silverbush. Fire suppression has reduced the size of the areas that burn and habitat fragmentation has prevented fire from moving across the landscape in a natural way. Thus, many pine rocklands are gradually becoming tropical hardwood hammocks. Fire suppression threatens the Blodgett's silverbush at more than half of its remaining sites (Bradley and Gann 1999, p. 6; K. Bradley, pers. comm. 2007). The staff at NKDR is beginning to monitor the response of rare plants, including Blodgetts silverbush, to prescribed fire after years of fire suppression on the Refuge (Anderson 2010, slide 20). They have noted an increase in Blodgett's silverbush post fire.

Approximately 20 plants were recorded in the monitored area prior to the burn, and 342 plants were detected 4 months post-fire (Anderson 2010, slide 20) (USFWS, 2016).

**Stressor:** Nonnative plants (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nonnative (exotic) plant taxa have significantly affected pine rocklands. As a result of human activities, at least 277 taxa of exotic plants are now known to have invaded pine rocklands throughout south Florida (Service 1999, p. 3-175). A few of these exotic plants include the Schinus terebinthifolius (Brazilian pepper), Neyraudia reynaudiana (Burma reed) and Melaleuca quinquenervia (melaleuca). Lygodium microphyllum (Old World climbing fern) is rapidly spreading and may become a serious problem (Volin et al. 2004, p. 445). Nearly all of the extant occurrences are threatened by exotic plant species (Bradley and Gann 1999, p. 6; Hodges and Bradley 2006, p. 43; K. Bradley, pers. comm. 2007). Exotic species have altered the type of fire that occurs in pine rocklands. Historically, pine rocklands had an open, low understory where natural fires remained patchy with low temperature intensity, thus sparing many native plants such as Blodgett's silverbush. The current density of exotic plant overgrowth throughout the range of Blodgett's silverbush may no longer allow the species to be conserved through fire. Dense growth can create intense fire temperatures and longer burning periods. Pine rockland plants cannot tolerate these extreme conditions. Given the current conditions, exotic plant control may require an alternate method, such as hand chopping followed by spot herbicide treatment, which requires extensive labor and is very costly. This method may not be feasible for publicly owned lands, because of the acreage and staffing and budget constraints (USFWS, 2016).

**Stressor:** Road maintenance (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Several occurrences exist near roads and road maintenance is a particular concern to each of these occurrences (Bradley and Gann 1999, p. 6; Hodges and Bradley 2006, pp. 11-15; K. Bradley, pers. comm. 2007). Clearing of vegetation along roads and the use of herbicides could impact populations; coordination needs to exist with road maintenance crews to prevent impacts (Hodges and Bradley 2006, pp. 11-15). Road enhancements (e.g., paving) or other infrastructure projects (e.g., underground cable, sewer and water lines) may also threaten some roadside populations (Hodges and Bradley 2006, pp. 11, 15). Illegal dumping is identified as a problem at two sites (Hodges and Bradley 2006, pp. 11, 13). Since Blodgetts silverbush (and 10 other rare species) are included in an Important Rare Plant Area (IRPA) on Big Pine Key, management along this FDOT right-of-way could improve (Gordon et al. 2007, pp. 2, 68) (USFWS, 2016).

**Stressor:** Natural disturbances (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Given the species narrow range and the small number of individuals at many sites, Blodgett's silverbush is vulnerable to natural disturbances, such as hurricanes. Storm surges associated with hurricanes result in inundation of habitat with saltwater for varying durations. In 2005, the Keys were impacted by three hurricanes (Katrina, Rita, and Wilma), and vegetation in

many areas was top-killed due to salt water inundation (Hodges and Bradley 2006, p. 9). Storm surges may pose a threat to the population at Cactus Hammock on National Key Deer Refuge; however, hurricanes may also ultimately help this species by creating canopy gaps where this species thrives (Hodges and Bradley 2006, p. 12). According to the National Oceanographic and Atmospheric Administration, Miami-Dade County, the Keys, and western Cuba are the most storm-prone areas in the Caribbean so this threat is expected to continue (USFWS, 2016).

**Stressor:** Inbreeding depression (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species occurs in a restricted range, and many occurrences are small and isolated. As a result, threats associated with small population size ensue. These include potential vulnerabilities from environmental (catastrophic hurricanes), demographic (potential episodes of poor reproduction), and genetic (potential inbreeding depression) threats (USFWS, 2016).

**Stressor:** Pesticide effects on pollinators (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Critical habitat regulations for Bartram’s scrubhairstreak butterfly and Florida leafwing have extended benefits to populations of these four plants and their pollinator guild by limiting mosquito insecticide activity in pine rocklands habitat in the Florida Keys. Nevertheless, we are proceeding cautiously and have initiated a multi-year research project to further investigate the level of impact pesticides have on these four plants and their pollinators throughout their ranges (USFWS, 2016).

**Stressor:** Fire suppression (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire suppression is a primary cause of habitat degradation in pine rockland preserves and is likely to suppress Blodgett’s silverbush seed germination (Possley et al. 2019). Fragmentation has also impacted the management of pine rockland habitat, as urbanization has encroached into native areas, leaving small habitat fragments that are increasingly difficult to burn. Habitat management with use of controlled burns remains a vital way to maintain pine rockland habitat. Without proper fire management, cover of hardwoods increase, along with invasion by non-native exotic plants, causing deterioration of ideal habitat for Blodgett’s silverbush. Hardwoods and non-native invasive plants directly compete with Blodgett’s silverbush for space, light, water, and nutrients. Although the species can tolerate some human disturbance and sometimes even seems to benefit from it if these disturbances create canopy openings (e.g., trails in within preserves or mowing along roadsides), five populations and four subpopulations are now extirpated due to development or significant disturbance of its habitat. Other populations growing on private property remain at high risk of extirpation due to development or disturbance and roadside populations in Monroe County are vulnerable to impacts from road maintenance projects such as herbicide application, grading, and resurfacing (USFWS, 2023).

**Stressor:** Climate Change (USFWS, 2023)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate Change. Climate change presents a variety of threats to Blodgett's silverbush and its habitat. Florida's average annual temperature has risen more than 2˚F since 1900 and estimates project further increases between 2.3-11.4˚F by 2100, depending on the greenhouse gas emission rates and the region in Florida (Runkle et al. 2022). In addition, it is predicted that south Florida will experience drier summers (Sun et al. 2015; Runkle et al. 2022). Higher temperatures and changes in precipitation patterns could alter relative humidity levels and evapotranspiration rates, leading to the potential for more frequent and intense droughts and wildfire events. Although Blodgett's silverbush has evolved to grow in habitats that experience frequent fire, prolonged periods of record high temperatures associated with droughts contribute to dry conditions that are driving hotter, more intense wildfires than would naturally occur. Intense wildfires can cause drastic changes in species composition, changes in tree density, and potentially kill Blodgett's silverbush (Possley et al. 2022a). Sea Level Rise. Sea level rise, saltwater intrusion, and storm intensification are also anticipated impacts of climate change and increasing threats to south Florida and Blodgett's silverbush. By 2100, it is predicted that sea levels in south Florida and the Keys will rise between 2.13 ft (0.64 m) and 7.12 ft (2.17 m) (Sweet et al. 2022). Based on this, areas supporting Blodgett's silverbush (e.g., coastal Miami, Florida Keys) will likely become partially or completely inundated by 2100. For example, approximately 75 percent of land mass in the Florida Keys is predicted to be inundated at 1.9 ft (0.59 m) of sea level rise (The Nature Conservancy 2011) and 94 percent of the Keys would be inundated at 5.9 ft (1.8 m) of sea level rise (Zhang et al. 2011). Sea level rise and saltwater intrusion have been found to reduce pine rockland acreage in the lower Keys (Ross et al. 1994) and will have impacts on other habitats as well. Prior to surface inundation, Blodgett's silverbush habitats may undergo vegetation shifts triggered by changes to hydrology, increased salinity, and more frequent storm surge and king tide events (S. Saha et al. 2011). Even if high tide or surge flooding is infrequent, most pine rocklands, rockland hammocks, and coastal berms in the Florida Keys will still slowly degrade and shift to buttonwood/mangrove or marsh habitats (Ross et al. 2009; A. Saha et al. 2011), making some sites unsuitable for Blodgett's silverbush. Hurricanes and Extreme Weather Events. Hurricane rainfall and intensity are expected to increase as the climate warms (Runkle et al. 2022). Given the small, isolated populations and restricted range of Blodgett's silverbush in locations prone to storm influences, nearly all known populations are at substantial risk from hurricanes and storm surges. Although this species naturally occurs in an area historically affected by hurricanes and has evolved to persist under such disturbances, an increase in storm intensity and its impacts could negatively affect populations. Hurricane winds and debris can cause mortality by defoliation, mechanical injury, or uprooting of individuals, leading to irreversible desiccation. Storm surge physically washes away plants and substrate and leads to salinization of soils. These pulses of salinization will exacerbate saltwater intrusion and accelerate habitat modification and loss. Blodgett's silverbush may have experienced these disturbances historically but had the benefit of more abundant and contiguous habitat to buffer populations from extirpation. With much of the historical habitat having been destroyed or modified, smaller populations are particularly vulnerable to local extirpations due to these events. The impacts of Hurricane Ian, which passed over the Keys with tropical storm force winds in October of 2022, have not yet been assessed and may have negatively impacted Blodgett's silverbush populations, especially in the Lower Keys (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Not relevant.

Recovery Priority Number: 8

**Delisting Criteria:**
Not defined; a Recovery Plan has not been issued as of December 2019.

**Recovery Actions:**

- Not defined; a Recovery Plan has not been issued as of December 2019.
- Prevent further destruction or degradation of existing pine rocklands and hammocks (Service 1999, p. 3-191).
- Acquire available fragments, promote conservation easements and landowner agreements, work with private landowners, and enforce regulatory protection of pine rocklands (Service 1999, p. 3-191).
- Prevent further degradation of existing preserves from exotic plant species, fire exclusion, anthropogenic fires, unauthorized site uses, illegal dumping, improper siting of facilities (including interpretive trails), collecting of plants, hydrologic modifications including drainage, flooding and salt-water intrusion, and herbicides by working with Federal, State, county, and municipal agencies and non-governmental organizations (Service 1999, p. 3-192).
- Restore existing degraded pine rocklands through active management (e.g., where possible restore natural connections, natural fire regimes, and areas impacted by anthropogenic fires, unauthorized site uses, illegal dumping) (Service 1999, p. 3-192).
- Monitor populations on a regular basis to track trends within the population and changes in management needs (Hodges and Bradley 2006, p. 19).
- Design and implement a coordinated system of informing maintenance crews about populations of Blodgett's silverbush occurring along roads and rights-of-way (Hodges and Bradley 2006, p. 19). Raise awareness among maintenance workers and contractors.
- Evaluate the use of herbicide application along roadside populations.
- Conduct studies involving reproductive biology or life history (Hodges and Bradley 2005, p. 19). Ephemeral populations of this species present challenges; little is known about long-term continuity of population sizes (Hodges and Bradley 2005, p. 19). Reproductive biology studies would provide information on effects of unnatural disturbance and mosquito spraying on pollinators (Hodges and Bradley 2006, p. 19).
- Use prescribed fire and incorporate monitoring into plans to determine the effectiveness of the prescription; monitor the health of the community and species that occur with Blodgett's silverbush (Bradley and Gann 1999, p. 4).
- Consider a plan of action to establish a Florida Keys pine rockland core conservation area and ex-situ conservation of this species (Ross et al. 2009, p. 477)
- • For populations in pine rockland habitat (all populations in Miami-Dade County, except Fuchs Hammock Preserve, and the National Key Deer Refuge populations in Monroe County), ensure that prescribed fire is frequent enough to maintain the open, sunny habitat required by Blodgett’s silverbush and to promote seed germination. • For populations in hammock or other areas where fire is not feasible (Fuchs Hammock Preserve and most of the Monroe County populations), clear dense undergrowth regularly. • Continue invasive

species removal at conservation areas with Blodgett's silverbush. • Acquire or pursue conservation agreements for populations or subpopulations on nonconservation private lands that are extant (Ludlam Florida Power and Light Easement and Marathon International Airport) and uncertain (Camp Choee, Country Ridge Estates, Epmore Drive Pineland, Boot Key, Big Munson Island, and Stock Island Golf Course), if it is determined that Blodgett's silverbush is extant. • Bank seeds from wild populations, with a focus on those that are not yet represented or are under-represented in storage (see section II.C.1.g., above for which populations are represented). Efforts should be especially concentrated on collecting seeds from populations of the Florida Keys, which are currently not represented in any seed banks. • Consider augmenting known extant natural and introduced populations or subpopulations with fewer than 10 individuals (George N. Avery Pineland, Pine Ridge Sanctuary, John Kunkel Small Pineland, Tavernier Roadside, Green Turtle Hammock, Key Tree Cactus Preserve, National Key Deer Refuge – Watson Hammock Area, and Key West Tropical Forest and Botanical Garden) (USFWS, 2023).

***Conservation Measures and Best Management Practices:***

- Monitoring/Research Activities • Initiate long-term, detailed demographic studies in a subset of populations which includes the geographic range of the species and a variety of habitat types, including pine rockland, rockland hammock, coastal berm, and disturbed areas. • Conduct range-wide surveys at uncertain and extirpated populations and adjacent parcels with potential habitat to determine the status of populations and/or to fine-tune population size estimates. Repeat every 5-10 years. • Survey Blodgett's silverbush populations after storms since population sizes could change substantially due to more open habitat. • Re-test seeds that Fairchild has banked at 5 years, to determine how long viability is retained in storage and repeat tests every 5 years thereafter. • Conduct germination experiments with seeds collected in the Florida Keys to determine if germination requirements are different to mainland populations and populations in the Florida Keys. • Further research on the reproductive biology and life history of Blodgett's silverbush (e.g., pollinators). • Conduct genetic research to determine the amount of genetic variation between populations from the mainland and the Florida Keys, and between Florida populations and those of Argythamnia argothamnoides populations across the Caribbean and northern South America (USFWS, 2023).

USFWS 2013. U.S. Fish and Wildlife Service Species Assessment and Listing Priority Assignment Form for Argythamnia blodgettii (Blodgett's silverbush). U.S. Fish and Wildlife Service, 03/26/2013, Region 4, Southeast Region. 17. p.

# SPECIES ACCOUNT: *Asclepias meadii* (Mead's milkweed)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 9/1/1988; Midwest Region (R3) (USFWS, 2016)

**Physical Description**

A perennial herb with a single slender unbranched stalk, 8-16 inches (20-40 centimeters) high without hairs but with a whitish waxy covering. The hairless leaves are opposite, broadly ovate, 2-3 inches (5-7.5 centimeters) long, 3/8-2 inches (1-5 centimeters) wide, with a whitish waxy covering. A solitary umbel at the top of the stalk has 6-15 greenish ivory/cream colored flowers. Young green fruit pods appear by late June and darken as they mature, reaching 1.5-4 inches (4-8 centimeters) by late August or early September. Seeds are mature by mid-October (USFWS, 2003).

**Taxonomy**

Mead (1846) originally identified the plant as Asclepias cordata, but it was later described as a separate species by Torrey as Asclepias meadii (Gray 1856) (USFWS, 2003).

**Historical Range**

Indiana, Kansas, Missouri, Iowa, Illinois, and Wisconsin (USFWS, 2012)

**Current Range**

Extant populations are present in eastern Kansas, Missouri, south-central Iowa, and southern Illinois. Populations have been introduced into Indiana and Wisconsin; natural populations are considered extirpated (USFWS, 2012).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual, Asexual (USFWS, 2003)

**Lifespan**

Adult: 15 years or more (USFWS, 2003)

**Dependency on Other Individuals or Species**

Adult: Bumblebees and miner bees for pollination (USFWS, 2003)

**Breeding Season**

Adult: Flowers in late May and early June; fruits from June to October (USFWS, 2003)

**Reproduction Narrative**

Adult: Flowers in late May and early June; fruits from June to October. This species has low reproductive rate; research suggests that Mead's milkweed will require 15 years or more to mature from a germinating seed to a flowering plant. Species is long-lived and may persist indefinitely or until destroyed by chance impacts from animals or pathogens (USFWS, 2003). Reproduction is apparently rare. In an 11 year study, Kettle et al. (2000) found that only 15% of flowering stems produced mature fruit (NatureServe, 2015).

**Habitat Type**

Adult: Terrestrial (USFWS, 2003)

**Habitat Vegetation or Surface Water Classification**

Adult: Tallgrass prairie, hay meadows, thin soil glades or barrens (USFWS, 2003)

**Geographic or Habitat Restraints or Barriers**

Adult: Mead's milkweed usually occurs between 800-1200 feet above sea level on middle and upper portions of slopes less than 20 percent (Freeman 1988) (USFWS, 2003).

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Habitat Narrative**

Adult: Mead's milkweed usually occurs between 800-1200 feet above sea level on middle and upper portions of slopes less than 20 percent (Freeman 1988). Such habitats are often described as drymesic and represent a wide range of landtypes and substrates. The southern part of this species' range is unglaciated, and soils are developed in loess or residual material from underlying sandstone, chert, dolomite, shale, and igneous bedrock. These soils are acidic and nutrient poor in comparison to the soils found in northern populations. In the northern part of its range, soils are developed in glacial drift often with a deep mantle of loess. A single population found in the driftless area of Wisconsin probably occurred in loess over dolomite. These soils are calcareous and high in nutrients and organic matter. Soils in Kansas habitats have intermediate pH levels, nutrients, and organic matter. In general, Missouri and southern Illinois sites are acid and nutrient poor, Kansas sites are intermediate, and Iowa and northern Illinois sites are calcareous and nutrient-rich (Table 2) (USFWS, 2003). Restricted to sites that have never been plowed and only lightly grazed, and hay meadows that are cropped annually for hay (USFWS, 2003).

***Dispersal/Migration***

**Motility/Mobility**

Adult: Abiotic, Bird, Mammal (EPA, 2016)

**Dispersal/Migration Narrative**

Adult: Seeds are wind dispersed from follicles (USFWS, 2003)

***Population Information and Trends***

**Population Trends:**

Decline of 70-80% (NatureServe, 2015)

**Species Trends:**

Decline of 10-30% (NatureServe, 2015)

**Number of Populations:**

346 (USFWS, 2021)

**Population Size:**

Uncertain (NatureServe, 2015)

**Population Narrative:**

As of February, 2015, there are approximately 212 occurrences observed since 1994: 177 in Kansas, 30 in Missouri, 3 in Iowa, and 2 in Illinois. The clone-forming nature of the species makes it difficult to determine number of individuals at each site. In addition, non-flowering stems are difficult to detect in tall grass (Alexander et al. 1997). There are 22 occurrences with good viability/integrity (NatureServe, 2015).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mead’s milkweed habitat is threatened by urbanization, conversion to agricultural land, and habitat fragmentation. Many Mead’s milkweed populations are also experiencing habitat loss due to the lack of appropriate prairie management such as prescribed fire. Fire suppression provides opportunities for subsequent woody vegetation encroachment, and invasion by exotic cool season grasses. Habitat destruction from feral hogs has also reduced Mead’s milkweed habitat (USFWS, 2012).

**Stressor:** Disease or predation (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Weevil damage to stems and developing fruits can affect seed viability. Other milkweed species may act as reservoirs for weevil populations, which then migrate to the rarer Mead’s milkweed. Herbivory of Mead’s milkweed from white-tailed deer has been observed at many sites across the species range and contributes to a lack of fruit production. Grazing by cattle and to a lesser degree by bison can adversely affect Mead’s milkweed populations, especially when grazing occurs during flowering and fruiting periods from April to September. In Missouri, some Mead’s milkweed populations are also experiencing fungal attacks (USFWS, 2012).

**Stressor:** Hay mowing (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Over 50% of Mead's milkweed sites are usually mowed annually for hay. Haying during the growing season prevents seed production of Mead's milkweed and results in reduced genetic diversity. Although haying and grazing occur on a large scale and may be a much more serious threat to the species, off-road vehicle use, in some cases associated with oil wells on a site, and trampling by researchers and school groups also adversely affects Mead's milkweed through excessive disturbance to its habitat. A proposed pipeline replacement project and highway construction project could potentially affect several Mead's milkweed populations in Kansas, however project sponsors are discussing alternatives with the USFWS Kansas Field Office (USFWS, 2012).

**Stressor:** Herbicide application (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the Osage Plains physiographic region, reference to herbicide damaged Mead's milkweed plants was specifically made in occurrence records for three populations (Doering Place, Mount Hope Prairie, and Nodding Polytaenia Prairie). Constant herbicide application has been reported as a contributing factor in the decline of Mead's milkweed in railroad prairies (USFWS, 2012).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The protection of federally threatened plants on privately-owned lands is extremely limited in all states throughout the Mead's milkweed range, leaving those populations vulnerable to habitat destruction and eventual extirpation. Currently, only about 11% of Mead's milkweed sites have legal protection. Most Mead's milkweed populations occur on private land, most of these are hay meadows, and most are, therefore, not protected from habitat destruction, the primary threat to this species (USFWS, 2012).

**Stressor:** Other natural or manmade factors affecting its continued existence (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change will be a particular challenge for endangered, threatened and other at-risk-species because the interaction of additional stresses associated with climate change and current stressors may push them beyond their ability to survive. In addition, populations of some species that are near the southern end of the range may be at particular risk. There is uncertainty about the exact nature and severity of climate change related impacts that may be anticipated to occur within the Mead's milkweed's range. A number of scientific studies project that there will be increased duration and intensity of heat waves in summer, higher levels of humidity and evaporation, changing patterns of precipitation with fewer rain events of greater intensity, increased frequency and more severe dry spells, and more flooding from heavy rains. Research has suggested that climate change may also negatively impact pollinator species if plants and their pollinators respond differently to climate change. These climatic changes may threaten the Mead's milkweed in a variety of direct and indirect ways including: changes in the timing of blooming, loss of suitable habitat, loss of inter-specific relationships with pollinators, and

increased threats from invasive species (USFWS, 2012).

**Stressor:** Feral Swine (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Feral swine were originally introduced to the southeastern United States and California in the early 1500s, but their range has increased substantially over the last several decades across the United States. The distribution and abundance of feral swine varies with habitat type but is highly correlated with the presence of public lands. Feral swine damage natural resources by destroying native vegetation, causing soil erosion, degrading water quality, and acting as a vector for many diseases. Feral swine have contributed to substantial habitat destruction in Missouri including severe damage to Mead’s milkweed plants at some locations (Mark Twain National Forest 2009, USFWS 2012). Feral swine have been reported in all states of the Mead’s milkweed distribution; however, swine are believed to be eradicated from Wisconsin and Iowa, with near eradication achieved in Illinois and Indiana (USDA-APHIS 2020). Historically, feral swine have overlapped in the Mead’s milkweed distribution in 4 counties in Kansas (accounting for 138 Mead’s milkweed sites), 11 counties in Missouri (58 sites) and 1 county in Illinois (1 site; Figure 2). (USFWS, 2022)

**Stressor:** Climate Change (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Long-term changes in environmental conditions (e.g., patterns of temperature and precipitation) have had observable impacts on plants, wildlife, ecosystems, and the ecosystem services they provide to society (Groffman et al. 2014, USGCRP 2018). Mead’s milkweed may be directly impacted by the changes to water quality, drought and flooding, and the spread of invasive species. Such changes are projected to continue. Without substantial and sustained reductions in global greenhouse gas emissions, extinctions and transformative impacts on some ecosystems cannot be avoided in the long term. More frequent and intense extreme weather and climate�related events, as well as changes in average climate conditions, are expected to continue to damage infrastructure, ecosystems, and social systems that provide essential benefits to communities (USGCRP 2018). The frequency of flood events has increased across the southeastern region and across most of the Midwestern U.S. over the past two or more decades (Neri et al. 2019). Climate change projections predict warming average temperatures, more days with extreme heat, increased extreme precipitation events, and longer periods of drought (IPCC 2014, USGCRP 2018) (USFWS, 2022)

**Stressor:** Pollinator Declines (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mead’s milkweed are primarily pollinated by large bees, including the species European honeybee (Apis melifera), rusty patched bumblebee (Bombus affinis), brown-belted bumblebee (B. griseocollis), Southern Plains bumblebee (B. fraternus) and the chimney bee (Anthrophora abrupta), (Betz et al. 1994, Edens-Meier et al. 2017). Hallmann (2017) reported severe losses of flying insects across the globe, with several taxa of pollinators (e.g., butterflies,

wild bees, and moths) experiencing large declines. In most ecosystems, bees are the dominant pollinators; however, compounding stressors (e.g. habitat loss, food stress, exposure to pesticides, pathogens, and climate change-related impacts) have led to wide scale declines (Rhodes 2018). In North America, losses of bees in grasslands commenced in the early 19th century (Samson and Knopf 1994), while a largescale bee decline in the U.S. Midwest occurred as agriculture practices intensified between the 1940s and 1960s (Grixti et al. 2009). Mead's milkweed pollinators, particularly bumblebees, have declined throughout the United States. (USFWS, 2022)

***Recovery***

**Reclassification Criteria:**
Not available.

**Delisting Criteria:**
1. Twenty-one populations are distributed across plant communities and physiographic regions within the historic range of the species (USFWS, 2003).

2. Each of these 21 populations is highly viable. A highly viable population is defined as follows: more than 50 mature plants; seed production is occurring and the population is increasing in size and maturity; the population is genetically diverse with more than 50 genotypes; the available habitat size is at least 125 acres (50 hectares); the habitat is in a late-successional stage; the site is protected through long-term conservation easements, legal dedication as nature preserves, or other means; and the site is managed by fire in order to maintain a late-successional graminoid-vegetation structure free of woody vegetation (USFWS, 2003).

3. Monitoring data indicates that these populations have had a stable or increasing trend for 15 years (USFWS, 2003).

**Recovery Actions:**
- Assess the viability of populations and protect habitat. Assess the viability of each population. Contact landowners and encourage conservation. Seek legal dedication. Increase number of sites managed or owned for the conservation of plant communities associated with Mead's milkweed in perpetuity (USFWS, 2003).
- Manage habitat. Conduct management assessment of public and private lands. Perform prescribed burns on a regular basis in Mead's milkweed habitat. Control invasive species in habitat with extant populations of Mead's milkweed (USFWS, 2003).
- Increase size and number of populations. Assess genetic condition of extant populations. Estimate the number of ramets and genotypes by collecting morphological data. Determine if genetic lineages occur among populations. Increase genetic diversity by introducing seeds or plants. Select sites for introduction and restoration. Select sites for augmentation based on variables in population viability index. Introduce or restore new populations in historic sites and newly identified habitat. Establish new populations using seeds or plants (USFWS, 2003).
- Conduct field surveys for new population occurrences or potential habitat for introduction
- Conduct research on restoration, management, and introduction techniques

- Maintain conservation populations. Collect and store seeds. Grow and maintain plants (USFWS, 2003).
- Promote public understanding. Produce a fact sheet and make it available on Service website. Hold workshops on managing Mead's milkweed sites. Create a traveling display. Promote news reports and press releases (USFWS, 2003).
- Review and track recovery progress. Reassess the viability of each population. Develop a post-delisting monitoring plan (USFWS, 2003).
- It is recommended that a plan be developed and implemented to collect information required to complete a thorough Population Viability Index for each population of Mead's milkweed. Data that is currently missing for most populations include population trend, number of genotypes, habitat size, and management condition. Regular population monitoring will be required in order to establish a population trend. A prioritization of sites based on the population's potential to become highly viable and contribute to recovery should be considered, however, this prioritization cannot be completed without the data that is currently missing from most populations. At the time a prioritization of sites is possible, this information should be provided to all recovery partners (state, federal, and non-government organizations) to provide guidance on where recovery should best be targeted. Protection through conservation easement, acquisition and dedication, or other protection should be sought for Mead's milkweed populations within each physiographic region that have high viability or that have the potential to become highly viable. Land acquisition funding sources should be explored including the U.S. Fish and Wildlife Service's Non-Traditional Section 6 Recovery Land Acquisition Grant Program (USFWS, 2012).
- The number of populations managed with prescribed burns and removal of invasive species should be increased. Over 50% of sites continue to be mowed for hay. This activity prevents seed production and results in reduced genetic diversity. Increasing the number of hay meadows that are managed to allow reproduction of Mead's milkweed through a reduction in haying and grazing, especially on public lands, would be beneficial to Mead's milkweed populations. The exploration of incentives offered by the U.S. Department of Agriculture, Natural Resource Conservation Service's (NRCS) Conservation Programs, whereby landowners are encouraged to manage their lands for the conservation of natural resources, may be beneficial in recovering Mead's milkweed. Some populations are also experiencing herbivory by deer or habitat destruction by feral hogs. Grazing, in general, adversely affects Mead's milkweed and patch/burn/graze management appears to be reducing the quality of Mead's milkweed habitat. In addition, information on habitat size and management condition may already be available but needs to be compiled. Management condition can also be assessed during population monitoring (USFWS, 2012).
- Although management efforts to improve habitat and remove threats have occurred in some populations, actual increase in population size has been rare. Seven high priority recovery populations have been targeted in Missouri for intense recovery efforts. Introductions are underway in Illinois, Indiana and Wisconsin and planned in Missouri. Augmentation occurred in Illinois, Missouri, and Kansas (Kindscher et al. 2008; Menard 2012), in order to increase genetic diversity and promote successful reproduction. These introductions are not always located in the physiographic regions or community types indicated in the recovery criteria. For this reason, surveys are needed to locate suitable locations for the introduction and establishment of new populations in the physiographic regions and community types listed in the recovery criteria. Because Mead's milkweed grows slowly and rarely reproduces, it may be decades before the already introduced

populations become viable (USFWS, 2012).

- There is a need for greater understanding of the species' life history requirements, specifically: phenology, pollination biology, and information on the species' reproduction in natural populations. Research indicates that introduction by transplanting juveniles reared in nurseries or greenhouses reduces time to reproduction and therefore should increase the potential viability of introductions (Bowles et al. 2003). Further research on restoration, management, introduction techniques, and the lack of reproduction in natural populations of Mead's milkweed will assist in the recovery of the Mead's milkweed. Establishing long-term seed collection of representative populations as well as establishing new, and maintaining current, propagation nurseries will also assist in the recovery of Mead's milkweed. Although a genetically diverse nursery population of Mead's milkweed is being maintained at the Morton Arboretum for introduction and augmentation purposes, a long-term seed collection protocol focused on representing populations throughout the range has not been established and would contribute to recovery of Mead's milkweed (USFWS, 2012).
- Statewide recovery groups have been developed in Missouri and Kansas. It is recommended that the states of Illinois, Iowa, and Wisconsin also develop recovery groups, which can be defined as either one recovery group for each state or one recovery group for all three states (WI, IA, and IL) that would include representatives from each state (USFWS, 2012).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Conduct surveys and monitoring. The PVI analysis conducted for Mead's milkweed was originally implemented as a preliminary calculation, and likely overestimates viability. It is important that more accurate analyses are conducted; however, to do so the current status of each population is needed with regular monitoring following. 2. Complete a Species Status Assessment. Since listing, many populations have not been monitored and their status remains unknown. Threats from feral swine, climate change, and a lack of appropriate management compound the risks to Mead's. Once sufficient data is gathered for a more accurate viability analysis, a species status assessment (SSA) may be helpful to determine if the species should remain the same or reclassified under the ESA. 3. Coordinate with partners on monitoring and management needs. Coordination among Federal, State, and private entities on monitoring and management needs to be enhanced and improved. As noted in Moore et al. (2011), an adaptive decision/management framework is recommended to assess various management actions, as well as augmentations to increase genetic diversity. The proliferation of virtual meeting platforms (e.g., Zoom, and Microsoft Teams) allows for collaboration at a distance, which can facilitate meetings and conservation planning. Federal, State, private conservation groups, species experts, geneticists, management experts, university researchers, expert ecologists, and invertebrate specialists (especially pollination experts) should be included in these discussions. 4. Prioritize populations for restoration efforts. After site surveys are updated, sites that are considered optimal habitat with low genetic diversity or ramet counts should be identified for future reintroductions. 5. Manage sites to improve fecundity in Mead's milkweed. Generally, high fruit set was found when populations had >50 ramets flowering at once. Therefore, populations with fewer than 50 flowering ramets should be augmented, though sites left fallow for several years and then burned may show a large increase in flowering ramets. Synchronous flowering among populations of Mead's milkweed may also improve fecundity. Coordinating the timing of controlled burns across multiple sites is one way to accomplish this (Wagenius et al. 2020). A study investigating the effects of fire return interval and seasonality on flowering is needed to test this hypothesis. 6. Conduct studies on the impacts of climate change. Climate change will likely alter future viability of many Mead's milkweed populations, and future viability analyses should adjust for changing environmental conditions. Studies like Molano-Flores et al. (2019) should be conducted throughout the range of the species. 7. Conduct pollination research studies to assess limitations. To test for pollen limitation, a pollen supplementation study is needed that compares fecundity in open and hand‐pollinated treatments across populations with varying numbers of flowering ramets. Additionally, studies are needed to test for pollinator limitation. 8. Conduct genetic analysis to facilitate augmentations. Promote widespread gene flow across the range of Mead's milkweed. Future augmentations should focus on adding seedlings sourced from multiple different maternal plants to maintain levels of genetic diversity in populations. Additional genetic analyses of small populations are needed to test mate limitation and the presence of the Allee effect in Mead's milkweed. 9. Encourage voluntary management. Because the protection status of many populations is either unknown or the sites are unprotected, conservation organizations should encourage voluntary management strategies with landowners. 10. Evaluate the impacts of imperiled insect management. In managing Mead's milkweed habitat, we should also evaluate various management prescriptions on other listed and candidate species that co-occur with Mead's, especially invertebrates such as Rattlesnake master borer moth (Papaipema eryngii) and Monarch butterflies (Danaus plexippus). (USFWS, 2022)

- CONSERVATION MEASURES: Iowa: Powell Prairie in Taylor County and Woodside Prairie in Adair County are sites where Mead's milkweed has been reliably located. After approximately 20 years without surveys, both sites were surveyed in 2020 with only 1 sterile plant observed at Woodside Prairie. While both sites are small, these highly diverse prairie remnants located on private property recently underwent active conservation management for Mead's milkweed. These sites were burned, and habitat improvements also included removal of red cedar (Juniperus virginiana) trees. Indiana: The Indiana Plant Conservation Alliance (INPCA) has recently identified rare plants for conservation prioritization, including Mead's milkweed. A Mead's milkweed conservation team has been formed, and conservation planning includes future monitoring, conducting a literature review, and identifying appropriate habitat for potential future reintroductions (V. Witting – Indiana Plant Conservation Alliance, pers. comm. 2022). Monitoring of reintroduced populations is ongoing and continues to be managed for prairie species including Mead's milkweed recovery (S. Namestnik – Indiana DNR, pers. comm. 2022). Kansas: The Grassland Heritage Foundation has purchased a 15-acre prairie in Anderson County with a small population of Mead's milkweed. In 2018, a conservation easement was placed on a privately-owned, 80-acre prairie in Anderson County with a large Mead's population (M. McNulty - USFWS, pers. comm. 2022). Managing agencies have initiated burns at the formerly hayed Lexington Lake Park site in Johnson County, Kansas (C. Edwards – Missouri Botanical Garden, pers. comm. 2022). Missouri: Missouri Department of Conservation (MDC) acquired Berrier (formerly known as South Fork upland and Winn's Prairie) in 2020 and has initiated burns on the site (C. Edwards – Missouri Botanical Garden, pers. comm. 2022). Together with Missouri Botanical Garden (MoBOT), MDC conducted an augmentation at Berrier in 2020 (C. Edwards – Missouri Botanical Garden, pers. comm. 2022). Plantings occurred in 2011 and 2012, and these sites were monitored annually 2015-2017 to estimate establishment success and persistence. They continue to be monitored during the flowering season immediately after a prescribed burn. Remnant populations that are regularly managed and easily accessible are also surveyed immediately following a prescribed burn. Prescribed burns are predominately occurring during the dormant season. Seed pods were collected in 2013, and used to establish a propagation plot in 2015 at Powell Gardens. As of 2022, there are approximately 50 individuals within the plot. A seed pod was produced in 2019 but succumbed to insect damage. There have been a few flowering individuals in recent years and the plot is expected to serve as a seed source for future propagation efforts. Following recent studies that have provided better understanding of genetic diversity, future propagation efforts are expected, along with follow up studies to investigate the lack of seed production that is observed at several locations. Management activities (e.g., haying and burning) likely affect the height of individual plants and the number of observable plants, possibly contributing to low rates of fecundity (USFWS 2012). Another potential cause of low fecundity is a resource limitation. Upcoming research funded by MDC and conducted by the Missouri Botanical Garden is expected to evaluate these possibilities. Wisconsin: Three populations have been surveyed in the last 10 years and continued monitoring of these locations is planned. Interest has been expressed in identifying optimal habitat for future reintroductions (R. Henderson, pers. comm. 2022). (USFWS, 2022)

# SPECIES ACCOUNT: *Asclepias prostrata* (Prostrate milkweed)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered

**Physical Description**

Prostrate milkweed is an herbaceous, flowering, perennial species with cream, yellow, greenish, or pinkish flowers (see Figures 4a and 4b). The plant has a distinctive odor, similar to the tree tobacco (Nicotiana glauca) (Santore 2019a, unpaginated). This species is distinctive in its prostrate habit; the leaves and stems hug the ground and sprawl outward from a woody crown (Figure 2). No other Asclepias species within the range has a prostrate habit; however, shortcrown milkvine and mesquite plains milkvine occur within the range of prostrate milkweed and are similar in appearance (USFWS, 2020).

**Taxonomy**

The taxonomic status of prostrate milkweed, Asclepias prostrata W.H. Blackwell, is well accepted. The species was first described by Blackwell in 1964 from a type specimen collected in 1960 in Tamaulipas (Blackwell 1964, p. 178; University of Texas Herbarium, #TEX00372529). The Genus Asclepias was formerly classified within its own family, the Asclepiadaceae (milkweed family); more recent phylogenetic analyses revealed that the genus is nested within Apocynaceae, the dogbane family (Sennblad and Bemer 1996, entire) (Table 1). No other synonyms have been proposed for this species (Poole et al. 2007, p. 98). Prostrate milkweed is a member of the Podostemma clade (Fishbein et al. 2011, p. 1018; Worcester 2015, p. v), which includes six species of milkweeds sharing a common ancestor (Fishbein et al. 2011, p. 1018; Worcester 2015, p. v). Most species in this clade have distributions that straddle the U. S.-Mexico border, with ranges of some extending to Central America or the U. S. Midwest (Figure 2 below). This clade contains Emory's milkweed (A. emoryi), Zizotes milkweed (A. oenotheroides), Mojave milkweed (A. nyctaginifolia), hierba de la mula (A. standleyi; Woodson 1954, p. 160), sand milkweed (A. arenaria), and prostrate milkweed (Fishbein et al. 2011, p. 1015). Prostrate milkweed is also morphologically similar to the species of subgenus Podostemma (USFWS, 2020).

**Historical Range**

In the United States, prostrate milkweed has been recorded from 16 populations in Starr and Zapata counties (Table 3). In Mexico, there are at least 8 known populations for this species occurring in isolated pockets widely scattered in northern Tamaulipas and eastern Nuevo León, many over 100 miles from the Rio Grande and 220 miles southeast of the northernmost population in Zapata County (Figures 11 and 12; Strong and Williamson 2015, p. 35). It is possible that prostrate milkweed was historically more abundant in Texas and Mexico and may once have had a larger range. Specifically, it is likely that there were populations of prostrate milkweed between their current known occurrences in Texas and Mexico; however, by 1990, the species was considered rare in Tamaulipas, Mexico (USFWS, 2020).

**Current Range**

As of 2020, in Texas, prostrate milkweed is restricted to 16 assumed extant populations in Starr and Zapata counties with all known populations of prostrate milkweed within 9 miles of the Mexican border (Figure 13). It is likely that prostrate milkweed occurs in other locations on private lands in Starr and Zapata counties that have simply not been surveyed or reported (USFWS, 2020).

**Critical Habitat Designated**

Yes; 3/30/2023.

**Legal Description**

We, the U.S. Fish and Wildlife Service (Service), are listing the prostrate milkweed (Asclepias prostrata), a plant species from Texas, as an endangered species and designating critical habitat under the Endangered Species Act of 1973, as amended (Act). We are designating approximately 661.0 acres (267.5 hectares) in Starr and Zapata Counties, Texas, as critical habitat for the prostrate milkweed under the Act.

**Critical Habitat Designation**

Critical habitat units are depicted for Starr and Zapata Counties, Texas.

**Primary Constituent Elements/Physical or Biological Features**

Within these areas, the physical or biological features essential to the conservation of Asclepias prostrata consist of the following components: (i) Well-drained sandy soil overlying strata of sandstone or indurated caliche

(ii) High soil gypsum concentration

(iii) Open savannas and grasslands of the Tamaulipan shrubland ecological region

(iv) Vegetation composition that includes abundant, diverse pollen and nectar plants and healthy populations of native bee and wasp species

(v) Less than 20 percent cover of Pennisetum ciliare (buffelgrass)

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. The features essential to the conservation of this species may require special management considerations or protection to reduce the following threats: nonnative, invasive grass; rootplowing and conversion of native vegetation to buffelgrass pasture; ROW construction and maintenance from energy development and road and utility construction; border security development and law enforcement activities; and small population sizes. Management activities that could ameliorate these threats include, but are not limited to: prescribed burning, grazing, and/or brush thinning; nonnative, invasive grass control; protection from activities that disturb the soil; and propagation and reintroduction of plants in restorable areas. There are a variety of ways to manage the land to address the threats facing prostrate milkweed. In summary, we find that the occupied areas we are designating as critical habitat contain the PBFs that are essential to the conservation of the species and that may require special management considerations or protection. Special management considerations or protection may be required of the Federal action agency to eliminate, or to reduce to negligible levels, the threats affecting the PBFs of each unit.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual, Asexual (USFWS, 2020)

**Lifespan**

Adult: Unknown. Possibly 1-2 yrs (USFWS, 2020)

**Dependency on Other Individuals or Species**

Adult: Insect pollinators (USFWS, 2020)

**Breeding Season**

Adult: Flowers Mar-Oct, sporadic and dependent upon rainfall (USFWS, 2020)

**Key Resources Needed for Breeding**

Adult: Rainfall (USFWS, 2020)

**Other Reproductive Information**

Adult: Milkweeds have remarkably complex flowers with unusual morphology making pollination a multi-step process (Wyatt and Broyles 1994, pp. 424-426). Milkweeds produce waxy masses of pollen in sacs called pollinia. Pollen remains enclosed in the pollinium until inserted into the stigma of another flower by an insect or other pollinator (Holdrege 2010 p. 13). The stigmatic surfaces are also enclosed with just a narrow slit for an opening (Holdrege 2010 p. 15). This specialization means that relatively few pollinia are successfully inserted into a stigmatic chamber (Holdrege 2010 p. 15). However, the design of the milkweed flower is all about attracting pollinators with nectar and ensuring that the pollinators pick up and move pollinia to a different flower to complete pollination (Dellinger 2016, unpaginated). No formal studies have been conducted regarding pollinators of prostrate milkweed. While all Asclepias species have highly specialized flowers, many are effectively pollinated by generalist insect pollinators. South Texas has a high species richness for Hymenoptera, so various species of bees and wasps may be pollinators (Damude and Poole 1990 p. 24). Milkweed pollinia are usually large structures so insects that are relatively large may be better able to function as pollinators (Maclvor et al. 2017 p. 8459; Dellinger 2016, unpaginated). Any insect large enough to acquire and transport the pollinia can serve as an effective pollinator of milkweed (Ivey et al. 2003, p. 215). Some insects are not robust enough to remove their legs from the anther slits with the attached pollinia and are trapped to die there if they do not lose their appendage first (Dellinger 2016 p. unpaginated). However, among 12 species of milkweed studied, the rare or uncommon species, specifically A. hirtella (tall green milkweed), Mead's milkweed, A. lanuginosa (woolly milkweed), and A. viridiflora (small green milkweed), seemed to have very few insect visitors attracted to them, compared to the common species (common milkweed, whorled milkweed, and Asclepias incarnata (swamp milkweed)) (Betz et al. 1994, p. 58), indicating a possible link between rare plants and pollinator declines (USFWS, 2020).

**Reproduction Narrative**

Adult: The specific reproductive biology of prostrate milkweed is unknown but may be inferred from similar milkweed species. While many milkweeds are rhizomatous (Fishbein In prep) and form clones via ramets (stems) in adjoining areas, it is not universal and has not been reported for prostrate milkweed. Prostrate milkweed has highly specialized pollinia (pollen sacs) and complex flowers containing both male and female structures (Damude and Poole 1990 p. 23). Further, most milkweed species are self-incompatible and require outcrossing, meaning that in order to produce fruit and seeds, flowers must receive pollen from another unrelated plant (Luna and Dumroese 2013, p. 11; Weitemier 2016, p. 3). Prostrate milkweed plants produce 1 to several tubers that form 30 cm (12 in) or more underground (see Figures 6 and 7). These tubers allow individuals to persist through long droughts, and may provide a limited amount of clonal reproduction. However, the species does not primarily reproduce through asexual means, such as rhizomes (USFWS, 2020).

**Habitat Type**

Adult: prairies/grasslands, and areas converted to pasture land (USFWS, 2020)

**Spatial Arrangements of the Population**

Adult: Clumped (Inferred from USFWS, 2020)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2020)

**Habitat Narrative**

Adult: Prostrate milkweed plants usually occur in open spaces with full sun, and with little to no competition from surrounding plants (Poole and Janssen 1997, p. 117). They require occasional rain and pollinators. Prostrate milkweed occurs in a warm, semiarid climate in sparsely vegetated sites, including disturbed sites, road rights-of-way, openings in shrub-invaded grasslands, open areas of Tamaulipan thornscrub, prairies/grasslands, and areas converted to pasture land on level or gently sloping sites on upland terraces and floodplains of the Rio Grande (Singhurst et al. 2015, p. 25; Carr 2004, p 30; Damude and Poole 1990, p. 13; Strong and Williamson 2015, p. 36). Elevations range from near sea level to 200 meters (656 feet) above sea level (Fishbein In prep., unpaginated; Martinez Avalos 2019, pers. comm.). Commonly associated native shrub and grass species include blackbrush (Acacia rigidula), honey mesquite (Prosopis glandulosa), lotebush (Ziziphus obtusifolia), cenizo (Leucophyllum frutescens), Texas pricklypear (Opuntia engelmannii var. lindheimeri), lovegrass (Eragrostissp.), grama (Bouteloua sp.), and hooded windmillgrass (Chloris cucullata) (USFWS, 2020).

***Dispersal/Migration***

**Dispersal**

Adult: Likely dispersed by wind (USFWS, 2020)

***Population Information and Trends***

**Population Trends:**

Decreasing (inferred from USFWS, 2020; USFWS, 2023)

**Number of Populations:**

28 (16 in U.S.) (USFWS, 2023)

**Population Size:**

Largest population has more than 50 individuals. All other populations <50 (USFWS, 2023)

**Additional Population-level Information:**

Only one of the 28 currently known occurrences (16 in TX) has more than 50 individuals, and all are far below the estimated MVP level of 1,600. the documented EOs are located on highway ROWs, two national wildlife refuge tracts, or a few private ranches that granted access for surveys, and comprise a very small proportion of the potential habitat. Plant populations are delimited by the extent of gene flow through seed dispersal and pollination. The potential range of wind-dispersal of prostrate milkweed seeds is unknown, but may be large. Furthermore, the spider wasp pollinators include some of the largest wasps, which presumably have relatively large forage ranges; hence, effective outcrossing may occur among individuals that are relatively distant. The ample nectar reward that milkweed flowers provide justifies foraging over a relatively extensive range. Therefore, it is likely that the documented EOs are small fragments of much larger populations that are, or were, widely dispersed over intact rangelands. We have no information on the forage ranges of spider wasps, but the default EO separation distance of 1.0 km is an acceptable preliminary estimate (USFWS, 2023).

**Population Narrative:**

Populations and gene flow. We estimate that the minimum viable population size (MVP) of prostrate milkweed is about 1,600 mature individuals (USFWS 2020, pp. 36–38). The 16 EOs in Texas, as well as the four newly-reported occurrences, all had very small populations when last observed; the largest had only 62 individuals, and 9 had no observed plants (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Nonnative grass
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nonnative grasses continue to spread, especially near roads and into areas with disturbed ground; Highway 83 continues to be heavily infested. Ranchlands are less infested, where grazing keeps nonnative grass somewhat in check. Refuges and lands with conservation easements may increase control efforts.

**Stressor:** Mowing and Herbicides:
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mowing and herbicide treatments can either be a threat or a benefit, depending upon the timing of the action. In this scenario, mowing and herbicide treatments are not scheduled around dormant periods and are therefore usually harmful. Exceptions are in the populations that co-occur with listed plant species.

**Stressor:** Development
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Road projects are planned in several populations; some county roads are graded at least once a year, often during flowering and fruiting periods. The increase in wind energy projects will require more frequent road maintenance by the counties.

**Stressor:** Border security
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A new road is planned on a refuge tract population and other populations could be damaged by drag strip operations.

**Stressor:** Climate change
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Changes in rainfall events, drought severity, soil moisture, and evaporation will have no effect or minimal effects.

***Recovery***

# SPECIES ACCOUNT: *Asimina tetramera* (Four-petal pawpaw)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/27/1986; Southeast Region (R4)

**Physical Description**

Asimina tetramera is a 1 to 3 m tall aromatic shrub that has one to several stems arising from a deep taproot. Leaves are oblong to oblanceolate, 5 to 10 cm long, arranged alternately on the stem, and are yellow-green to deep green. The leaves are narrow at the base (A. Cox, Florida International University, personal communication 1995), have broadly acute or blunt tips, and lack stipules. The flowers are maroon and fetid. They occur singly in the leaf axil; however, if the plant is burned or damaged, two or three flowers may develop. Perianth parts are typically in whorls of three, but may vary. The petals usually form whorls. The stamens are spirally arranged on an elevated torus or ballshaped receptacle, surrounding one to many separate carpels. After fertilization, the receptacle expands as fruit develops. The fruit is an aggregate of developing carpels, or monocarps, on the expanding receptacle. The monocarps are indehiscent and berry-like. An individual flower may produce from one to eight monocarps with one to nine seeds each (A. Cox, Florida International University, personal communication 1995). The fruit are oblong and greenish-yellow, emitting a banana-like aroma when ripe (A. Cox, Florida International University, personal communication 1995). The laterally flattened seeds are dark brown and shiny (Austin and Tatje 1979, Kral 1983). (USFWS, 1999)

**Taxonomy**

The four-petal pawpaw was discovered at Rio, Florida, in 1924 and subsequently named ityothamnus tetramerus (Small 1926, 1933). However, the new genus was rejected by other taxonomists (Kral 1960). According to Kral (1960), Asimina tetramera is grouped with A. pygmaea, A. longifolia, and A. nashii. These species have several common characteristics, including flower development on new growth, sparsely and omentulose young shoots, and glabrous petioles, peduncles and leaf surfaces. Kral (1960) concluded A. tetramera more closely related to A. pygmaea than to the other Asimina species based on floral similarities. Both species have strongly recurved inner petals, are maroon, have a pungent aroma and flower between April and July. However, several differences separate these two species: the gynoecium of A. tetramera is larger than A. pygmaea, adult plants of A. tetramera are larger than adult plants of A. pygmaea, and A. tetramera is limited to sand pine scrub ridges in Martin and Palm Beach counties, while A. pygmaea occurs in mesic slash pine or long leaf pine habitats and savannas. (USFWS, 1999)

**Historical Range**

Historically, A. tetramera occurred in sand pine scrub habitat on the coastal dune system in Martin and northern Palm Beach counties, Florida (USFWS, 1999)

**Current Range**

15 sites in Martin and northern Palm Beach Counties, Florida, along a 30-mile stretch of sand pine scrub. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 1999)

**Breeding Season**

Adult: Flowering peaks in April and May, and continues throughout the summer. (USFWS, 1999)

**Other Reproductive Information**

Adult: Beetles are the most likely pollinators, although Dipterans (flies), Hymenopterans (wasps), and other insects have been observed visiting flowers. Gopher tortoises (Gopherus polyphemus), and small mammals such as the Florida mouse (Podomys floridanus) (Jones 1989) eat the fleshy fruit and may disperse seeds. Ingestion by animals is not necessary for seed germination. Asimina tetramera seeds germinate from September to March. Old, stored, or dried seeds will not germinate. Germination may take from 1 to 8 months after the seed is planted. The root system establishes several months before shoot emergence, and two to seven leaves are produced the first year. Asimina tetramera plants are deciduous, or partly so, with new leaves emerging in April and continuing to develop into summer. Buds are borne in the axils of the leaves as shoots develop. Flowers occur on new growth, and flower maturation proceeds from the base of the shoot toward the tip. Damaged stems sprout, producing new growth and may flower as late as September. Flowering peaks in April and May, and continues throughout the summer, with fruit ripening in 2 to 3 months. (USFWS, 1999)

**Reproduction Narrative**

Adult: Reproduction in A. tetramera is sexual. The perfect flowers open before all the parts are fully developed, and mature from the base of the stem toward the developing tip. They are protogynous, meaning that the stigmatic surface becomes receptive before anther maturation and pollen release. The petals fall from the flowers within one day of pollen release, and carpel development and receptacle enlargement follow successful pollination and fertilization. Flowers that are not pollinated fall soon after pollen release. (USFWS, 1999)

**Habitat Type**

Adult: sand pine scrub vegetation (USFWS, 1999)

**Habitat Vegetation or Surface Water Classification**

Adult: Terrestrial

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 1999)

**Habitat Narrative**

Adult: Asimina tetramera is found only in sand pine scrub vegetation on old, coastal dunes (Austin and Tatje 1979). The species grows in excessively-drained, quartz sand of both the Paola and the St. Lucie soil series (Austin et al. 1980; A. Cox, Florida International University, personal communication 1995); however, it shows a preference for the Paola soils (Farnsworth, 1988).

Asimina tetramera is found in various seral stages of sand pine scrub, ranging from open [no canopy] to mature [closed canopy] (A. Cox, Florida International University, personal communication 1997). A. tetramera is adapted to infrequent, intense fires, perhaps every 20 to 80 years (FWS 1988). Abundant flowering and fruitset occur in years following fire and diminish with maturation of the community and subsequent canopy closure (A. Cox, Florida International University, personal communication 1996b). (USFWS, 1999)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Gopher tortoises, and small mammals such as the Florida mouse (Podomys floridanus) (Jones 1989) eat the fleshy fruit and may disperse seeds.

***Population Information and Trends***

**Population Trends:**

Approximately half of the extant populations appear to be stable or increasing, while the rest are decreasing, or their status is unknown. (USFWS, 2022)

**Number of Populations:**

15 (USFWS, 2019)

**Population Narrative:**

The four-petal pawpaw can be found in sand pine scrub habitat in the coastal dune system of limited areas of Martin and Palm Beach Counties in southeast Florida (Kral 1960; Austin and Tatje 1979; Service 1999). The remaining four-petal pawpaw populations are declining due to further loss of habitat and may be characterized as existing on fragmented parcels within the historical range. While the four-petal pawpaw was historically documented in sand pine scrub areas of the south-central Atlantic Coastal Ridge of coastal Martin and northern Palm Beach counties, much habitat for the species has been destroyed or converted (Kral 1960; Service 1999; Florida Natural Areas Inventory (FNAI) 2000), and it is now found in a much smaller area from north of Palm Beach Gardens to the Savannas Preserve State Park in Martin County (Cox pers. comm. 1996a; Service 1999; Gann et al. 2002). The remaining populations of four-petal pawpaw occur within a narrow region of sand pine scrub habitat fragments that in 2018 included 15 sites — 11 public and 4 private sites (Service 1999; Gann et al. 2002; Cox pers. comm. 2018). Current information in 2018 shows four (4) of the 15 existing sites (27 percent) exist on private lands: three (3) in Martin County and one (1) in Palm Beach County (Cox pers. comm. 2018). Four-petal pawpaw occurred on approximately 26-27 historically known sites (Peterson 2008; Service 2009). (USFWS, 2019). Four-petal pawpaw is a long-lived shrub that occurs in coastal sand pine scrub within a limited range in Martin and Palm Beach counties, Florida. Remaining occurrences are fragmented and isolated within this range, and the species is estimated to occur in only 9 populations made up of 14 natural and augmented sub-populations with approximately 1,400 plants (Table 1). The previous status review (Service 2009) reported 16 populations made up of 21 sub-populations with approximately 1,800 plants. The status of some populations has been well documented while others remain in question due to accessibility issues. Approximately half of the extant populations appear to be stable or increasing, while the rest are decreasing, or their status is unknown. (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Continued habitat loss, fragmentation, and changes in land use threaten the existence of four-petal pawpaw. Where plants occur on private sites, development has led to both direct destruction of habitat as a result of land clearing and habitat degradation from lack of management. Even though 68 percent of the sites containing four-petal pawpaw are publicly owned and not at risk of being developed, the plants on these sites may still be vulnerable to habitat degradation from encroachment of exotic plant species and lack of fire or other mechanical treatment. If sites are not properly managed, ecosystem health may deteriorate. Because the sites are fragmented on a developed landscape, fire management may not always be feasible and encroachment by exotic plant species from neighboring properties is likely. Degradation to habitat can also occur from damage by feral hogs . Therefore, habitat loss, degradation, and fragmentation due to increasing development and lack of management in sand pine scrub habitat and the encroachment of exotic plants will continue to threaten four-petal pawpaw. (USFWS, 2009)

**Stressor:** Inadequacy of existing regulatory mechanisms
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The ESA provides limited protection for the species and its habitat. Existing federal regulations prohibit the removal or destruction of listed plant species on Federal lands. The four-petal pawpaw is also listed by the Florida Department of Agriculture and Consumer Services (FDACS) as endangered (5B-40.0055 Regulated Plant Index), but this legislation does not provide any direct habitat protection. State regulations require both written permission from the owner or legal representative and a permit issued by FDACS to collect or remove plants listed as endangered on the Florida Regulated Plant Index. However, these regulations afford no protection to listed plants on private lands. Existing regulatory mechanisms do not appear to be adequate, as several properties with pawpaws on private lands have been developed. Because this plant occurs in habitat along the Atlantic coastal ridge, which is desirable for development due to its elevation, it remains vulnerable to development pressures where it occurs on private property. Where the species occurs on public land, there is protection from development but not necessarily from habitat degradation. (USFWS, 2009)

**Stressor:** Inadequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species occurs in scrub habitat, which is typically maintained by fire. On many privately owned sites, fire has historically been suppressed and habitat has not received regular maintenance. Because fragmented habitat is interspersed on a developed landscape, burning may also be unlikely due to proximity to neighbors (Peterson 2008). If sites are not regularly maintained through fire or mechanical treatment, the overall health of the scrub system may be compromised and flowering and fruit set of fourpetal pawpaws may be reduced. (USFWS, 2009)

**Stressor:** Invasive nonnative plants
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Another major threat to pawpaws is the establishment of exotic plant species such as Brazilian pepper, rosary pea (Abrus precatorius), guinea grass (Panicum maximum), and natal grass (Rhynchelytrum repens) in the absence of maintenance, especially where native soil is disturbed. However, herbicides used to control overgrowth, if not properly applied, also pose a threat to the four-petal pawpaw. Broad application of herbicide to remove Brazilian pepper and tall grasses can be especially damaging (Cox in litt. 2009). It is thought that plants on at least two sites have been affected by herbicide treatments (Cox 2006). (USFWS, 2009)

**Stressor:** Limited distribution and specialized habitat
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species' restriction to specialized habitat, its limited distribution, and its limited reproductive capacity also renders it vulnerable to random natural events, such as hurricanes and drought. Although the species faired well through the 2004 and 2005 hurricanes, specific conditions such as storm surge and amount of debris dumping following the event vary greatly with each hurricane and may render sites with few plants vulnerable to destruction. Unfortunately, long-term seed storage does not seem to be a viable option for this species, as the seed does not persist (Peterson et al. 2008). (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations and sites needed to ensure 20 to 90 percent probability of persistence for 100 years (USFWS, 1999)

2. When sites within the historic range of A. tetramera are adequately protected from further habitat loss, degradation, and fragmentation (USFWS, 1999)

3. When these sites are managed to maintain the coastal sand pine scrub communities to support A. tetramera (USFWS, 1999)

4. When monitoring programs demonstrate that these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. (USFWS, 1999)

Recovery Priority Number: 11

**Delisting Criteria:**
1. At least 25 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (Factor A) (USFWS, 2019)

2. Populations (as defined in criterion 1) occur in coastal sand pine scrub and are distributed across the historical range of the species. (Factor A, E) (USFWS, 2019)

3. Populations (as defined in criterion 1) must be protected via a conservation mechanism and/or managed such that enough suitable habitat is present for the species to remain viable for the foreseeable future. (Factor A, D, E) (USFWS, 2019)

**Recovery Actions:**

- Determine current distribution of A. tetramera. Some portions of A. tetramera's range have been well surveyed yet a total distribution has not been ascertained for this  pecies. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Atlantic Coastal Ridge has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Continue research on life history characteristics of A. tetramera. To effectively recover this species more specific biological information is needed. (USFWS, 1999)
- Monitor existing populations of A. tetramera. Develop monitoring protocol to assess population trends for A. tetramera. Develop a quantitative description of the population structure of A. tetramera. Monitor introduced plants. (USFWS, 1999)
- Provide public information about A. tetramera. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of A. tetramera and other rare species requires self-sustaining, secure, natural populations in existing native scrub habitat. S6. Establish delisting criteria. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Continue habitat-level research projects. Monitor habitat/ecological processes. Provide public information about xeric vegetative communities and their unique biota. (USFWS, 1999)
- Surveys: - Continue to survey potential habitat and pursue conservation agreements/implement management recommendations and/or acquire land and investigate incentives to encourage land managers to manage scrub for ecosystem health and listed species.  - Conduct additional surveys for four-petal pawpaw on all known and potentially suitable sites in the two counties of occurrence and provide updated information to FNAI for consistent tracking. - Continue monitoring for plants on both reintroduced and natural sites. - Monitor sites of special interest, such as those with altered water tables or in ecotonal areas at lower elevations. (USFWS, 2009)
- Management:  - Continue management actions to include removal of debris and exotics through careful herbicide application, controlling public access, and the reintroduction of prescribed fire into the ecosystem. - Portions of sites with four-petal pawpaw and dense sand pines should be burned on a regular basis to prevent accumulation of large fuel loads. - Focus conservation efforts on marginal and small sites to preserve the genetic diversity of the species. - Identify additional reintroduction sites and establish reintroduced populations;

population augmentations should also be implemented. (USFWS, 2009)

- Research: - Conduct research on the response of four-petal pawpaw to fire and fire prescriptions necessary to benefit the species. - Conduct additional research on the biology, ecology, genetics, and management needs of the species. - Continue demographic studies to determine the age class structure and long-term viability of the species, especially in areas with active recruitment, and determine critical life stages. - Compare the viability of the small sites in the northern portion of the range to the much larger southern site. - Conduct additional life history studies to enhance our understanding of observed genetic variance. - Continue to evaluate insect pollinators associated with the species over a longer term, and evaluate impacts to pollinators from aerial mosquito spraying, especially in the small, isolated sites in the northern portion of the species' range. - Continue seed germination studies and make efforts to develop additional outplanting techniques. - Continue genetic characterizations on sites that have not yet been studied, and apply this knowledge to future introductions and population augmentations. - Continue to collect germ plasm from the remaining sites not currently represented in the Center for Plant Conservation's National Collection of Endangered Plants. - Continue propagation efforts. - Evaluate the effects of climate change on the species, including those that result from precipitation pattern changes and temperature rise. (USFWS, 2009)
- Other: - Partnerships should be promoted to share information, conduct collaborative research on coastal scrub habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. - Conduct an ad hoc meeting to compile new information, discuss recovery actions, share land management strategies, and set and prioritize five- and ten-year goals. - Seek opportunities to include the media in conservation efforts to provide information about this species to the public. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES A detailed discussion of recovery actions and criteria are presented in the Recovery Plan and amendment (Service 1999 and 2019, respectively). During this status review, new and/or targeted potential recovery activities were identified and are included below. Recovery Activities: • Collect germplasm from the remaining sites not currently represented in the Center for Plant Conservation's National Collection of Endangered Plants for ex situ safeguarding. • As informed by research on best methods and site characteristics (see Research/Monitoring below), continue seed collection, propagation, and direct planting for both augmentations and introductions. • Identify the most suitable introduction sites and carefully monitor any plants translocated or seeds planted. Use irrigation to help increase plant survival the first year. • If suitable habitat remains on publicly owned sites with extirpated populations, consider re-introducing four-petal pawpaw. Where habitat has degraded in areas of historical populations, perform restoration to return to suitable scrub pine habitat. • Carefully apply herbicide to invasive plant species in pawpaw habitat as needed and avoid pawpaw plants by ensuring all applicators know exactly where it is safe to spray. • Conduct prescribed fires, preferably in the spring lightning season, within appropriate fire return intervals to prevent accumulation of large fuel loads and create more favorable conditions for pawpaw reproduction. • If habitat/landscape level burns are not feasible because of wildland-urban interface or other challenges, experiment with conducting micro-burns around pawpaw plants. • As informed by additional genetic analysis (see Research/Monitoring below), focus conservation efforts on marginal and small sites to preserve genetic diversity. • As landowners are willing, acquire private sites with remaining pawpaw populations to ensure their protection or alternatively, enact conservation easements. • As a last resort and where needed, perform rescues of plants on private sites to be developed and translocate to protected land with suitable habitat. Research/Monitoring: • Investigate methods and site characteristics that lead to long-term introduction success. • Continue to survey potential coastal sand pine scrub habitat for new occurrences and provide updated information to FNAI. • Continue demographic monitoring on sites where populations have been followed and begin demographic monitoring on those sites where populations only have been periodically observed. Data on population size, reproductive rates, age class structure, and habitat conditions should all be documented. • Closely monitor for recruitment and determine the conditions required for growth. • Obtain permission from private landowners with historical pawpaw occurrences to survey and determine the status of these populations. If present, foster partnerships/working relationships with these landowners to protect plants. • Complete genetic analysis of populations to determine the amount and spatial distribution of diversity remaining to help inform further conservation actions, such as appropriate translocation material and locations. • Collect and analyze RAPD data on leaf samples from unsampled populations and create an updated dendrogram. • Continue to evaluate insect pollinators associated with the species and determine the status of these insect populations. • Evaluate the effects of climate change on the species, including those that result from precipitation pattern changes and temperature rise. Outreach/Collaboration Activities: • Promote partnerships between county, state, and federal agencies to share information and conduct collaborative research on coastal scrub habitat conservation. • Convene another ad hoc meeting to compile new information, discuss recovery actions, share land management strategies, and set and prioritize five- and ten-year goals. • Seek opportunities to include the media in conservation efforts to provide information about this species to the public. • Continue educating landowners with properties near pawpaw-occupied protected lands on the benefits of prescribed fire. • Continue using volunteer assistance (e.g., Florida Native Plant Society) and engaging youth in the monitoring and recovery of this species. (USFWS, 2022)

# SPECIES ACCOUNT: *Astragalus ampullarioides* (Shivwits milk-vetch)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 09/28/2001; Mountain-Prairie Region (Region 6) (USFWS, 2015)

**Physical Description**

Stems may grow along the ground or to a height of 8-20 in. (20-50 cm), although ungrazed flowering stems may attain a height of 40 in. (1 m). The leaves are pinnately (arranged opposite) compound, 1.6-7.1 in. (4-18 cm) long, and have 11 to 23 elliptical leaflets. Each plant produces approximately 45 small cream-colored flowers about 0.8 in. (2.0 cm) long on a single stalk in the spring. Seeds are produced in small pods, and the plant dies back to its root crown after the flowering season. The fruit is a short, broad pod between 0.3-0.6 in. (0.8-1.5 cm) long and 0.2-0.5 in. (0.6-1.2 cm) wide. (USFWS, 2006)

**Taxonomy**

Kartesz (1999), Isely (1998), and Barneby (1989) do not recognize this entity, at either the species or infraspecific levels, instead including Astragalus ampullarioides (also known as A. eremiticus var. ampullarioides) in A. eremiticus, with no varieties recognized. USFWS and Welsh (1998) recognize at the full species level: A. ampullarioides (Great Basin Naturalist 58(1):51). Barneby (1989) questioned the taxonomic significance of the variety and submerged A. eremiticus var. ampullarioides within typical A. eremiticus. Later research by Harper and Van Buren (1998) and Stubben (1997) demonstrated significant ecological and genetic differences between typical A. eremiticus and A. eremiticus var. ampullarioides. These differences are summarized as follows-(1) A. ampullarioides has more flowers per stem, (2) A. ampullarioides has longer flower stalks (from last leaf to flower), (3) A. ampullarioides has wider pods, (4) A. ampullarioides has taller stems, (5) A. ampullarioides has hollow stems while A. eremiticus stems are solid, and (6) A. ampullarioides plants are highly palatable to grazing animals while typical A. eremiticus is seldom if ever eaten (Barneby 1989; Welsh 1986, 1998; Welsh et al. 1987; Van Buren 1992; Harper and Van Buren 1998). (USFWS, 2006)

**Historical Range**

Historical distribution is not known for either species, that is, records are not available to ascertain whether the current distribution of A. holmgreniorum and A. ampullarioides populations represents either a loss of individual populations or a range contraction for either species. (USFWS, 2006)

**Current Range**

All known locations of A. ampullarioides occur within Washington County, Utah. Known populations of A. holmgreniorum occur within approximately 10 miles (mi) (16 kilometers (km)) of St. George in Washington County, Utah, and Mohave County, Arizona. (USFWS, 2006)

**Critical Habitat Designated**

Yes; 12/27/2006.

**Legal Description**

On December 27, 2006, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Astragalus ampullarioide (Shivwits milk-vetch) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes four critical habitat units (CHUs), in Utah (71 FR 77972-78012).

**Critical Habitat Designation**

The critical habitat designation for Astragalus ampullarioide includes four CHUs in Washington County, Utah. This species critical habitat encompasses approximately 2,181 acres (2,545 ha) (71 FR 77972-78012).

Unit 1—Pahcoon Spring Wash This unit includes 134 ac (54 ha), all on BLM UT lands adjacent to the Shivwits Indian Reservation. Astragalus ampullarioides was known to occupy this area at the time of listing. This population occurs in a small area where the density of A. ampullarioides is high (Van Buren and Harper 2004b, p. 3). In 2005, this population was estimated to contain approximately 300 to 350 individuals (Van Buren 2005). Unit 1 is determined to be critical habitat because it contains features essential to conservation of A. ampullarioides, is occupied by the species, and represents the northwestern-most occurrence of the species. Resources within this unit support the identified PCEs associated with outcroppings of the Chinle Formation. Special management may be required to minimize disturbance to the surface and subsurface structure within this unit, to control invasive species, to maintain the identified vegetation types, and to maintain pollinator habitat essential to the conservation of the species. Cattle grazing activities are present within this unit. The Chinle soils are soft and easily susceptible to erosion. A cost-share agreement between BLM UT and The Nature Conservancy (TNC) provides funding for signs and protective fencing; contracting for the fence is in process. As a part of the agreement, BLM UT and TNC will compare past plant survey data with population surveys to be completed in 2007 and 2009 to evaluate the effectiveness of the fence in eliminating habitat degradation.

Unit 3—Coral Canyon This unit, known to be occupied at the time of listing, is located adjacent to a golf course near Harrisburg Junction, and was estimated to contain 100 individuals in 2005 (Van Buren 2005). Land ownership for the 87 ac (35 ha) is 87 percent SITLA, 12 percent BLM UT, and 1 percent private. We included occupied habitats and adjacent areas of suitable soils and vegetation to allow for maintenance of the seed bank, seed dispersal, and pollinator services. This unit is determined to be critical habitat because it contains features essential to conservation of the taxon, is occupied by the taxon, is centrally located and may provide connectivity between populations, and contains a persistent occupied site of Astragalus ampullarioides. Plants within this subunit face threats from urban development. Special management may be required to minimize disturbance to the surface and subsurface structure within this subunit, maintain the identified soil and vegetation types, and control invasive weeds.

Unit 4—Harrisburg Junction In 2001, the final listing rule (66 FR 49560; September 28, 2001) referred to a population near Harrisburg Junction that contained four separate sites. Unit 4 is comprised of two subunits encompassing 759 ac (307 ha) that are spatially separated based on geography (Harrisburg Bench/Cottonwood and Silver Reef). Each of these subunits contains two of the plant occurrence sites that were known to be occupied at the time of the final listing rule (66 FR 49560; September 28, 2001). In 1999, the 4 sites contained approximately 300 plants (England 1999; Utah Natural Heritage Program 1999; Van Buren 2000). In the area of Harrisburg Junction, Astragalus ampullarioides populations or subpopulations are restricted to outcroppings of the Chinle soil. Each area may be relatively self-sustaining; however, their long-term persistence and stability relies on a balance of site extinctions and colonization of suitable, unoccupied outcroppings through dispersal events (Hanski 1985, p. 341; Olivieri et al. 1990, pp.

207–209; Hastings and Harrison 1994, pp. 175– 176, 180). Subunit 4a—Harrisburg Bench and Cottonwood This 297–ac (120–ha) subunit is 88 percent BLM land and 12 percent private land. Approximately 100 individual plants were located in this subunit during 2005 surveys (Van Buren 2005). This subunit contains PCEs necessary to support Astragalus ampullarioides growth, reproduction, and establishment. Land found between the northbound and southbound lanes of I–15 contains an occupied site. This intervening area within the highway right-of-way may allow pollinator flow between occupied sites (Douglas 2005). Habitat areas between known occupied sites are included in the critical habitat designation to support pollinators and seed dispersal between sites. Pollinator habitat and seed dispersal are considered important for the species' long-term survival (Steffan-Dewenter and Tscharntke 1999, pp. 437–438; Steffan-Dewenter 2003, pp. 1039–1040; Greenleaf 2005, pp. 72–74; Van Buren and Harper 2003a, p. 242). This subunit is determined to be critical habitat because it contains features essential to conservation of Astragalus ampullarioides, is occupied by the species, and contains a persistent occupied site for A. ampullarioides that is centrally located and may provide connectivity between other units. At the Harrisburg site, Bromus tectorum (cheatgrass) is a closely associated species (Van Buren 2005, p. 14). Part of this unit, east of I–15, burned during a wildfire in 2005; however, no suppression occurred in areas of occupied habitat. The status of seeds within the seed bank is unknown. Also unknown, but likely, is that most of the above-ground stems and foliage died back at the time of the fire (Van Buren 2005, p. 14). Revisits in 2006 indicated that Astragalus ampullarioides occupies the site and was not adversely affected by the fire (Van Buren 2006). Plants within this subunit may be threatened by urban development, recreation, and invasive plant species. Special management may be required to control invasive plant species, minimize disturbance to the surface and subsurface structure, and maintain the identified soil and vegetation types. BLM UT and TNC have entered into a cost-share agreement to provide signs and protective fencing to minimize human use at one occupied area within this subunit. Subunit 4b—Silver Reef The 462 ac (187 ha) in this subunit are composed of 90 percent BLM lands and 10 percent private lands. Astragalus ampullarioides individuals are found along intermittent outcroppings of the Chinle Formation. Approximately 150 individuals were identified in a partial survey in 2005 (Van Buren 2005). This subunit is determined to be critical habitat because it contains features essential to conservation of A. ampullarioides, is occupied by the species, contains a thriving population, and maintains a prevalence of soil substrate necessary for future expansion to maintain metapopulation dynamics. Special management may be required to minimize recreational use and disturbance to the soil surface and subsurface structure, control invasive plant species and domestic animals, maintain the identified vegetation types, and maintain pollinator habitat essential to the conservation of the species. Quantitative information on impacts from cattle grazing or recreational use is unknown. One occupied area within this subunit is under a cost-share agreement for protective fencing, which is to begin in the near future. Monitoring will be used to evaluate the effectiveness of the fences in eliminating habitat degradation from cattle and recreational use. Additional areas in this subunit remain unfenced, and special management may still be necessary to reduce impacts to habitat.

Unit 5—Zion The 1,201 ac (486 ha) in Unit 5 occur entirely on lands managed by Zion National Park. The population consisted of approximately 300 to 500 individuals in 2000 (66 FR 49560; September 28, 2001). More recent surveys document almost 4,200 individuals in the unit (Miller 2006). This unit is determined to be critical habitat because it contains features essential to conservation of Astragalus ampullarioides, is occupied by the species, is one of five known populations, represents the northeastern-most range of the species, and contains the largest known population of the species. The land within this unit supports the PCEs necessary for growth, reproduction, and establishment. Special management is necessary in this unit to minimize recreation disturbance to the soil surface and subsurface structure, control invasive weedy species, maintain the identified vegetation types, and maintain pollinator habitat essential to the conservation of the species. Recreational use of Zion National Park and disturbance from park visitors and horses may affect Astragalus ampullarioides. An established hiking and horse trail that is used infrequently from November through April occurs near populations of Astragalus ampullarioides. Plants and habitat within this unit also are threatened by invasive nonnative plants, including Moluccella laevis (bells of Ireland), an introduced species not found at other sites. Although this unit is in a sparsely vegetated habitat that in the past did not carry fire, the invasions of exotic grasses are creating more continuous fuels. No management plan exists specific to Astragalus ampullarioides in Zion National Park; however, the current Zion National Park Fire Management Plan includes restrictions on fire management within a 0.75-mi (1.2-km) buffer zone of the area where A. ampullarioides is found. Zion National Park worked with us to complete a recovery plan for the species (71 FR 57557, September 29, 2006), and is partnering with the USGS to investigate biotic soil conditions and invasive weed interactions with A. ampullarioides.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation.  The PCEs of Astragalus ampullarioide critical habitat consists of three components (71 FR 77972-78012):

(i) Outcroppings of soft clay soil, which is often purplish red, within the Chinle Formation and the Dinosaur Canyon Member of the Moenave Formation, at elevations from 920 to 1,330 m (3,018 to 4,367 ft);

(ii) Topographic features/relief, including alluvial fans and fan terraces, and gently rolling to steep swales with little to moderate slope (3 to 24 percent), that are often markedly dissected by water flow pathways from seasonal precipitation; and

(iii) The presence of insect visitors or pollinators, such as Anthophora captognatha, A. damnersi, A. porterae, other Anthophora species, Eucera quadricincta, Bombus morrissonis, Hoplitis grinnelli, Osmia clarescens, O. marginata, O. titus, O. clavescens, and two types of Dialictus species.

**Special Management Considerations or Protections**

Critical habitat does not include manmade structures existing on the effective date of this rule and not containing one or more of the primary constituent elements, such as buildings, aqueducts, airports, and roads, and the land on which such structures are located.

The features essential to the conservation of A. holmgreniorum and A. ampullarioides, in all areas we are designating, may require special management considerations and protections, including measures necessary to alleviate the effects of urban development, retaining plants and their habitat on Federal lands, fencing small populations, removing or limiting access routes, ensuring vehicles and pedestrians stay on designated routes, reducing land use practices that disturb the hydrologic regime, minimizing the effects of grazing and recreation use, managing invasive nonnative plant species, evaluating revegetation and restoration with native plant species, developing adequate fire management buffers for these plant species and their habitat, and educating fire management staff on the location of the plants. Additionally these areas may require special management considerations and protections for ground-nesting and local pollinator communities.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2006)

**Lifespan**

Adult: Unknown; >9 years (USFWS, 2007)

**Dependency on Other Individuals or Species**

Adult: Primary pollinators of A. ampullarioides include the native bees Anthophora coptognatha, A. dammersi, Anthophora spp., Eucera quadricincta, Bombus morrisoni, Hoplitis grnnellei, Osmia clarescens, O. marginata, and O. titusi, as well as the nonnative honeybee Apis mellifera (Tepedino 2005). A. ampullarioides relies solely on the production of seeds for reproduction, and pollination is thus highly linked to the survival of the species. (USFWS, 2007)

**Breeding Season**

Adult: April to May (USFWS, 2007)

**Reproduction Narrative**

Adult: Collection of demographic and life history data for A. ampullarioides began in 1992. A. ampullarioides, a perennial herb, has an unknown lifespan, although tracking of seedlings from 1995 indicates a lifespan of at least 9 years (Van Buren and Harper 2003b). A. ampullarioides does not reproduce through vegetative methods, and their sexual reproduction is contingent on pollen reaching receptive stigmas for seed production. Flowering occurs between April and late May; by the end of June plants dry up, although vestiges of dried plants may persist for several months. Each A. ampullarioides plant is capable of bearing up to 45 flowers per flower stalk (Welsh et al. 2003, 66 FR 49560), and plants frequently have several stalks. From 1992 to 2000, Van Buren and Harper (2003a) documented an average of 86.7 flowers per plant. The number of seeds per pod ranges from 2 to 17, with 7 to 80% of all ovules producing seed (Tepedino 2005). (USFWS, 2006; USFWS, 2007)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Great Basin Pinyon-Juniper Woodland, Colorado Plateau Blackbrush-Mormon-tea Shrubland, Mojave Mid-Elevation Mixed Desert Scrub, Intermountain Basins Mixed Salt Desert Scrub, Sonora Mojave Creosote-Whitebursage Desert Scrub, Intermountain Basins Semi-Desert Shrub Steppe, and North American Warm Desert Lower Montane Riparian Woodland and Shrubland (USFWS, 2007)

**Dependencies on Specific Environmental Elements**

Adult: Adequate rainfall (USFWS, 2007)

**Geographic or Habitat Restraints or Barriers**

Adult: A. ampullaroides populations are found at elevations between 3,018-4,367 ft (920-1,330 m); sparsely vegetated habitat with an average of 12% cover (USFWS, 2007)

**Environmental Specificity**

Adult: Narrow / specialist (USFWS, 2007)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from USFWS, 2007)

**Habitat Narrative**

Adult: A. ampullaroides populations are found at elevations between 3,018-4,367 ft (920-1,330 m), typically on purple-hued patches of soft clay soil of which 99% are associated with isolated outcrops of the Petrified Forest member of the Chinle Formation (Armstrong and Harper 1991; Harper and Van Buren 1997; M. Miller, pers. comm. 2006). This substrate, which is light, airy, and unstable when dry (Van Buren and Harper 2003a), expands greatly with precipitation, becoming slick and glue-like and forming mounds (Harper 1997). Equal contraction upon drying often results in the formation of deep, wide fissures, constricting root systems so that few perennial plants persist on Chinle soils (Harper 1997). A. ampullarioides is documented from the following soil map units described by USDA et al. (1977) C Stony colluvial land; Naplene silt loam, 2-6% slope; Eroded land-Shalet complex; Badland, very steep; Mathis-Rock outcrop complex, 20-50% slope; Rock land, stony; Bond sandy loam, 1-10%; Clovis fine sandy loam, 1-5% slope; Badland; and Rock land Hobog association (USFWS unpubl. data 2005). Soil texture by weight is 48.9% clay, 25.1% silt, and 26.0% sand, with an undetermined depth (Van Buren and Harper 2001). Percentage of gravel and rock on site is much lower than A. holmgreniorum and measures 13.8% (Van Buren and Harper 2003a). A. ampullarioides habitat is sparsely vegetated, with an average 12% cover (Van Buren and Harper 2003a). Due to soil shrinkage and expansion, native plant species found with A ampullarioides are generally herbaceous forbs and grasses including Calochortus flexuosus (sego lily), Dichelostemma pulchellum (bluedicks), Hilaria rigida (galleta), H. jamesii (James' galleta), Sporobolus airoides (alkali dropseed), and Lotus humistratus (hill lotus) (Van Buren and Harper 2003a; M. Miller, pers. comm. 2006). The perennial rootstock allows A. ampullarioides to survive dry years, and in a drought year plants may not emerge (Van Buren and Harper 2003b). Dormancy is one strategy by which longer-lived plant species can survive changing climatic conditions, particularly in relation to rainfall (Epling and Lewis 1952). (USFWS, 2007)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Methods of A. ampullarioides seed dispersal have not been researched. However, water patterns, landscape erosion, and soil slumping likely contribute to the development of appropriate habitat sites and may transport seeds within sites (Van Buren and Harper 2003a). The disjunct populations of A. ampullarioides also could imply bird dispersal (S.L. Welsh, pers. comm. 2005). (USFWS, 2007)

***Population Information and Trends***

**Population Trends:**

Stable (USFWS, 2021)

**Number of Populations:**

6 (USFWS, 2021)

**Population Size:**

4,000-5,000 (USFWS, 2021)

**Population Narrative:**

The latest range-wide estimate for Shivwits milkvetch is 4,000 – 5,000 individuals in six populations; approximately 83 percent of known individuals occur in the Zion population (USFWS, 2021).

***Threats and Stressors***

**Stressor:** Habitat loss (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat loss due to the growing development pressures in the vicinity of St. George and associated infrastructure also threaten A. ampullarioides populations. (USFWS, 2007)

**Stressor:** Recreation (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Within the Zion population, a recreational trail poses a potential threat to individuals and habitat, albeit the frequency of habitat disturbance and/or direct plant loss is unknown. Research on user impact has been suggested so that Zion National Park can better manage and assess continuing threats of this species on its lands. (USFWS, 2007)

**Stressor:** Electric power transmission line (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the final listing rule, an electric power transmission line was projected to pass through the Pahcoon Spring Wash and Shivwits A. ampullarioides populations at the western edge of the species' range, as well as through the easternmost population within Zion National Park. Prior to these projects, surveys conducted for this species did not result in any new A. ampullarioides sites being found (L. England, pers. comm. 2006). In response to potential adjacent utility corridor activities, the Shivwits band of the Paiutes fenced the main area of plant occupancy. (USFWS, 2007)

**Stressor:** Silver mining (USFWS, 2007)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Silver mining diminished by the early 1900s (R. Douglas, pers. comm. 2005) and is not believed to be a future threat for A. ampullarioides. Other mining, such as removal of landscaping rock, exists at a distance to the Pahcoon Springs Wash population but does not appear to constitute a threat. (USFWS, 2007)

**Stressor:** Off-road vehicles (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, habitat degradation from ORV use was identified as a threat for A. ampullarioide,s and it continues to be a serious threat, given the increasing popularity of ORV activities in Washington County (see A. holmgreniorum above for more details). The ORV activities in A. ampullarioides habitat are particularly damaging, as the localized clay substrate lacks soil stability and is easily disturbed. The ORV activities lead to associated plant loss, habitat degradation, and changes in native plant communities. Although fencing will not abate all ORV use within A. ampullarioides habitat, fencing at the Pahcoon Spring Wash, Harrisburg Bench and Cottonwood, and Silver Reef population, which is expected to be completed in October 2006, will reduce direct ORV impacts to sites on BLM lands. The Silver Reef population currently experiences the highest levels of ORV use, but a portion of this population has been incorporated into the Red Cliffs Desert Reserve (Washington County Habitat Conservation Plan (HCP), 1995) due to a boundary adjustment (J. Crisp, pers. comm. 2006) and thus will be afforded better protection through site-specific planning for recreational management, recreation use monitoring, and law enforcement. (USFWS, 2007)

**Stressor:** Trampling (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Milk-vetch habitat degradation is caused by cattle trampling, which disturbs the soil surface and seedbanks for these species. This is an issue for the Pahcoon Spring Wash, Shivwits, and Silver Reef A. ampullarioides populations. In particular, the Pahcoon Spring Wash habitat has recently experienced severe cattle trampling (Van Buren 2005), disturbing the fragile clay soils found on the Chinle and Moenave formations and crushing individual plants. Supporting soils are especially susceptible to disturbance and compaction caused by trampling and overuse (R. Van Buren, pers. comm. 2006). In addition to cattle trampling, A. ampullarioides may incur damage during survey efforts if these activities are conducted without sufficient caution. Cattle or human trampling is expected to diminish in the future in light of recently funded fencing projects expected to be completed in October 2006. (USFWS, 2007)

**Stressor:** Fires (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Finally, as described for A. holmgreniorum, St. George, Utah, and surrounding areas are experiencing an increase in fires due to exotic, nonnative grasses such as cheatgrass and red brome. In 2005, fire ran through the Harrisburg Bench site of the Harrisburg Bench and Cottonwood population. Site visits in 2006 documented species presence and indicated a

healthy return. Timing of the 2005 fire coincided with annual plant dormancy patterns, which appears to have reduced detrimental effects (R. Van Buren, pers. comm. 2006). Fires in past years and in 2006 occurred close to the Pahcoon Springs Wash and Shivwits populations on the eastern slopes of the Beaver Dam Mountains. Both BLM and the Tribe are aware of A. ampullarioides population locations and efforts will be made to protect the plants. (USFWS, 2007)

**Stressor:** Development (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Residential and commercial development, which indirectly affects known occupied areas, is occurring at the Coral Canyon population and, to a lesser degree, at the Harrisburg Bench and Cottonwood and Silver Reef populations. (USFWS, 2007)

**Stressor:** Roads (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** New roads, highways, electric power transmission lines, and pipelines were constructed in A. ampullarioides areas prior to the final listing rule and probably caused past impacts on A. ampullarioides populations. For example, the construction of highway I-15 altered the Cottonwood site within the Harrisburg Bench and Cottonwood population areas. not known if additional utility or transportation corridors will be constructed in the future. Current and future highway maintenance (see A. holmgreniorum above for description of projected activities) is a potential threat. (USFWS, 2007)

**Stressor:** Herbivory (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In terms of predation, A. holmgreniorum may be occasionally susceptible to herbivory, while A. ampullarioides is extremely palatable to both wildlife and domestic livestock. Tepedino (2005) indicates losses to herbivores, including cattle for research done at the State Line (A. holmgreniorum) and Coral Canyon (A. ampullarioides) populations; however, this information was not quantified. At the time of listing, livestock grazing at the two western A. ampullarioides populations, Pahcoon Spring Wash and Shivwits, was of concern. However, protective fencing at the Shivwits population has greatly reduced the threat at that site, as will fencing slated to be installed at the Pahcoon Spring Wash in October 2006. (USFWS, 2007)

**Stressor:** Overgrazing (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Overgrazing by livestock can eventually cause a shift in the plant communities, favoring invasive plants to the detriment of both A. holmgreniorum and A. ampullarioides (see Factor E). Recent herbivory at the A. ampullarioides demography study site at Pahcoon Spring Wash population is tentatively attributed to rabbits (Van Buren 2005), although it is not known if

the level of herbivory negatively affects the plants at the population level. Some degree of natural herbivory occurs every year in A. ampullarioides populations (Van Buren 2005). High herbivory was seen in preliminary research conducted in 2006 at Zion National Park, where 90% reduction in fruit production was attributed to vertebrate herbivores. (USFWS, 2007)

**Stressor:** Parasitism and insect infestations (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** One additional factor that warrants further research is the potential for parasitism and insect infestations, particularly in regard to potential effects on A. ampullarioides populations. Past monitoring documented aphid infestations associated with A. ampullarioides. Also, an outbreak of white moths, which visited flowers in April 2005, may have restricted production of seeds. By May, flowers dropped off the stem, inhibiting fruit development, and these symptoms could either be related to white moth predation or to a coincidental lack of pollination. If this reoccurs, it will become a priority for further investigation. (USFWS, 2007)

**Stressor:** Invasive species (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Past habitat disturbance has caused the proliferation of invasive annual weeds into both species' occupied habitat (Harper 1997 and Van Buren and Harper 2000a, 2000b in 66 FR 49560). In fact, all populations of both A. holmgreniorum and A. ampullariodes have been affected to some degree by invasive nonnative annuals, which make up the highest percentage of living cover in the habitat of both species (Van Buren 2004). Because invasive annuals tend to emerge prior to the milk-vetches, competition for soil moisture and nutrients and displacement of the milk-vetches is an emerging threat. (USFWS, 2007)

**Stressor:** Fragmented habitats (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A. holmgreniorum and A. ampullarioides are pollinated by native solitary ground-dwelling bees (Tepedino 2005). Fragmented, disjunct habitats hamper pollinator exchange between populations, which could cause genetic isolation and potentially lead to inbreeding and local extirpation of isolated populations (Heschel and Paige 1995). Urban expansion and associated impacts may directly and indirectly affect pollinators through loss of pollinator habitat (Tepedino 2005). For both species, lack of pollinators would result in a gradual decrease in the number of seeds in the seedbank (Tepedino 2005). Additionally, small and restricted sites of other rare Astragalus were found to receive lower levels of pollinator vistors (Karron 1987). The Gardner Well, Stucki Spring, South Hills, and Purgatory Flat A. holmgreniorum sites are small and disjunct. Similarly, all A. ampullarioides sites, except for Zion, are small and disjunct. (USFWS, 2007)

**Stressor:** Climate change (USFWS, 2007)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Climate change has emerged as a significant concern, particularly in regard to the potential for increasingly prolonged drought cycles (Miller 2005; R. Van Buren, pers. comm. 2006). Both A. holmgreniorum and A. ampullarioides have higher germination and survivorship rates during and following years of increased precipitation (Van Buren and Harper 2003a), and if consecutive years of low reproductive output caused by drought conditions outlast seedbank longevity, the affected populations could become extirpated (R. Van Buren, pers. comm. 2006). Given that drought events occur at a regional scale (Miller 2005), this could prove to be a serious limiting factor for both species. Frost kill also affects both species and could become a more prevalent problem with long-term seasonal changes (R. Van Buren, pers. comm. 2006). (USFWS, 2007)

**Stressor:** Stochastic events (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Additionally, some A. holmgreniorum and A. ampullarioides are small-sized and could be threatened by stochastic events. (USFWS, 2007)

*Recovery*

**Reclassification Criteria:**
1. Species presence is maintained at all recovery populations. (USFWS, 2006)

2. Population trends for four out of six recovery populations of each species are primarily stable or improving, as indicated by occupied habitat, density of occupied habitat, and predictive modeling. (USFWS, 2006)

3. The habitat base for each recovery population is large enough to allow for natural population dynamics, population expansion where needed, and the continued presence of pollinators, with sufficient connectivity to allow for gene flow within and among populations. (USFWS, 2006)

4. Population and habitat management is implemented for all recovery populations of each species in accordance with site-specific management plans. (USFWS, 2006)

5. Permanent land protection is achieved for at least four recovery populations of each species. (USFWS, 2006)

6. Site-specific conservation agreements are in place for all recovery populations and their habitat to protect these milk-vetches within existing State laws. (USFWS, 2006)

7. The conservation of these species is included in a long-term State plant conservation agreement. (USFWS, 2006)

8. Adverse population-level effects from herbivory, disease, or predation, if any, are identified and abated within A. ampullarioides and A. holmgreniorum recovery populations. (USFWS, 2006)

9. For at least four recovery populations of each species, effective measures are in place to control potential negative effects on invasive nonnative species that could harm these milk-vetches and/or their habitats. (USFWS, 2006)

10. The protected habitat base for at least four recovery populations of each species is large enough to offset loss or restriction of the species' pollinators. (USFWS, 2006)

11. Use of pesticides or herbicides detrimental to either of the milk-vetches or their pollinators is prohibited in the vicinity of all recovery populations. (USFWS, 2006)

12. Research indicates genetic fitness, alleviating concern about inbreeding or outbreeding depression. (USFWS, 2006)

13. Seed collection/storage is underway for all extant A. holmgreniorum and A. ampullarioides populations. (USFWS, 2006)

Recovery Priority Number: 5C

**Delisting Criteria:**

1. Two additional populations of each species are either located or successfully introduced to habitat in proximity to extant populations. Thus, a minimum of eight recovery populations will be needed to delist each species. (USFWS, 2006)

2. The available habitat base for each newly discovered or introduced recovery population is large enough to allow for natural population dynamics, population expansion where needed, and the continued presence of pollinators, with sufficient connectivity to allow for needed gene flow within and among populations. (USFWS, 2006)

3. Population trends for all A. holmgreniorum and A. ampullarioides recovery populations are primarily stable or improving, as indicated as indicated by species presence, occupied habitat, density of occupied habitat, and demographic modeling. (USFWS, 2006)

4. Each of the eight A. holmgreniorum and eight A. ampullarioides recovery populations has a post-delisting conservation plan with the species' conservation as a primary objective. (USFWS, 2006)

5. Permanent land conservation is achieved for all recovery populations whether extant or introduced (a minimum of 8 populations), such that Endangered Species Act (ESA) protection is no longer needed to compensate for regulatory inadequacies. (USFWS, 2006)

6. Adverse population-level effects from herbivory, disease, or predation, if any, are identified and abated within all A. ampullarioides and A. holmgreniorum recovery populations. (USFWS, 2006)

7. A long-term offsite conservation program is ongoing for all milk-vetch recovery populations. (USFWS, 2006)

**Recovery Actions:**

- Conserve known extant A. holmgreniorum and A. ampullarioides populations and their habitat. (USFWS, 2006)
- Locate and conserve additional extant populations, if any. (USFWS, 2006)
- Monitor A. holmgreniorum and A. ampullarioides sites for population information and trends. (USFWS, 2006)
- Establish a set of need-based research priorities aimed at abating or reducing threats and increasing population health and numbers. (USFWS, 2006)
- Develop and implement a rangewide strategy for augmentation and/or introduction of milk-vetch populations. (USFWS, 2006)
- Augment extant populations and/or establish new populations of each species in accordance with the rangewide strategy. (USFWS, 2006)
- Promote effective communications with partners and stakeholders regarding the milk-vetches' recovery needs and progress. (USFWS, 2006)
- Develop and implement educational and outreach programs. (USFWS, 2006)
- Develop and implement educational and outreach programs. (USFWS, 2006)
- Establish a technical working group to regularly review the status of the species and track the effectiveness of recovery actions. (USFWS, 2006)
- Revise the recovery program when indicated by new information and recovery progress. (USFWS, 2006)
- In collaboration with interested local, State, and Federal agencies, institutions, and Indian Tribes, BLM will prepare conservation agreements and strategies designed to stabilize declining populations, and will promote protective management to ensure survival of the species. (USFWS, 2007)
- To reduce conflicts and additional disturbance, habitat areas will be designated as rights-of-way avoidance areas and closed to fuelwood and mineral material sales. Plants will be protected by restricting mountain bike use and off-road vehicle travel to designated roads and trails. (USFWS, 2007)
- Prior to surface-disturbing exploration or development associated with fluid mineral leasing, botanical surveys will be completed and known populations avoided to eliminate the taking of plants. (USFWS, 2007)
- Habitat areas will be kept free from use of chemical pesticides and herbicides. (USFWS, 2007)
- Where necessary to protect small isolated populations of Hermit's milk-vetch (aka Shivwits milk-vetch) under 10 ac (4 ha) in size, BLM will fence areas to prevent inadvertent destruction of plants. (USFWS, 2007)

***Conservation Measures and Best Management Practices:***

- Recommendations on species status: After reviewing available scientific information and recovery criteria, we conclude that Shivwits milkvetch remains an endangered species. Our review of new information compiled since 2007 does not change our evaluation of the species status and threats affecting the species under the factors in 4(a)(1) of the Act from our most recent 5-year review (Service 2007). The downlisting and delisting criteria for Shivwits milkvetch are not met (Service 2006a). Therefore, we recommend no change in status. (USFWS, 2021)

# SPECIES ACCOUNT: *Astragalus applegatei* (Applegate's milk-vetch)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/27/1993; Pacific Southwest (R8)

**Physical Description**

A tap-rooted, herbaceous, perennial plant. The numerous tufted or trailing stems are 2.5-8 decimeters (10-33 inches) long, simple or branching, and may be smooth or have sparse stiff, short hairs. Leaves are 3.5-12 centimeters (1.5-5 inches) long, are on petioles, and have 7-1 1 linear to linear-elliptic flat leaflets, the terminal one usually the longest. Racemes typically bear 5-20 pea-like flowers with lavender-tipped white petals. The 8-13 millimeters (0.4-0.6 inches) long, stalked fruit pods are oblong, compressed, have short hairs and frequently have green or purple speckled valves. Pods split apart from the top (dehisce apically)then downward through the ventral suture, and contain up to 10 (but usually fewer than 3) dark brown minutely dotted seeds with depressions. (USFWS, 1998)

**Taxonomy**

Member of the Fabaceae (pea family). First discovered near Klanlath Falls, Oregon, in 1927 by Morton Peck. Peck subsequently collected the species 2 miles (3.2 kilometers) east of Keno, Oregon, in 1931 and then described It (Peck 1936). It was thought to be extinct until its rediscovery in 1983 by James Kagan of theOregon Natural Heritage Program (Kagan 1983).(USFWS, 2009).

**Historical Range**

Endemic to the Lower Klamath Basin, in Klamath County, Oregon, about fifteen miles north of the Oregon-California border. (USFWS, 1998)

**Current Range**

Lower Klamath Basin, in Klamath County, Oregon (USFWS, 2019a)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual; self-fertilization and crossing occur (NatureServe, 2015)

**Dependency on Other Individuals or Species**

Adult: Plebejus melissa (USFWS, 2009)

**Breeding Season**

Adult: June - September (USFWS, 2009)

**Key Resources Needed for Breeding**

Adult: Possibly other insect pollinators (USFWS, 1998)

**Reproduction Narrative**

Adult: Reproduction is sexual; self-fertilization and crossing occur (4/98 Recovery Plan) (NatureServe, 2015). Flowers are present from June to September. The Melissa blue butterfly (Plebejus melissa) is a specific known pollinator (58 FR 40548). Despite ample production of viable seeds, very few Applegate's milk-vetch seedlings have been observed in native populations. Applegate's milk-vetch plants have eight to ten ovules per pod that can mature into seeds; however, it is rare that more than three do so (USFWS 1998) (USFWS, 2009). Applegate's milk-vetch is visited by numerous insects, with prominent visitors including bumble bees (Apidae: Bombus spp.), other polylectic bees (Megachilidae: Osmia spp.; Andrenidae: Andrena spp.), bee-flies (Bombylidae), and the butterflies Lycaedes argyrognomon (Yamamoto 1985) and Plebejus melissa (ODA, unpublished) (USFWS, 1998).

**Habitat Type**

Adult: Terrestrial, wetland, riparian (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Floodplain grasslands (NatureServe, 2015); interior alkali grassland (USFWS, 2009)

**Dependencies on Specific Environmental Elements**

Adult: Probably periodic flooding (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs ~1250 m elevation (NatureServe, 2015)

**Environmental Specificity**

Adult: Very narrow (USFWS, 2009)

**Habitat Narrative**

Adult: Inhabits flat seasonally moist remnants of alkaline floodplain grasslands of the Klamath Basin, at about 1250 meters. The substrate is poorly drained fine silt loam (an underlying hardpan impedes drainage). Prior to irrigation and water control along the Klamath River, periodic flooding probably limited the dominance of other species and provided openings for establishment of Astragalus applegatei (NatureServe, 2015). This species is limited to a very specific soil regime resulting in a very specific habitat type. The vegetative community in which Applegate's milk-vetch sites occurs is classified as interior alkali grassland (TNC 1999). Soils in typical Applegate's milk-vetch habitats are characterized as being gray in color, slightly alkaline, with a shallow water table and groundwater with a relatively high salinity due to periodic flooding and evaporation (TNC 1999). The soils on these sites belong to the Henley, Laki, and Poe series with inclusions in the Calimus series, and are very deep, coarse-loamy, mixed superlative, mesic Haplic Durixeroll (TNC 1999). A weakly developed duripan at 127 to 254 inches is usually present and accounts for the pooled surface water during the spring at most sites (TNC 1999) (USFWS, 2009).

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 1998)

**Dispersal/Migration Narrative**

Adult: Fruits shed their seed shortly after flowering and exhibit no specialized mechanisms for long-distance seed dispersal. Some seed dispersal may take place through ingestion by rodents or jackrabbits, although this has not been documented. Localized seed dispersal is supported by field observations, which document that the majority of seedling establishment is immediately adjacent to mature plants (Yamamoto 1985, Oregon Department of Agriculture [ODA]unpublished) (USFWS, 1998).

***Population Information and Trends***

**Number of Populations:**

8 (USFWS, 2019a)

**Population Size:**

!80,000 individuals (USFWS, 2019a)

**Population Narrative:**

Ongoing demographic monitoring of naturally occurring populations is providing data related to life stages and survival rates (Byrnes 2017b). The discovery of additional occupied sites through opportunistic observation increased the total number of known sites from two in 1993 to the current number of eight, although the current status of two smaller sites is uncertain (USFWS 2019a). Based on previous survey results, populations at four of the eight known sites appear to suggest population stability or growth. Population of a fifth site appears to be declining while the status of the remaining three populations is uncertain due to lack of data (USFWS 2019a). 2019 preliminary survey results from the Collins site also suggest site population stability and growth (J. Spaur, personal communication 7/17/19). Three of the sites are privately owned, two are state owned, one is city owned, and one is owned by an environmental organization for the purpose of Applegate's milk-vetch conservation. (USFWS, 2019a)

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The final rule states that irrigation and water control along the Klamath River have eliminated the seasonal flooding that once occurred along floodplains supporting the species. While some adverse affects cannot be ruled out from this hydrologic alteration, declines appear to be mostly due to declines appear to be mostly due to other factors. Agricultural and urban development has resulted in widespread depletion, fragmentation, and modification of Applegate's milk-vetch habitat, to the extent that even small (an acre or less) parcels of truly undisturbed habitat are uncommon (USFWS 1998). Habitat loss and modification from both urban and commercial development and expansion are still the most significant threats to the species within its historic range. At the Klamath Falls Airport, there are plans to expand and develop the area where the largest occurrence of Applegate's milk-vetch is currently found. The airport is currently filling in wetlands around the perimeter of the property to reduce bird

collisions with the air traffic where milk-vetch occurs. Additionally, the airport has plans to expand runways, build more hangers, and is looking to alter areas to provide better drainage along runways (USFWS, 2009).

**Stressor:** Herbivory (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In 1991 and 1992, ORNHIC (2007b) noted that the Miller Island population was struggling due to rabbit grazing. In 2007, ORNHIC reported observations of jack rabbit pellets at several Applegate's milk-vetch sites at Miller Island (ORNHIC 2007a). Jack rabbits are plentiful at the Klamath Falls Airport site as well (Hancock, pers. comm. 2007). As a result of seed collection efforts, Oregon Department of Agriculture reported that the reduced seed output of Applegate's milk-vetch in 2002 appeared to be caused by predispersal seed predation by insects. Most seed pods showed damage by insects and the seed collection bags were littered with the bodies of seed weevils and beetles (Gisler 2002a). Limited seed production coupled with seed predation may be significantly affecting the reproductive opportunities of Applegate's milk-vetch occurrences but additional studies are needed to determine population-level effects. Cattle are currently grazed at the Collins site and it has been documented that cattle do consume this species. Herbivory from insects includes the larvae of the Melissa blue butterfly. The larvae of the Melissa blue butterfly have been observed defoliating Applegate's milk-vetch plants and chewing through large plant stems near their bases (Gisler and Meinke 2001). Herbivory is not likely a major threat to the species, but when combined with the limited distribution and population size of Applegate's milk-vetch, habitat loss or modification due to herbivory and seed predation on this species could have a negative impact on its reproductive output and therefore recovery (USFWS, 2009).

**Stressor:** Nonnative plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat colonization by non-natives could indirectly limit Applegate's milk-vetch by increasing input of plant litter and nitrogen fixation by introduced legumes, and creating conditions favorable to secondary succession by shrubs and other herbaceous species historically restricted by harsh, bare soils (USFWS 1998). Likewise, habitat colonization by weeds, especially thatch-forming grasses, could promote greater densities of voles and other potential plant herbivores and granivores through increased cover and protection from predators (USFWS 1998). Thatch-forming grasses are also problematic for this species because it's difficult for seedlings to germinate and penetrate the thatch layer. All of the extant occurrences of Applegate's milk-vetch have some non-native weeds present. Elitrigia or Elytrigia repens (creeping quackgrass), Lactuca serriola (prickly lettuce) and Apera interrupta (dense silky bent) are just a few of the weed species found at Applegate's milk-vetch sites. Creeping quackgrass is present at the Ewauna Flat Preserve, Miller Island and Washburn Way-Railroad sites. The Miller Island and Klamath Falls Airport sites are mostly dominated by planted Thinopyrum intermedium (intermediate wheatgrass) (ORNHIC 2007a). Non-native plants at the Klamath Falls Airport site include: Agropyron cristatum (crested wheatgrass), intermediate wheatgrass, Poa bulbosa (bulbous bluegrass) and Holosteum umbellatum (jagged chickweed) (ORNHIC 2007a), although these species do not occur in high densities. Low densities of weedy species have also been observed at

the Collins Tract site, but of particular concern at this site is Hordeum murinum (mouse barley) and Cirsium spp. (thistles) (USFWS, 2009).

**Stressor:** Stochastic events (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The final rule for Applegate's milk-vetch states that with the small number of occurrences, and small number of individual plants for each occurrence, there is an increased potential for extinction from stochastic events such as flood or fire. The limited gene pool may depress reproductive vigor or a single human-caused or natural environmental disturbance could destroy many of the individuals of this species. There is no information available about the genetic diversity of the few occurrences of this species (USFWS, 2009).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** State-level protections do not apply to private lands. Federal protections under the Clean Water Act may not be protective. (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
1. A minimum of four self-sustaining populations/sites are under protected management3 for the benefit of the species. Includes the development of an Applegate's milk-vetch management plan addressing the mitigation and prevention of stressors and threats including agricultural and urban development (Factor A); wildlife and cattle grazing (Factor C); lack of regulatory protection (Factor D); and poor reproduction, competition with exotic weeds, seed predation, and low population viability (Factor E). (USFWS, 2019)

2. For a site to contribute as a self-sustaining population/site, a minimum of 2,200 reproductive plants need to be present at the site over five consecutive years of monitoring. (USFWS, 2019)

Recovery Priority Number: 5

**Delisting Criteria:**
1. A minimum of four self-sustaining populations/sites are under secured management7 for the benefit of the species or six self-sustaining recovery populations/sites are under protected management for the benefit of the species. Habitat being managed for Applegate's milk-vetch under the oversight of long-term land ownership that is not expected to change (e.g., the Miller Island recovery area that is owned by the State and managed as a Wildlife Management Area or the Airport property owned and managed by the City). (USFWS, 2019)

2. A minimum of 2,200 reproductive plants occurring over five consecutive years of monitoring at each site that contributes toward the delisting threshold. (USFWS, 2019)

**Recovery Actions:**

- Conserve natural and introduced Applegate's milk-vetch populations. The heart of recovery efforts for Applegate's milk-vetch will be to: 1) increase the species' representation from the current three areas to at least six areas with a minimum of two populations occurring at each of the recovery areas; and 2) develop management strategies that provide for long-term stability. (USFWS, 1998)
- Long-term, off-site seed storage. Banking (long-term cryogenic storage) of Applegate's milk-vetch seeds will provide an additional level of security to the recovery and survival of the species, by creating a demographic and genetic reserve of plant propagules. Off-site seed storage may be particularly vital in instances when natural soil seed banks are depleted due to poor seed production and pre- and post-dispersal seed mortality, or destroyed by natural or anthropogenic catastrophe. Stored seeds may be useful in establishing and augmenting Applegate's milk-vetch populations, mitigation of future population losses, and potential sources of genetic variability in the event populations suffer from inbreeding depression and/or allele fixation through drift. (USFWS, 1998)
- Conduct further research. The following areas of research must be addressed to increase our knowledge about the nature and extent of Applegate's milk-vetch threats, and improve the species' prospects of recovery. Define population self-sustainability. Perfect population establishment and augmentation techniques. Assess efficacy of habitat management strategies. Edaphic and hydrologic requirements. (USFWS, 1998)
- Develop and implement an outreach program. Increasing public awareness of Applegate's milkvetch will facilitate efforts to preserve this plant and restore its habitat. Prepare informational brochures, audiovisual, and sign programs on habitat restoration and recovery. Disseminate the brochures to affected landowners and other community facilities. Provide the audio-visual materials to public facilities such as National Wildlife Refuge interpretive programs and school programs. (USFWS, 1998)
- Recommended Future Action: While our Applegate's milk-vetch knowledge has increased substantially since its listing, much remains unknown regarding the species' life stages and resource requirements. Demographic monitoring efforts are currently ongoing for both naturally occurring populations and outsourced plants, including the collection of survivorship and life stage data. Data analysis for the first three years of the natural population survival study returned results for seedling survival at 11.5% for year one and 8.5% for year two. Work is needed to determine methods to increase seedling survival rates. (USFWS, 2019a)
- Recommended Future Action: Another key remaining research question is the identification of the species or group of species of mycorrhizae that are necessary for Applegate's milk-vetch survival. Once we know how to identify the species/group of species, we'll be able to more successfully determine where future transplanting should occur, as we'll be able to test if the mycorrhizae/other potentially important soil microbiota are present in the soil. The Service will also gain a better understanding of how and when it colonizes milk-vetch roots. Preliminary efforts have been initiated but additional study is needed. (USFWS, 2019a)
- Recommended Future Action: The Service believes that the highest priority actions during the next five years are to determine methods to increase seedling survival rates and to identify the species/group of species of mycorrhizae that are necessary for Applegate's milk-vetch survival. The next highest research priorities are those focusing on genetic or pollinator studies. Therefore, the Service recommends that current efforts continue and that additional methods are developed and implemented toward answering these highest

priority research questions. (USFWS, 2019a)

- Recommended Future Action: The Service also periodically receives new information about potential sites where Applegate's milk-vetch may have been seen. It is recommended that the Service survey these sites, to the extent that there is access. (USFWS, 2019a)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: To work towards delisting, the Service recommends implementing a plan for annual surveying of ASAP populations, including indication of life stage, for all populations close to reaching the benchmark of 2,200 reproductive individuals. Surveys for other populations are recommended at least once every five years, also with indication of individual life stage. All surveys should also include a habitat condition and composition component. Previous research results indicate the need for additional study related to ASAP restoration and management. The Service recommends the continued research of population reinforcement and the role of AMF communities related to ASAP as restoration tools and to explore the response of ASAP to various management options, including fire, mowing, and scraping. As mentioned above, a current research collaboration between ODA, ODPR, HSU, and the Service is underway at the OC&E site to 1) census and map the entire OC&E site ASAP population; 2) collect baseline abundance information on the species through establishment of plots; 3) apply experiment management treatments that may foster population growth; 4) monitor responses to the treatments; 5) collect soil samples and sequence microbiome to characterize soil microbiome associations and habitat characteristics; 6) analyze data; and 7) report findings. Results are preliminarily expected in 2025 with a final report in 2026 (ODA, 2023). (USFWS, 2024).

# SPECIES ACCOUNT: *Astragalus bibullatus* (Guthrie's (=Pyne's) ground-plum)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 9/26/1991; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

A low perennial herb with a stout taproot bearing 5-10 simple, glabrous, slender stems, 5-15 cm long. Leaves are alternate and pinnately compound with small leaflets. Flowering stems are 5-8 cm long, ascending with purple, pea-shaped flowers in compact clusters of 10-16 and blooming in April and May. Fruits are plump, fleshy globe shaped pods that ripen in May and lie on the ground, becoming red on the side facing the sun and yellow on the bottom. In the summer, the pods dry to stiff, 2-valved papery pods with flattened small dull black seeds (Somers and Gunn 1990). (NatureServe, 2015)

**Taxonomy**

Specimens that are now assigned to A. bibullatus were apparently first collected as early as 1881 by the Tennessee botanist, Augustin Gattinger. For over 100 years, this material was assigned to A. crassicarpus, a related but morphologically and geographically distinct species that occurs approximately 750 kilometers (466 miles) to the west. Milo Pyne discovered the Rutherford County, Tennessee, site in 1979, which later became the type locality for the species. Botanists familiar with the genus Astragalus determined that the plants found by Pyne might represent a new species. In 1985, flowering and fruiting material from the type locality was sent by Jerry Baskin to Rupert Barneby, a monographer of the genus at the New York Botanical Garden. Barneby concluded that this was a new species, A. bibullatus, and described it with Edwin Bridges (Barneby and Bridges 1987). Kartez (1994) recognizes A. bibullatus as the correct name for plants in Tennessee (USFWS, 2011a).

**Historical Range**

Astragalus bibullatus is endemic to the cedar glades of middle Tennessee (USFWS, 2011a).

**Current Range**

Extant occurrences are located in the Stones River watershed in the vicinity of Murfreesboro, Rutherford County, Tennessee (USFWS, 2011a).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (EPA, 2016)

**Dependency on Other Individuals or Species**

Adult: Insect pollinators (Bees) (USFWS, 2024)

**Breeding Season**

Adult: April - May (USFWS, 2011b)

**Other Reproductive Information**

Adult: Most pollinators that have been documented for A. bibullatus are species of bees, a taxonomic group experiencing a global decline in diversity (USFWS, 2024)

**Reproduction Narrative**

Adult: Flowering occurs April to May and fruiting occurs May to June. Obligate sexual reproduction most likely occurs via insect pollination (USFWS, 2011b).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Limestone cedar glade ecosystems; barrens, forest edge, forest/woodland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Partial shade (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 500 - 700 ft. elevation (USFWS, 2011b)

**Spatial Arrangements of the Population**

Adult: Clumped (see population narrative)

**Environmental Specificity**

Adult: Narrow to moderate (inferred from USFWS, 2011a)

**Habitat Narrative**

Adult: Limestone cedar glade ecosystems in the Middle Tennessee Central Basin. The plants are associated with Lebanon limestone and occur in transitional areas or glade margins where the soils are deeper (5-15 cm) and there is partial shade from shrubs and small trees. Environmental conditions in limestone glades are extreme - wet in the spring and very dry in the summer (NatureServe, 2015). Occurs between 500 to 700 ft. elevation. Soil types generally associated with rock outcrops in Rutherford County are the Gladeville and Talbott series (USFWS, 2011b). It should be noted that the most recently discovered occurrence was found in a small opening in a closed cedar forest, suggesting the potential for long-term persistence of A. bibullatus in less than ideal conditions provided that habitat is not destroyed (USFWS, 2011).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds are dispersed by gravity and water (USFWS, 2011b).

***Population Information and Trends***

**Population Trends:**
Decline of 10-90% (NatureServe, 2015)

**Species Trends:**
Stable (USFWS, 2011a)

**Number of Populations:**
12 extant wild, 9 extant reintroduced (USFWS, 2024)

**Population Size:**
The number of individuals at most of these occurrences ranges in the tens to hundreds; only one occurrence has been observed to consist of greater than 1,000 individuals (USFWS, 2019)

**Adaptability:**
Low (inferred from USFWS, 2011a)

**Additional Population-level Information:**
Since the 2019 5-year review (Service 2019, entire), when there were 12 known extant occurrences of Astragalus bibullatus, 9 additional occurrences have been established through reintroductions. As of 2024, there are 21 occurrences of Astragalus bibullatus, 12 of which exist as the result of introductions established by outplanting nursery-grown juvenile plants (Table 1). In addition, there are two wild occurrences that have been augmented with outplanted individuals to increase abundance. More than 1,600 individuals of A. bibullatus were outplanted across these introduced or augmented occurrences, and there were 761 surviving plants across these sites as of 2023, representing both planted individuals and plants recruited from reproduction in the wild since the time of outplanting (USFWS, 2024).

**Population Narrative:**
It is known from three extant populations. Two populations of Astragalus bibullatus (collected in 1901 and 1948 respectively) are believed to have been extirpated (USFWS 1991). This species has experienced a long-term decline of 10-90% (NatureServe, 2015). The species status is stable based on the 2011 Recovery Data Call. It is presently known from 8 extant occurrences. The extant occurrences of A. bibullatus are typically small, consisting of tens to hundreds of individuals (Table 1). Only one occurrence has ever been estimated to include greater than 1,000 individuals. Morris et al. (2002) surmised that, because of environmental changes, A. bibullatus populations were reduced in size and gene flow among them was likely restricted, leaving them vulnerable to effects of genetic drift and inbreeding. An occurrence that TVA biologists discovered during a 2006 survey of a powerline right-of-way extended the currently known range approximately 16 km (10 mi) to the southwest and expanded the area encompassing the species’ current range to approximately 235 km2 (90 mi2) (USFWS, 2011).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2011a)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** All the occurrences of Astragalus bibullatus are within a short distance of the rapidly growing middle Tennessee city of Murfreesboro. Five of the occurrences are located on public lands and as such are protected from development threats. However, the three remaining occurrences are located on private lands where development pressures are great. Limestone cedar glades are relatively flat and clear areas that often attract developers. One occurrence (population 2 in the listing rule) has been either destroyed or significantly altered by commercial development since A. bibullatus was listed and is now believed to be extirpated. Habitat degradation due to ORV use of sites on private lands remains a potential threat, as does illegal ORV use on sites protected by public ownership (USFWS, 2011a).

**Stressor:** Invasive species (USFWS, 2011a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** All the known Astragalus bibullatus occurrences are threatened by the encroachment of more competitive herbaceous vegetation and/or woody plants, such as eastern red cedar, that produce shade and compete for limited water and nutrients. Invasive exotic species that currently are either being managed or have been noted as potential threats at A. bibullatus occurrences include spotted knapweed (Centaurea biebersteinii), Japanese honeysuckle (Lonicera japonica), privet (Ligustrum spp.), and sericea lespedeza (Lespedeza cuneata), among others. Active management to reduce or eliminate vegetation encroachment is required to ensure that the species continues to survive at all the sites (USFWS, 2011a).

**Stressor:** Herbivory (USFWS, 2011a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory has been observed to varying degrees during monitoring of A. bibullatus occurrences. Albrecht and McCue (2010) observed that some spring transplants were browsed, and Walck (2007) observed herbivory or signs of it at three sites (USFWS, 2011a).

**Stressor:** Climate change (USFWS, 2011a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Service identified extended drought conditions as a threat to Astragalus bibullatus, because of the likely reduced resilience of the three small populations that were known at the time of listing to endure such stochastic environmental events (56 FR 48750, Service 1991). The occurrence of severe drought in middle Tennessee, during the summers of 2007 and 2008, provides an opportunity to assess effects of drought to populations that are periodically monitored. It is possible that alterations in precipitation and drought frequency or severity that might accompany climate change could pose a growing threat to A. bibullatus in the future. Estimates of the effects of climate change using available climate models lack the geographic precision needed to predict the magnitude of effects at a scale small enough to discretely apply to the range of Astragalus bibullatus. However, data on recent trends and predicted changes for the Southeast United States (Karl et al. 2009) provide some insight for evaluating the potential threat of climate change to A. bibullatus. Since 1970, the average annual

temperature of the region has increased by about 2o F, with the greatest increases occurring during winter months. The geographic extent of areas in the Southeast region affected by moderate to severe spring and summer drought has increased over the past three decades by 12 and 14 percent, respectively (Karl et al. 2009). These trends are expected to increase. Rates of warming are predicted to more than double in comparison to what the Southeast has experienced since 1975, with the greatest increases projected for summer months. Depending on the emissions scenario used for modeling change, average temperatures are expected to increase by 4.5o F to 9o F by the 2080s (Karl et al. 2009). While there is considerable variability in rainfall predictions throughout the region, increases in evaporation of moisture from soils and loss of water by plants in response to warmer temperatures are expected to contribute to increased frequency, duration, and intensity of droughts (Karl et al. 2009) (USFWS, 2011a).

**Stressor:** Population fragmentation (USFWS, 2011a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small population sizes and fragmentation of cedar glade habitats could influence genetic structure of Astragalus bibullatus populations. As noted above, Morris et al. (2002) concluded that the among-site genetic structure they detected within the youngest soil seed layers of A. bibullatus occurrences was likely attributable to an increased incidence of inbreeding over time, due to the isolation of populations caused by fragmentation. They surmised that, because of increased fragmentation of cedar glade habitats and increased shading due to vegetation encroachment in those that remain, A. bibullatus populations were reduced in size and gene flow among them was likely restricted, leaving them vulnerable to effects of genetic drift and inbreeding (USFWS, 2011a).

***Recovery***

**Reclassification Criteria:**
There are 11 viable, protected occurrences distributed throughout the cedar glade ecosystem of the Stones River Basin within Davidson, Rutherford, or Wilson counties (USFWS, 2011a).

Recovery Priority Number: 2

**Delisting Criteria:**
There are 16 viable, protected occurrences that are distributed throughout the cedar glade ecosystem of the Stones River Basin within Davidson, Rutherford, and Wilson counties (USFWS, 2011a).

**Recovery Actions:**
- Protect and manage existing occurrences and habitats (USFWS, 2011b).
- Search for new occurrences (USFWS, 2011b).
- Conduct long-term monitoring and assess population growth rates and viability (USFWS, 2011b).
- Conduct biological and ecological research (USFWS, 2011b).
- Develop protocols for establishing new occurrences or augmenting existing ones (USFWS, 2011b).

- Communicate with local officials to coordinate city and county planning (USFWS, 2011b).
- Develop and implement public education materials (USFWS, 2011b).
- Periodically assess the success of recovery efforts for the species (USFWS, 2011b).
- Federal and state regulatory protection (USFWS, 2011b).
- Investigating the species' biology, ecology, and life history (USFWS, 2011b).
- Preserving germplasm and establishing or augmenting occurrences (USFWS, 2011b).
- Site protection and management (USFWS, 2011b).
- Surveys and monitoring (USFWS, 2011b).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS A. Continue to pursue protection and/or cooperative management for occurrences located on privately owned lands. Highest priority should be given to protecting or managing the Rockvale site (EO 18), due to its genetic distinctiveness relative to other occurrences throughout the species range. Demographic monitoring also should be conducted for EO 18. B. Coordinate with private landowners to gain permission for collecting seed to preserve germplasm representing currently unprotected occurrences. Collect seed from these sites to add to existing accessions held at MBG. C. Determine whether redundant seed accessions are needed, in order to eliminate potential for losing all germplasm currently held in ex situ collections. If they are not currently established, coordinate with MBG to establish redundant accessions at another facility. D. Implement site-specific management recommendations listed below. Note that recommended timing for prescribed burns is November through mid-February. When prescribed burns are conducted late in this timeframe, pre-burn inspections should be conducted to determine whether spring growth has been initiated in A. bibullatus. If plants are found to be actively growing, measures should be taken to remove fuels from the immediate vicinity of A. bibullatus plants to prevent damaging them. Site-specific Recommendations Davis site (EO 5) – This small population, semi-protected on private land, has low viability but apparently contains some unique alleles. Albrecht and Dell (2019) recommended applying judicious and light manual thinning of eastern red cedar trees staggered over several years to avoid potential impacts of drought. They also recommend the collection of seeds and seed banking for possible use in augmentation at the adjacent Overbridge DSNA. Augmentation attempts should be staggered over several years. Overbridge DSNA (EO 4) – As of 2018, this is a very small population with only six non-reproductive individuals and is not likely to have positive population growth without augmentation. In recent years, thinning of eastern red cedar and prescribed burning have been conducted on the natural area; however, tree canopy cover remains >50% (Albrecht and Dell 2019). MBG recommends augmentation of this population using material from the adjacent Davis site to increase population size. Genetic material from Flat Rock Cedar Glades and Barrens DSNA could also be used if needed. Manus Road Glade DSNA (EO 9) – Population dynamics are more variable at this site; however, the long-term trend is projecting a population decline. It is possible that the low population growth rate is in response to multiple interacting variables such as herbivory, drought, and untimely application of a spring prescribed burn (Albrecht and Dell 2019). Management at this site has been more active over the last six years especially with thinning woody encroachment and use of prescribed fire. Albrecht and Dell (2019) recommended that no management occur for a period of 2-3 years to see how the population recovers. Herbivore exclusion plots were established here in 2018. Prescribed fires should be conducted during the dormant season (November to mid-February) at an interval of > 5 years. Recent fires were too close together (March 2016-Fall 2017) and likely resulted in high mortality for seedling and small juvenile plants (Albrecht and Dell 2019). Flat Rock Cedar Glades and Barrens DSNA – • Airport site (EO 1a) – This site contains the largest population of A. bibullatus and the highest population growth rates. The population is near demographic equilibrium (i.e., population growth models indicate that demographic structure is sufficient to maintain a stable population, $\lambda \approx 1$) and has high survival rates for both small and large plants, and Albrecht and Dell (2019) recommended continuing to mow this site with a bush hog every 5-10 years from late June to December. This site has less woody canopy cover than other sites and experienced the lowest population growth rates during drought years when most other sites showed higher growth rates (Albrecht and Dell 2019). • Alexander site (EO 1b) – This site is across the road from the Airport site and has similar characteristics. Woody encroachment has been steadily increasing at this site and, therefore, Albrecht and Dell (2019) recommended continued mowing every 5-10 years from late June to December. • Davenport East site (EO 3a) – This small population is completely surrounded by forest despite thinning of woody vegetation and management with prescribed burning. It is near demographic equilibrium but expected to slowly decline. Albrecht and Dell (2019) recommended creating a large canopy gap around the A. bibullatus population through selective removal of canopy trees like eastern red cedar and non-oak species. Dormant season burning of the surrounding woodland may also promote population expansion. Because an herbivore exclusion plot was established here in 2018, Albrecht and Dell (2019) recommended delaying management for 2-3 years. • Davenport West site (EO 3b) – This site has been managed with woody encroachment thinning and prescribed burning. Despite its small size, the population is near demographic equilibrium. Albrecht and Dell (2019) recommended management to expand the size and spatial extent of the suitable habitat to increase population resilience to environmental change. This may be accomplished with dormant season prescribed burning every 6- 10 years. Small population augmentations may also be needed to hedge against the loss of large adult plants, which currently dominate the population. (USFWS, 2019)

- RECOMMENDED FUTURE ACTIVITIES A detailed discussion of recovery actions and criteria are presented in the Recovery Plan for Pyne's ground-plum (Service 2011b). During this status review new and/or targeted potential recovery activities were identified and are included below. Recovery Activities Continued management is needed to restore or maintain habitat conditions for long-term population growth at A. bibullatus occurrences. The recovery plan calls for developing and implementing adaptive management plans for each occurrence. General management plans that identify goals and procedures for management of limestone glade habitats exist for state-owned conservation lands where A. bibullatus occurs. To achieve recovery criteria, these management plans should include specific goals and objectives related to A. bibullatus conservation, an adaptive management strategy, and a commitment of resources for achieving them. To be adaptive, these plans should incorporate a framework for using available monitoring data to assess when and where management actions are needed and to evaluate the species response to management actions and environmental variation. Management plans should also be prepared for sites on private lands where landowners are willing to manage habitat for A. bibullatus recovery. Monitoring and Research Activities Continued long-term demographic monitoring as outlined in the recovery plan is needed to effectively gage resiliency of wild and introduced occurrences to environmental variation, assess when and where management actions are needed, and understand how management influences demography and, therefore, resiliency. A rigorous analysis of available demographic monitoring data would improve our understanding of how population dynamics are influenced by environmental variation and effects of habitat management and facilitate identification of sitespecific management actions that would reduce threats and promote stable or increasing growth trends. A monitoring program to track pollinator diversity and abundance in limestone glades is needed to improve understanding of how variation in pollinator abundance and rates of visitation to A. bibullatus influences reproductive output in populations. (USFWS, 2024)

# SPECIES ACCOUNT: *Astragalus brauntonii* (Braunton's milk-vetch)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 02/28/1997; Pacific Southwest (R8)

**Physical Description**

A robust, short-lived perennial in the pea family (Fabaceae) (Hickman 1993). It is one of the tallest members of the genus, reaching a height of 1.5 meters (5 feet) and is covered with fine, entangled hairs throughout. The stems are white, the leaves pale to greenish. A thick taproot and woody basal stem gives rise to several stems. The 4 to 16 centimeters (1.5 to 6.5 inches) long leaves are pinnately compound with 25 to 33 oblong-ovate, abruptly pointed leaflets. The light purple flowers are clustered in 35 to 60 flowered racemes (flowers are borne on stalks) 4 to 14 centimeters (1.5 to 5.5 inches) long. The beaked, slightly curved pods are oblong-ovoid, 6.5 to 9 millimeters (2.5 to 3.5 inches) long and two-celled, front to back, with three to six seeds. Astraga/us brauntonii is readily distinguished from the only other perennial species ofAstraga/us in the area, A. trichopodus, by being woolly tomentose (covered with densely matted hairs) as opposed to strigose (covered with sharp, stiff-appressed hairs) or glabrous (without hairs), and by the twochambered, rather than one-chambered pods (Barneby 1964). (USFWS, 1999)

**Taxonomy**

Member of the pea family (Fabaceae) (USFWS, 2009). Astragalus brauntonii was described by Samuel Parish (1903) based on a specimen collected by Dr. H. E. Hasse in 1899 above Santa Monica. It was named for Ernest Braunton. Per Axel Rydberg published the name Brachyphragma brauntonii in his revision of the genus. However, Rydberg’s fragmentation of the genus Astraga/us has not been accepted by other botanists. Systematic treatments (Bameby 1964) and floristic treatments (Munz 1974, Spellenberg 1993) recognized Parish’s original treatment of this taxon (USFWS, 1999).

**Historical Range**

See Current Range.

**Current Range**

Occurs in five disjunct geographic areas in Ventura, Los Angeles, and Orange Counties, California (USFWS, 2009). The occurrences can be grouped into four areas: the Santa Monica Mountains, the south slope of the Simi Hills, the San Gabriel Mountains near Monrovia, and the Santa Ana Mountains. At the time of listing in 1997 (Service 1997), A. brauntonii was described as being found in the same four general areas, with 6 occurrences distributed among those areas. The recovery plan identified 20 occurrences (it combined EO# 15 and EO# 17, and listed an EO# 21 which is not currently recognized; Service 1999 pp. 8–10). The critical habitat designation (Service 2006) did not list occurrences, and the 2009 5-year review did not add any new occurrences (USFWS, 2023).

**Critical Habitat Designated**

Yes; 12/14/2006.

**Legal Description**

On November 14, 2006, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective December 14, 2006) for Astragalus brauntonii (Braunton's milk-vetch) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in California (71 FR 66374-66423).

**Critical Habitat Designation**

The critical habitat designation for Astragalus brauntonii includes six CHUs (including 10 subunits) in Ventura, Orange and Los Angeles Counties, California. Approximately 3,300 acres (ac) (1,337 hectares (ha)) fall within the boundaries of the critical habitat designation. The critical habitat is located in Ventura, Los Angeles, and Orange Counties, California. Brief descriptions are presented below; detailed coordinates and maps are included in the Final Rule. (USFWS, 2006).

Unit 1: Northern Simi Hills Unit: This unit is located south of Simi Valley in the northern Simi Hills in Ventura County and consists of 21 ac (9 ha) of local agency land (Rancho Simi Recreation and Parks District) and 413 ac (166 ha) of private lands. It is divided into four subunits mapped from occurrences identified after the time of listing but currently occupied; all occur within 1.5 mi (2.5 km) of each other. Unit 1, inclusive of the four subunits, is located within the same physiographic area (the Simi Hills) as Unit 2.

Unit 2: Southern Simi Hills Unit: This unit is located along the southern Simi Hills in Ventura and Los Angeles Counties and consists of 196 ac (80 ha) of Federal lands, 118 ac (48 ha) of State land, 427 ac (173 ha) of local agency lands (Conejo Open Space Conservation Authority (COSCA), City of Thousand Oaks, Santa Monica Mountains Conservancy, and Rancho Simi Recreation and District), and 278 ac (113 ha) of private land. This unit is divided into six subunits mapped from records known at the time of listing and occurrences identified after listing. These subunits are all within 3.2 mi (5.2 km) of each other and occur along the southern perimeter of the geologic Chatsworth Formation.

Unit 3: Santa Monica Mountains Unit: This unit is located in the eastern Santa Monica Mountains in upper Zuma Canyon, north of Point Dume in Los Angeles County. It consists of 172 ac (70 ha) of Federal land within the Santa Monica Mountains National Recreation Area, and 56 ac (23 ha) of private land. It includes an area where more than 300 plants were found in 1999 after a prescribed burn, and the entire unit is mapped from an occurrence identified after listing.

Unit 4: Pacific Palisades Unit This unit is located in the Santa Ynez Canyon north of Pacific Palisades in Los Angeles County and consists of 439 ac (178 ha) of State lands within Topanga State Park and 66 ac (27 ha) of private land. It includes plants found in three separate locations that are part of a single population complex, and is mapped from occurrences known at the time of listing.

Unit 5: Monrovia Unit This unit is located in the San Gabriel Mountains in the City of Monrovia in Los Angeles County and consists of 218 ac (88 ha) of local agency land owned by the City of Monrovia and managed as open space (Monrovia Wilderness Preserve) and 64 ac (26 ha) of private land. It includes plants found in several locations that are part of a single population complex, and is mapped from an occurrence known at the time of listing.

Unit 6: Coal Canyon Unit This unit is located south of the City of Yorba Linda in Coal Canyon and Gypsum Canyon in Orange County and consists of 589 ac (238 ha) of State land (Chino Hills State

Park and California Department of Fish and Game—Coal Canyon Ecological Reserve) and 243 ac (98 ha) of private land. This unit includes plants found in several locations that are part of a large population complex, and is mapped from occurrences known at the time of listing.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Astragalus brauntonii critical habitat consists of three components (71 FR 66374-66423):

(i) Calcium carbonate soils derived from marine sediment;

(ii) Low proportion (less than 10 percent) of shrub cover directly around the plant; and

(iii) Chaparral and coastal sage scrub communities characterized by periodic disturbances that stimulate seed germination (e.g., fire, flooding, erosion) and reduce vegetative cover.

**Special Management Considerations or Protections**

Threats that may require special management are specified in the Final Rule for each Critical Habitat Unit: Unit 1. Road maintenance, which could result in disturbances that are too frequent and prevent replenishment of the seed bank, invasion of nonnative plants which could crowd out A. brauntonii, cattle grazing, and recreation activities such as equestrian and foot traffic, which could result in trampling of plants. Unit 2: Road and trail maintenance that could result in disturbances that are too frequent and prevent replenishment of the seed bank, invasion of nonnative plants that could crowd out Astragalus brauntonii, edge effects from urban development, and recreation activities such as off-road vehicles and equestrian and foot traffic, which could result in trampling of plants. Subunit 1c is threated by additional part development. Unit 3: Road maintenance that could result in disturbances that are too frequent, preventing establishment or replenishment of the seed bank. Unit 4: Road maintenance that could result in disturbances that are too frequent, preventing establishment or replenishment of the seed bank, and growth of nonnative plants that could crowd out Astragalus brauntonii. Unit 5: Maintenance of fire roads, the growth of nonnative plants that could crowd out Astragalus brauntonii, and recreation activities such as foot and bicycle traffic, which could result in trampling of plants. Unit 6: Maintenance of fire roads and the growth of shrubs and nonnative plants, which could crowd out Astragalus brauntonii. (USFWS, 2006)

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: self-fertilization, cross-pollination (USFWS, 2009)

**Lifespan**

Adult: 2 - 3 years (NatureServe, 2015); possibly 5+ years in favorable conditions (USFWS, 2009)

**Key Resources Needed for Breeding**

Adult: Fire/disturbance (NatureServe, 2015); insect pollinators (bees known), soil seed bank (USFWS, 2009)

**Reproduction Narrative**

Adult: The seeds germinate after fire or other disturbance and the plants live only 2-3 years before senescing (NatureServe, 2015). A. brauntonii is self-fertile, but also produces seed through cross-pollination (Fotheringham and Keeley 1998). Known pollinators include megachilid bees (Ashmeadiella spp.) and bumblebees (Bombus spp.) (Fotheringham and Keeley 1998). Disturbances such as fire, erosion, and mechanical scraping of soil (e.g., during road or trail maintenance) are known to stimulate germination (Fotheringham and Keeley 1998). Each plant may support upwards of several hundred flowers, and each seed pod produces three to six seeds (Barneby 1964), therefore, each plant can produce a large number of seeds which are deposited in the soil (seed bank). Individual plants have a lifespan of two to three years, although some individuals may live five years or more if conditions are favorable, and then plants are not visible again until the next disturbance (Fotheringham and Keeley 1998) (USFWS, 2009).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Brush/chaparral (NatureServe, 2015); coastal sage scrub (USFWS, 2009)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire; interval unknown (possibly 20 - 100+ years) (USFWS, 1999)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs ~800 - 2,100 ft. elevation, shade-intolerant (USFWS, 2009)

**Spatial Arrangements of the Population**

Adult: Patchy (USFWS, 2009)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2009)

**Habitat Narrative**

Adult: Brush/chaparral communities. The natural frequency of fire in the species' habitat is unknown. The plants may be restricted to limestone substrates (NatureServe, 2015). The species appears to be limited to shallow calcium carbonate soils derived from marine substrates; it occasionally occurs on non-carbonate soils at down-wash sites near other known occurrences, although survivorship of plants may be reduced on noncarbonate soils (Mistretta 1992, Fotheringham and Keeley 1998, Landis 2005). Astragalus brauntonii is associated with chaparral and coastal sage scrub plant communities and generally occurs along the tops of knolls ranging from 800 to 2,100 ft. (244 to 640 m) in elevation (Fotheringham and Keeley 1998, CNDDB 2007, Landis 2005). The habitat has been described as scrub dominated by chaparral with a high overall percentage (>80 percent) of vegetative cover, however, the species does not tolerate shading and is associated with surrounding bare ground (Carroll 1987, Fotheringham and Keeley 1998). It requires a low proportion (<10 percent) of shrub cover directly around the plant. Many of the plant species that comprise chaparral and coastal sage scrub communities regenerate after fire, either through the release of a dormant seed bank whose germination is stimulated by fire, or through basal burl sprouting (Hanes 1971, Keeley and Zedler 1978). The above-ground expression of A. brauntonii populations are patchy over time and space as a result of the dormant seed bank and are subject to the dynamic habitat conditions and physical processes where it occurs (USFWS, 2009). The natural fire interval in the habitat of. brauntonii is unknown. Estimates range from 20 to more than 100 years, with an average of 70 year intervals (Minnich 1989; O'Leary 1990) (USFWS, 1999).

***Dispersal/Migration***

**Dispersal**

Adult: Low to moderate (inferred from USFWS, 2009)

**Dispersal/Migration Narrative**

Adult: Neither the fruits or the seeds have specialized adaptations to facilitate seed dispersal by wind; therefore, it is likely that most seeds fall within a short distance of the parent plant (Cain et al. 2000). Long-distance dispersal, however, is likely achieved by water (during rainstorms), and by transport of seeds by wildlife. Small mammals facilitate seed dispersal through consumption and elimination of undigested seed and through seed caching (Cain et al. 2000, Sieg 1987) (USFWS, 2009)

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

57 EOs. 52 extant (USFWS, 2023)

**Population Size:**

Variable; tens to thousands per population, depending on disturbance cycle (USFWS, 2009)

**Population Narrative:**

This plant is only visible for a short time following disturbance such as a fire (NatureServe, 2015). There are currently 20 known occurrences. In most cases, the number of plants within a population is in the hundreds to thousands following a disturbance, and declines to fewer than ten plants within a few years (CNDDB 2007). (USFWS, 2009). Currently, the California Natural Diversity Database (CNDDB) recognizes 57 Element Occurrences (EOs, Table 1, CDFW 2023) of A. brauntonii. An EO is a group of plants separated by at least 400 meters (1/4 mile) from the closest group of plants of the same species (CNDDB 2018 entire). The occurrences can be grouped into four areas: the Santa Monica Mountains, the south slope of the Simi Hills, the San Gabriel Mountains near Monrovia, and the Santa Ana Mountains. At the time of listing in 1997 (Service 1997), A. brauntonii was described as being found in the same four general areas, with 6 occurrences distributed among those areas. The recovery plan identified 20 occurrences (it combined EO# 15 and EO# 17, and listed an EO# 21 which is not currently recognized; Service 1999 pp. 8–10). The critical habitat designation (Service 2006) did not list occurrences, and the 2009 5-year review did not add any new occurrences (Service 2009). Most of the occurrences (52 of 57, Table 1) are presumed by CNDDB to be extant, and most of the presumed extant occurrences (39 of 52) may be at least partly on land managed for resource conservation. Most of the occurrences are in the Santa Monica Mountains and Simi Hills (22 and 24 respectively), with only 4 in the San Gabriel Mountains and 7 in the Santa Ana Mountains (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat destruction and degradation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Land management actions that result in frequent disturbances, such as yearly road maintenance where Astragalus brauntonii occurs, may be contributing to the decline of populations by mowing and removing plants before seeds mature and replenish the seed bank. This has been known to occur for plants along unpaved fire access roads and utility corridors. Other land management activities such as herbicide application, cattle grazing, and recreational activities such as off-road vehicle and equestrian use that results in trampling of plants may be affecting A. brauntonii. Of the currently known 20 occurrences, the Service is unaware of protections for the 6 occurrences on private lands and for 4 of the 8 occurrences on local agency lands, and therefore presumes they could be threatened by indirect or direct effects from existing or future urban development, recreational activities, or other land management activities. Since the time of listing, one occurrence in Oak Park on lands owned by Rancho Simi Recreation and Parks District was extirpated due to park expansion. Another occurrence was partially removed by the Ventura County Public Works Agency for creation of a detention basin, and the remaining portion of this occurrence has been proposed for development into the Lang Ranch Community Park by Conejo Recreation and Park District (USFWS, 2009).

**Stressor:** Altered fire cycles (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** One threat to Astragalus brauntonii discussed in the listing rule is the impact of fire management policies over the last 200 years on southern California ecosystems. The listing rule stated that fire exclusion has resulted in an accumulation of fuels in woody vegetation, making fire intensity and duration more severe. However, wildlands near urban areas have been experiencing increased fire frequencies, resulting in vegetation changes from shrub to grass and facilitating the spread of non-native, invasive annual plants. Despite efforts to suppress fires in coastal southern California, the current fire frequency of every 15 years or less, is substantially higher than it was historically, which is thought to be every 50 to 100 years (Keeley 2006). The impacts of fire suppression and/or increased fire frequencies near urban areas on Astragalus brauntonii are unclear. As of 1997, the Service believed that fire suppression activities resulted in the extirpation of A. brauntonii during the Old Topanga fire of 1993 (Service 1997); however, more recent surveys have revealed plants growing in that area (CNDDB 2007). Extirpation of populations is unlikely as long as habitat remains, although above-ground plants may cease to grow for many years until a disturbance stimulates dormant seeds to germinate. Therefore, A. brauntonii habitat that has undergone succession and is dominated by dense woody shrubs may not be harmful to the long-term persistence of the plant as long as periodic disturbances are allowed to occur (USFWS, 2009).

**Stressor:** Stochastic events (USFWS, 2009)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Astragalus brauntonii may be vulnerable to extirpation by stochastic factors including demographic stochasticity, environmental stochasticity, and genetic stochasticity (Shaffer 1981). Demographic stochasticity refers to random variability in survival or reproduction among individuals within a population (Shaffer 1981), and could play a role in the extirpation of small populations of A. brauntonii. In most cases, the number of plants within a population is in the hundreds to thousands following a disturbance, and declines to fewer than ten plants within a few years (CNDDB 2007). The disjunct distribution of A. brauntonii decreases genetic exchange between populations, which could impair the species' ability to adapt to changes in the environment or contribute to inbreeding depression (i.e., loss of reproductive fitness or vigor) (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Service recognizes that climate change is an important issue with potential effects to listed species and their habitats. While the Service lacks adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors such as small population size, will affect Astragalus brauntonii, small ranged species, such as Astragalus brauntonii, may be more vulnerable to extinction due to these changing conditions (Pimm and Raven 2000, Loarie et al. 2008) (USFWS, 2009).

**Stressor:** Trampling (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Occurrences on both private and public lands are subject to damage from trampling of plants from activities including hiking, mountain biking, off-highway vehicle use, equestrian use, and, in a few cases, grazing. In some situations, the disturbance of these activities can stimulate germination of an existing soil seed bank, with the resulting plants succumbing to trampling before being able to produce seeds. Trampling by recreational use remains a threat to the species when trails cross through occurrences (USFWS, 2023).

**Stressor:** Pollination Reduction (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The recovery plan (Service 1999 p. 10) and critical habitat designation (Service 2006 p. 66387) listed a reduction in pollinators because of habitat fragmentation as a possible threat. A pollination study (Fotheringham and Keeley 1998 pp. 14–15) found that the species selfpollinates and produces seeds at a rate not significantly different than if it is open to visitation by generalist bees. The study did not investigate the genetic consequences of the lack of pollination by other A. brauntonii within or between occurrences. There could be local inbreeding effects if there was no effective pollen transfer between occurrences, but this remains to be investigated. The magnitude of the threat of reduction of pollinators is unclear (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
1. All 20 current populations are fully protected (including seed banks), and managed with the primary intention of preserving the populations in perpetuity. (USFWS, 1999)

2. Seed is securely stored and plants are successfully germinated from collected seed and/or historic sites e.g. propagation techniques for reintroduction are developed. (USFWS, 1999)

Recovery Priority Number: 2

**Delisting Criteria:**
1. When monitoring shows that the habitat is secure; provisions for ecological requirements exist; and conditions for the species indicate stability over a minimum of 15 years. This 15 years of monitoring will be extended by an additional 5 years of monitoring which is required by the Endangered Species Act for newly listed species. (USFWS, 1999)

**Recovery Actions:**
- Protect and secure populations and habitat on unprotected lands. Habitat for the listed plants must be protected and secured in perpetuity, from identified threats of loss. Methods for securing lands include permanent conservation easements established through land use decisions, in-fee purchase, gifts of easement, or fee interest by property owner (USFWS, 1999).
- Manage and monitor protected areas. The process of evaluating past and current management and making adjustments as needed is termed “adaptive management.” Public and private conservation lands should be adaptively managed to maximize their potential to support listed species and their habitats. (USFWS, 1999)
- Survey historic locations and other potential habitat where species may occur, Surveys of the potential albeit limited, habitat within the species range should be done. Several California Natural Diversity Database occurrence records for the listed species are represented only by observations. Information on population status, threats, and abundance is also needed for these sites. Information gathered from the additional details will be used to provide lead agencies to determine protective land use designation for the listed plant species . Data gathered will assist in determining the range of site characteristics, population vigor, and species viability to help establish minimum population standards for rare plant reserves, and consequently, for recovery. (USFWS, 1999)
- Conduct biological and ecological research to define life history strategies and population dynamics to guide recovery/conservation efforts. A better understanding of the population dynamics and identification of ecological factors that may be affecting those dynamics are needed to develop appropriate management plans to recover the plant species. (USFWS, 1999).
- Develop outreach plans to conserve the species. Outreach is an important component of implementing this recovery plan. This plan should be developed to enhance the public’s understanding of issues related to conservation and recovery of the listed species. Participation from both public and private entities should be encouraged for the establishment of conservation plans for the listed species. (USFWS, 1999)

- Recommendations for Future Actions from 2009 5-Year Review: 1) Work with private landowners and local agencies to protect and manage habitat for Astragalus brauntonii. This may be accomplished by conservation easements or other permanent devices. 2) Work with local agencies, fire departments, and utility companies to ensure that maintenance activities, such as grading of roads and/or mowing along dirt fire access roads and utility corridors, do not negatively impact Astragalus brauntonii. This includes conservation measures such as waiting until seeds mature to cut plants, and depositing plants and seeds on-site so that they replenish the seed bank. 3) Examine genetic diversity in the species and incorporate that data into the sampling and maintenance methodologies for seed banking called for in the recovery plan. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Conduct thorough population census surveys of all known occurrences and areas of suitable habitat, especially in the San Gabriel Mountains and Santa Ana Mountains areas. These surveys are needed to accumulate baseline information about distribution so that it can be compared with distribution after wildfire or other disturbance. 2. Develop and implement a monitoring plan for all occurrences. Monitoring should include population abundance surveys, habitat condition assessment, and documentation of existing and potential threats. Monitoring data should be in place so that comparisons can be made if at future dates the monitoring areas burn. 3. Review protective measures in place for all occurrences on public lands. 4. Work with public and private entities to prevent damage to plants and raise public awareness to support appropriate conservation measures. 5. Develop a method to assess the number of seeds in the soil seed banks of occurrences, and test how that relates to numbers of plants that germinate after disturbance. 6. Increase the number of accessions in conservation seed banks so that a greater number of known occurrences are represented and add accessions for previously collected occurrences so that a greater number of years is represented (USFWS, 2023).

# SPECIES ACCOUNT: *Astragalus clarianus* (Clara Hunt's milk-vetch)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/22/1997; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A slender, sparsely leafy annual herb, mostly 7-12 cm in height. Flowers (March-April) are bicolored, with the wings whitish and the banner and keel bright purple-tipped (NatureServe, 2015).

**Taxonomy**

Name generally spelled "clarianus" (e.g., by Barneby (Astragalus), Kartesz 1994 and 1999, Hickman 1993, and USFWS); has also appeared as the strictly Latinized version "claranus" but that spelling does not appear to be in current usage (NatureServe, 2015). A member of the pea family (Fabaceae) (USFWS, 2009).

**Historical Range**

Historically, Clara Hunt’s milkvetch was known from six occurrences in Sonoma and Napa counties (Service 1997, p. 55792). It is possible that this plant has always been rare, but more common in the hills surrounding the Napa Valley and possibly on the valley floor itself, before the planting of vineyards (Service 2019, p. 3). By the time of listing in 1997, two of the known occurrences had been extirpated due to urbanization and viticulture, leaving only one occurrence in eastern Sonoma County (Diversity Database #3 - Saint Helena Road) and three occurrences in northwestern Napa County (Diversity Database #7 - Bothe-Napa Valley State Park, Diversity Database #11 - Lake Hennessey, and Diversity Database #12 - Lewelling Lane) (Service 1997, p. 55792). As noted in the 2009 status review, one additional occurrence of Clara Hunt’s milkvetch was discovered in 1998 within Spring Valley (Diversity Database #13) in Napa County, approximately 3.2 kilometers (2 miles) east of Lake Hennessey (Service 2009, p. 3). At the time of the 2019 status review, the species was still known from these five occurrences; however, the status of the Bothe-Napa Valley State Park occurrence was uncertain as no plants had been observed at the site since 2009 despite multiple survey attempts (USFWS, 2024).

**Current Range**

Highly limited today due to development of vineyards and urbanization (NatureServe, 2015). The species is currently known from five localities in Napa county and Sonoma county (USFWS, 2009). The species is restricted to six localities in northwestern Napa County and eastern Sonoma County. Habitat destruction and modification due to urbanization and competition from invasive plant species pose the most significant threats to this species (USFWS, 2024).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2009)

**Breeding Season**
Adult: March - April (USFWS, 2009)

**Reproduction Narrative**
Adult: Flowers from March through April (USFWS, 2009).

**Habitat Type**
Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**
Adult: Manzanita and oak woodlands (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**
Adult: 75 - 225 m elevation (NatureServe, 2015)

**Environmental Specificity**
Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**
Adult: Openings in manzanita and oak woodlands, on thin, rocky clay soils derived from volcanic materials or on serpentine substrates. Occurs at 75 - 225 m elevation (NatureServe, 2015).

***Dispersal/Migration***

**Dispersal/Migration Narrative**
Adult: Not available

***Population Information and Trends***

**Population Trends:**
Not available

**Species Trends:**
Declining (NatureServe, 2015)

**Number of Populations:**
6 (USFWS, 2024)

**Population Size:**
>2,000 (USFWS, 2024)

**Population Narrative:**
Only about 500 total plants in normal year. This species is declining due to habitat modification (USFWS 1997) (NatureServe, 2015). Currently, three occurrences support fewer than 100 individuals (CNDDB 2008) (USFWS, 2009). The species is restricted to six localities in northwestern Napa County and eastern Sonoma County. Habitat destruction and modification

due to urbanization and competition from invasive plant species pose the most significant threats to this species (USFWS, 2024). In 2021, two Clara Hunt's milkvetch plants were found at the Bothe-Napa Valley State Park occurrence (Bjerke 2021, p. 3). The reappearance of Clara Hunt's milkvetch at this occurrence after its absence for over a decade may be attributed to the 2020 Glass Fire (Bjerke 2021, p. 2). The 2021 survey of the occurrence found that patches of habitat had burned at low intensity and most of the woody debris and herbaceous layer had been burned away in the immediate vicinity of the two Clara Hunt's milkvetch plants (Bjerke 2021, p. 2). The Saint Helena Road and Saddle Mountain/Hayfork Ranch occurrences were also within the perimeter of the 2020 Glass Fire (Watershed Emergency Response Team 2020, p. 20). The distribution of the species at both of these occurrences expanded the year following the fire (Bjerke in litt. 2024). All Clara Hunt's milkvetch plants observed at the Saint Helena Road occurrence in 2021 were found in areas that burned during the Glass Fire or that were bulldozed to create a fire break (Bjerke 2021, p. 4). A total of approximately 2,300 plants were observed at the Saddle Mountain/Hayfork Ranch occurrence the year following the fire (Bjerke 2021, p. 4). This is one of the largest population sizes recorded for the species (Bjerke 2021, pp. 3–4; Diversity Database 2024, entire). Fifty-three plants were counted on the Saddle Mountain Open Space Preserve and approximately 1,000–2,500 plants were present within the adjacent portion of the occurrence on Hayfork Ranch (Bjerke 2021, p. 3). The smaller, occupied area to the west on Hayfork Ranch was estimated to contain approximately 500 plants (Bjerke 2021, p. 4). In 2022 and 2023, the species was present at the Saint Helena Road and Saddle Mountain/Hayfork Ranch occurrences in similar densities, which were more abundant than prior to the Glass Fire (Bjerke in litt. 2024; Delmartini in litt. 2024) (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The loss and modification of habitat via development, recreational activities and uprooting by feral pigs continues to threaten this species, especially in areas where urbanization is expected to expand further. Three populations are located on private lands where potential development is not precluded; the general trend of habitat loss due to urbanization has continued and will likely continue at or adjacent to known populations (USFWS, 2009).

**Stressor:** Competition with introduced species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Centaurea solstitialis (yellow star-thistle) has infested the Lake Hennessey and Bale Grist Mill populations and threatens A. claranus via competition for resources. The threat posed by introduced species may become more sever with climate change. The Lewelling Lane population is threatened by competition from Genista monospessulana (French Broom) (CNDDB 1996). Based on its annual habit and size, it is thought that A. claranus has difficulty competing with introduced annual grasses (Howald, in litt. 2008) (USFWS, 2009).

**Stressor:** Community succession (USFWS, 2009)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Plant succession at Bale Grist State Historic Park is excluding or reducing the population of A. claranus (Ruygt 1994). Fire suppression has reduced fire frequency, allowing new manzanita seedlings to become established, which results in less space available for A. claranus (USFWS, 2009).

**Stressor:** Small population size (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Having few individuals leaves A. claranus susceptible to extirpation throughout a significant position of its range from random events and increases the threat of genetic drift and inbreeding. Therefore, this species is threatened with extinction or extirpation throughout a significant portion of its range due to random events such as flood, drought, disease, or other events (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** While the particular impacts of climate change on A. claranus have not been investigated, evidence suggests that the distribution of appropriate habitat elements (microclimate, community associations) may be altered in the coming decades resulting in a further decline of the species (USFWS, 2009).

**Stressor:** Pesticides (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Environmental Protection Agency (Agency) recently released final biological evaluations assessing the effects of labeled uses of three neonicotinoid pesticides on listed species (Agency 2022a, entire; Agency 2022b, entire; Agency 2022c, entire). The three pesticides (clothianidin, imidacloprid, and thiamethoxam) are registered for use on a variety of agricultural crops; there are also some non-agricultural applications. The three pesticides target insect species by acting on their neurotransmitters to cause excessive nervous stimulation, paralysis, and death. The overall importance of pollinating insects for Clara Hunt’s milkvetch is poorly understood (Ruygt 1994, p. 45; Department 2019, p. 5). However, bee pollination is a common mode of pollination in the milkvetch genus (Astragalus) (Watrous and Cane 2011, Table 1, pp. 228–229) and bees have been observed visiting Clara Hunt’s milkvetch plants (Liston 1992, p. 376). The Agency’s final biological evaluations determined that all three pesticides are highly toxic to bees, have the potential to result in bee brood and colony reductions, and if affected bee colonies decline near Clara Hunt’s milkvetch, there is a potential for the three pesticides to indirectly adversely affect the species (USFWS, 2024)

***Recovery***

**Reclassification Criteria:**

Not available - this species does not have a recovery plan.

Recovery Priority Number: 5C

**Delisting Criteria:**
Not available - this species does not have a recovery plan.

**Recovery Actions:**
- Not available - this species does not have a recovery plan.
- Complete a recovery plan for Astragalus claranus (USFWS, 2009).
- Develop habitat suitability model for Astragalus claranus and then project anticipated shifts in range and occurrences under various climate change scenarios (USFWS, 2009).
- Secure landowner agreements with property owners at the Lake Hennessey, Spring Valley, Lewelling Lane and St. Helena Road populations to facilitate the management of Astragalus claranus habitat to reduce or eliminate competition with introduced plant species and uprooting by feral pigs (at Lewelling Lane) (USFWS, 2009).
- Conduct three consecutive years of surveys at each of the five localities to better understand population sizes and inter-annual population fluctuations. Surveys should also include an assessment of current threats facing the A. claranus populations (USFWS, 2009).
- Work with California Department of Parks and Recreation at Bale Crist Mill State Historic Park to manage habitat (e.g., conduct introduced species control) near the A. claranus population in the park (USFWS, 2009).

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS Here we propose several habitat conservation and management recommendations which will aid in the recovery and conservation of the Clara Hunt's milkvetch. Some of these recommendations have already been discussed in previous Service recovery documents (Service 2009, p. 13; Service 2019, p. 2) or were identified during the Department's 5-Year Status Review of the species (Department 2019, p. 25) and remain valid. 1. Secure landowner agreements with property owners for the Lake Hennessey, Spring Valley, and Lewelling Lane occurrences to protect the occurrences from development and facilitate the management of Clara Hunt's milkvetch habitat to reduce or eliminate competition with introduced plant species and uprooting by feral pigs, if still an issue at Lewelling Lane. 2. Conduct annual demographic monitoring at all six localities. Monitoring surveys should also include an assessment of current threats facing the Clara Hunt's milkvetch at each locality. 3. Collect seeds from the Bothe-Napa Valley State Park and Saddle Mountain/Hayfork Ranch occurrences and request that the California Botanic Garden conduct seed viability tests on previously collected seeds. Seeds were collected from the other four occurrences of Clara Hunt's milkvetch in 2009 and are stored at the California Botanic Garden. 4. Work with California Department of Parks and Recreation at Bothe-Napa Valley State Park to manage habitat (e.g., vegetation removal, introduced species control, prescribed burns) occupied by Clara Hunt's milkvetch. If habitat management efforts do not result in growth and reproduction of the species, discuss the possibility of implementing population augmentation with the California Department of Parks and Recreation and the California Department of Fish and Wildlife. 5. Conduct coordinated research or adaptive management to identify effective habitat management techniques for maintaining Clara Hunt's milkvetch habitat (preventing community succession) and controlling invasive plant species. 6. In collaboration with the City of Napa, investigate ways to reduce impacts from recreational use, invasive species, and

remnant topsoil piles at the Lake Hennessey population (USFWS, 2024).

# SPECIES ACCOUNT: *Astragalus lentiginosus var. piscinensis* (Fish Slough milk-vetch)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; Pacific Southwest (R8) (USFWS, 2016) The Fish Slough milkvetch (Astragalus lentiginosus var. piscinensis) was originally listed on October 6, 1998 as threatened (63 FR 53596) and critical habitat was designated on June 9, 2005 (70 FR 33774). The Service completed a recovery plan that addresses the species (Service 1998), and a 5-year review in 2009 (Service 2009). In the 5-year review, the Service determined that no change was needed to the classification as threatened.

**Physical Description**

A perennial herb with a few hairy, branched, prostrate stems radiating from a central rootstock. Stems can be as long as 1 m and individual plants can occupy a 2.7 square m area. Leaflets are reduced to only two lateral pairs with an elongate terminal leaflet longer than the leaf stalk. The flowers, arranged in loose racemes, are pale lavender and number from 5 to 12 per inflorescence. Loose clusters of pale lavender flowers bloom in late spring. Fruits are brightly mottled, strongly inflated, leathery pods, with a complete septum and an incurved beak (USFWS 1998NatureServe, 2015). Fish Slough milk-vetch is distinguished from other varieties of Astragalus lentiginosus by its three to five linear-oblanceolate leaflets, and its densely strigose, strongly inflated pods (Barneby 1977).

**Taxonomy**

Astragalus lentiginosus var. piscinensis was described by Barneby (1977) based on a collection made by Mary DeDecker in 1974, from BLM Spring, Fish Slough, northwest of Bishop, California. Spellenberg (1993) retained this variety in his treatment of Astragalus for the Jepson Manual, and no other changes in taxonomic classification or nomenclature have been made since then. (USFWS, 2009) Dicot.

**Historical Range**

At the present, Astragalus lentiginosus var. piscinensis is restricted to the same range as it was at the time of listing, a 10 kilometer (6 mile) stretch of alkaline flats paralleling Fish Slough. The slough supports the species on less than 540 acres (219 hectares; USFWS 2009).

**Current Range**

Restricted to a 10-kilometer mile stretch of alkaline flats paralleling Fish Slough, Mono County, California. (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 6/9/2005.

**Legal Description**

On June 9, 2005, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Astragalus lentiginosus var. piscinensis (Fish Slough milk-vetch) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in California (70 FR 33774-33795).

**Critical Habitat Designation**

The critical habitat designation for Astragalus lentiginosus var. piscinensis includes one CHU Mono and Inyo Counties, California. In total, approximately 8,007 acres (ac) (3,240 hectares (ha)) fall within the boundary of the critical habitat designation (70 FR 33774-33795).

Mono Counties, California. From USGS 1:24,000 quadrangle maps Chidago Canyon and Fish Slough, California.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Astragalus lentiginosus var. piscinensis critical habitat consists of four components (70 FR 33774-33795):

(i) Alkaline soils that occur in areas with little or no slope, and which overlay a groundwater table that is 19 to 60 in (48 to 152 cm) below the land surface;

(ii) Plant associations dominated by Spartina-Sporobolis, or where a sparse amount of Chrysothamnus albidus occurs in the transition zone between Spartina-Sporobolis and Chrysothamnus albidus-Distichlis plant associations;

(iii) The presence of pollinator populations for Astragalus lentiginosus var. piscinensis; and

(iv) Hydrologic conditions that provide suitable periods of soil moisture and chemistry for Astragalus lentiginosus var. piscinensis germination, growth, reproduction, and dispersal.

**Special Management Considerations or Protections**

The SBNF is planning a revision of their Resource Management Plan in the near future that, among other functions, would provide conservation benefits to the two carbonate plant species and their habitat in this unit. These lands, however, currently do not have approved management provisions for the carbonate plants and their habitat, and habitat degradation may still be occurring due to ongoing activities identified in the final listing rule for these species (see USFWS 2001b). Therefore, the subject lands continue to require special management and protection to ensure the conservation of these species and their habitat. The core occurrences of the two carbonate plants in this unit are important as potential sources for the colonization events (e.g., seed dispersal) necessary to maintain the natural population dynamics of the species. Every carbonate plant occurrence in this unit is important as a seed source to colonize unoccupied sites and therefore maintain an equilibrium between local colonization and extirpation events. Every carbonate plant occurrence in this unit potentially provides important genetic material through pollen and seed dispersal which may help maintain genetic diversity and reduce the likelihood of regional extirpation events.

When designating critical habitat, we assess whether the physical and biological features determined to be essential for conservation may require special management considerations or protection. As we undertake the process of designating critical habitat for a species, we first evaluate lands defined by those physical and biological features essential to the conservation of the species for inclusion in the designation pursuant to section 3(5)(A) of the Act. Secondly, we then evaluate lands defined by those features to assess whether they may require special management considerations or protection. In 1982, BLM established the Fish Slough ACEC in an effort to provide protection for the federally endangered Owens pupfish, several rare plant taxa including Astragalus lentiginosus var. piscinensis, and the wetland and riparian habitats upon which these species depend. The Fish Slough ACEC has three zones (BLM 1984). The designated critical habitat unit is predominantly located within Zone 1 of the ACEC, includes a very small portion of Zone 2, and also extends slightly beyond the southern boundary of the ACEC. The land in Zone 1 is owned by BLM, CDFG, LADWP, and one private landowner. The portion of the designated critical habitat unit in Zone 2, or in the area immediately south of the ACEC, is owned by BLM or LADWP. A management plan for the ACEC was finalized in 1984, but the plan has not been revised since it was completed. Previously identified threats to Astragalus lentiginosus var. piscinensis include the presence of roads, effects related to the use of OHV, effects related to cattle grazing, and effects from herbivory by native vertebrates and insects (Service 1998). A potential threat to A. l. var. piscinensis not previously identified in other documents includes competition with, or displacement by, nonnative plant species (P. Hubbard, LADWP, pers. comm. 2003). The modification of wetland habitats that results from groundwater pumping or water diversion activities altering the surface and underground hydrology of Fish Slough is also a threat to the species (Service 1998). The suite of threats affecting Astragalus lentiginosus var. piscinensis is complex. The establishment of the Fish Slough ACEC has helped provide some benefit for A. l. var. piscinensis by coordinating the activities of staff from BLM, LADWP, and CDFG on various land management challenges that exist in the local area. Because the long, narrow configuration of the slough is bounded by upland habitat, the amount of alkaline habitat that can be occupied by A. l. var. piscinensis is limited. Ferren (1991b) summarizes threats to botanical resources at Fish Slough, noting that those threats related to the enhancement of fisheries (construction of ponds, impoundments, roads, and ditches) may have had the greatest effect on the Fish Slough ecosystem because they modified the hydrological conditions that historically occurred in Fish Slough. In the central portion of the slough, Fish Slough Lake appears to have expanded in size between 1944 and 1981. This increase may be due to natural geologic subsidence, the construction of Red Willow Dam, or the construction of water impoundments by beavers. The increase in aquatic habitat has likely resulted in the loss of alkaline habitat for Astragalus lentiginosus var. piscinensis as soils near the lake are now saturated for greater portions of the year (Ferren 1991c). Some earthquake events in Chalfant Valley appear to have resulted in decreases in spring discharge or changes in local water table levels (Brian Tillemans, LADWP, pers. comm. 2000), thereby making it more difficult to clearly understand the nature of the local aquifer. Modifications to the slough environment from changes in the local hydrology are not well understood or easily reversed. These factors, in combination with essential data gaps that include, but are not limited to, a more thorough understanding of the ecology and habitat requirements of the species, have made it difficult for local land managers to understand and reverse the decline in the number of A. l. var. piscinensis within the ACEC over he past decade. A downward trend in the species' abundance during the past decade suggests that, despite the ongoing efforts by the relevant land management agencies, additional factors need to be addressed to reverse the decline in the status of A. l. var. piscinensis. We believe that the designated critical habitat unit may require special management considerations to maintain the identified primary constituent elements. These include the potential need to respond to the following: (1) Activities that have the potential to change the hydrology of Fish Slough and adversely affect the survivorship, seed germination, growth, or photosynthesis of Astragalus lentiginosus var. piscinensis, unless such activities are designed and have the effect of recreating the historic environmental conditions that existed in Fish Slough; (2) Activities that have the potential to adversely affect the suitability of alkaline areas that could provide habitat for Astragalus lentiginosus var. piscinensis including, but not limited to, OHV use, levels of cattle grazing that could result in increased soil compaction, road construction and maintenance activities, and water diversion activities; (3) Activities that have the potential to modify the species composition, character, or persistence of the native plant associations that are associated with Astragalus lentiginosus var. piscinensis; (4) Activities that could adversely affect the insect pollinators that inhabit the native upland desert scrub community that is adjacent to alkaline habitats in Fish Slough, including, but not limited to, livestock grazing at levels that would increase soil compaction, use of heavy-wheeled vehicles or OHVs (including motorcycles and all terrain vehicles), pesticide use, and incompatible recreational activities; and (5) Management activities, particularly those that involve cattle grazing and road maintenance, which have the potential to introduce new nonnative plant species that may compete with or displace Astragalus lentiginosus var. piscinensis.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 1998). Astragalus lentiginosus var. piscinensis cannot self-pollinate; therefore, seed production is dependent on cross-pollination (Mazer and Travers 1992).

**Lifespan**

Adult: 15 to 35 years; median of 10 years (USFWS, 2009)

**Dependency on Other Individuals or Species**

Adult: the most likely pollinators (based on records of pollinators on other Astragalus) include bumble bees, leafcutting and mason bees (Megachilidae: Anthidium spp., Hoplitis spp., Osmia spp., Megachile spp.), non-corbiculate (no pollen basket on hind tibia) Apidae (Anthophorinae, Eucerini: Melissodes spp., Synhalonia spp., and Anthophorini: (Anthophora spp., Habropoda spp.), and Andrenidae (Thorp in litt. 2004). (USFWS, 2009)

**Breeding Season**

Adult: Late spring (USFWS, 2009)

**Reproduction Narrative**

Adult: Astragalus lentiginosus var. piscinensis cannot self-pollinate; therefore, seed production is dependent on cross-pollination (Mazer and Travers 1992). Although specific pollinators of A. lentiginosus var piscinensis have not been studied, the most likely pollinators (based on records of pollinators on other Astragalus) include bumble bees, leafcutting and mason bees (Megachilidae: Anthidium spp., Hoplitis spp., Osmia spp., Megachile spp.), non-corbiculate (no pollen basket on hind tibia) Apidae (Anthophorinae, Eucerini: Melissodes spp., Synhalonia spp., and Anthophorini: (Anthophora spp., Habropoda spp.), and Andrenidae (Thorp in litt. 2004). Astragalus lentiginosus var. piscinensis is an herbaceous perennial that produces relatively few seeds with narrow germination requirements and low probability of dispersal. Seed scarification is essential for seed germination. The potential life span is estimated at 15 to 35 years, but median life span appears to be about 10 years. (USFWS, 2009) Fish Slough milk-vetch may grow as much as 30 cm (12 in.) per month during its growing season, which lasts from May to September. Flowering usually begins in late spring and bumblebees (Bombus sp.) are the only flower visitors that have been identified. Fruit is typically set in June and July. Pollinator exclusion experiments demonstrated that Fish Slough milk-vetch is not self-fertilizing. Reproductive output is correlated with plant size and differs between colonies in the north and middle areas o fFish Slough. Grazing of flowering and fruiting branches by jackrabbit (Lepus californicus) and rodents reduced reproductive output during the study period (Mazer and Travers 1992).

**Habitat Type**

Adult: Terrestrial and palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Alkali flats (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: The establishment, survival, and growth of juvenile Fish Slough milkvetch plants are strongly influenced by hydrologic conditions at specific sites (Service 2009). Water table level is of ecological importance to Fish Slough milkvetch. Under experimental conditions, this taxon's physiological performance, growth, and fecundity (seed mass, seed production per plant) are limited by hydric soils in excess of approximately 40 percent water content per volume. The taxon's net photosynthetic rates, growth rates, and seed mass were highest in areas of slough habitat where early season (May-June) water table depths exceeded approximately 11.8 in (30 cm) (Murray and Sala 2003). Studies have also indicated that the growth and survival of Fish Slough milkvetch in relatively nitrogen-limited alkali flat habitats are related to the acquisition of biologically fixed nitrogen (root symbiotic bacteria).

**Geographic or Habitat Restraints or Barriers**

Adult: Found along borders of a slough but not in lower wetter habitats (USFWS, 2009)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2009; NatureServe, 2015)

**Site Fidelity**

Adult: High (USFWS, 2009)

**Habitat Narrative**

Adult: Ferren (1991) and Odion et al. (1991) characterized Fish Slough soils and plant communities and provided information about the habitat of Fish Slough milk-vetch. This taxon occurs in the alkali flats in Spartina-Sporobolus plant associations and in the transition zone between Spartina-Sporobolus and Distichlis-Chrysothamnus plant associations described by Odion et al. (1991). It is frequently found with alkali ivesia (Ivesia kingui var. kingui) but rarely in wetter alkali habitats (USFWS 1998).

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 2009)

**Dispersal/Migration Narrative**

Adult: The seeds have narrow germination requirements and low probability of dispersal. (USFWS, 2009)

***Population Information and Trends***

**Population Trends:**

results suggest an increase in populations, however it is unclear how survey effort may be affecting census numbers (USFWS 2018).

**Resiliency:**

Low (inferred from USFWS, 2009)

**Representation:**

Low (inferred from USFWS, 2009)

**Redundancy:**

Low (inferred from USFWS, 2009)

**Number of Populations:**

7 (USFWS 2009)

**Population Size:**

9,131 individuals (USFWS 2018)

**Additional Population-level Information:**

Harrison et al 2019 found that the three regions are genetically distinct. The range of Astragalus lentiginosus var. piscinensis within Fish Slough is divided into seven zones across three regions. These regions and their zones are as follows: northern region (Zones 6 and 7), middle region (Zones 1 [a and b] and 5), and southern region (Zones 2, 3, and 4). Plants in the northern region of Fish Slough are entirely on Los Angeles Department of Water and Power (LADWP) lands, while those in the middle and southern regions are on lands managed by both LADWP and BLM (See Figure 1.) Censuses of the populations have occurred in 1992, 2000, 2008, and 2016. Results of these surveys are provided in Table 1. Data for 2008 and earlier is the same as presented in the 2009 5-year review. Census methods have combined data for adult and juvenile plants and early census efforts did not collect seedling data. (USFWS, 2022)

**Population Narrative:**

The first comprehensive assessment of the abundance and distribution of Astragalus lentiginosus var. piscinensis was conducted in 1992. At that time, zones (also called colonies) were identified to delineate occupied and/or suitable habitat There are seven zones within three regions located across the range of Astragalus lentiginosus var. piscinensis. These regions and their zones are as follows: Northern Region (Zones 6 and 7), Middle Region (Zones 1 (a and b) and 5), and Southern Region (Zones 2, 3, and 4). Plants in the northern region of Fish Slough are entirely on LADWP lands while those in the middle and southern regions are on lands managed by both LADWP and BLM. The Northern Region contains the largest percentage of the Astragalus lentiginosus var. piscinensis population whereas the Southern Region has the lowest. Similar surveys were conducted in 2000, 2008, and 2016, which identified seven colonies grouped in three regions. Results of these surveys are provided in Table X. Table X. Number of adult and juvenile Astragalus lentiginosus var. piscinensis counted during each census (modified from Service 2018). Year Region Total Number of Plants (Adults and juveniles) Northern Middle Southern 1992 1,993 1,076 94 3,163 2000 717 747 79 1,543 2008 3,299 1,063 131 4,493 2016* 6,274 2,783 74 9,131 *The survey conducted in 2016 was not a true census since the survey did not cover the entire range of the species. The fewest plants were observed in 2000 and the most were observed in 2016. There is little to no information from the previous censuses to compare how survey effort may have varied over time (Service 2018). Survey effort affects ability to accurately compare population counts across years.

***Threats and Stressors***

**Stressor:** Grazing (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the listing rule we noted that grazing that began in the 1860s was ongoing on all LADWP lands except in the northern 80 ac (32 ha) exclosure (63 FR 53608). Over time, trampling by livestock has the potential to alters the composition of the plant community by reducing or eliminating those that cannot tolerate trampling and increasing those species that tolerate disturbance. This may also introduce taxa that were not previously part of the native plant community. (USFWS, 2009)

**Stressor:** Alteration of habitat- hydrology and non-native plants (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Past modifications to Fish Slough hydrology include creation of dams and weirs in the main channel of Fish Slough, construction of a dirt road through milkvetch habitat, and soil compaction and trail creation by cattle. These activities have altered hydrology by causing an increase in permanently flooded habitats, artificial ponding, alteration in drainage patterns, and changes in seasonal flooding of milkvetch habitat (Service 1998a). Recovery actions for Owens pupfish that elevate groundwater levels also reduce habitat suitability for Fish Slough milkvetch. Ferren and Davis (1991b) summarized impacts to botanical resources at Fish Slough, noting that those related to the enhancement of fisheries (construction of ponds, impoundments, roads, and ditches) have resulted in the greatest losses to the milkvetch's specific alkali habitats. IN addition, impacts to groundwater that affect spring flow feeding spring springs around Fish Slough and thus the Slough itself (such as those discussed in Zdon et al. 2020) may result in changes to hydrologic conditions needed by the species. Undesirable plant species may be introduced and flourish under disturbance caused by grazing or other sources. Their presence may reduce or eliminate Fish Slough milkvetch through competition for resources (Service 1998a, 2009). Undesirable plant species such as perennial pepperweed are a threat to Fish Slough milkvetch (USFWS, 2009).

**Stressor:** Herbivory (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Herbivory remains a threat to Astragalus lentiginosus var. piscinensis. Seedling herbivory remains a threat to recruitment of new individuals. Field observations suggest that several factors (herbivory, seed germination requirements, seedling establishment, and interspecific competition) interact, placing constraints on Astragalus lentiginosus var. piscinensis survival (Murray and Sala 2003). Infestations of vegetative parts and root systems by phloem-sucking insects and red ants, respectively, and high rabbit herbivory were all reported for individuals of Astragalus lentiginosus var. piscinensis in the middle region of Fish Slough by Mazer and Travers (1992). (USFWS, 2009)

**Stressor:** Lack of recruitment (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, the Service noted that lack of recruitment was a potential threat to Astragalus lentiginosus var. piscinensis. Potential causes cited in the rule were high rabbit/rodent herbivory of seedlings (discussed in Factor C) and changes in soil hydrology or chemistry that make the area less hospitable for seedlings (63 FR 53608). We also discussed the threat of livestock grazing under Factor E of the rule. However, Factor A (which would include alteration in habitat due to cattle grazing) and Factor C (which would include grazing of individual Astragalus plants) are more appropriate. Data on numbers of individuals of A. lentiginosus var. piscinensis, collected from plots in cattle-grazed or trampled and ungrazed areas of Fish Slough from 1991 to 1996, suggest that some recruitment was occurring in both the grazed and ungrazed sample areas. Because the alkali meadow habitat that A. lentiginosus var. piscinensis occupies is likewise moist, cattle may facilitate the establishment of new individuals. (USFWS, 2009)

**Stressor:** Seismic activity (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fish Sough was created recently by geologic events. Although not mentioned in the listing rule, seismic activity leading to changes in hydrology have and will likely continue to have significant effects on the distribution and extent of water availability in Fish Slough and will influence the distribution and viability of Astragalus lentiginosus var. piscinensis habitat (Halford in litt. 2007). (USFWS, 2009) Seismic instability at the Northeast Spring area of Fish Slough was demonstrated in 1986 when an earthquake occurred and changed spring seep patterns.(USFWS, 2009)

**Stressor:** Small population size (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Astragalus lentiginosus var. piscinensis may be vulnerable to extirpation by stochastic factors including demographic stochasticity, environmental stochasticity, and genetic stochasticity (Shaffer 1981). Demographic stochasticity refers to random variability in survival or reproduction among individuals within a population (Shaffer 1981), and could play a role in the extirpation of small populations of A. lentiginosus var. piscinensis. Environmental stochasticity is the variation in birth and death rates from one season to the next in response to weather,

disease, competition, predation, or other factors external to the population (Shaffer 1981), and this could also play a role in extirpations of small populations. Genetic stochasticity results from the changes in gene frequencies due to founder effect, random fixation, or inbreeding (Shaffer 1981). The naturally disjunct distribution of A. lentiginosus var. piscinensis decreases genetic variation within the population, which could impair the species' ability to adapt to changes in the environment or contribute to inbreeding depression (i.e., loss of reproductive fitness or vigor). Small population size makes it difficult for A. lentiginosus var. piscinensis to persist while sustaining the impacts of high seedling herbivory rates and changes in soil hydrology or chemistry that make the area less hospitable for seedlings; while impacts from cattle grazing have been reduced, they still remain a concern, exacerbating concerns about the risks associated with small population size. (USFWS, 2009)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change was not discussed at the time of listing. Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). Recently, the potential impacts of climate change on the flora of California were discussed by Loarie et al. (2008). Based on modeling, they predicted that species' distributions will shift in response to climate change and that the species will "move" or disperse to higher elevations and northward, depending on the ability of each species to do so. Increases in species diversity in these higher elevations and northern locations due to climate change have the potential to result "…in new species mixes, with consequent novel patterns of competition and other biotic interactions…" with unknown consequences to the species which currently exist there (Loarie et al. 2008). While we lack adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors such as small population size, will affect Astragalus lentiginosus var. piscinensis; small ranged species, such as Astragalus lentiginosus var. piscinensis, are more vulnerable to extinction due to these changing conditions (Loarie et al. 2008). (USFWS, 2009)

**Stressor:** Roads and off highway vehicles
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The use of motorized off-road vehicles and the presence of roads have affected habitat occupied by Astragalus lentiginosus var. piscinensis. Approximately 19 mi (30.6 km) of roads exist within 3,280 ft (1,000 m) of the alkaline habitats within Fish Slough. South of BLM Spring, on the east side of the slough, a road bisects one cluster of the listed plants, and off-road vehicle use in the central portion of the slough has been documented (Novak 1992). Soil compaction and topographic changes resulting from road presence and off-road vehicle activity can affect soil moisture regimes in Fish Slough, and potentially result in changes in seasonal inundation patterns that may adversely affect A. l. var. piscinensis. Roads through upland areas in Fish Slough also create increased levels of human visitation that would otherwise be unlikely if roads were absent. Roads have been associated with negative impacts that alter the biotic integrity of both terrestrial and aquatic habitats (Trombulak and Frissell 2000). A growing body of published literature indicates that vehicular traffic along road networks in terrestrial habitats

increases the likelihood that non-native plant seeds will be introduced into areas where they were previously absent (Wace 1977; Schmidt 1989; Lonsdale and Lane 1994). Some of the non-native plant species in Fish Slough (e.g., five hook bassia (Bassia hyssopifolia)) are identified as pest plants of ecological concern (CalEPPC 1999) and have the potential to invade and degrade the quality of alkaline habitats and compete with Astragalus lentiginosus var. piscinensis.

**Stressor:** Pesticides
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Pesticides have the ability to directly affect the species and its pollinators.

**Stressor:** Groundwater Conditions (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** There have been documented declines in spring flows that support Fish Slough and its vegetation communities since the 1920s, which may be related to increased groundwater pumping in the neighboring valleys referred to as the Tri-Valley area (Service 2005, CDFW 2020, Owens Valley Groundwater Authority [OVGA] 2021). The Tri-Valley area includes the Benton Valley approximately 20 miles (32 kilometers) north, Hammil Valley 9 miles (14 kilometers) north, and the Chalfant Valley approximately 2 miles (3 kilometers) to the northeast of Fish Slough. These three valleys in addition to Fish Slough make up the service area of the Tri-Valley Groundwater Management District. In California, groundwater withdrawal must be managed and monitored in those basins that have been adjudicated or are required to develop and implement a Groundwater Sustainability Plan (GSP) under the Sustainable Groundwater Management Act (SGMA; SB 1168, SB 1319, and AB 1739, effective January 1, 2015). The Tri-Valley area is the northernmost extension of the Owens Valley groundwater basin and Fish Slough is identified as a subbasin (California Department of Water Resources 1975). Because the aquifer in the Tri-Valley area has not been adjudicated and is part of a basin that has been classified as low-priority under SGMA, groundwater withdrawals in this basin are not currently subject to limits pursuant to a court decree or GSP. (USFWS, 2022)

**Stressor:** Genetic stochasticity (USFWS, 2022)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In our 2009 5-year review, we stated that because of its small population size, Fish Slough milkvetch is vulnerable to genetic stochasticity. Lack of genetic diversity impairs the species' ability to adapt to changes in its environment and contributes to inbreeding depression (i.e., loss of reproductive fitness and vigor). However, Harrison et al. 2019 completed genetic analyses on A. lentiginosus. var. piscinensis and found that the three regions of Fish Slough (northern, middle, and southern) came out as three genetically distinct groups, despite being spatially proximate (less than 1 kilometer between regions). Harrison et al. (2019) hypothesized that the genetic grouping is due to habitat-associated local adaptation, specifically due to differences in soil composition across Fish Slough. They recommended that genetic structure be considered for any outplanting efforts and greenhouse studies be conducted to better understand species' responses to various soil conditions. In addition, Harrison et al. (2019) found

low levels of inbreeding and suggested this may be due to larger effective populations sizes than other A. lentiginosus varieties. They also noted that Mazer and Travers (1992) thought that A. lentiginosus rarely self -pollinates and that insect pollination would likely facilitate increased genetic variation. All that being said, the spatial extent of the species remains small and thus stochastic events that decrease population size could result in genetic bottleneck effects in the future. (USFWS, 2022)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 9

**Delisting Criteria:**
1. The Fish Slough vegetation communities [specifically for Astragalus lentiginosus var. piscinensis] are restored and are being managed to maintain conditions such as those described in the Natural Resources Conservation Service (NRCS) Ecological Site Descriptions, the Bureau of Land Management’s (BLM) Desired Plant Community Definitions for springs and wet meadows, and the guidelines for riparian zone proper functioning condition. (USFWS, 2009)

2. Colonies in the north, middle and south regions of the slough are secured from the negative effects of invasive nonnative species, livestock grazing and other human induced threats. (USFWS, 2009)

3. Recruitment of new individuals into the populations and other demographic factors appear sufficient to ensure viability over time as determined by monitoring over a 10 to 15-year period. (USFWS, 2009)

4. Unless research and monitoring show otherwise, population targets for juvenile and adult plants should be a minimum of 2,100 plants in the northern region of Fish Slough, 1,200 in the middle region of Fish Slough and 105 plants in the southern region of Fish Slough; these targets assume that habitat restoration will increase carrying capacity beyond the 1992 levels. (USFWS, 2009)

**Recovery Actions:**
- Needed recovery actions include protection of spring discharges, modification of livestock grazing to ensure that its habitat is not being degraded, restoration of previously suitable habitat that no longer supports the milk-vetch, removal and control of nonnative species and other threats that may arise, protection of lands on which the milk-vetch occurs through a conservation easement or other permanent mechanism, and research to determine its critical life history and habitat components and how these are affected by management actions. Continued monitoring will also be needed. (USFWS, 1998)
- CDFG, BLM and LADWP should work to lower water levels by regulating flow in Fish Slough Lake and monitor Astragalus lentiginosus var. piscinensis recruitment results. (USFWS, 2009)
- BLM should study the benefits of soil disturbances on Astragalus lentiginosus var. piscinensis recruitment. (USFWS, 2009)

- BLM should continue with propagation and out-planting projects to enhance recruitment. (USFWS, 2009)
- BLM should study the extent and population impacts of herbivory and ant colony infestations on Astragalus lentiginosus var. piscinensis recruitment. (USFWS, 2009)
- The Service should work with LADWP to develop and implement a grazing plan for LADWP cattle allotment lands within the Fish Slough ACEC. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- • Conduct annual monitoring of A. lentiginosus var. piscinensis. If negative effects from activities are detected, take corrective action. • Ensure grazing leasees operating in areas with A. lentiginosus var. piscinensis are aware of this federally-listed species and measures that can help to minimize impacts from grazing such as adjusting season of use, stocking rates, and careful placement of supplements • Implement appropriate rest/rotation grazing to allow for seed maturity and seed set and to reduce trampling of plants. • Conduct a robust analysis of the impacts of grazing on A. lentiginosus var. piscinensis ; report outcome of analysis to partners. • If using herbicides in A. lentiginosus var. piscinensis occupied habitat, implement measures to avoid chemical contact with this species. These measures include using licensed applicators; follow all label directions, warnings, and precautions to avoid surface runoff and drift; using backpack sprayers or wicking applicators (rather than broadcast spraying); avoiding spraying in/near known locations of milkvetch plants to avoid direct spray and drift; and conducting spot treatments of weeds to confine the area sprayed to the smallest possible area to avoid A. lentiginosus plants and their pollinators.
- Fish Slough Area of Critical Environmental Concern has been established that includes much of the species habitat.
- CDFG, BLM and LADWP should work to lower water levels by regulating flow in Fish Slough Lake and monitor Astragalus lentiginosus var. piscinensis recruitment results. (USFWS, 2009)
- BLM should study the benefits of soil disturbances on Astragalus lentiginosus var. piscinensis recruitment. (USFWS, 2009)
- BLM should continue with propagation and out-planting projects to enhance recruitment. (USFWS, 2009)
- BLM should study the extent and population impacts of herbivory and ant colony infestations on Astragalus lentiginosus var. piscinensis recruitment. (USFWS, 2009)
- The Service should work with LADWP to develop and implement a grazing plan for LADWP cattle allotment lands within the Fish Slough ACEC. (USFWS, 2009)
- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Improve the monitoring approach to be able to assess population trend and recruitment rates and to document progress toward meeting other recovery criteria, including restoration and maintenance of the vegetation community, achieving proper functioning condition of springs and riparian areas, and documenting/reducing threats such as invasive species, grazing, and groundwater pumping. 2. The RFWO and recovery partners may consider the need to re-evaluate the recovery criteria for population goals as outlined in the Recovery Plan (Service 1998) based on any modifications to the monitoring approach and best available science. Developing recovery benchmarks based on current threats to the species, the three R’s (resiliency, redundancy, and representation), and the best available science will accurately represent recovery (Smith et al. 2018, entire). 3. Continue investigations of surface and groundwater patterns and structure within and around Fish Slough to understand future impacts on Fish Slough and Fish Slough milkvetch from groundwater pumping and climate change. 4. Continue implementation of recovery tasks as outlined in the 1998 recovery plan and 2009 5-year review (Service 1998b, 2009). (USFWS, 2022)

# SPECIES ACCOUNT: *Astragalus phoenix* (Ash meadows milk-vetch)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 5/20/1985; Pacific Southwest Region (R8) (USFWS, 2015)

**Physical Description**

A low, mat-forming perennial herb; mats up to 5 dm in diameter. Purple flowers are borne on tiny erect stems from April to early May (NatureServe, 2015).

**Taxonomy**

A member of the Fabaceae (pea family) (USFWS, 2009).

**Historical Range**

This species is endemic to the Ash Meadows area of Nye County, Nevada (USFWS, 2009).

**Current Range**

Occurs in a 7 x 3 mile area in Ash Meadows, Nye Co., Nevada (NatureServe, 2015). The range of the species encompasses the Ash Meadows National Wildlife Refuge and adjacent Bureau of Land Management and private lands (USFWS, 2009).

**Critical Habitat Designated**

Yes; 5/20/1985.

**Legal Description**

On May 20, 1985, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Astragalus phoenix (Ash meadows milk-vetch) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Nevada (50 FR 20777-20794).

**Critical Habitat Designation**

The critical habitat designation for Astragalus phoenix includes one CHU in Nye County, Nevada (50 FR 20777-20794).

Nevada, Nye County, Ash Meadows.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Astragalus phoenix critical habitat consists of one component (50 FR 20777-20794):

Known primary constituent elements include dry, hard, white, barren, saline, clay flats, knolls, and slopes.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Self-fertilization (USFWS, 2009)

**Lifespan**

Adult: Unknown, presumed > 10 years (USFWS, 2009)

**Dependency on Other Individuals or Species**

Adult: Probably Anthophora porterae (USFWS, 2009)

**Key Resources Needed for Breeding**

Adult: Winter and early spring rains (USFWS, 2009)

**Reproduction Narrative**

Adult: Flowers are present from April to early May (Reveal 1979, pp. 2 - 4 and 14 - 15). The biology and life history of the Ash Meadows milkvetch are consistent with a stress-tolerant life history as described by Grime (1977, pp. 1175 - 1181; 1984, pp. 29 - 33). Stress-tolerant plants are typically relatively long-lived with low annual seed production, except during favorable conditions (Grime 1977, pp. 1174 and 1180). Reveal notes winter and early spring rains are required to produce large numbers of flowers, but some flowering probably occurs each year regardless of conditions. During a year with above average precipitation, seed production was estimated to be between 45 and 246 fully formed seeds per average size plant. An examination of the seed to ovule ratio in mature fruits suggested that the ash Meadows milkvetch is an inbreeding species with no pollinator limitations (Pavlik et al. 2006, p. 29). More recent studies indicate that it is visited by a bee (Anthophora porterae) that is likely a vital pollinator for the species (Bio-West 2009, pg 3). Germination events and seedlings are rare (Reveal 1978, p. 12). The lifespan of individual pants is not known, but is believed to exceed 10 years (USFWS, 2009).

**Habitat Type**

Adult: Terrestrial, wetland, spring (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Desert wetland (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: 2,200 - 2,300 ft. elevation (USFWS, 2009)

**Environmental Specificity**

Adult: Very narrow (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: High (inferred from USFWS, 2009; see reproduction narrative)

**Habitat Narrative**

Adult: Occurs on dry, hard, white, barren flats, washes, and knolls of calcarious alkaline soils at Ash Meadows - a desert wetland ecosystem maintained by several dozen springs and seeps (NatureServe, 2015). Given the presence of salt crusts and occurrence of halophytes, it is likely that Ash Meadows milkvetch has adaptations that allow it to tolerate saline soils. It grows between 2,200 and 2,300 feet above sea level. Surface and/or subsurface groundwater that reaches the surface through capillary action may be an important habitat determinant for at least some populations (USFWS, 2009).

***Dispersal/Migration***

**Dispersal**

Adult: Low (USFWS, 2009)

**Dispersal/Migration Narrative**

Adult: Wind and water appear to be the primary vectors for dispersal (Reveal 1978, p. 12). Reveal (1978, p. 14) observed much of the seed produced probably does not disperse long distances and remains within the leaves and branches of the parent plant (USFWS, 2009).

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Improving (USFWS, 2009)

**Number of Populations:**

12 (USFWS, 2020)

**Population Size:**

~15,606 (USFWS, 2020)

**Population Narrative:**

At the time of listing, it was estimated that there were 1,000 Ash Meadows milk-vetch individuals (Reveal 1978). In 2001, the Ash Meadows milk-vetch population was estimated to be approximately 1,943 individuals (Morefield 2001). Results from the 2008–2010 Refuge-wide rare plant survey estimate that 15,606 individuals are present on the Refuge (Table 1; BIOWEST 2011). Distribution of Ash Meadows milk-vetch is provided in Figure 1. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Groundwater pumping (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species depends, in part, on near-surface water for its survival. Although the Service has established water rights to 96% of the spring discharge within the Refuge, the Service will have to demonstrate through analyses that the net impact of any change applications will have a negative effect on Ash Meadows. To the extent that the Service is unsuccessful in demonstrating net negative impacts in at least some of these cases, additional incremental declines in spring discharge may occur at Ash Meadows. Such incremental declines could be difficult to attribute to any particular cause after the fact and, therefore, would be difficult to remedy (USFWS, 2009).

**Stressor:** Surface mining (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The playa sediments covering much of the ash Meadows area contain clays and other minerals, which may be considered "uncommon varieties", and therefore could potentially be classified as "locatable minerals" under existing mining laws. New mineral claims and subsequent mining could cause direct loss of Ash Meadows milkvetch habitat, as well as indirect impacts by diverting or draining water away from occupied habitat. About 80% of the known occurrences of Ash Meadows milkvetch within the Refuge are open to mineral entry (USFWS, 2009).

**Stressor:** Nonnative species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Over 100 nonnative species occur on the Refuge. Of these, salt cedar, Russian knapweed, five hook bassia, Malta star thistle, yellow star thistle, and hoary cress are noxious weeds that could potentially threaten the Ash Meadows milkvetch (Service 2006, p. 8). Cheatgrass, red brome, Mediterranean grass, and annual fescue are annual grasses that could potentially threaten the Ash Meadows milkvetch (USFWS, 2009).

**Stressor:** Rabbit herbivory (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** During a demographic study initiated in the spring of 2005, Pavlik et al. (2006, p. 9) found that a very high proportion of developing fruits had been clipped off at the pedicel and eaten by rabbits. They found an 80% loss of potential reproductive output across all subpopulations. Herbivory poses no short-term threat to Ash Meadows milkvetch because individual plants are long-lived, but the significance of any threat posed by rabbits to its persistence over the foreseeable future is poorly understood (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
1. All non-native animals and plant species must be eradicated for essential habitat. These non-native species currently include sailfin mollies, mosquito fish, largemouth bass, black bullheads, bullfrogs, crayfish, turban snails, wild horses, salt cedar, and Russian olive (USFWS, 2009).

2. Secure and protect the Ash Meadows aquifer so that all spring flows return to historic discharge rates, and the water level in Devils Hole is maintained at a minimum level of 1.4 feet below the copper washer (USFWS, 2009).

3. Reestablish water to historic springbrook channels, which are free of barriers that eliminate genetic exchange between populations by preventing movement of native fishes throughout their historic range (USFWS, 2009).

4. The essential habitat must be secure from detrimental human disturbance including mining, OHVs, and the introduction of non-native species (USFWS, 2009).

Recovery Priority Number: 8

**Delisting Criteria:**
1. Criteria shown above for downlisting from endangered to threatened (USFWS, 2009).

2. Secure, protect, and maintain in natural vegetation, corridors, and adjacent buffer areas for gene flow and dispersal of listed plant species within the essential habitat (USFWS, 2009).

3. Native plant communities and aquatic communities have been reestablished to historic structure and composition within all essential habitats (USFWS, 2009).

4. All of the listed plant species and the candidate plant species are present in all the sites that they have historically occupied as identified in Appendix A Table XV of the Recovery Plan. Within each critical habitat unit, the listed plant has a frequency value equal to or greater that the frequency value determined by Task 644 needed as an indicator of a self-sustaining plant population (USFWS, 2009).

**Recovery Actions:**
- Secure habitat and water sources for the Ash Meadows ecosystem (USFWS, 1990).
- Conduct research on the biology of the species (USFWS, 1990).
- Conduct management activities within essential habitat (USFWS, 1990).
- Reestablish populations/monitor new & existing populations (USFWS, 1990).
- Determine/verify recovery objectives (USFWS, 1990).
- Over the next five years, the Service should focus on clarifying or resolving the uncertainties regarding the significance of the remaining threats to Ash Meadows milkvetch, i.e., groundwater pumping, surface mining, and herbivory (USFWS, 2009).
- The Service anticipates that major issues with respect to the significance of the threat posed by groundwater pumping will become clear over the next five years. Specifically, we expect that the Nevada State Engineer will clarify how Order 1197 will be implemented. In addition, environmental analyses will likely be completed on the anticipated effects of at least some of the proposed solar energy projects, and these should include detailed assessments of the potential effects of any groundwater development requirements on the regional and local aquifers, including potential effects on the springs and groundwater table within the Refuge. The Service should participate in the review of these analyses to ensure that they adequately disclose all potential impacts that could affect Ash Meadows milkvetch. The Service will also continue its participation in interagency monitoring, modeling, and assessment of the Death Valley Groundwater Flow System (USFWS, 2009).
- The Service and BLM should continue to work toward the completion of the land and mineral withdrawals for public lands within the Refuge and the ACEC. This will likely require that once the withdrawal packages have been forwarded by BLM's Nevada State Director to BLM's Washington Office, that briefings be scheduled with the Service's Washington Office to ensure that the importance of this withdrawal to all of the listed spies at Ash Meadows, as well as the ash Meadows ecosystem, is recognized (USFWS, 2009).

- Research on the potential significance of the rabbit herbivory on the long-term viability of Ash Meadows milkvetch should be prioritized, especially research focused on whether a sufficient seed bank is present to support recruitment when the proper environmental conditions occur. This research should also address potential management options to mitigate the impacts of herbivory on Ash Meadows milkvetch. Additional research is also needed on the sensitivity of the species to hydrological alterations and, in particular, its dependency on soil moisture drawn by capillary action from the near surface groundwater table. Finally, research is needed on the role of hydrologic process in seed dispersal and the extent to which past surface modifications have disrupted this process and the degree to which that affects the viability of current populations (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Over the next five years, the Service should focus on: • Monitor compliance with Nevada Revised Statute Order 1197A (January 12, 2018), Curtailment of New Appropriations of Groundwater within the Amargosa Valley Hydrographic Basin 230, that prohibits new applications for water or water diversions within 25 miles of Devils Hole (and by proximity Ash Meadows NWR). Order 1197A supersedes 1197, which imposed similar regulations at 10 miles from Devils Hole. Water levels in Devils Hole are affected by pumping centers in the Amargosa Desert and the Ash Meadows groundwater basins (Halford and Jackson 2020). • Collaborate with the Ash Meadows NWR to implement the Desert National Wildlife Refuge Complex – Ash Meadows, Desert, Moapa Valley, and Pahranagat National Wildlife Refuges Final Comprehensive Conservation Plan and Environmental Impact Statement, Volume I – August 2009 (Service 2009) and also the Draft Ash Meadows Natural Resource Management Plan in review (Service 2020); • Support Ash Meadows milk-vetch research at the Ash Meadows NWR to monitor the population as identified in the Recovery Plan for the Endangered and Threatened Species of Ash Meadows (Service 1990); • Monitor the future activity of mineral rights in the Ash Meadows area. The BLM ACEC surrounding the refuge is withdrawn from mining and entry until 2029 (PLO# 7737, signed November 2, 2009), but requires renewal every 20 years. Mining can still occur on private inholdings within the refuge, but no active mining permits exist at this time. • Continue to research and implement a jackrabbit exclusion study to determine the impacts jackrabbits are having on reproduction of Ash Meadows milk-vetch. (USFWS, 2020)

# SPECIES ACCOUNT: *Astragalus pycnostachyus var. lanosissimus* (Ventura Marsh Milk-vetch)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 5/21/2001; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

Astragalus pycnostachyus var. lanosissimus is a short-lived herbaceous perennial. It has a thick taproot and multiple erect, reddish stems, 40 to 90 centimeters (cm) (16 to 36 inches (in)) tall that emerge from the root crown. The pinnately compound leaves are densely covered with silvery-white hairs with 27 to 39 leaflets that are 5 to 20 millimeters (mm) (0.2 to 0.8 in) long. The numerous yellowish-white to cream colored flowers are in dense clusters and are 7 to 10 mm (0.3 to 0.4 in) long with 2 to 4 cm (0.8 to 1.6 in) peduncles (Spellenberg 1993). The calyx tube is 3 to 4 mm (0.12 to 0.16 in) long with 1.2- to 1.5-mm (0.04-in) long calyx teeth (Spellenberg 1993). The nearly sessile, single-celled pod is 8 to 11 mm (0.31 to 0.43 in) long (Barneby 1964) (USFWS, 2010).

**Taxonomy**

Member of the Fabaceae (pea family) (USFWS, 2010).

**Historical Range**

Historically, Ventura to Orange County, California; along the coast in salt marshes (NatureServe, 2015).

**Current Range**

Currently known from one naturally-occurring site in Ventura County (U.S. Fish and Wildlife Service 2001). There are also four introduction sites, two in Ventura County and two in Santa Barbara County (which is outside the historic range of this taxon) (M. Meyer pers. comm. 2010) (NatureServe, 2015).

**Critical Habitat Designated**

Yes; 5/20/2004.

**Legal Description**

On May 20, 2004, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Astragalus pycnostachyus var. lanosissimus (Ventura Marsh Milk-vetch) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three critical habitat units (CHUs), in California (69 FR 29081-29100).

**Critical Habitat Designation**

The critical habitat designation for Astragalus pycnostachyus var. lanosissimus includes three CHUs in Santa Barbara and Ventura Counties, California. This species critical habitat encompasses approximately 420 acres (ac) (170 hectares (ha)) (69 FR 29081-29100).

Mandalay Unit: The Mandalay Unit is approximately 153 ac (62 ha) in size and is essential to the conservation of Astragalus pycnostachyus var. lanosissimus because it contains the only known location where Astragalus pycnostachyus var. lanosissimus naturally exists and the remainder of the unit also supports the primary constituent elements. The State-owned Mandalay State Beach is managed by the Ventura County Parks and Recreation Department and comprises about 49 ac (20 ha) of this unit. The remaining area of the unit is privately owned and is currently undeveloped, but has been chosen as the site for a 300-housing-unit subdivision (Economic and Planning Systems, Inc. 2003). The pending development is called North Shore at Mandalay and would occur in the eastern portion of this critical habitat unit. The project includes a 1.65-ac (0.67-ha) ''milk-vetch preservation area'' encompassing the entire natural population (California Coastal Commission 2002), which in turn, would be inside a 23.8-ac (9.6-ha) resource protection area (RPA). The RPA would be buffered from adjacent residential development by a 50-ft (15 m) wide landscaped area. The population will be mostly isolated from surrounding vegetation, and the ecological processes sustaining the population may be interrupted. Also, the project may allow increased human intrusion, provide habitat for nonnative plants and snails, alter the hydrologic regime, and introduce pesticides and fertilizers that adversely affect the plants. Therefore, the risk of extinction of the subspecies is high without the development of additional populations. The portion of this unit on Mandalay State Beach is identified by Wilken and Wardlaw (2001) as a possible site for establishing a new population of Astragalus pycnostachyus var. lanosissimus. In 2003, the first efforts at researching how new populations could be established in this unit were begun. The proximity of Mandalay State Beach to the extant population indicates that some natural exchange of seeds or pollen could take place if a second population were established at Mandalay State Beach. The site contains one or more of the primary constituent elements defined for Astragalus pycnostachyus var. lanosissimus critical habitat, although Wilken and Wardlaw (2001) note some dense cover of nonnative annuals. Also, using their five parameters, Wilken and Wardlaw (2001) ranked the Mandalay State Beach portion of this unit as one of the most similar to the natural occurrences of Astragalus pycnostachyus var. lanosissimus and the closely related Astragalus pycnostachyus var. pycnostachyus, and hence one of the top candidates for establishing a new population. California Department of Parks and Recreation (CDPR) has approved experimental introductions of Astragalus pycnostachyus var. lanosissimus conducted by the CDFG. Because the area is public land owned by the CDPR and the species is Statelisted, we will work with the State to develop conservation strategies to reintroduce the subspecies and develop and manage reserves. As discussed above, this unit is essential for the conservation of Astragalus pycnostachyus var. lanosissimus because it contains the primary constituent elements for Astragalus pycnostachyus var. lanosissimus. The population of Astragalus pycnostachyus var. lanosissimus at the North Shore at Mandalay site is the only naturallyoccurring, self-perpetuating population of the species in existence. It has provided all of the initial propagules for establishing research populations of the species at other sites, and continues to be the source of genetic variability for future propagation. The research populations at McGrath State Beach and Carpinteria Marsh are not intended to become new populations for the recovery of the species, but were established to generate data on the species' needs when such introductions for recovery begin. Their persistence is uncertain, and we have observed some failures (see Background section). Consequently, the population of Astragalus pycnostachyus var. lanosissimus on the North Shore at Mandalay site is currently the only one of which we can be relatively certain that the plants will persist. If this population is extirpated, and the research populations ultimately fail, all of the remaining individuals of Astragalus pycnostachyus var. lanosissimus will exist as seeds in collections or propagated in greenhouses. The designation of the North Shore at Mandalay site as critical habitat recognizes that this population is essential to the species' conservation. This southernmost unit is geographically separated from other critical habitat within its historical range. This will reduce the likelihood of all populations being destroyed by one naturally occurring catastrophic event.

McGrath Unit: The site within McGrath Beach State Park is adjacent to McGrath Lake on the leeward side of the southern end of the lake, between the lake and Harbor Boulevard. The unit covers 62 ac (25 ha). It includes 35 ac (14 ha) of private land and 27 ac (11 ha) of State-owned land managed by CDPR. Of the sites they examined, Wilken and Wardlaw (2001) identify the McGrath Lake area as having the best combination of habitat characteristics similar to that of the extant population of Astragalus pycnostachyus var. lanosissimus and its closest relative, Astragalus pycnostachyus var. pycnostachyus based upon five parameters (i.e., dominant vegetation composed of a shrub canopy less than 75 percent; absence of competitive annual or perennial exotic plants; water table in close proximity; soil types consistent with that at the site of the extant population; and native habitat supporting pollinators). CDPR agreed to allow CDFG and RSABG establish a research population on this site. This effort is still in its early stages, and no conclusive data have yet been retrieved. Because the area is currently operated by CDPR and is public land, there is opportunity to work with the State to develop reintroduction strategies for Astragalus pycnostachyus var. lanosissimus and to form manageable reserves. This unit is also one of the last known places where the subspecies was observed growing naturally, and it is close to the extant population and shares many of the broader climatic and habitat features of that site. As discussed above, this unit is essential for the conservation of Astragalus pycnostachyus var. lanosissimus because it once supported a population Astragalus pycnostachyus var. lanosissimus until it was extirpated in 1967. It contains the primary constituent elements for Astragalus pycnostachyus var. lanosissimus. It includes habitat that is necessary for the expansion of the only known population, which may become nonviable in the future. It contains habitat features that are essential for this species including, but not limited to, high diversity of native plants, open canopy, sandy dune hollows, seep margin areas, subterranean water table. This central unit is geographically separated from other critical habitat within Astragalus pycnostachyus var. lanosissimus historical range. This will reduce the likelihood of all populations being destroyed by one naturally occurring catastrophic event.

Carpinteria Salt Marsh Unit: The Carpinteria Salt Marsh Unit extends from the Southern Pacific Railroad tracks south and west to Sand Point Drive and Santa Monica Creek and is approximately 205 ac (83 ha) in size. The entire unit is managed by the UC, Santa Barbara. This unit includes saltmarsh habitat, which is essential to support the pollinators and other ecological processes that Astragalus pycnostachyus var. lanosissimus requires for its survival. The research population of Astragalus pycnostachyus var. lanosissimus was introduced in April 2002 into a portion of the unit. As of February 2003, 44 percent (68) of the 155 original plants survived. By June 2003, only 20 seedlings had been produced by plants at one of the planting sites. We have determined that this area contains the primary constituent elements necessary for the introduction of Astragalus pycnostachyus var. lanosissimus based on Wilken and Wardlaw's (2001) description of five parameters of habitat suitability. These parameters closely parallel the primary constituent elements, so one or more of the elements are represented at this site. The diverse native vegetation provides for a robust pollinator community. The unit is bordered by a residential community where nonnative snails were observed; protection is required for herbivory by snails on Astragalus pycnostachyus var. lanosissimus plants. This site in Santa Barbara County is near the range of the subspecies as predicted by the historical collections and described by Skinner and Pavlik (1994), who list the known counties as Ventura, Los Angeles, and Orange. We have included this unit because, although it is outside the historical range for Astragalus pycnostachyus var. lanosissimus: (1) Insufficient suitable habitat for the subspecies remains within its historical range; and (2) the area has habitat features essential to the conservation of the subspecies, which suggests a high potential for successful establishment of a new population (Wilken and Wardlaw 2001). This unit is essential for the conservation of Astragalus pycnostachyus var. lanosissimus because it supports the pollinators and other ecological processes for Astragalus pycnostachyus var. lanosissimus. It contains habitat features that are essential for this species including, but not limited to, dominant vegetation composed of a shrub canopy less than 75 percent; absence of competitive annual or perennial exotic plants; water table in close proximity; soil type; and native habitat supporting pollinators. Seedling recruitment has been observed at this site in the research population. This northernmost unit is geographically separated from other critical habitat. This will reduce the likelihood of all populations being destroyed by one naturally occurring catastrophic event.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Astragalus pycnostachyus var. lanosissimus critical habitat consists of five components (69 FR 29081-29100):

(i) Vegetation cover of at least 50 percent but not exceeding 75 percent, consisting primarily of known associated native species, including but not limited to, Baccharis salicifolia, Baccharis pilularis, Salix lasiolepis, Lotus scoparius, and Ericameria ericoides;

(ii) Low densities of nonnative annual plants and shrubs;

(iii) The presence of a high water table, either fresh or brackish, as evidenced by the presence of channels, sloughs, or depressions that may support stands of Salix lasiolepis, Typha spp., and Scirpus spp.;

(iv) Soils that are fine-grained, composed primarily of sand with some clay and silt, yet are well-drained; and

(v) Soils that do not exhibit a white crystalline crust that would indicate saline or alkaline conditions.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the areas determined to be essential for the conservation of the species may require special management or protections. The Mandalay Unit may require special management considerations or protections due to the threats to the species and its habitat posed by development (e.g., loss of native vegetation, disruption of pollinator community, herbivory by snails, increase in non-native plants, soil remediation), herbivory by rabbits, and trampling as a result of human activity. Currently, competition by non-native plants, herbivory by snails and rabbits, and human activity are ongoing in the Mandalay Unit. The McGrath Unit may require special management considerations or protections due to the threats to the species and its habitat posed by invasive, non-native plants and trampling as a result of human activity. Currently, competition from non-native plants and human activity are ongoing in the McGrath Unit. The Carpinteria Salt Marsh Unit may require special management considerations or protections due to the threats to the species and its habitat posed by nonnative plants and high salinity. Currently, competition from non-native plants and fluctuations in salinity levels are ongoing in the Carpinteria Salt Marsh Unit.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: self-pollination, cross-pollination (USFWS, 2010)

**Lifespan**

Adult: 3 - 4 years (USFWS, 2010)

**Breeding Season**

Adult: July - October, one observation in June (USFWS, 2010)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2010); soil seed bank (USFWS, 2004)

**Reproduction Narrative**

Adult: It is believed to have a 3 to 4-year life span (Wilken and Wardlaw 2001). The blooming time has been recorded as July to October (Barneby 1964); however, the population at the site where the plants were rediscovered, referred to as the site of natural occurrence, was observed in flower in June 1997. Wilken and Wardlaw (2001) observed peak flowering of the plants at this site in mid-July with most flowers maturing into fruits by early September. The variety appears to be self-compatible and partly self-pollinating (Wilken and Wardlaw 2001); however, the flower structure of this variety, and other Astragalus species, suggests that pollination requires manipulation of flower parts by insects (Wilken and Wardlaw 2001). Wilken and Wardlaw (2001) observed a limited number of skippers (family Hesperidae) and bumblebees (Bombus spp.) visiting the plants. Other researchers have observed various bee and butterfly species frequently visiting A. pycnostachyus var. lanosissimus (Meyer 2007a, Jensen 2007), indicating that insects may be the natural pollinators of this plant. The life cycle of A. pycnostachyus var. lanosissimus likely requires a pollinator community to be present (Greer et al. 1995; Karron 1987). Wilken and Wardlaw (2001) observed an average of 26 inflorescences per plant, with an average of 36 flowers per inflorescence, and between 7 and 9 ovules per ovary (a potential maximum of 7 to 9 seeds per flower). However, the number of seeds per fruit was only approximately 2 on average. This level of productivity is low relative to many other species of Astragalus that are known to be self compatible and therefore would be expected to produce more seed (Karron 1987). Seed production is suspected to be limited by a lack of pollination. This delayed seed germination, combined with the observation that plants may not become reproductive until 18 to 30 months following germination, and a low seedling survival rate (Wilken and Wardlaw 2001), indicates a low recruitment rate for the variety (USFWS, 2010). The population is able to persist due to having established a seedbank (not all seeds produced in one year will germinate the following year) (USFWS, 2004).

**Habitat Type**

Adult: Terrestrial, wetland, aquatic (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Dune, grassland, shrubland, spring, herbaceous wetland (NatureServe, 2015); coastal dune-swales (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**

Adult: 0 - 30 m elevation (NatureServe, 2015); high competition from other plant species (USFWS, 2010)

**Environmental Specificity**

Adult: Very narrow to narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Historically probably occurred on open sites near the coast on soils with a high water table, such as on bluffs or flats near seeps or bodies of brackish or fresh water, or in or near coastal marshes. Currently, a population occurs on an abandoned oil-field waste site in remnant backdunes. This area has an artificially compact substrate of clay, sand, and small gravel, above a capped oil layer, generally about 45 cm below the soil surface. Occurs from 0 - 30 m elevation. The environmental specificity is very narrow to narrow, although habitat requirements are poorly understood (NatureServe, 2015). Based on existing information from historical collections, Wilken and Wardlaw (2001) concluded that the variety occurs in low elevation coastal dune-swale areas where freshwater levels (in the form of saturated soils or groundwater) are high enough to reach the roots of the plants. The soils associated with Astragalus pycnostachyus var. lanosissimus are well-drained, yet contain a mix of sand and clay. Meyer (2007a) indicated that low competition from native and nonnative species contributes to the success of Astragalus pycnostachyus var. lanosissimus establishment in these areas (USFWS, 2010). Primary constituent elements include vegetation cover of at least 50 percent but not exceeding 75 percent; low densities of nonnative annual plants and shrubs; the presence of a high water table, either fresh or brackish; soils that are fine-grained, composed primarily of sand with some clay and silt, yet are well-drained; and soils that do not exhibit a white crystalline crust that would indicate saline or alkaline conditions (USFWS, 2004).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Decline of 50-90% (NatureServe, 2015); believed extinct until 1997 (USFWS, 2010)

**Species Trends:**

Declining (USFWS, 2010)

**Population Growth Rate:**

Slow (inferred from USFWS, 2004)

**Number of Populations:**

4 (USFWS, 2023)

**Population Size:**

>700 individuals in 4 populations (USFWS, 2023)

**Adaptability:**

Low (inferred from NatureServe, 2015)

**Population Narrative:**

For the only known naturally-occurring population, low population size increases vulnerability to decline/extirpation from stochastic events. This species has experienced a long-term decline of 50-90%. Recent population sizes at the naturally-occurring site include 104 plants (60 flowering) in 2006 and 27 plants (19 flowering) in 2009 (M. Meyer unpublished data 2010). This represents an overall decline corresponding to two low rainfall years and completion (in 2007) of remediation on the surrounding area outside the 1.6 acre exclosure in which plants occur. Collectively, the four introduced sites had 801 plants (283 flowering) in 2009; most of these individuals were at one of the Santa Barbara County sites (M. Meyer unpublished data 2010). Most historical or extirpated; one naturally-occurring site discovered in Ventura County in 1997 (U.S. Fish and Wildlife Service 2001). The presumption is that the original source of seed at this site came from some either onsite or nearby top soil brought in to cap the oil waste facility when it closed in 1982 (M. Meyer pers. comm. 2010). There are also four introduction sites, two in Ventura County and two in Santa Barbara County (which is outside the historic range of this taxon). As yet, it is unclear whether these introductions will persist and become self-sustaining populations (M. Meyer pers. comm. 2010) (NatureServe, 2015). It was believed to be extinct until its rediscovery in 1997. Currently the North Shore site supports only 31 individuals and the habitat at the site has possibly been permanently negatively altered by remediation activities in areas surrounding the plants. Research was conducted to identify potential suitable habitat characteristics and introductions were attempted at several sites within and outside the historic range of the species, including Ormond Beach, Mandalay State Beach, McGrath Beach, Carpinteria Salt Marsh, and Coal Oil Point. Astragalus pycnostachyus var. lanosissimus did not survive at Ormond Beach. Plants currently remain at the other outplanting sites, but have shown a relatively steady decline in abundance since the heavy rains of 2004-2005, and may benefit from another substantially wet season (USFWS, 2010). The single natural population of Astragalus pycnostachyus var. lanosissimus near the city of Oxnard is in a degraded backdune community. Due to the combination of poor seedling and young plant survivorship and low seed production, the single naturally occurring population of Astragalus pycnostachyus var. lanosissimus has continued to decline since its rediscovery in 1997 and through the 2001 season (Impacts Sciences 1997, 1998; Wilken and Wardlaw 2001; Dieter Wilken, Santa Barbara Botanic Garden, pers. comm. 2002) (USFWS, 2004). Ventura marsh milk-vetch (Astragalus pycnostachyus var. lanosissimus) was historically found in Los Angeles and Ventura County coastal wetlands. There is one known naturally occurring population (North Shore), and eight deliberately planted populations, which were all planted from North Shore seed stock. Four of the planted populations are north of the historically known range, justified by available planting locations and anticipated climate change. There are 4 populations of reproductive adults (the rediscovered population and three introduced populations), 2 populations of seed banks in suitable habitat, and 3 populations of seed banks in unsuitable habitat. (USFWS, 2020) The four currently occupied sites are North Shore, McGrath Parcel, North Campus Open Space, and Carpinteria Salt Marsh (Table 1), and occupy four unique ecological, ownership, and management situations. For a new site to be established with the goal of establishing a new population, it would need to be spatially and ecologically distinct from any existing sites (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat destruction (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** much of the habitat that supported historical populations of Astragalus pycnostachyus var. lanosissimus has been altered or destroyed such that it is no longer suitable for the species. Habitat conditions at the North Shore site have been altered by remediation activities, but will be protected by a preserve created as part of the MOU between CDFG and the project proponent (USFWS, 2010).

**Stressor:** Disease and predation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The seeds of Astragalus pycnostachyus var. lanosissimus at the site of natural occurrence were heavily infested with seed beetles (Bruchidae: Coleptera) in 1997. In a seed collection made for conservation purposes in 1997, most fruits partially developed at least 4 seeds but seed predation reduced the average number of undamaged seeds to only 1.8 per fruit (Steeck and Meyer, in litt. 1997). The nonnative milk snail (Otala lacteal) was observed causing damage to the foliage of Astragalus pycnostachyus var. lanosissimus in 1998 and 1999 concurrent with a dramatic decline in seedling plants (Meyer 2007a). European brown garden snails (Helix aspera) are frequently observed at the outplanting sites and can potentially defoliate individual plants, damage new growth, and compromise vigor (Jensen 2007; Meyer 2007a). Meyer (2007a) reports that gophers (Thomomys bottae), rabbits (presumably Lepus spp. or Sylvilagus spp.), and meadow voles (Microtus spp.) are common at the milk-vetch outplanting sites and impact plants by removing seedlings and damaging established plants. Sooty fungus continues to be occasionally observed on A. pycnostachyus var. lanosissimus individuals, but does not appear to substantially adversely affect the health or productivity of the plants (USFWS, 2010).

**Stressor:** Stochastic events (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing Astragalus pycnostachyus var. lanosissimus in 2001, the Service discussed that the taxon is threatened with extinction from unanticipated human activities and natural events by virtue of the very limited number of individuals in, and the small area occupied by, the only known extant population. A wildlife predation event in the summer before seeds have matured, a plane crash (the taxon is under the extended center flight line of the Oxnard airport and a crash occurred on the site in 1995), and other natural or unanticipated human-caused events could eliminate the existing population and result in the extirpation of this taxon from the only known remaining site of natural occurrence in the wild.

**Stressor:** Inadequate preserve design (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The small size of the preserve and its proximity to future urban and suburban uses makes it subject to the effects of nonnative, invasive plant and animal species, increased nutrient-rich water supply due to suburban irrigation runoff and increased impervious surfaces, and chemicals such as herbicides, pesticides, and fertilizers (see Conservation Biology Institute 2000, CDFG 2000 and references therein). Independently or in combinations, these factors present difficult management challenges which, if not adequately addressed, could lead to the elimination of A. pycnostachyus var. lanosissimus from the North Shore site. Nonnative plant and animal species are competitors and predators, respectively, that can directly reduce survival of native plants and they can also upset the invertebrate (pollinator) and vascular plant associations upon which native plants depend (Conservation Biology Institute 2000). While the life history requirements of A. pycnostachyus var. lanosissimus are not well understood, any factor that substantially alters the hydrology of the site, such as increases or decreases in urban/suburban runoff, may make the site unsuitable for this wetland species (Conservation Biology Institute 2000). Likewise, increased levels of chemicals arriving via runoff or drift can be expected in small preserves and can harm native species (Conservation Biology Institute 2000). These increases could harm A. pycnostachyus var. lanosissimus directly, or alter the pollinator or plant associations upon which it depends (USFWS, 2010).

**Stressor:** Competition (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nonnative weeds such as iceplant, as well as some native species such as Anemopsis californica (yerba mansa), Potentilla anserina (silverweed) and Distichlis spicata (salt grass) can form dense continuous patches that exclude Astragalus pycnostachyus var. lanosissimus (Meyer 2007a) (USFWS, 2010).

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Recently, the potential impacts of climate change on the flora of California were discussed by Loarie et al. (2008). Based on modeling, they predicted that species' distributions will shift in response to climate change, and that species will "move" or disperse to higher elevations and northward, depending on the ability of each species to do so. While the Service lacks adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors such as small population size, will affect Astragalus pycnostachyus var. lanosissimus, small-ranged species, such as A. pycnostachyus var. lanosissimus, are generally more vulnerable to extinction due to these changing conditions (Pimm and Raven 2000, Loarie et al. 2008) (USFWS, 2010).

**Stressor:** Sea level rise (USFWS, 2010)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** An increase in the rate of sea level rise has been predicted for the coast of California (California Climate Change Center 2006). The occurrences of Astragalus pycnostachyus var. lanosissimus at Mandalay State Beach, McGrath Lake, and Carpinteria Salt Marsh Reserve are bounded by residential, industrial, or agricultural areas that would preclude the taxon’s migration inland as sea level rises (USFWS, 2010).

***Recovery***

**Reclassification Criteria:**
Ventura marsh milk-vetch may be considered for downlisting when all the following criteria are met: 1. Abundance within each of four sites is an average of 100 or more reproductive individuals per site with a stable or increasing trend based on a minimum of 10 years of data. Funding and resources are available so that if a population drops below 25 reproductive individuals in any single year, supplemental seed or seedlings may be planted, or artificial disturbance applied. 2. The four sites are managed such that the functions of disturbance, colonization, and succession allow for successful Ventura marsh milk-vetch population persistence, including site plant species composition comprised of at least 50% appropriate native species, with native species vegetative cover being greater than non-native species vegetative cover. Details of suitable habitat conditions are described in the SSA (Service 2020, pp. 12-20). 3. Management at the four sites is assured in perpetuity and is shown to be effective by stable or increasing populations based on a minimum of 10 years of data. 4. Ex situ recovery seed banks are established and maintained over time with sufficient seed so that stored seed may be used for recovery efforts while not exhausting the seed supply and decreasing seed bank genetic diversity. At a minimum, seed should be stored within a longterm storage facility such as the National Laboratory for Genetic Resources Preservation in Fort Collins, Colorado, as well as in at least two institutions approved by the Center for Plant Conservation with the capability to test viability and germination as needed. New accessions are added to each institution as new sites are established, and seed is added so that the most recent accession is no more than 15 years old (USFWS, 2023).

Recovery Priority Number: 6C

**Delisting Criteria:**
Once the downlisting criteria have been met, Ventura marsh milk-vetch may be considered for delisting when all the following criteria are met: 1. Two additional sites are established (for a total of six) that have an average abundance of 100 or more reproductive individuals per site with a stable or increasing trend over 10 years of data. Funding and resources are available so that if a population drops below 25 reproductive individuals in any single year, supplemental seed or seedlings may be planted, or artificial disturbance applied. 2. The two additional sites are managed such that the functions of disturbance, colonization, and succession allow for successful Ventura marsh milk-vetch population persistence, including site plant species composition comprised of at least 50% appropriate native species, with native species vegetative cover being greater than non-native species vegetative cover. Details of suitable habitat conditions are described in the SSA (Service 2020, pp. 12-20). 3. Management at the two additional sites is assured in perpetuity and is shown to be effective by stable or increasing populations based on a minimum of 10 years of data (USFWS, 2023).

**Recovery Actions:**

- 1. Manage habitat that supports the species to reduce or eliminate threats, including supplemental seeding, irrigation, vegetation composition and density, and herbivore control. (Priority 1) 2. Conduct annual monitoring to identify population trajectories and environmental conditions that might be adversely affecting the species. (Priority 1) 3. Protect currently unprotected habitat where the taxon occurs or could occur. (Priority 2) 4. Collect seed and deposit accessions into a permanent conservation seed bank. (Priority 2) 5. Conduct experimental research projects, including those that examine the roles of biotic and abiotic environmental effects, natural soil seed banks, and disturbance. (Priority 2) (USFWS, 2023)
- Convene a recovery team and develop a recovery plan for Astragalus pycnostachyus var. lanosissimus (USFWS, 2010).
- Work with CDPR staff to continue iceplant removal and habitat restoration around McGrath Lake to improve and expand available habitat for Astragalus pycnostachyus var. lanosissimus (USFWS, 2010).
- Determine if changes in the upper aquifer at the North Shore site have resulted from remediation activities surrounding the plants, and determine whether a supplemental watering system can compensate for altered water availability, or if additional measures are needed to compensate for negative impacts (USFWS, 2010).
- Build on the work of Meyer, Jensen, Wilken, and others to identify freshwater-dominated coastal wetlands with sufficient surrounding area and proper vegetation (i.e., sufficiently sparse areas, free of dense mats of vegetation) for Astragalus pycnostachyus var. lanosissimus introduction (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Develop a recovery plan for Astragalus pycnostachyus var. lanosissimus. 2. Continue habitat restoration at McGrath Parcel to improve and expand available habitat for Astragalus pycnostachyus var. lanosissimus. 3. Monitor the success of the North Campus Open Space planting site. 4. Enhance the sites with extant seed banks and potential habitat. 5. Build on previous work to identify appropriate fresh-water dominated coastal wetlands of sufficient area and proper conditions (sparsely vegetated, free of mats of perennial vegetation, proper hydrology) for Astragalus pycnostachyus var. lanosissimus introduction. (USFWS, 2020)
- FUTURE SCENARIO 2 (INCREASING MANAGEMENT) Under Future Scenario 2, management activities that benefit Astragalus pycnostachyus var. lanosissimus increase at past and current reintroduction sites. Key management activities that increase the suitability of habitat include non-native and native species management to reduce competition for juvenile and adult individuals of the species, controlling herbivory through exclusion fencing, removing snails, and decreasing shrub and tree vegetation in order to reduce cover for and thus discourage herbivorous mammals. Currently, supplemental planting is used infrequently at introduced sites, only when reproducing adults have not been present for several years and when conditions are believed to be suitable. This is done to both check site suitability at that time and to increase the local seed bank if the supplemental plants successfully produce seed. Supplemental watering is used to establish populations at initial introduction or when supplemental planting occurs. Additional supplemental water is used sparingly to reduce the effects of drought and desiccation from changes in seasonal precipitation. These activities already occur at the North Shore site and the McGrath Parcel and will continue under this scenario. Additional sites for reintroduction are identified and managed under Future Scenario 2.

This includes the North Campus Open Space (NCOS) Restoration Project and the Ormond Beach Restoration and Public Access Project. Restoration activities at the NCOS restoration site are likely to have positive influences on associated species and vegetation cover facilitating the survival of individuals planted in 2019. Those adults will contribute to a growing seedbank as they reach reproductive maturity. The success of this restoration project will provide future opportunity for introducing Astragalus pycnostachyus var. lanosissimus into newly suitable habitat in other areas within the NCOS restoration site. The expansion of natural environments within the broader Devereux Slough ecosystem may also provide some ability for the migration of suitable habitat reducing the negative effects of climate change at this specific location. In this scenario we also expect a new population to be introduced to a unique location at the newly restored Ormond Beach Restoration and Public Access Project (not at the location of the extirpated Ormond Beach site). The Coal Oil Point Reserve pond site, Carpinteria Salt Marsh Reserve, and McGrath State Beach will have increased management resulting in the reestablishment of reproductive adults in these populations. Weed management and supplemental planting are likely to have the greatest effect at these sites. Development surrounding the North Shore site has negative impacts on the North Shore population, but these will be mitigated through continued and/or additional measures as necessary because of the requirement to manage in perpetuity. The North Shore population continues to be conservation reliant in this scenario. The effects of climate change are still significant in this scenario, with decreases in winter precipitation frequency, increases in winter precipitation intensity, and increases in average, maximum, and minimum temperatures. The results increase stress and mortality on existing and potential future Astragalus pycnostachyus var. lanosissimus populations while decreasing the amount of available suitable habitat. The effects are offset only slightly through management activities since they cannot directly address declining water tables and broad shifts in precipitation patterns and temperature. The management under this scenario does improve habitat locally at all sites, as well as potential sites, resulting in a greater ability for migration of vegetation and suitable habitat. (USFWS, 2020a)

# SPECIES ACCOUNT: *Astragalus robbinsii var. jesupi* (Jesup's milk-vetch)

***Species Taxonomic and Listing Information***

**Commonly-used Acronym:** JMV

**Listing Status:** Endangered; 7/6/1987; Northeast Region (R5)

**Physical Description**

A short-lived perennial, herbaceous legume that is 10 to 50 centimeters (cm) (4 to 20 inches [in]) tall with a tap root. Jesup’s milk-vetch stems originate from a single root crown and may branch several times. Older plants tend to be more profusely branched than younger plants. Its leaves are pinnately compound, divided into 9 to 15 oblong to elliptical, glabrous leaflets 8 to 20 millimeters (mm) (0.3 to 0.8 in) long. The first true leaves of seedlings are produced in triads and arrayed in a clover-leaf fashion; as plants mature, the number of leaflets per leaf increases. The raceme2 of 8 to 21 small (9 to 12 mm [0.3 to 0.5 in long]), pale bluish-violet, pea-like flowers is borne at the top of the stem. Flowering plants may have from 1 to 120 racemes. The inflorescence is compact initially, but as flowering proceeds, the axis of the raceme continues to elongate somewhat throughout fruit development, especially in more shaded conditions (Farnsworth and Harvey 2004). The fruit is a legume about 1.5 to 2 cm (0.6 to 0.8 in) long, borne on a short stem, narrowed at both ends and terminated with a distinctive beak 1.5 to 3 mm (0.8 to 0.1 in) long. The body of the legume has scattered black, appressed hairs. Inflorescences produce, on average, approximately 56 seeds per inflorescence (8 legumes per inflorescence, 7 seeds per legume), although larger plants produce more legumes and seeds per legumes. (USFWS, 2019)

**Taxonomy**

A member of the legume family (Fabaceae). Jesup’s milk-vetch was first collected in 1877 at Sumner Falls in Plainfield, NH by Professor Henry Griswold Jesup of Dartmouth College. The variety (as “jesupi”) was subsequently described by Eggleston and Sheldon in 1894 in Minnesota Botanical Studies 1: 155, following collection of the specimens (deposited at MINN) by Eggleston on June 7, 1891, on “old ledges above high water of the Connecticut River near Hartland, Vt.... and on ledges near Sumner Falls, near Plainfield, N.H.” (Barneby 1964: 131; Revised Jesup’s Milk-Vetch Recovery Plan 4 w 3Tropicos Database 2019). Recent synonyms for this taxon include Astragalus jesupii (Egglest. & Sheldon) Britt. (published in Britton 1901: 1048) and Atelophragma jesupii (Egglest. & Sheldon) Rydberg published in Bulletin of the Torrey Botanical Club 55: 125 (1928). Although the taxon was federally listed endangered under the variant spelling Astragalus robbinsii var. jesupi, and the first recovery plan recognized the taxon as Astragalus robbinsii var. jesupi, the current nomenclature for the species is Astragalus robbinsii var. jesupii, following the standards outlined in the International Code of Botanical Nomenclature (accessed February 4, 2019). (USFWS, 2019)

**Historical Range**

In Sullivan County, New Hampshire, and Windsor County, Vermont. Known from five distinct sites along a 16-mi sector of the Connecticut River between central New Hampshire and central Vermont. (USFWS, 2019)

**Current Range**

In Sullivan County, New Hampshire, and Windsor County, Vermont. Extant at three distinct sites along a 16-mi sector of the Connecticut River between central New Hampshire and central Vermont. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect and Self-fertilization (USFWS, 2019)

**Lifespan**

Adult: Generally 3 years (USFWS, 2019)

**Breeding Season**

Adult: Flowers in late May or early June; sets seed through August (USFWS, 2019)

**Other Reproductive Information**

Adult: The Jesup's milk-vetch life cycle consists of seed germination and growth to seedling in year one; emerging as a small, generally nonflowering plant in year two, flowering and dying after flowering in year three. Some plants may produce small Revised Jesup's Milk-Vetch Recovery Plan 14 numbers of flowers in the second year, in which case the plants will typically flower again the following year. Alternatively, depauperate plants may live for 4 years with minimal flowering. Some vegetative plants survive to a fourth year. Self-fertilization is commonly documented in the genus Astragalus, facilitated by simultaneous maturation of anthers and stigmas (Barneby 1964). Experiments that excluded pollinators from flowers have shown Jesup's milk-vetch to be capable of selffertilization. The most common insect visitors of Jesup's milk-vetch flowers are bumblebees identified as Bombus vagans vagans Smith (USFWS, 2019)

**Reproduction Narrative**

Adult: Jesup's milk-vetch plants emerge in April (or as soon as ice cover and temperature permits), and bloom in early- to mid-May. Flowering times are variable year to year (Dunlop 1994). Dunlop (1994) observed that the plants closest to the water's edge at all three sites are the last to flower, possibly reflecting longer periods of spring inundation or a cooling effect on the lower slope. Flowering generally lasts to early July, and seed set occurs from late June to mid-July (Brumback 2009). Most fruits have dehisced by early July. Some fruiting stems have typically withered by mid-August, but vegetative stems usually remain green until September or October (Brumback and Piantedosi 2018a). Seed germination is delayed until the following year (or later) (Brumback 2009). This latter group typically includes depauperate individuals that have not previously flowered or produced very sparse blooms. (USFWS, 2019)

**Habitat Type**

Adult: Terrestrial (USFWS, 2019)

**Habitat Vegetation or Surface Water Classification**

Adult: Calcareous bedrock outcrops which are ice-scoured annually (USFWS, 2019)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2019)

**Habitat Narrative**

Adult: Jesup's milk-vetch inhabits bedrock outcrops of chlorite or phyllite schist that are periodically scoured by flooding and ice-rafting along the Connecticut River. As such, these riparian ledges are sparsely vegetated; however, they support a globally rare natural community type and several rare plant species in addition to Jesup's milk-vetch. Plants at each site occupy a narrow band between a lower bound determined by typical water levels during the growing season and an upper bound defined by the deep shade of long-lived woody vegetation that is at a high enough elevation to survive the occasional severe scouring by ice. (USFWS, 2019)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seed dispersal mechanisms are unknown for this species, although there is evidence that long distance dispersal is extremely unusual. Given the proximity of the populations to water, it is reasonable to expect that flooding, especially spring freshets, would play a role in transporting overwintering seeds among sites. However, seed dispersal may be naturally limited since mature seeds readily sink in water (Kane 2011a, It is probable that the vast majority of seeds produced by a population likely remain in close proximity to parent plants and that long-distance dispersal is rare. (USFWS, 2019)

***Population Information and Trends***

**Population Trends:**

Tenuous (USFWS, 2019)

**Species Trends:**

Stable (inferrred from USFWS, 2019)

**Number of Populations:**

3 (USFWS, 2019)

**Population Size:**

Approx 736 natural plants (USFWS, 2019)

**Population Narrative:**

This species is known from only three extant populations along the Connecticut River in New Hampshire and Vermont: Sumner Falls and Jarvis Hill (NH) and Hartland Ledges (VT). These populations comprised 736 plants in 2018 (not including introduced plants at one site). Population sizes are highly variable among years; in the years between 1997 and 2018, the global population has ranged from 260 plants to over 2,000 plants. As thie 2018 population value is based on careful searches of all available habitat at all known populations, it is unlikely to underestimate actual population size by a considerable amount. The Jarvis Hill population has been consistently and significantly larger than the other two populations throughout this time period. Despite intensive surveys, no additional extant Jesup's milk-vetch populations were discovered, although potential suitable habitat was documented. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Herbivory (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Herbivory has been noted on the stems, leaves, fruits, and seeds of Jesup's milk-vetch since 1990. The major herbivores remain unidentified, but deer and woodchucks were suspected in 1990 and 1992, respectively. The proportion of stems affected is generally small (less than 10 percent). Nothnagle noted the loss of an "estimated 95 percent of flowers to herbivory in 1998" without identifying the herbivore (NHNHI 2002). No similar incidents of large-scale herbivory have been documented in the last decade. (USFWS, 2019)

**Stressor:** Trampling (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Trampling of plants has been noted at Sumner Falls on several occasions: 1990, 1992, and 2001. Sumner Falls receives many visits from kayakers who shoot the nearby rapids, fishermen, and other recreational users. Picnicking, boat landing, and campfire building can threaten plants. Vandalism was noted in the past; several plants were "pulled up" in 1990. Likewise, activities nearby can also have inadvertent impacts: a crew erecting signage at Sumner Falls in 2003, for example, dumped brush very near to the plants (but fortunately did not damage any). With so few plants present at the site, the population is vulnerable to even small-scale disturbances. Other sites are not as attractive for boat landings, they are too steep to access from the water and overland access points are in private ownership. (USFWS, 2019)

**Stressor:** Land use change (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Because Jesup's milk-vetch habitats typically occur far apart from each other, colonization of new habitat and establishment of new populations depends on rare long-distance dispersal events. Land use changes that reduce the availability of appropriate Jesup's milk-vetch habitat can reduce the prospects for successful establishment of new populations. Residential and recreational development is increasing along the Connecticut River. While local regulations may prevent siting of new development in the riparian buffers that provide potential habitat for Jesup's milk-vetch, logging and construction activities in the upland areas can cause erosion of shoreline habitats, lead to dumping of materials (e.g., coarse woody debris) in shoreline habitats, and result in increased human visitation to shoreline habitats. These effects can result in degradation of Jesup's milk-vetch habitat and trampling of Jesup's milk-vetch plants. (USFWS, 2019)

**Stressor:** Invasive Species (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Jesup's milk-vetch relies on the availability of open habitat, which is maintained in an early-successional state by periodic flooding and ice scour. Populations of black swallowwort, shrubby honeysuckle, cypress spurge, and purple loosestrife have been noted by surveyors at one or more sites since 1997. As of 2002, all of these species were present at all three sites (with the exception of purple loosestrife, which occurred only at Hartland Ledges and Jarvis Hill) and (with the exception of cypress spurge) are the focus of intensive removal efforts. Recently, Cardamine impatiens (bushy rock-cress) is being treated manually at Sumner Falls and Hartland Ledges (Brumback and Piantedosi 2018b) (appendix 3 and 4). The Hartland Ledges site has the highest percent cover of invasive species. Black swallowwort appears to be spreading more rapidly than other species, particularly at Hartland Ledges, where a nearby railroad bed is infested in places with up to 100 percent cover and plants are rapidly spreading into the surrounding forest and down onto the riverbank and the rock outcrops where Jesup's milk-vetch grows. Despite repeated herbicide application to control swallowwort at Hartland Ledges, the upslope population by the railroad continues to shed seed, providing the source for recruitment of this highly invasive species. Shrubby honeysuckle has been increasing more slowly. Several other native, aggressive species are also increasing in cover at the sites, including Toxicodendron radicans (poison ivy) and Apios americana (ground-nut) at Hartland Ledges. (USFWS, 2019)

**Stressor:** Problems intrinsic to small populations (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Jesup's milk-vetch populations are subject to dramatic "boom and bust" cycles. In 2003, 2009, and 2012 through 2014, all three populations were at some of their lowest numbers since consistent monitoring began in 1997 (appendix 6). While apparent rebounds have occurred after some of the precipitous declines (e.g., 2004 and 2010), monitoring data indicate that these are likely to be followed by future dips under normal conditions. However, extreme storm events in 2008, 2009, and 2011 may have been responsible for the prolonged decline in total plant numbers from 2012 through 2014. Demographic stochasticity can lead to random extinction, and small populations are particularly vulnerable (Morris and Doak 2002; Farnsworth 2008). These populations are also clearly subject to environmental stochasticity, which further compounds year-to-year variation in population size and is a major driver of extinction probabilities in rare plants.The distinctiveness of the three populations is critical to maintaining the genetic diversity represented by each population. The loss of any population would result in a substantial loss of the species-wide genetic diversity and potentially impact the species' ability to respond to stochastic changes in the environment, including climate change. Maintaining genetic representation of all three populations will be critical in the recovery of the species. (USFWS, 2019)

**Stressor:** Hydrological alteration (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** The extant Jesup's milk-vetch populations are located in the 90-mi (145-km)8 stretch of river with flows directly affected by two hydropower dams, Wilder Dam (Wilder, VT/Hanover, NH) and Bellows Falls Dam (Rockingham, VT/Walpole, NH) (NHNHB 2014). Specifically, the three Jesup's milk-vetch populations occur in the 25 mi (40 km) of free-flowing river between the two dams. The Sumner Falls population is approximately 9.5 river-mi (15 river-km) downriver of Wilder Dam, the Hartland Ledges population is approximately 12.5 river-mi mid-way between the Wilder Dam and BellowsFalls Dam (20 river-km), while the Jarvis Hills population is above the head of the impoundment for the Bellows Falls Dam. Both dams influence the hydrology of the Connecticut River in the vicinity of the Jesup's milk-vetch populations. (USFWS, 2019)

**Stressor:** Climate change (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change models predict that precipitation will increase by 14 percent with the greatest increase in the fall and winter and in the form of rain rather than snow (Runkle et al. 2017a; Runkle et al. 2017b). In Jesup's milk-vetch habitat, riverbank ledges are kept clear by ice scour and spring flooding. These disturbances remove other vegetation that might colonize Jesup's milk-vetch habitat and shade out Jesup's milk-vetch seedlings (USFWS 1989), and/or deposit alluvial sediment to renourish Jesup's milk-vetch plants. The most significant annual floods currently occur during spring runoff, with decreasing flows during the summer. With increasing winter temperatures and winter precipitation in the form of rain, the decrease in snowpack may result in reduced spring flooding and ice scour, critical components to reduce competing vegetation in the rock outcrops. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
Demographic criteria: 1a: A minimum of four persisting populations occurring within the historically known and/or expanded that conserve the genetic diversity of the species. (USFWS, 2019)

Demographic criteria: 1b: A persisting population is defined as having a site-specific median number of total plants (excluding transplants)11 over 5 consecutive years (based on a minimum of one generation) as described below. (i) Sumner Falls: A median of 113 natural plants; (ii) Hartland Ledges: A median of 132 natural plants; (iii) Jarvis Hill: A median of 477 natural plants; (iv) expanded range populations: (1) sites similar in area to the Sumner Falls population: a median of 100 plants; and (2) sites similar in area to the Jarvis Hill population: a median of 400 plants. (USFWS, 2019)

Threats-abatement criteria: 2a: A long-term landowner agreement or other mechanism is in place for each of the four persisting populations that provides: (i) protection against habitat loss. For example, forested buffers are established/maintained between a population and developed land (agricultural land, development, etc.); and (ii) access for long-term monitoring and management. (USFWS, 2019)

Threats-abatement criteria: 2b: A rapid response plan is in place for each of the four persisting populations that addresses new threats (e.g., invasive species) and the need for population augmentation (adaptive management). (USFWS, 2019)

Recovery Priority: 6

**Delisting Criteria:**
Demographic criteria 1a: A minimum of six resilient populations occurring within the historically known and/or expanded ranges that conserves the genetic diversity of the species. (USFWS, 2019)

Demographic criteria 1b: A resilient population is defined as having a site-specific median number of plants and a median number of total inflorescences (excluding transplants) over 8 consecutive years (based on a minimum of three generations) as described below. (i) extant populations: (1) Sumner Falls: A median of 113 natural plants and a median of 193 inflorescences; (2) Hartland Ledges: A median of 132 natural plants and a median of 507 inflorescences; (3) Jarvis Hill: A median of 477 natural plants and a median of 4337 inflorescences; (ii) expanded range populations: (1) sites similar in area to the Sumner Falls population: A median of 100 plants and a median of 193 inflorescences; and (2) sites similar in area to the Jarvis Hill population: a median of 400 plants and a median of 4,337 inflorescences. (USFWS, 2019)

Threats-abatement criteria 2a: A long-term landowner agreement or other mechanism is in place for each of the six resilient populations that provides: (i) protection against habitat loss. For example, forested buffers are established/maintained between a population and developed land (agricultural land, development, etc.); and (ii) access for long-term monitoring and management. (USFWS, 2019)

Threats-abatement criteria 2b. A rapid response plan is in place for each of the six resilient populations that addresses new threats (e.g., invasive species) and the need for population augmentation (adaptive management). (USFWS, 2019)

**Recovery Actions:**
- Protect extant and introduced populations: Securing Jesup's milk-vetch populations requires protecting them from land and water use impacts that cause habitat loss or degradation or result in direct mortality of plants. Protect occupied habitat with conservation easements, management agreements, or acquisition. Conserve vegetative buffers at Jesup's milk-vetch populations. Develop protective hydrological management regimes for dams potentially impacting historically known and expanded range populations. (USFWS, 2019)
- Establish additional populations: Increasing population redundancy for Jesup's milk-vetch requires establishment of additional populations. Introduced populations should represent the range of genetic diversity of the three populations. Because no suitable introduction sites have been identified within the historically known range to date, populations must be established at suitable introduction sites outside the historically known range. (USFWS, 2019)
- Evaluate status of existing populations: Annual quantitative monitoring of historically known and expanded range populations is necessary to assess population trends and status. Annual monitoring of Jesup's milk-vetch populations will determine whether augmentation is warranted and whether there are a sufficient number of plants to allow for seed collection. Annual monitoring for the presence and density of invasive plant species will

determine recovery management actions needed to maintain viable Jesup's milkvetch populations, or document new threats from future invasive species. (USFWS, 2019)

- Manage Habitat: Securing Jesup's milk-vetch populations requires managing their habitats to reduce threats from invasive plant species, recreational activities, and herbivory. Habitat management protocols must be thoroughly documented and data collected in a statistically meaningful way so that successes can be replicated elsewhere and future failures averted. (USFWS, 2019)
- Bank seeds and perfect propagation and transplantation techniques: Seed banking provides insurance against catastrophic declines in natural populations by enabling the propagation of seedlings for population augmentation or introduction efforts. Genetic representation of all populations is maintained by collecting and preserving seed from the three extant populations. Jesup's milk-vetch seeds are collected and banked at NPT. (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Protect extant and introduced populations. Secure conservation easements or management agreements to ensure that population monitoring, invasive plant species management, and population augmentation will continue. 2. Establish additional populations by conducting conservation introductions and translocations in suitable habitat. 3. Establish rapid response plans that incorporate decision making matrices for invasive plant species management and population augmentation. 4. Bank seeds and perfect propagation and transplantation techniques. Experiment with direct seeding. 5. Investigate the potential for early spring high water release from upriver hydropower projects. Identify the flows needed to scour occupied habitat. (USFWS, 2021)

# SPECIES ACCOUNT: *Astragalus tener var. titi* (Coastal dunes milk-vetch)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/12/1998; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A small annual herb with slender stems, usually 1-1.2 dm tall. Flowers (March-May) are 5-6 mm long, lavender to purple in color. Seed pods are straight to half-moon shaped, 1-2.5 cm long (NatureServe, 2015).

**Taxonomy**

A member of the pea family (Fabaceae) (USFWS, 2009).

**Historical Range**

It was once a regional endemic with a range including San Diego, Los Angeles, and Monterey counties; it was never very common in its range though, being restricted to a very specific habitat (NatureServe, 2015).

**Current Range**

Today it is only verified at one area in Monterey County. The total known range in the 3 areas adds up to about 270 sq mi (NatureServe, 2015). It is currently known from one highly fragmented population located on a coastal terrace grassland along 17-Mile Drive in Pebble Beach on the Monterey Peninsula, Monterey County, California. The population is bordered along one side by the Pacific Ocean and the other side by a golf course; 17-Mile Drive bisects the population. (USFWS, 2019).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual, self-fertilization (USFWS, 2009)

**Breeding Season**

Adult: March - May (USFWS, 2004)

**Reproduction Narrative**

Adult: Crossing studies conducted by Liston (1992) indicate that the plants are self-compatible and capable of self-fertilization. Doak et al. (2000) investigated reproductive biology. They found that seed set could be high; mean seed set in plants not damaged by gophers or other herbivores was 44 seeds per individual, and of 207 pods checked for seed production, approximately 70 percent had a seed set of between 4 and 7 seeds per pod. At the same time, they observed only one pollinator in the field over the course of 3 years, and also that greenhouse-grown plants without access to pollinators set high numbers of seed. Based on these combined observations, they concluded that this species is a successful self-pollinator and that pollinators are not a strong concern in the establishment and maintenance of populations (Doak et al. 2000) (USFWS, 2009). Astragalus tener var. titi flowers between March and May. Small bees have been presumed to be its main pollinators based on floral structure (USFWS, 2004).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Coastal terrace, dune (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs within 100 ft. of ocean surf zone, 25 ft. elevation; shade-intolerant (USFWS, 2004)

**Spatial Arrangements of the Population**

Adult: Scattered clumps (USFWS, 2009)

**Environmental Specificity**

Adult: Very narrow (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from USFWS, 2004)

**Habitat Narrative**

Adult: The extant population grows in shallow swales on the flat surface of a coastal terrace. These depressions hold standing water during wet winter and spring seasons. The substrate is a loamy fine sand. The plants are associated with the non-native hottentot fig (Carpobrotus edulis) and cut-leaf plantain (Plantago coronopus). The environmental specificity is very narrow; it is only known from 3 small areas along the immediate coarse in sandy soil (NatureServe, 2015). The entire distribution of the population occurs on patches of remaining habitat that is interspersed with roads, trails, golf greens, and other recreational facilities (USFWS, 2009). Astragalus tener var. titi occurs on sandy soil within 30 meters (100 feet) of the ocean surf zone and 25 ft. above sea level. plants occur primarily on Antioch soils, with a few colonies found on compacted Sheridan soils (Jones and Stokes Associates 1996). Astragalus tener var. titi plants will germinate and grow to healthy maturity in areas of low-level disturbance, such as that caused by gophers or light pedestrian traffic (Doak et al. 2000, M. Stromberg in litt. 2002). Research conducted on plants under cultivation confirms that any competition or shading will result in unhealthy plants (V. Yadon, in litt. 2002, M. Stromberg in litt. 2002) (USFWS, 2004).

***Dispersal/Migration***

**Dispersal**

Adult: Low (inferred from USFWS, 2004)

**Dispersal/Migration Narrative**

Adult: Under cultivation, seed capsules may burst and throw their seeds up to 2 meters (6.5 feet) (V. Yadon in litt. 2002). Many capsules are not dehiscent and simply drop to the soil where they may float to other areas to colonize if those areas become flooded during winter rains (V. Yadon, in litt. 2002) (USFWS, 2004).

***Population Information and Trends***

**Population Trends:**

Decline of 70 - 90% (NatureServe, 2015)

**Species Trends:**

10 - 30% decline (NatureServe, 2015)

**Number of Populations:**

1 (USFWS, 2022)

**Population Size:**

Variable; 100 - 7,000 depending on climatic conditions (USFWS, 2009). Approximately 2,000 individuals were observed in 2011, the last year that the population was surveyed. (USFWS, 2019).

**Adaptability:**

Low (inferred from NatureServe, 2015)

**Population Narrative:**

Very vulnerable due to habitat type and small size. Long term trend is one of steep decline due to habitat destruction in 3/4 of its range. This species has experienced a long-term decline of 70-90%. The short term trend is one of decline (10 - 30%) due to presence on private land. The Pebble Beach Corporation site on the Monterey Peninsula had 4000 plants in 1995. 6 known EO's, but 5 are extirpated or historical. Only 1 extant occurrence is known (NatureServe, 2015). Annual population numbers have fluctuated between less than 100 and approximately 7,000, depending on winter and spring climatic conditions (USFWS, 2009).

***Threats and Stressors***

**Stressor:** Habitat loss and degradation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although vehicles have been prevented from entering the habitat of the plant in one roadside area, the individuals remain vulnerable to vehicles as well as trampling from other recreational activities along other portions of the roadside. Inundation by salt water and beach cobble during storm events may be new threats that may affect the portion of the population closest to the ocean. Little opportunity for population expansion is available adjacent to the existing population because habitat has already been converted to other uses, including roads, trails, and golf courses (USFWS, 2009).

**Stressor:** Predation (USFWS, 2009)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** California voles (Microtus californicus), which are known to harvest seeds of many species in general (Martin et al. 1951, Peronne 2002), are known to occur in the area occupied by the plant (Yadon in litt. 2002; Stromberg in litt. 2002). No data have been gathered to determine the extent of this threat. Since the time of listing, herbivory by snails (various species), slugs (various species), and aphids (Aphis spp.) has also been observed on both vegetative and reproductive structures (Doak et al. 2000, Stromberg in litt. 2002) (USFWS, 2009).

**Stressor:** Stochastic events (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The existence of only one population and small number of individuals in the population place Astragalus tener var. titi at extreme risk of extinction from stochastic events. The conservation biology literature commonly notes the vulnerability of taxa known from one or very few locations and/or from small and highly variable populations (e.g., Shaffer 1981, 1987; Primack 2006; Groom et al. 2006). In particular, although the plants are apparently self-compatible and capable of self-fertilization, the small size of the population makes it difficult for this species to persist while sustaining the impacts of soil damage (compaction and erosion) and habitat alteration that favors non-native species (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). In addition, an increase in the rate of sea level rise has been predicted for the coast of California (California Coastal Commission (CCC) 2001, California Climate Change Center 2006). In particular, ocean bluffs along the coast will be subject to greater and more frequent wave attack, resulting in erosion and shoreline retreat (CCC 2001). The extent to which such events are caused by climate change and the extent to which it could affect Astragalus tener var. titi are unknown at this time (USFWS, 2009).

***Recovery***

**Reclassification Criteria:**
1. At least five viable populations (i.e., populations that are stable or increasing based on multiple years of monitoring, including at least two populations in San Diego or Los Angeles Counties) occur on suitable habitat with few to no nonnative competitors, and no threats from trampling. The area surrounding each population should allow for movement and expansion (USFWS, 2009).

2. A minimum of five populations are on land that is permanently protected from development (e.g., residential, commercial, recreational, etc.) including the population that currently exists on Pebble Beach Company and Monterey Peninsula Country Club property. Funds must be

available for appropriate long-term management. Protected habitat must be of adequate size and configuration to ensure that ecosystem and community processes (e.g., hydrologic regime, food webs, pollinator fauna, coastal dune community associates, and associated species) are maintained, and an adequate diversity of sites exist for colonization of new areas as microhabitat conditions change (USFWS, 2009).

3. Site selection, restoration, and plant reintroduction has been initiated in at least two historical localities in Los Angeles or San Diego Counties. These two reintroduced populations will be considered as part of the five populations of plants described in 1 (a) and 1(b) above (USFWS, 2009).

4. The populations of plants are being adequately maintained, such that encroachment by nonnative plants, excessive herbivory, fire prevention activities, or other threats are not negatively affecting Astragalus tener var. titi directly or indirectly (USFWS, 2009).

5. The 17-Mile Drive population and additional populations have been appropriately managed such that monitoring has determined that these populations are stable or increasing for a minimum of 3 consecutive years (USFWS, 2009).

6. A seed bank has been established at a recognized institution that is certified by the Center for Plant Conservation (CPC) (USFWS, 2009).

Recovery Priority Number: 6C

**Delisting Criteria:**
Delisting Criterion 1) threats are reduced or eliminated so that protected populations are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species. The most outstanding management needs currently are: protection from recreational activities such as hiking, picnicking, equestrian use, and golfing; research is needed on soil seed bank dynamics. (USFWS, 2019).

Delisting Criterion 2) unoccupied habitat in the area has been assessed for its suitability for reintroduction efforts directly adjacent to occupied patches to allow for expansion, especially to offset losses of patches along the immediate coast due to storm surge and saltwater intrusion; and three additional, new populations are established and protected where appropriate, with a goal of increasing redundancy and representation with the establishment of new populations on the Central Coast, in Los Angeles County, and San Diego County. (USFWS, 2019).

Delisting Criterion 3) all protected populations remain viable for at least 10 years to demonstrate long-term viability under a range of environmental conditions. We expect above-ground population size to fluctuate annually, based on response to amount and timing of rainfall (e.g. see Fox et al. 2006). Therefore, a period of 10 years should be long enough to include most of the variability in rainfall that occurs in this region (Zedler & Black 1989; NOAA 2018). (USFWS, 2019).

**Recovery Actions:**

- Secure and protect existing populations and habitat on private or unprotected lands through willing landowners (USFWS, 2004).
- Manage lands to control or eliminate threats to the plants and their habitat (USFWS, 2004).
- Conduct research to document life history characteristics and plants' responses to vegetation management (USFWS, 2004).
- Survey for additional populations and suitable habitat for reintroduction or reestablishment and establish new populations (USFWS, 2004).
- Develop management strategies and monitor populations to determine effectiveness of management (USFWS, 2004).
- Coordinate recovery actions with other listed species or species of concern (USFWS, 2004).
- Develop and implement a public outreach program (USFWS, 2004).
- Reevaluate recovery criteria and revise recovery plan based on knowledge obtained from research, monitoring, and management (USFWS, 2004).
- Work with Pebble Beach Company and Monterey Peninsula Country Club to clarify current management practices within Astragalus tener var. titi habitat and determine if any modifications could be made to improve the status of the taxon (USFWS, 2009).
- Develop and implement a population monitoring design that focuses on aerial extent of populations rather than exact population counts, and includes the full range of the population (USFWS, 2009).
- Experiment with establishment of new populations in other coastal terrace habitat on the Monterey Peninsula or at Point Lobos State Reserve. If these efforts are successful, attempts to establish other populations could be undertaken in Los Angeles and San Diego Counties (USFWS, 2009).
- Survey historical occurrence areas and potential habitat in San Luis Obispo, Los Angeles, and San Diego counties to detect populations and assess habitat for potential restoration and reintroduction. This effort should include a broader habitat definition to accommodate previously overlooked potential habitat (USFWS, 2009).
- Continue with research on seed characteristics, particularly to determine whether there is a difference in seed viability between those produced from self-fertilization and those produced by cross-pollination (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Establish a minimum 10-year monitoring program for coastal dunes milk-vetch on the Monterey Peninsula that includes the entirety of the population. The monitoring program should include annual systematic surveys of abundance and more frequent assessments of invasive species, trampling, or other emergent threats. 2. Evaluate the existence of a seed bank at sites in Monterey that have been recently occupied (within the past 3 years) and sites that have not been occupied for at least 5 years. 3. Conduct restoration and outplanting trials at suitable sites in Monterey County. 4. Conduct surveys, site evaluation, restoration and outplanting trials at sites in Los Angeles and San Diego County after successful trials in Monterey County (USFWS, 2022)

# SPECIES ACCOUNT: *Astrophytum asterias* (Star cactus)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/18/1993; Southwest Region (R2) (USFWS, 2016)

**Physical Description**

A small, spineless, disk or dome-shaped member of the Family Cactaceae (Cactus Family). It is 2 to 15 centimeters (1S6 inches) across, and up to 7 centimeters (3 inches) tall. Star cactus is dull green-to-brown in color, often speckled with a covering of tiny white scales. The body is divided into eight, vaguely triangular sections. Each triangular section has a central line of circular indentations (areoles) filled with whitish, wooly hairs. During periods of adequate moisture, star cactus is usually a dull green color; however, during droughts, the cactus becomes brownish and loses fullness so that it becomes flush with the ground and almost perfectly camouflaged (Figure 2). Flowers are yellow with orange centers, and up to 15 centimeters (6 inches) in diameter. The fruits of star cactus are green to grayish-red, somewhat obscured by white wooly hairs, about 1.25 centimeters (0.5 inches) long, oval, and fleshy when mature. The seeds are glossy, dark brown with an enlargement of a chamber of the seed coat forming a flaring collar that encircles the hilum (Damude and Poole 1990, Benson 1982) (USFWS, 2003).

**Taxonomy**

This plant is a member of the cactus family (Cactaceae) (USFWS, 2016). Astrophytum asterias was originally collected by Baron von Karwinsky in 1843 and described as Echinocactus asterias by Joseph Zuccarini in 1845 (Damude and Poole 1990, USFWS 2003). Charles Lemaire described the new genus Astrophytum in 1868, into which he placed A. asterias. Common names for A. asterias include: Biznaga-algononcillo de estrella, sand dollar, sea urchin star cactus, and false peyote (Integrated Taxonomic Information System 2011) (USFWS, 2013).

**Historical Range**

The historical range of star cactus included Hidalgo, Starr, Zapata, and possibly Cameron Counties in South Texas and the States of Nuevo Leon and Tamaulipas in Mexico. The Nuevo Leon site near Linares was probably extirpated by collectors (USFWS, 2003). When listed in 1993, only two extant populations of A. asterias were known, one population in the United States, in Starr County, Texas; and one population in Tamaulipas, Mexico (USFWS, 2013).

**Current Range**

Currently only known from Starr County in extreme south Texas and the adjacent state of Tamaulipas, Mexico (NatureServe, 2015).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Food/Nutrient Narrative**

Adult: Two growth rates were determined using different calculation methods. Based on the assumption that the mean annual growth rate is constant among all size classes, the growth rate was determined to be 2.71 millimeters (mm)/year (0.10 in/year). The second method took into account the premise that growth rates differ by size class (growth rates range from -0.85 – 3.65 mm/year (-0.03 – 0.14 in/year). This resulted in the mean diameter growth rate of 2.1 mm/year (0.08 in/year) (USFWS, 2013).

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2013)

**Dependency on Other Individuals or Species**

Adult: Diadasia rinconi (USFWS, 2013)

**Breeding Season**

Adult: March - May (USFWS, 2013)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2013)

**Reproduction Narrative**

Adult: Flowers usually bloom from March - May, opening in the morning and closing in the evening. Astrophytum asterias is an obligate outcrosser (USFWS 2003, 2013). Using the estimated growth rates, it would take 15 - 25 years to reach the 4-cm (1.57 in) benchmark for reproductive maturity. The cactus specialist bee Diadasia rinconis was found to be the most effective of all the observed pollinators (Janssen et al. 2010). Other insects visited the flowers more frequently but because of low effectiveness, they are not considered the most important (Janssen et al. 2010) (USFWS, 2013). Fruiting occurs April through June (USFWS, 2003).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Historical: subtropical grassland or grassland/savannah; current: shrubland, non-native grassland (NatureServe, 2015); Tamaulipan thornscrub (USFWS, 2013)

**Dependencies on Specific Environmental Elements**

Adult: Partial shade (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Currently, this species is found in sparse, fairly open brushland. It is most often found growing in gravelly, sometimes saline, clays or loams in the partial shade of other plants or rocks. The vegetation in these areas was originally a subtropical grassland or grassland/savannah, but fire suppression, overgrazing, and pasture improvement have converted it to thorny shrublands and stands of non-native pasture grass. It is uncertain what habitat this species occupied in the original grassland ecosystem (NatureServe, 2015).

Astrophytum asterias occurs on flats in shrublands and grasslands in Tamaulipan thornscrub. Soil analysis indicates that the highest density of A. asterias was found on saline-sodic, followed by saline soils (Janssen et al. 2010) (USFWS, 2013).

***Dispersal/Migration***

**Dispersal**

Adult: Low (inferred from USFWS, 2013)

**Dispersal/Migration Narrative**

Adult: Seed dispersal mechanisms in the wild are virtually unknown. Mature fruits appear to disintegrate while still attached to the plant and leave a small cluster of seed on top of the plant. Wind and rain may carry the seeds away to establishment sites. Small rodents may also store the seeds at cache sites. Additionally, ants may play a role in seed dispersal (USFWS, 2013).

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

U.S.: 24; Mexico: 9 (USFWS, 2013)

**Population Size:**

U.S.: 5,125; Mexico: 1,275 (USFWS, 2013)

**Population Narrative:**

This species has experienced a short term decline of > 30%; the Nuevo Leon site is believed to have been extirpated by collectors, and the Tamaulipas site has been reduced to very few individuals (NatureServe, 2015). In Starr County, Texas, 2011 surveys brought the known total of extant A. asterias populations to 24, containing a total of 5,125 individual plants. There are nine populations in Mexico, totaling 1,275 plants (Janssen et al. 2010, Martinez-Avalos 2002) (USFWS, 2013).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The leading threat to A. asterias throughout its range currently, and at the time of listing, is habitat loss. All A. asterias populations in Starr County, Texas, are located on private property; the majority of which do not have signed conservation agreements. An extensive land area in Starr County has been root-plowed and converted to buffelgrass (Pennisetum ciliare) pasture; this has presumably destroyed an unknown amount of star cactus habitat. Mechanical disturbance makes habitat unsuitable for A. asterias. An additional but unknown amount of habitat has probably been lost to urban and residential development and highway construction. Highly competitive introduced grasses (specifically buffelgrass) are clearly incompatible with A.

asterias conservation. Buffelgrass reduces native vegetation coverage, density, species richness, and diversity (Sands et al. 2009). Seismic surveys, oil and gas well development, and other construction related to oil and gas exploration can cause surface damage and irrevocably damage or completely destroy the habitat (Conner 2011) (USFWS, 2013).

**Stressor:** Overutilization due to collection (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Collectors for many years have removed cacti for private collections. Astrophytum asterias are collected by individuals for personal use or trade, sometimes being mistaken for peyote (Lophophora williamsii). The demand for rare cacti by collectors has escalated in the United States and in other countries, including Asia and Europe (Westlund 1991). In 1991 the TPWD published a report on the cactus trade, monitoring impacts by investigating 72 individual collectors, family nurseries, and commercial nurseries (Westlund 1991). Although many of these collectors/growers had less than 50 individual cactus plants, representing only three to four species, one "digger" had more than 1,000 freshly dug cacti of 13 subspecies. Four hundred field-collected A. asterias were observed in nurseries, and eight mail order catalogs had A. asterias listed for sale (USFWS, 2013).

**Stressor:** Disease and predation (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the U.S. and Mexican populations, the leading cause of mortality was found to be herbivory by Mexican-ground squirrels. It does appear that during periods of drought, the level of herbivory is increased. Other causes of mortality were found to be insect herbivory and fungal infections. Combination of pathogens and herbivory was shown to greatly reduce the population by over 50 percent (Martinez-Avalos 2007). Several animal and insect species appear to utilize and destroy A. asterias. The threat to A. asterias continues to remain high, especially during periods of drought (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Rising temperatures might enable the species to survive further north than at present, but might also reduce the southern limit of the range. Similarly, changes in the frequency and amount of precipitation could favor a shift in geographic range or habitat type. However, the limited seed dispersal range, and the existence of new barriers to migration could impede alteration of the range of A. asterias (Malanson and Cairns 1997). Changes in temperature and rainfall amounts and patterns could alter the species' competitive advantage in the unique micro-habitats it now inhabits. Regardless of how these changes may affect the autecology of A. asterias, the altered synecology may be far more significant. For example, higher winter temperatures could increase competition from invasive grasses (Patterson 1993) (USFWS, 2013).

**Stressor:** Reduction of genetic variability (USFWS, 2013)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** At the time of listing, the one site known to have the star cactus present contained fewer than 2,100 plants. Genetic variability and viability decrease with reduced numbers of plants across the range (Ledig 1986). This, along with the pressures of other natural and anthropogenically-induced threats, increases the possibility of extinction of the species in the wild (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
1. Maintain or establish ten geographically distinct, fully protected, self-sustaining populations of star cactus in the United States or Mexico, each with a minimum of 2,000 individuals and an age class structure reflecting that plants are reproducing and becoming naturally established within the population (USFWS, 2013).

2. Develop and implement a formal conservation agreement between the U.S. and Mexico (USFWS, 2013).

Recovery Priority Number: 2

**Delisting Criteria:**
1. Over a 60-year period, maintain the 5 fully protected sites in each designated recovery unit at the MVP of 2,500 individuals per site with at least 50% being of reproductive age. All sites will be fully protected, self-sustaining sites occurring across the species known range within each recovery unit. (USFWS, 2019)

**Recovery Actions:**
- Protect and manage existing star cactus populations and habitat in the United States and Mexico (USFWS, 2003).
- Gather information for management and monitoring programs for star cactus (USFWS, 2003).
- Search for new populations of star cactus in the United States and Mexico (USFWS, 2003).
- Establish and maintain a botanical garden population of star cactus (USFWS, 2003).
- Establish new populations in natural habitat as necessary to meet reclassification criteria (USFWS, 2003).
- Develop and implement a formal conservation agreement for star cactus between the United States and Mexico through the Trilateral Agreement (USFWS, 2003).
- Develop a public education and awareness program for the species (USFWS, 2003).
- Evaluate progress toward recovery, management direction, and status of information needed for development of delisting criteria within five years (2008-2009) (USFWS, 2003).
- Continue periodic monitoring of the known populations in Texas and Mexico to track demographic trends, and to detect and attempt to alleviate threats to these populations (USFWS, 2013).
- Conduct public outreach efforts to encourage conservation of the species and its habitat on private lands. Work with private landowners to establish a private landowner support group and pursue conservation agreements with landowners (USFWS, 2013).

- Conduct surveys of high-potential habitat within the known range of the species in South Texas and Mexico, focusing on sites that have not previously been surveyed (USFWS, 2013).
- Develop an official reintroduction plan for A. asterias. Collect seeds from the known populations, propagate in a greenhouse to produce seedlings, and reintroduce at protected sites, in accordance with Service policy on controlled propagation of endangered species (65 FR 56916) (USFWS, 2013).
- Although the recovery plan (USFWS 2003, p. 13) stated that at least two distinct tracts of National Wildlife Refuge (NWR) land in Texas have the type of soil and habitat necessary for A. asterias reintroduction, and Recovery Action 5 further stated that reintroduction could be implemented on Lower Rio Grande Valley NWR, subsequent habitat assessments, conducted by two separate teams of star cactus experts (in 2005 and in 2010), did not find any suitable star cactus habitat on any existing tracts of Lower Rio Grande valley NWR. However, this refuge could target some future land acquisitions to include suitable habitat for A. asterias (USFWS, 2013).
- Amended recovery criteria 1. Maintain or establish at least 5 sites (>1 km of separation between sites) within each of a total of 3 designated recovery units in Texas and Mexico. Recovery units will be based on geology and/or soils. Each site will contain at least 2,500 individuals, 50% of which will be of reproductive age as determined by a size of ≥ 4 cm diameter. The sites must occur across the species known range within each recovery unit; however, coalescence of sites due to recovery or discovery of new sites will not reduce the number of recognized sites. 2. All sites described above in downlisting criterion 1 must be fully protected in perpetuity and managed appropriately for the species, its habitat, and pollinators. 3. Develop and implement a formal conservation agreement for star cactus between the U.S. and Mexico. (USFWS, 2019)

USFWS. 2019. Recovery Plan Amendment for 20 Southwest Species. 14 pp.

# SPECIES ACCOUNT: *Atriplex coronata var. notatior* (San Jacinto Valley crownscale)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/13/1998; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb, 1-3 dm tall, with gray-scaly herbage. Flowers are inconspicuous, with rounded, often bumpy bracts developing in the fruiting stage. Usually flowers in April and May and sets fruit by May or June (NatureServe, 2015).

**Taxonomy**

Atriplex coronata var. notatior (San Jacinto Valley crownscale) was first described by Willis Jepson in 1914, eased on specimen material he collected ii 1901 from the dried bed of San Jacinto Lake. Riverside County, California This taxon was considered a minor variant in a monographic treatment of the genus Atriplex (Hall and Clements 1923) and was generally not recognized as distinct from A. coronata until Munz (1974) concurred in Jepsons findings in his treatment of southern California plants (USFWS, 1994). It is a member of the Chenopodiaceae (goosefoot family) (Zacharias 2012, p. 629) (USFWS, 2012).

**Historical Range**

See Current

**Current Range**

Restricted to the San Jacinto, Perris, Menifee, and Elsinore Valleys of western Riverside County, California. Occurrences are associated primarily with the San Jacinto River and Old Salt Creek tributary drainages, with an additional occurrence near Lake Elsinore (USFWS 2008) (NatureServe, 2015).

**Critical Habitat Designated**

Yes; 4/16/2013.

**Legal Description**

On April 17, 2012, the U.S. Fish and Wildlife Service (Service) proposed to designate critical habitat for San Jacinto Valley crownscale (Atriplex coronata var. notatior) under the Endangered Species Act of 1973, as amended (77 FR 23008 - 23057). On April 26, 2013, the Service issued a Final Rule in which no critical habitat was designated for San Jacinto Valley crownscale (78 FR 22626 - 22658). The Final Rule states "The Secretary is exercising his discretion to exclude approximately 8,020 ac (3,246 ha) of previously proposed critical habitat for Atriplex coronata var. notatior. The Service determined that the benefits of exclusion outweigh the benefits of inclusion for lands previously proposed as critical habitat within areas covered under the Western Riverside County Multiple Species Habitat Conservation Plan, the Rancho Bella Vista Habitat Conservation Plan, and the Southwestern Riverside Multi-species Reserve Cooperative Management Agreement." On October 13, 2005, the Service issued a Final Rule that did not designate critical habitat for this species (70 FR 59952 - 59974).

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: April - August (USFWS, 2012)

**Key Resources Needed for Breeding**

Adult: Wind (USFWS, 2012)

**Reproduction Narrative**

Adult: Seeds may remain viable for more than five years, such that a soil seed bank may be present at occupied and formerly-occupied sites (USFWS 2008) (NatureServe, 2015). Atriplex coronata var. notatior is monoecious (plants bear separate male and female flowers on the same plant) and is believed to be wind-pollinated. Atriplex coronata var. notatior is reported to be a prolific seed producer (Ogden Environmental and Energy Services Corporation [OEESC] 1993, p. 27). Seeds generally germinate in the spring as flows recede, flower in April and May, and set fruit by May or June (Bramlet 1992, pers. comm.). The flowering period may extend to August in years when the water recedes late in the spring season (Munz 1974, p. 355; California Native Plant Society [CNPS] 2001, p. 93) (USFWS, 2012).

**Habitat Type**

Adult: Wetland, terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Alkali vernal plain, alkali playa, alkali scrub, alkali grassland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Dynamic hydrological regime (NatureServe, 2015); seasonal large-scale flooding (USFWS, 2012)

**Environmental Specificity**

Adult: Very narrow to narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Occurs in seasonal wetlands, such as floodplains and vernal pools, on slow-draining alkali soils; communities include alkali vernal plain, alkali playa, alkali scrub, and alkali grassland. Sites are typically flooded by winter rains, after which the water drains or evaporates over a variable period of time. Prefers areas with a dynamic hydrological regime that includes both local and large-scale flooding events (USFWS 2008). The environmental specificity is very narrow to narrow (NatureServe, 2015). It is associated with alkaline-saline soils. A hydrologic regime that includes seasonal and large-scale flooding in combination with slow drainage in alkaline soils with low nutrient loads is a key habitat element for this taxon. Atriplex coronata var. notatior is adapted to grow in slow-draining alkaline-saline clay soils, primarily the Willows soil series and, to a lesser extent, the Domino, Traver, Waukena, and Chino soils series (Knecht 1971, p. 23; Bramlet 1993, p. 4) (USFWS, 2012).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Fruits appear capable of floating, which would allow them to be dispersed by annual flood waters (NatureServe, 2015).

***Population Information and Trends***

**Population Trends:**

Decline of 50 - 90% (NatureServe, 2015)

**Species Trends:**

50 - 70% decline (NatureServe, 2015)

**Number of Populations:**

15 (USFWS, 2021)

**Population Size:**

106,000; variable depending on year (USFWS, 2012)

**Adaptability:**

Low (inferred from USFWS, 2012)

**Population Narrative:**

The U.S. Fish and Wildlife Service (1998) estimates that approximately 75% of this taxon's historically suitable habitat has been destroyed or heavily impacted. This species has experienced a long-term decline of 50-90%. Between 1992 and 1998, the number of individuals and area occupied appeared to decline about 70% (U.S. Fish and Wildlife Service 1998). Between 1998 and 2008, the overall extent of the range did not change appreciably, but fragmentation of the spatial distribution within the range (in both space and time) continued due to ongoing threats (USFWS 2008). In 2000, the rangewide population was estimated to be 106,000 individuals (Glen Lukos Associates cited in USFWS 2008); as of 2008, this was still considered the best available estimate. However, the 2000 survey was conducted under the unusually favorable conditions of a two-year suspension of discing and manure dumping by the majority of landowners; these activities have since resumed and are expected to have decreased the number of plants (USFWS 2008). In addition, this annual plant undergoes significant year-to-year fluctuations in the number of standing individuals in response to annual rainfall, extent of winter flooding, temperature, and habitat conditions; therefore, estimates of plant numbers based on short-term data should be used very cautiously (USFWS 2008). Approximately 8 occurrences are believed to have excellent or good viability (CNDDB 2008) (NatureServe, 2015). The Service has defined three geographic locations representing four occurrences of A. c. var. notatior in western Riverside County. A rangewide population estimate of 106,000 individuals of Atriplex coronata var. notatior is based on estimates from surveys conducted in the spring of 2000 (Glenn Lukos Associates, Inc. 2000, p. 15). This taxon exhibits several attributes that might limit its distribution and population growth; particularly habitat specificity and dependence on hydrologic processes represent significant vulnerabilities for Atriplex coronata var. notatior (USFWS, 2012).

***Threats and Stressors***

**Stressor:** Urban and agricultural development (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Alberhill Creek occurrence of Atriplex coronata var. notatior in the floodplain north of Lake Elsinore is located in an increasingly urbanized area that contains both local and private lands. An example of a recent development threat at this occurrence is a proposed subtransmission line (in association with a recently completed electrical power substation), as part of the Southern California Edison Valley-Ivyglen Subtransmission Line and Fogarty Substation Project (W. Worthey, Consultant, 2011, pers. comm.). Efforts are in place to reduce threats to Atriplex coronata var. notatior from urban development and related infrastructure; however, comprehensive surveys have not been conducted for the Lower San Jacinto and Alberhill Creek occurrences. An increase in the addition of manure and biosolids along the Lower San Jacinto River occurrence related to agricultural activities has been observed (USFWS 2008, p. 10). These soils amendments can permanently impact alkaline soil habitat where Atriplex coronata var. notatior is found as a result of: (1) disruption of essential physical or biological features due to continued ground disturbance and (2) alteration of soil chemistry, which causes permanent habitat conversion to a different plant community and expansion of nonnative plants that invade and may outcompete native taxa (Roberts 1999, pers. comm.). The Service believes that these agricultural developments continue as important direct threats to Atriplex coronata var. notatior within the Lower San Jacinto River occurrence. However, based on the best available information, the magnitude of this threat is high for this occurrence because many of the point localities of A. c. var. notatior in portions of the Upper and Lower San Jacinto River occurrences are found on private land that continue to be tilled for dryland farming or negatively impacted by soil amendments. Within the Upper San Jacinto River occurrence, overland flows that cross over agricultural lands into Mystic Lake during major flood events (i.e., winter storms) can transport sediments containing nutrients into the lake, which has increased in recent years as smaller flow events have caused failure of the Diversion Channel levees and flooding of agricultural lands in the San Jacinto Gap region (Tetra Tech and WRIME 2007, Appendix A, p. 1) (USFWS, 2012).

**Stressor:** Alteration of hydrology (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitats that support Atriplex coronata var. notatior are vulnerable to alteration of the supporting watershed, including prolonged inundation from increases in urban run-off as well as drainage of wetlands from removal of water supply (USFWS 1998, pp. 54984–54985). These alterations of hydrological processes are often the result of agriculture or urban development activities adjacent to alkaline wetlands. The San Jacinto River floodplain is often dry due to groundwater infiltration enhanced by low groundwater levels from excessive pumping and limited recharge (Tetra Tech and WRIME 2007, p. 28), which alter the seasonal flooding cycle. The Upper Salt Creek occurrence is bisected north to south by the San Diego Aqueduct Canal and currently includes open fields and cow pastures within the remaining alkaline vernal pool, alkaline grassland, and alkali scrub habitats (RECON 1995, pp. 15, 17; CNDDB 2012, EO 9). Additionally, historical drainage patterns in the Upper Salt Creek occurrence are disrupted by local roads, road ditches, and agricultural drainage ditches, which have reduced the degree and duration of ponding during the wet season (RECON 1995, p. 18) (USFWS, 2012).

**Stressor:** Disking (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** More than 500 ac (200 ha) of occupied or potential habitat for Atriplex coronata var. notatior has been disked for the purposes of fire suppression or weed abatement (USFWS 1998, p. 54984, citing Roberts 1993, p. 2). Disking (or tilling) is also used to prepare areas for farming activities. This activity changes the microtopography of the natural floodplains and the alkaline soils themselves, both of which are important features for establishment of this taxa and other native plants found in these seasonally flooded habitats (Bramlet 2009, pers. comm.). Disking for dryland farming has been an ongoing activity in the San Jacinto River floodplain for perhaps 100 years; however, this activity was, in the past, intermittent, allowing for recovery periods for Atriplex coronata var. notatior during fallow periods (Roberts 1999, pers. comm.) (USFWS, 2012).

**Stressor:** Invasive nonnative plants (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Displacement of Atriplex coronata var. notatior by nonnative plants was identified as a threat at the time of listing. In particular, the expansion of a nonnative grass, Crypsis schoenoides (swamp prickle grass), was described as an important threat as a result of its seeding as a food source for migratory waterfowl along the San Jacinto River (USFWS 1998, p. 54988). establishment of nonnative plants such as Brassica nigra (black mustard) and Salsola traga (Russian thistle) as a result of manure and sludge dumping along the Lower San Jacinto River floodplain has been documented (USFWS 2008, pp. 15–16). The continued planting of cover crops such as Festuca perennis (rye grass) (as Lolium multiflorum (Italian rye grass)) or Festuca (as Lolium) rigidum (Wimmera ryegrass; rigid Italian rye grass) for waterfowl, competes with existing alkali plant communities (Bramlet 2009, pers. comm.), displacing Atriplex coronata var. notatior and other native plants. The prevalence of nonnative plants remains a threat to Atriplex coronata var. notatior due to continued disturbance of these areas and the proximity of A. c. var. notatior occurrences to consistent sources of nonnative species of grasses and forbs from nearby residential development and highways (USFWS, 2012).

**Stressor:** Sheep grazing (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, intensive sheep grazing was described for the San Jacinto River and Hemet floodplain areas occupied by Atriplex coronata var. notatior (USFWS 1998, p. 54985). Sheep grazing in habitat occupied by A. c. var. notatior in the Upper Salt Creek occurrence was reported in 2005 (Roberts 2005, pers. comm.). Grazing is a recurring threat to the taxon at the Upper Salt Creek and the Lower San Jacinto River occurrences (USFWS, 2012).

**Stressor:** Trampling (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Sheep grazing has been previously described as the primary impact related to trampling to individual stands of plants. Trampling resulting from off-road vehicle use is likely to be a localized, individual threat to some populations of Atriplex coronata var. notatior within the most southern portion of the Lower San Jacinto River occurrence based on visible off-road trails and land disturbance observed with aerial imagery (ESRI 2010) (USFWS, 2012).

**Stressor:** Climate change (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Projected effects of climate change in the southwestern California ecoregion occupied by Atriplex coronata var. notatior from regional climate models indicate a mean annual temperature increase of 1.7 to 2.2º Celsius (C) (3.06 to 3.96º Fahrenheit (F)) by 2070, and a general consensus of a 2º C (3.6º F) increase in most months over the next 100 years (Point Reyes Bird Observatory [PRBO] Conservation Science 2011, p. 40). Vegetation changes are also expected. Drier climatic conditions can increase the threat to taxon such as Atriplex coronata var. notatior that rely on seasonal rainfall (USFWS 1998, p. 54989). Although there is currently uncertainty with current model projections of precipitation in southern California, the Service believes that predictions of warmer temperatures and increased variability in extreme rain or flood events are a threat to A. c. var. notatior through resultant changes in precipitation patterns that create conditions essential for maintaining habitat that supports plant populations (USFWS, 2012).

***Recovery***

**Reclassification Criteria:**
Not available - this species does not have a recovery plan.

**Delisting Criteria:**
Not available - this species does not have a recovery plan.

**Recovery Actions:**
- Not available - this species does not have a recovery plan.
- Survey all historical and extant occurrences to determine the location, status, and acreage of occupied and suitable habitat of each population to establish a comprehensive baseline against which to measure future changes. Surveys should be concentrated on the remaining Willows soil series within the basin and valley floors that form the U-shaped region surrounding the Lakeview Mountains, encompassing the San Jacinto River and Upper Salt Creek 100-year floodplains. Additionally, a more focused survey for Atriplex coronata var. notatior should be conducted within the Alberhill Creek floodplain during a year with above average rainfall (USFWS, 2012).
- Conserve or preserve Atriplex coronata var. notatior occurrences on private lands. Continue to identify key property easements or parcels in the San Jacinto and Upper Salt Creek floodplains for Partners for Fish and Wildlife programs or purchase through the Act’s section 6 funding program (USFWS, 2012).
- Manage Atriplex coronata var. notatior occurrences to prevent potential impacts from recreational activities, dumping, or other human-related activities. This may include fencing or posting to prevent access to managed areas and evaluation of appropriate use of disking

practices for fire suppression and weed abatement (USFWS, 2012).
- Engage in the State of California’s TMDL program to ensure that water quality (as discussed in FACTOR A and FACTOR D) within habitat occupied by sensitive taxon, such as Atriplex coronata var. notatior, is evaluated in determining “beneficial uses” within the Temescal Creek (and its tributaries) and Lake Elsinore TMDL process (USFWS, 2012).
- Develop a Population Viability Analysis model such as a metapopulation occupancy model for Atriplex coronata var. notatior to determine the key features for survival. Conduct a sensitivity analysis to identify those elements that represent the most important threats to maintaining minimum population size (USFWS, 2012).
- Conduct research to evaluate reproductive life history characteristics such as seed germination requirements, mechanism of seed dispersal, and seed viability. This will assist in identifying reasons for the persistence of certain occurrences and actions needed to help conserve others (USFWS, 2012).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed below are to be completed over the next 5 years. Successful implementation of these actions will reduce threats to Atriplex coronata var. notatior and provide information to better understand the biological and physical factors limiting the population growth and distribution. We recognize that conservation of this taxon will require cooperation and coordination with partners to minimize impacts from current threats and aid with future restoration efforts. 1. Survey all historical and extant occurrences during the late spring-early summer subsequent to rainy seasons featuring average to above-average annual precipitation. This will help to determine the location, status, and acreage of occupied and suitable habitat of each population to establish a comprehensive baseline against which to measure future changes. Surveys should be concentrated on the remaining Willows, Traver, Domino, Chino, Waukena, Grangeville saline-alkaline, and Buchenau soil series within the basin and valley floors that form the U-shaped region surrounding the Lakeview Mountains, encompassing the San Jacinto River and Upper Salt Creek 100-year floodplains. Additionally, a more focused survey for A. c. var. notatior should be conducted within the Alberhill Creek floodplain during a year with above average rainfall. 2. Preserve A. c. var. notatior occurrences on private lands. Continue to identify key property easements or parcels in the San Jacinto and Upper Salt Creek floodplains for Partners for Fish and Wildlife programs or purchase through the Act’s Section 6 funding program. 3. Conduct research to understand important life history characteristics such as confirming the breeding system, seed germination requirements, mechanism of seed dispersal, and seed viability that will assist in identifying the underlying reasons for the persistence of certain occurrences and actions needed to help conserve others. 4. Develop an approach for restoring degraded alkali vernal pool and alkali meadow habitat suitable for reintroducing the species including: conducting a genetic study throughout the species range to inform seed collection efforts; collect and bank seed, develop a GIS-based habitat suitability model to determine appropriate areas for restoration, and model the species hydrological needs. 5. Manage A. c. var. notatior occurrences to prevent potential impacts from recreational activities, dairy waste deposition, or other human-related activities. This may include fencing or posting to prevent access to managed areas and evaluation of appropriate use and timing of discing practices for fire suppression and weed abatement. 6. Conduct research to understand the magnitude of the impacts associated with nonnative plant competition and develop appropriate techniques for managing nonnative plant species, where appropriate. In particular, determine the effects of Oncosiphon pilulifer, Hordeum murinum, and Hordeum marinum on A. c. var. notatior recruitment and persistence. Research appropriate timing and techniques to control the two nonnative barley species and O. pilulifer while minimizing impacts to A. c. var. notatior and the two, co-occuring native dwarf barley species (Hordeum intercedens and H. depressum). 7. Develop a Population Viability Analysis model such as a metapopulation occupancy model for A. c. var. notatior to determine the key features for survival. Conduct a sensitivity analysis to identify those elements that represent the most important threats to maintaining minimum population size. (USFWS, 2021)

# SPECIES ACCOUNT: *Ayenia limitaris* (Texas ayenia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 09/23/1994; Southwest Region (R2)

**Physical Description**

A spineless shrub with a canopy reaching up to 2.0 meters (m) (6.6 feet [ft]) in height and 2.8 m (9.2 ft) in breadth. However, mature, reproductive plants may be as little as 0.3 m (1.0 ft) tall and broad. The alternate, soft, heart-shaped leaves have minute hairs and toothed margins; microscopically, the hairs on the lower surfaces of the leaves are stellate. The older, woody stems are reddish-brown, up to 2 centimeters (cm) (0.8 inches [in]) thick, and dotted with cream-colored lenticels. Inflorescences arise from the leaf axils, from 1 to 4 per node; the peduncles are about 1 cm (0.4 in) long, usually bearing 3 flowers on pedicels up to 1 cm (0.4 in) long. The flowers are about 6 millimeters (mm) (0.24 in) wide, with five greenish, 3 mm- (0.12 in-) long sepals and 5 yellow- to cream-colored, kidney-shaped petals (having two prominent, ovate lobes) bearing filamentous claws. The fruit, a five-chambered capsule up to 1 cm (0.4 in) in diameter before drying, is covered with curved, velcro-like appendages that may adhere to the hair of animals. Capsules produce up to 5 dark brown to black, tuberculate seeds 4 to 5 mm (0.16 to 0.20 in) in length. The maturing capsules turn from green to straw-colored; eventually the 5 chambers split apart, ejecting the seeds up to about 3 m (10 ft) from the parent plant. (USFWS, 2016)

**Taxonomy**

Tamaulipan kidneypetal was first collected by C.G. Pringle (Pringle no. 2272) in 1888 in the vicinity of Hidalgo, Texas. This collection was initially identified as Ayenia berlandieri S. Watson; the genus Ayenia was classified at that time in the Sterculiaceae (cacao family). Robinson and Greenman (1896) based their description of a new species, Nephropetalum pringlei B.L. Rob. & Greenm., on Pringle’s specimen. Tamaulipan kidneypetal was collected several times in Cameron County, Texas, between 1924 and 1955 (see Table 3), and identified as A. berlandieri. Cristóbal (1960) first described the species limitaris, based on Shiller’s 1955 specimen from Brownsville, in her monograph on the genus Ayenia, which she also placed in the Sterculiaceae; this continues to be the authoritative treatment of the genus (Tropicos 2009). Both A. limitaris and N. pringlei were recognized as valid species until Dorr and Barnett (1986) established their synonymy. The name A. limitaris was retained, since Cristóbal had already described another species as A. pringlei Cristóbal. (USFWS, 2016)

**Historical Range**

In Texas, in Cameron, Hidalgo, and Willacy counties; also northeast Mexico. (USFWS, 2016)

**Current Range**

In Texas, in Cameron, Hidalgo, and Willacy counties, and northeast Mexico. (USFWS, 2016)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination, based on closely related species (USFWS, 2016)

**Lifespan**

Adult: Unknown; propagated plants: 10+ years (USFWS, 2016)

**Breeding Season**

Adult: May - June, September - November: bimodal (USFWS, 2016)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2010); direct sunlight, rainfall (USFWS, 2016)

**Reproduction Narrative**

Adult: A. limitaris is effectively pollinated by a locally abundant insect of the Rio Grande delta (USFWS, 2010). It appears to require at least some direct sunlight for successful reproduction. Herbarium specimens and observations of Tamaulipan kidneypetal in Texas indicate that wild plants flower most often in June, July, September, October, and November. The more consistent and prolific flowering and fruiting lasts from September through November; flowers and capsules may also be observed from May to June following significant rainfall. This pattern coincides with the prevailing bimodal rainfall pattern in the Rio Grande delta. During seasons when there has been little or no precipitation, Tamaulipan kidneypetal plants do not flower. Therefore, reproduction appears to be stimulated primarily by rainfall. Most members of the genus Ayenia, including A. limitaris, are obligately allogamous; their floral morphology renders self-fertilization mechanically impossible (Cristóbal 1960). The longevity of individual Tamaulipan kidneypetal plants is unknown. However, propagated plants in experimental plots and reintroduction sites have lived at least 10 years without any apparent decline in vigor. These plants began flowering and producing viable seed at about 1 to 2 years of age (USFWS, 2016).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Subtropical woodland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Partial shade (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**

Adult: Inland aridity, freezing temperatures, high elevations (USFWS, 2014)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2014)

**Habitat Narrative**

Adult: Dense subtropical woodland communities at low elevations. The current Texas site is within the Texas Ebony-Anacua (Pithecellobium ebano-Ehretia anacua) plant community - a closed-canopy community of riparian terraces that once covered much of the Rio Grande delta, but is now reduced to remnant fragments surrounded by agricultural fields, pastures, and urban areas. The site was once an active floodplain, and the effects of hydrologic changes on Ayenia limitaris are unknown (NatureServe, 2015). Wild populations have now been documented in a wide range of alluvial soil types, from fine sandy loam to heavy clay. The species establishes well and reproduces rapidly in disturbed soils. Wild populations frequently occur in partial shade, or at the edge of shrub canopies, rather than under dense shrub or forest canopies (USFWS, 2010). The species' range appears to be restricted by increasing aridity further inland and by the prevalence of freezing weather further north and at higher elevations in the mountain ranges of northeast Mexico (USFWS, 2016).

***Dispersal/Migration***

**Dispersal**

Adult: Low (inferred from USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: The capsules dehisce upon drying, scattering the seeds up to a few meters away from the parent plant. The recurved appendages of the fruit capsule may also serve to disperse entire capsules by adhering to animal hair or feathers. Additional seed dispersal may be caused by insects, water flow, or other factors (USFWS, 2010).

***Population Information and Trends***

**Population Trends:**

Declining (inferred from USFWS, 2016)

**Number of Populations:**

U.S.: 5; Mexico: 10 (USFWS, 2016)

**Population Size:**

U.S.: 1,400 - 1,800; Mexico: 4,000+ (USFWS, 2010)

**Minimum Viable Population Size:**

250 mature plants (USFWS, 2016)

**Population Narrative:**

Five extant populations, ranging from about 100 to 1,000 individuals, have been documented in the three southernmost counties of Texas. Ten extant populations, totaling at least 4,000 individuals, occur in two municipios of the Mexican State of Tamaulipas. At least seven populations in Texas have been extirpated. One population reported from Coahuila, Mexico has not been seen since 1936. A specimen was collected in 1985 in Topia, Durango, Mexico, but the species has not subsequently been reported from that area. (USFWS, 2016)

***Threats and Stressors***

**Stressor:** Habitat fragmentation and isolation (USFWS, 2016)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Fragmentation and isolation may prevent gene flow among populations and lead to a depletion of genetic diversity. Cristóbal (1960) stated that Ayenia species are allogamous and insectpollinated. Therefore, viable populations of Tamaulipan kidneypetal must be large enough to contain sufficient genetic diversity for out-crossing to occur, and habitats must be sufficiently large and diverse to sustain populations of the insect pollinators. The remaining habitats throughout the species' known range are greatly fragmented, and remaining populations are isolated from each other. Since the genetic diversity within and among populations has not been investigated, we do not know to what extent genetic depletion may have occurred or how soon it could occur. Currently, the known populations continue to reproduce successfully. In synthesis, we consider that habitat fragmentation and isolation and the resulting depletion of genetic diversity are real threats of unknown magnitude and immediacy. However, if not addressed, these are likely to become high magnitude, imminent threats. Furthermore, once genetic diversity has been lost it cannot be recovered. Therefore, the recovery actions that mitigate these threats should not be delayed. (USFWS, 2016)

**Stressor:** Ungulate browsing (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Ungulate browsing. Contreras-Arquieta (2005) observed several Tamaulipan kidneypetal sites in the municipio of Soto la Marina, Tamaulipas, that were used as goat pasture. He included goat browsing as a potential threat to the species. Although we have no information on the palatability of Tamaulipan kidneypetal to livestock, or the impacts of grazing on its populations and habitat, it is important to note that the largest U.S. population, and most if not all Mexican populations, occur on land that has been grazed by cattle. We conclude that cattle grazing is not a threat to the species and that goat browsing is an imminent but low-magnitude threat. Browsing by white-tailed deer (Odocoileus virginiana) may also constitute a threat where deer populations are high. (USFWS, 2016)

**Stressor:** Climate change (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** We do not know how past climate changes have affected Tamaulipan kidneypetal populations and distribution, nor can we predict how future climate changes, forecast by the range of models and emissions scenarios, will affect the synecology of the species and its habitat. For example, a reduced amount or frequency of rainfall could reduce the species' range, while a decreased incidence of freezing could expand its range northward or into higher elevations in Mexican mountains. Furthermore, if the optimal geographic range of Tamaulipan kidneypetal shifts, the species may not be able to migrate fast enough to keep up with the rapid pace of climate changes. Conditions favorable to Tamaulipan kidneypetal might also increase competition from invasive plants, such as guineagrass, or allow new parasites and pathogens to spread into its range, affecting both Tamaulipan kidneypetal and guineagrass in an infinitely complex aggregation of interacting effects. Consequently, we currently have no evidence that the combined effects of climate changes threaten Tamaulipan kidneypetal. However, it is possible that threats induced by climate changes, based on predicted slight increases in temperature and

evaporative deficit, may arise in the future. (USFWS, 2016)

**Stressor:** Competition from introduced invasive grasses (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Several introduced grass species of African and Asian origin are invasive throughout the Tamaulipan region of Texas and northeast Mexico, and have replaced much of the herbaceous plant diversity. In particular, guineagrass has been recorded at most Tamaulipan kidneypetal sites in Texas, and is probably present at all sites in Texas and Tamaulipas. Guineagrass competes directly with Tamaulipan kidneypetal for the same partially-shaded niches. Buffelgrass, King Ranch bluestem (Bothriochloa ischaemum), and Angleton bluestem (Dichanthium aristatum) were also listed as threats in the listing (USFWS 1994). Buffelgrass is extremely abundant throughout the region, and is a major threat to many rare plant species. Although buffelgrass is not shade-tolerant, it might exclude Tamaulipan kidneypetal from the more open portions of the habitat. Tamaulipan kidneypetal is probably threatened more by Kleberg bluestem and Angleton bluestem than by King Ranch bluestem. The former two grass species are abundant in alluvial, fine-textured soils in the deltas and flood plains of south Texas and northeast Mexico. The latter species prevails in well-drained, rocky uplands, such as the Edwards Plateau of central Texas. These three closely-related taxa pertain to a species complex often generically referred to as Old World bluestems; they are difficult to distinguish in the field and are often confused. Other invasive plants, such as introduced Kalanchöe species, may also threaten Tamaulipan kidneypetal in some sites. In summary, competition from introduced invasive grasses is a high-magnitude, imminent threat to all known populations of Tamaulipan kidneypetal. (USFWS, 2016)

**Stressor:** Loss of pollinators (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, flowers of Tamaulipan kidneypetal plants are effectively fertilized by unknown insect pollinators even when isolated from wild populations. This indicates that suitable pollinators are widespread and abundant in the region. Nevertheless, insect pollinators could be depleted, and pollinator access could be disrupted, by the loss and fragmentation of habitats, pesticide drift, or depletion of the native plant diversity. Pollinator loss is currently not a known, imminent threat, but could become a threat in the future. Several recovery actions included in this plan will help prevent the loss of Tamaulipan kidneypetal pollinators. (USFWS, 2016)

**Stressor:** Catastrophic events (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since there are few populations, most populations have few individuals, and populations are confined to limited geographic areas, individual populations are vulnerable to chance catastrophic events, such as hurricanes or the introduction of an invasive pathogen or parasite. However, due to the geographic range of known populations, it is unlikely that a single event could impact all populations. We conclude that catastrophic events represent a low-magnitude, non-imminent threat. (USFWS, 2016)

**Stressor:** Pesticide drift and runoff (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This potential threat has not been observed. However, due to the fragmentation and small size of occupied habitats and their proximity to agricultural fields and highway rights-of-way, herbicide and insecticide drift and chemical spills could harm some populations or the pollinators they depend on. Nevertheless, it is unlikely that accidental herbicide contamination will impact significant numbers of Tamaulipan kidneypetal plants. This low-magnitude, non-imminent threat can be further reduced through outreach to owners and managers of Tamaulipan kidneypetal habitats. (USFWS, 2016)

**Stressor:** Trampling (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Foot traffic can damage individual plants that occur along trails in parks and natural areas, or where people illicitly traverse habitats off-trail. Ordinarily, people avoid walking through dense thickets of spiny shrubs. However, undocumented aliens entering the U.S. from Mexico often pass through stands of native vegetation to avoid detection, and have damaged vegetation in natural areas along the border. Nevertheless, little if any actual damage to Tamaulipan kidneypetal plants has been observed from trampling. Consequently, we do not consider trampling to be a threat to the species. (USFWS, 2016)

**Stressor:** Oil and gas development (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In Texas, mineral rights owners take precedence over surface owners and may clear land for drilling operations without landowner consent. Many surface landowners in south Texas, including most federal and state conservation agencies and non-governmental conservation organizations, do not own mineral rights. Similarly, mineral rights in Mexico are owned by the Mexican federal government rather than the surface owner. Oil and gas exploration and extraction continues at a rapid pace throughout much of south Texas and northeast Mexico, and an ever-increasing proportion of the land has or will be cleared for drilling platforms, pipelines, access roads, and related infrastructure. In addition to the direct loss of populations and habitat through land clearing, these operations will increase the fragmentation of habitat and will create new colonization pathways for invasive grasses. Tamaulipan kidneypetal populations on private lands are particularly vulnerable, since the U.S. ESA does not protect endangered plants on private lands unless there is another form of prevailing federal nexus, such as a federally-funded program or regulated action. Therefore, oil and gas development is an imminent threat; the magnitude is medium to high, depending on the duration and intensity of hydrocarbon exploration that in turn is dependent on economic factors and the intricacies of energy markets. (USFWS, 2016)

**Stressor:** Altered vegetation structure and composition (USFWS, 2016)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Many ecologists believe that grasslands and savannas were more abundant in south Texas and northeast Mexico prior to European settlement, and that these vegetation types were converted to dense shrubland and forest as a consequence of poor rangeland management and changes in the natural fire cycle (see discussion in section I.d.-Ecology). This dramatic shift in vegetation composition and structure and fire dynamics may also have contributed to the decline of Tamaulipan kidneypetal. (USFWS, 2016)

**Stressor:** Unintended impacts of propagation and reintroduction (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The recovery actions proposed under the 2016 Recovery Plan include propagation and reintroduction of Tamaulipan kidneypetal into suitable habitats. These actions could cause unintended harm to the species, such as depletion of the seed banks of wild populations, genetic swamping due to excessive propagation from a genetically limited source population, inbreeding depression, outbreeding depression, and the spread of pathogens or parasites into healthy populations. Pilot reintroduction efforts conducted at LRGV NWR in the 1990s preceded the adoption, in 2000, of the USFWS policy on controlled propagation of endangered species (USFWS and NMFS 2000). This policy now requires that the potential risks of propagation be assessed and addressed prior to initiating propagation by USFWS or through USFWS support. Section E.13 of the policy requires preparation of a controlled propagation and reintroduction plan prior to the reintroduction of federally-listed threatened or endangered species. The plan should be based on strategies identified in an approved recovery plan, and should include protocols for health management, disease screening and disease-free certification, monitoring and evaluation of genetic, demographic, life-history, phenotypic, and behavioral characteristics, data collection, recordkeeping, and reporting, as appropriate. We conclude that, through compliance with USFWS policy on propagation and reintroduction, these actions will not threaten the species. (USFWS, 2016)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Tamaulipan kidneypetal is not protected by other U.S. federal or state laws. Federally-listed plants occurring on private lands have limited protection under the ESA, unless also protected by state laws; the State of Texas provides very little protection to listed plant species on private lands. Approximately 95 percent of Texas land area is privately owned. It is reasonable to assume that the vast majority of existing Tamaulipan kidneypetal habitat, including sites that have not been documented, occurs on private land. Therefore, most of the species' populations and habitats are not subject to federal or state protection unless there is a federal nexus, such as provisions of the Clean Water Act or a federally-funded project. (USFWS, 2016)

***Recovery***

**Reclassification Criteria:**

1. The successful accomplishment of threats reduction and mitigation is demonstrated by a stable or improving status of Tamaulipan kidneypetal, compared to the baseline conditions, throughout its known range over a period of at least 10 years. (Threat-based objective) (USFWS, 2016)

2: At least 10 populations of Tamaulipan kidneypetal, and at least 1 per recovery unit, are documented in optimal habitats for a period of at least 10 years. Habitat is considered optimal when: It is protected for conservation purposes; it is managed in a manner that promotes the long-term survival of Tamaulipan kidneypetal; it has less than 10% cover of introduced invasive plant species; it consists of at least 400 ha (988 ac) of contiguous habitat; and where Tamaulipan kidneypetal populations are observed to be stable or increasing. (Habitat-based objective) (USFWS, 2016)

3. Conserve, protect, and restore populations of Tamaulipan kidneypetal needed for its recovery. Populations must be self-sustaining, of sufficient size to endure climatic variation and stochastic events, of sufficient number to endure catastrophic losses, and must represent the full range of the species' geographic and genetic variability. (Population-based objective) (USFWS, 2016)

Recovery Priority Number: 8C

**Delisting Criteria:**
Criteria 1 through 3: Same as Downlisting Criteria (USFWS, 2016)

4: Twenty (20) or more protected populations, including no less than 5 per recovery unit, have maintained stable or increasing populations of at least 500 mature individuals, 47 and at least 1 population per recovery unit maintains 1,000 or more individuals, for a total of at least 20 years. (USFWS, 2016)

**Recovery Actions:**
- 1. Protect and conserve the known populations and their habitats in the U.S. and Mexico. Promote cooperative efforts to conserve occupied habitats and protect known populations from invasive grass competition, excessive browsing, trampling, and other potential threats. Seek sources of financial and technical assistance to support these efforts. This action faces the following challenges: 1) Several known populations in the U.S. occur on private land; 2) a majority of the known populations, and almost all of the species' global range, occur in Mexico; 3) the known Mexican populations all occur on private or ejido land. Consequently, the U.S. ESA confers no authority to enforce the degree of population and habitat protection that is necessary to prevent a significant decline (jeopardy) of the species. Therefore, this action must rely heavily on voluntary conservation efforts and on close collaboration with Mexican agencies and conservation organizations. Furthermore, since it is probable that some populations on private and ejido lands will be destroyed or deteriorated through urban and agricultural development or other causes, this action addresses an objective of no net loss of populations and habitats; losses and deterioration of some populations and habitats may be offset through successful habitat restoration, improved management and protection of existing occupied habitat, or the discovery of new occupied habitats. (Priority 1) [More details are available in the 2016 Recovery Plan] (USFWS, 2016)

- 2. Develop a monitoring plan, and monitor known populations and habitats. The objectives and requirements of the monitoring plan are discussed in II.1 of the 2016 Recovery Plan. Visit known populations at least once per year, if possible, to make qualitative observations of habitat conditions and the growth and reproduction of Tamaulipan kidneypetal. Determine if there are any new or existing threats to the population and recommend actions to alleviate threats. Collect quantitative data on population size and reproduction at least 5 times every 10 years to track long-term population dynamics. (Priority 1)[More details are available in the 2016 Recovery Plan] (USFWS, 2016)
- 3. Develop partnerships with Mexican government agencies, academic institutions, and NGOs to promote investigation, conservation, and recovery of the species in Mexico. Potential Mexican agency partners include the Secretaría de Desarrollo Urbano y Medio Ambiente (Secretary of Urban Development and Environment, State Government of Tamaulipas; SEDUMA) and SEMARNAT, CONANP, and CONABIO (federal). Academic institutions may include Universidad Autónoma de Tamaulipas, Universidad Autónoma de Nuevo León (particularly the Facultad de Ciencias Forestales [Forestry Sciences Department]), and the Instituto Tecnológico y de Estudios Superiores de Monterrey (Monterrey Institute for Technology and Advanced Studies; ITESM). Pronatura Noreste a.c., based in Monterrey, Nuevo León, is a potential NGO partner. (Priority 1) [More details are available in the 2016 Recovery Plan] (USFWS, 2016)
- 4. Improve management of known populations and habitats, based on monitoring data and the conclusions of scientific investigations (adaptive management). (Priority 2) [More details are available in the 2016 Recovery Plan] (USFWS, 2016)
- 5. Conduct public outreach in the U.S. and Mexico to promote the species' conservation and recovery. Disseminate outreach materials, attend public meetings, communicate with interested members of the public, and meet interested landowners to discuss conservation and recovery of Tamaulipan kidneypetal. (Priority 2) [More details are available in the 2016 Recovery Plan.] (USFWS, 2016)
- 6. Conduct scientific investigations necessary for conservation and recovery. (Priority 2) [More details are available in the 2016 Recovery Plan] (USFWS, 2016)
- 7. Search for new and historic populations in U.S. and Mexico. Seek permissions from public, private, and ejido landowners to conduct surveys in areas of intact habitat where the climate, soils, and vegetation are similar to known and historic populations. (Priority 2) [More details are available in the 2016 Recovery Plan] (USFWS, 2016)
- 8. Restore and subsequently manage native vegetation within the Rio Grande delta recovery units to increase the amount of suitable available habitat and to establish functioning ecological corridors that reconnect isolated habitat fragments. Restoration methods must use local ecotypes of native species, and must restore a diverse sub-shrub, native grass, and forb understory and a partially open tree and shrub canopy to be considered suitable for Tamaulipan kidneypetal. Effective habitat restoration will offset unpreventable losses of habitat on private lands, and will make the criterion of no net habitat loss more achievable and practical. (Priority 3) [More details are available in the 2016 Recovery Plan] (USFWS, 2016)
- 9. Augment and reintroduce populations in appropriate habitats within the known range in U.S. and Mexico. Augmentation is the supplementation of an existing population with progeny of the same population or another population that is genetically suitable. Reintroduction is the establishment of new populations within the species' known range and habitat types, but where a population currently does not exist. The objective in either

case is to attain the criteria of an MVP of 250 or more mature individuals per population, 5 or more populations per recovery unit, at least 1 population per recovery unit with 1,000 or more mature individuals, and a minimum of 20 populations overall. All propagation and reintroduction will conform to the guidelines stipulated in an established controlled propagation and reintroduction plan.(Priority 3) [More details are available in the 2016 Recovery Plan] (USFWS, 2016)

- 10. Prepare post-delisting monitoring plan. In accordance with ESA section 4(g)(1), upon recovery and removal from the endangered species list, the status of delisted species must be monitored for not less than five years. In consideration of the potential responses of 59 Tamaulipan kidneypetal populations, based on its lifespan, reproductive rate, and demography, to the removal of federal protection, monitoring should be continued for at least 10 years to ensure that the populations and criteria upon which delisting are based continue to be secure. Post-delisting monitoring must quantitatively document the extant populations upon which delisting is based, including population sizes, age structures, reproduction, recruitment and mortality, habitat conditions, invasive species impacts, degree and effectiveness of protection, and impacts of threats. (Priority 3) [More details are available in the 2016 Recovery Plan] (USFWS, 2016)
- Complete an approved recovery plan for the species (USFWS, 2010).
- Continue periodic monitoring and surveys of the known populations in Texas and Tamaulipas to track demographic trends, and to detect and attempt to alleviate threats to these populations (USFWS, 2010).
- Conduct surveys of high-potential habitat within the known range of the species in south Texas and Tamaulipas, focusing on sites that have not previously been surveyed (USFWS, 2010).
- Survey existing habitats in the municipios of Múzquiz, Coahuila and Topia, Durango to attempt to confirm extant populations at those sites (USFWS, 2010).
- Collect seeds from the known populations and implement a reintroduction program at LRGV NWR, in accordance with USFWS policy on controlled propagation of endangered species (65 FR 56916) (USFWS, 2010).
- Conduct scientific investigations of the species’ reproductive biology, the genetic structure of known populations, and the genetic relationship between Ayenia limitaris and closely related species (USFWS, 2010).
- Conduct scientific investigation of the species’ ecology, with emphasis on vegetation structure and fire ecology (USFWS, 2010).
- Conduct public outreach efforts to encourage conservation of the species and its habitat on private lands; establish a private landowner support group (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Follow recommended actions outlined by the 2016 Texas Ayenia Recovery Plan. • Continue periodic monitoring and survey of the known populations in Texas and Tamaulipas Mexico to track demographic trends, and to detect and attempt to alleviate threats to these populations • Conduct surveys of high-potential habitat within the known range of the species in south Texas and Tamaulipas Mexico, focusing on sites that have not previously been surveyed. • Survey existing habitats in the identified areas in Tamaulipas Mexico to attempt to confirm extant populations at those sites. • Collect seeds from the known populations and implement a reintroduction program at Lower Rio Grande Valley National Wildlife Refuge, in accordance with Service policy on controlled propagation of endangered species (65 FR 56916). •

Conduct scientific investigations of the species’ reproductive biology, the genetic structure of known populations, and the genetic relationship between Ayenia limitaris and closely related species. • Conduct scientific investigation of the species’ ecology, with emphasis on vegetation structure and fire ecology. • Conduct public outreach efforts to encourage conservation of the species and its habitat on private lands; establish a private landowner support group (USFWS, 2022).

# SPECIES ACCOUNT: *Baccharis vanessae* (Encinitas baccharis)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/7/1996; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A shrub, < 2 m tall, broom-like in appearance with dense, erect branches, often leafless when the plants are in flower. Leaves are linear. Herbage is generally sticky-resinous. Whitish flower heads, lacking rays, bloom in the fall (August-November), Male and female flowers are borne on separate plants (NatureServe, 2015).

**Taxonomy**

A member of the Asteraceae (sunflower family) (USFWS, 2011).

**Historical Range**

Endemic to a narrow band of central-coastal San Diego County, California, from Encinitas eastward to Woodson Mountain, near Poway and southward to Mira Mesa; an area of ca 30 km E-W by 17 km N-S. Reported from 45 historical occurrences distributed within the same general range as that known at the time of listing, except for a southward extension of the range based on an occurrence detected in the Otay Mountain area. (NatureServe, 2015).

**Current Range**

This species is restricted to a patchy distribution along the coast and occasionally interior areas of San Diego County, California (USFWS, 2011).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

<u>Adult:</u> Sexual: cross-pollination (USFWS, 2012)

**Lifespan**

<u>Adult:</u> Presumed long-lived (NatureServe, 2015)

**Breeding Season**

<u>Adult:</u> August - November (USFWS, 2011)

**Key Resources Needed for Breeding**

<u>Adult:</u> Wind, insect pollinators (USFWS, 2011)

**Reproduction Narrative**

<u>Adult:</u> The blooming period is between August and November (CNPS 2010; San Diego Plant Atlas 2010). Baccharis vanessae is dioecious, meaning separate plants of both sexes must be in close

proximity for pollination and subsequent seed production to occur. Pollinated Baccharis flowers develop one-seeded dry fruits (achenes). Baccharis vanessae is probably pollinated by both wind and insects. Steffan (1997, pp. 52–54) collected native wasps, flies, beetles, and true bugs (from the order Hemiptera) from Baccharis pilularis (coyote bush), a related species that has flowers similar to B. vanessae and which also occurs in the same chaparral habitat. It exhibits an apparently low incidence of successful seedling establishment (USFWS, 2011). This species is presumed to be long-lived (NatureServe, 2015).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Maritime chaparral, mixed chaparral (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Disturbance/fire (USFWS, 2011)

**Geographic or Habitat Restraints or Barriers**

Adult: 60 - 335 m elevation (NatureServe, 2015), tall leafy shrubs (USFWS, 2011)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2011)

**Habitat Narrative**

Adult: Occupies steep slopes on sandstone and volcanic (1 site) substrates in fairly open southern maritime chaparral and dense mixed chaparral communities. Occurs at 60 - 335 m elevation (NatureServe, 2015). Observations suggest that Baccharis vanessae is not able to compete with taller, leafier shrubs such as Arctostaphylos spp. (manazanita) and Ceanothus spp., (ceanothus) or that it is a short-lived plant (KEA 1999, p. 15). Baccharis vanessae appears to be a pioneer species that increases in numbers after disturbance, such as fire, that opens up the chaparral canopy (Messina 2001, pp. 2–3; CNDDB 2011, EOs 17 and 18). Overall, B. vanessae appears to increase in numbers in burned areas following fire events. Baccharis vanessae has been observed to occur on the following soil types: Cieneba series, Corralitos loamy sand alluvial Huerhuero, San Miguel Exchequer, granitic, andesite rock outcrops, and soils derived from acid igneous rock (CNDDB 2011) (USFWS, 2011).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Achenes are each attached to a cluster of bristly hairs (a pappus), which facilitates wind dispersal (Steinberg 2002, p. 5). (USFWS, 2011).

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Increasing (USFWS, 2011).

**Number of Populations:**
14 presumed extant (USFWS, 2021)

**Population Size:**
Unknown (USFWS, 2011)

**Adaptability:**
Low (inferred from USFWS, 2011)

**Population Narrative:**
The species is now presumed extant at 30 occurrences. accurate plant counts for B. vanessae do not exist because no rangewide surveys have been conducted using a single monitoring protocol. Life history traits and habitat specificity seem to comprise the most significant vulnerabilities of Baccharis vanessae. The number of occurrences currently considered extant increased from 16 to 30 since listing (USFWS, 2011). Our 2011 5-year review identified 45 occurrences of Baccharis vanessae. 30 were extant or presumed extant and 15 were extirpated or possibly extirpated. Our review of new information from the CNDDB and the SDMMP found that there are 45 occurrences of B. vanessae. Fifteen are extant, 14 are presumed extant, 10 are possibly extirpated, and 5 are extirpated, although the organization of the occurrences is different than the 2011 5-year review (Table 1, Figure 1, and Figure 2). (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Development (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Following listing, occurrences continued to be impacted by development. A portion of one occurrence in Rancho Cielo (CNDDB 2011 EO 7 that currently includes EOs 11, 13, and 14) was eliminated by urban development. development remains a threat to B. vanessae occurrences or portions of those occurrences as well as occurrences identified as REGSS points not encompassed by a CNDDB polygons or the quarter-mile buffer zone around them. Of the 30 extant occurrences, 11 continue to be threatened by development associated impacts (EOs 1, 3, 5, 7, 8, 9, 24, 25, 27, 31, and SD 115244) (USFWS, 2011).

**Stressor:** Altered fire regime (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In southern California, populated areas in proximity to natural vegetation often are under some form of fuel modification requirements. Fuel modification generally includes the clearing or thinning of fire prone natural vegetation, which would include that occupied by B. vanessae. Historically, natural fire regimes in southern California were likely characterized by many small lightning ignited fires in the summer and a few large fires in the fall of varying fire intensity (Keeley and Fotheringham (2003, pp. 242–243). The current fire regime in southern California results in numerous small fires that periodically escalate into megafires that are

generally driven by extreme "Santa Ana" weather conditions of high temperatures, low humidity, and strong erratic winds (Keeley and Zedler 2009, p. 90). The primary difference between the current fire regime and historical fire regimes in southern California is that human-induced or anthropogenic ignitions have increased primarily due to an increase in human population density since 1960, resulting in human-triggered fire ignitions and in particular, megafires in many more localities (Keeley and Fotheringham 2003, p. 240), than were known historically. The primary concern with frequent megafires is the plant mortality associated with these extensive and intense events which may kill individual plants and thereby potentially precludes recolonization of burned areas by B. vanessae. The lack of habitat clearing brushfires, of adequate frequency and intensity, may pose a threat to B. vanessae reproduction. The absence of an appropriate disturbance regime may also limit opportunities for recruitment of B. vanessae (USFWS, 2011).

**Stressor:** Nonnative plants (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Prevalence of nonnative plants is expected to increase with proximity to persistent sources such as residential development and highways. Nonnative plants may crowd out suitable establishment sites for B. vanessae, as may unchecked native plants, and they may alter the fire regime of the site. Carpobrotus edulis (iceplant, Hottentot fig) has the ability to invade maritime chaparral after brushfires (Zedler and Scheid 1988, pp. 196–201). The thick mat of this nonnative plant can prevent seedlings of native plants from becoming established (D'Antonio and Mahall 1991, pp. 886–888). Centaurea seeds are known to germinate much faster than those of some Baccharis species, grow rapidly during the winter and spring, and reduce the performance (biomass gain) of Baccharis seedlings (Gomez-Gonzalez et al. (2009, p. 81) (USFWS, 2011).

**Stressor:** Restricted distribution and small population size (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Baccharis vanessae is at risk of extinction from naturally occurring events because of its restricted distribution and small population size (USFWS 1996, p. 52381). The distribution of the species is relatively narrow and likely habitat limited. This situation may exacerbate any other threats that are rangewide in scope, such as wildfires or broad jurisdictional fire suppression efforts. The small size of many Baccharis vanessae populations increases the probability that those populations will disappear or be otherwise compromised through random fluctuations in the environment (such as severe droughts or fires), failure to be cross-pollinated, or random human caused events (such as the clearing of a parcel of southern maritime chaparral in northern Lux Canyon in 2009) (S. Vurbeff, City of Encinitas, pers. comm., 2010). Small populations are also more susceptible to the expression of deleterious genes (USFWS, 2011).

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The impacts of predicted climate changes on individuals and habitat of Baccharis vanessae and similar species are unknown at this time. Baccharis vanessae may already be suffering adverse effects from past climate changes resulting in a drier Holocene climate in

present-day southern California. The observed lack of B. vanessae seedlings could possibly indicate that this species is unable to survive the length, severity, or the current timing of the annual dry season in San Diego County. Williams and Hobbs (1989, pp. 62, 64–66) discovered that B. pilularis seedlings tend to survive only during rainy springs (March to May) brought on by rare mega-El Niños like the one in 1982 to 1983 because the seedlings' root growth is negligible prior to March (USFWS, 2011).

**Stressor:** Trampling (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Currently, unauthorized camping occurs at Oak Crest Park in Encinitas (CNDDB 2011, EO 1) even though the area is conserved (Thiede, pers. obs., 2010). Visitor foot traffic, as well as potential trail maintenance activities, also pose a threat to the B. vanessae populations at EOs 17 and 18, and rock climbers at Woodson Mountain likely impact plants at EO 15 (CNDDB 2011) (USFWS, 2011).

***Recovery***

**Reclassification Criteria:**
Not available - this species does not have a recovery plan.

Recovery Priority Number: 5C

**Delisting Criteria:**
Not available - this species does not have a recovery plan.

**Recovery Actions:**
- Not available - this species does not have a recovery plan.
- Survey all historical and extant occurrences to determine the location, status, age-class representation, and sex composition of each population to establish a comprehensive baseline against which to measure future changes. Survey all areas that support "maritime-like" southern mixed chaparral for additional occurrences (USFWS, 2011).
- Manage Baccharis vanessae occurrences to maintain plants of both sexes. Outplantings could be considered at occurrences such as EO 28 where only one plant has been observed (USFWS, 2011).
- Investigate the possible causes of seed mortality and low reproductive success, and identify likely remedies (USFWS, 2011).
- Conserve or preserve Baccharis vanessae occurrences on private lands. Property easements or purchases of parcels could also be made through the Act's section 6 funding and other programs (USFWS, 2011).
- Determine the appropriate use or substitute for a natural fire regime to perpetuate suitable habitat for Baccharis vanessae (USFWS, 2011).
- Determine which areas are most susceptible, to reduce impacts to Baccharis vanessae from fuel modification and fire suppression activities (i.e. using GIS analysis) (USFWS, 2011).
- Determine the distribution of genetic diversity in the species occurrences and identify the most appropriate means to preserve the diversity (USFWS, 2011).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed below are to be completed over the next 5 years. Successful implementation of these actions will reduce threats to Baccharis vanessae. We recognize that conservation of this taxon will require cooperation and coordination with partners to minimize impacts from current threats and aid with future recovery efforts. 1. Conduct surveys for B. vanessae, including 1) surveys of Regionally Sensitive Species (REGSS) points and CNDDB polygons on conserved land that are not monitored by the SDMMP or other partners, and 2) surveys of suitable habitat where the species has not been detected. 2. Support partners to enhance habitat and manage highest-magnitude threats at B. vanessae occurrences (for example, from nonnative invasive plants). 3. Coordinate with the SDMMP on the development of a Rare Plant Management Plan for B. vanessae, which includes species-specific best management practices and identifies research needs. Work with the SDMMP to prioritize research and management needs for B. vanessae. 4. Collect seed from B. vanessae occurrences and conserve in an ex situ (off-site) conservation seed bank. Coordinate with the SDMMP on the development of a Seed Banking and Bulking Plan for B. vanessae. (USFWS< 2021)

# SPECIES ACCOUNT: *Baptisia arachnifera* (Hairy rattleweed)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 5/27/1978; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

A perennial herb, 5-8 dm tall, that is covered with grayish-white cobwebby hairs. Leaves are heart-shaped. Flowers (late June-early August) are bright yellow, borne in terminal clusters. (NatureServe, 2015)

**Taxonomy**

Dr. Wilbur H. Duncan first collected the hairy rattleweed in the summer of 1942, and suspected that it was distinct from other Baptisia species which occur in the coastal plain of GA and FL. Subsequent collections in 1943 confirmed his suspicion (USFWS, 1984).

**Historical Range**

It is endemic to portions of Brantley and Wayne counties in southeastern GA (USFWS, 1984).

**Current Range**

Baptisia arachnifera only occurs in a 50-square mile area in Brantley and Wayne counties in Southeast Georgia, on the Lower Coastal Plain (Georgia Department of Natural Resources 1995). (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual (NatureServe, 2015); sexual (inferred from EPA, 2016)

**Dependency on Other Individuals or Species**

Adult: Insect pollinators, especially Say's weevil (EPA, 2016)

**Reproduction Narrative**

Adult: Capable of asexual reproduction if roots are cut (NatureServe, 2015). Flowering occurs June to August and fruiting occurs August to September. Pollinators are presumably insects. The weevil Apion rostrum Say (Say's weevil) is possibly a major pollinator (EPA, 2016). Humphrey (1987) estimated that 25% of plants reproduce and found the number of fruit per individual plant is highly variable, with a mean of 52 seeds per fruiting plant per year; therefore, the seed production per 100 plants has been estimated as 1300 (USFWS, 2011).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Longleaf pine-saw palmetto flatwoods (NatureServe, 2015); early successional forest (EPA, 2016)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fires (EPA, 2016)

**Geographic or Habitat Restraints or Barriers**

Adult: 55 - 85 ft. elevation (EPA, 2016)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow to moderate (inferred from EPA, 2016)

**Habitat Narrative**

Adult: This species naturally occurred in open sandy areas within longleaf pine-saw palmetto flatwoods. It is now persisting in intensively managed slash and loblolly pine plantations, powerline right-of-ways, roadsides and a few small natural areas. B. arachnifera can occur as widely scattered individual plants or in dense clusters. Research done by the Rayonier Corporation suggest that populations tend to be clumping (B. Krueger, written comm.) (NatureServe, 2015). Longleaf slash-pine flatwoods with sparse canopy, fewer larger shrubs, greater light penetration and greater cover of herbs (mainly wiregrass) and low shrubs of the Lower Coastal Plain of Georgia. Habitat has early successional characteristics of open canopy and low abundance of larger shrubs. Habitat includes mesic pine lowland forest or pine flatwoods. Also occurs in floristically similar but more open pine-wire grass (Aristida stricta) shrub woodlands with occasional oaks (Quercus laevis, Q. virginiana, Q. nigra). Fire adapted communities that would naturally burn every 2-4 years. Most abundant in communities with the early successional characteristics of open canopy and low abundance of larger shrubs. Often adjacent to/grades into pocosin or bay swamp habitats scrub-shrub wetlands toward the wetter end of spectrum to habitats typical of longleaf pine-turkey oak communities towards the drier end. Identified soils series include: Mascotte Sand, Rigdon Sand, Sapelo Fine Sand, Pottsburg Sand, and Olustee Sand. These are sandy to a depth of 3 ft or more and have spodic horizons within 20 inches of the surface. Acidic, low fertility. These soils are poorly drained to somewhat poorly drained and moderately permeable with Rigdon sand being the best drained. Runoff is slow and internal drainage is impeded by the shallow water table. Occurs at elevations between 55 to 85 ft. (known population sites) (EPA, 2016).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seed dispersal occurs September to March; plants break off in wind and may disperse tumbleweed fashion with seeds still on the plant (EPA, 2016).

***Population Information and Trends***

**Population Trends:**

Declining (inferred from NatureServe, 2015)

**Species Trends:**

Declining (USFWS, 2011)

**Number of Populations:**

28 extant hairy rattleweed populations (USFWS, 2019)

**Population Narrative:**

Occurrences are scattered over a 125 square mile area. An estimated 95-99% of its original habitat has been converted to pine plantations (NatureServe, 2015). 22 extant populations occur entirely in Lower Coastal Plain of Georgia (EPA, 2016). The species status is declining; overstocking of trees, lack of fire management and seed predation by insects are the factors driving the species' decline. Ceska et al. (1997) found a substantial genetic diversity and relative uniformity in ten sampled plots (USFWS, 2011). Overall, there are 28 extant hairy rattleweed populations, 1 historical population, and 6 populations of unknown status (Figure 1). Only two populations, the Lewis Tract and Needmore Road, are apparently stable or increasing. The remaining 18 populations are likely declining due to incompatible silvicultural practices (e.g. bedding and timber harvesting). (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Silvicultural practices in the timber industry have altered approximately 2741 acres of hairy rattleweed habitat and directly destroyed individual plants. Hairy rattleweed populations are able to survive clear-cutting, but site preparation and replanting severely impact populations (U.S. Fish and Wildlife Service 1984, Humphrey 1987, Kral 1980). The effects of bedding, unnaturally high stocking densities of seedlings and fire exclusion in pine plantations are dramatically impacting this species (U.S. Fish and Wildlife Service 1984, Tassin and McGee 1999, Humphrey 1988, Leege and Squire 2006). High stocking densities are used to maximize the Net Present Value on industrial timber land. As a result, canopy closure is achieved and growing space is fully occupied, resulting in shading and elimination of the herbaceous ground cover, including hairy rattleweed. Following timber harvest, populations do not respond to the release from shading and competition with increased recruitment, as might be expected. The loss of ground cover contributes to a change in the fire community and reduces the opportunity for natural fires to play a role in the ecology to the site. In the past, wildfires and use of fire by man maintained habitat suitable for hairy rattleweed (U.S. Fish and Wildlife Service 1984, Humphrey 1987). Suppression of fire has resulted in increased competition from shrubs, which is considered to be a major factor responsible for reduction in abundance of hairy rattleweed (U.S. Fish and Wildlife Service 1984). Fire is still used for forest management, but the frequency and time of year of burning may not be beneficial to hairy rattleweed (U.S. Fish and Wildlife Service 1984, Humphrey 1987). The use of herbicides in powerlines and road rights-of-way could adversely affect populations of hairy rattleweed, although, the effects of herbicides are solely based on field observations. Two extant populations occur on 274 acres of hairy rattleweed habitat in areas where rural housing development has occurred. The houses and surrounding landscaping

directly destroy hairy rattleweed (USFWS, 2011).

**Stressor:** Drought (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** It is expected that severe drought could be a threat to small populations and would likely reduce recruitment into the population (USFWS, 2011).

***Recovery***

**Reclassification Criteria:**
Four self sustaining populations are secured (USFWS, 2011).

Recovery Priority Number: 5

**Delisting Criteria:**
1. There are at least eight self-sustaining populations secured and maintained within its historic or current range (eight would provide a reasonable degree of security against catastrophic loss and/or site alteration) (USFWS, 2011).

2. The number of individuals in the various populations has reached an optimum level or cover percentage and frequency occurrence, as established by management studies (USFWS, 2011).

3. Its biology is sufficiently understood to allow perpetuation of the species should circumstances require immediate or drastic alteration of populations and/or sites (USFWS, 2011).

4. Continuing protection and management after delisting are assured (U.S. Fish and Wildlife Service 1984) (USFWS, 2011).

**Recovery Actions:**
- Protect habitat and existing populations of the hairy rattleweed (USFWS, 1984).
- Monitor populations and their habitats (USFWS, 1984).
- Conduct searches for new stands of the hairy rattleweed (USFWS, 1984).
- Preserve existing germ plasm through cultivation and storage (USFWS, 1984).
- Conduct autoecological research (USFWS, 1984).
- Develop public awareness and support (USFWS, 1984).
- Investigate potential for longleaf pine planting on private land. Projects could be partially funded by the US Fish and Wildlife Service (USFWS, 2011).
- Secure funding for land acquisition to facilitate permanent protection for recovery of populations (USFWS, 2011).
- Implement conservation easements where possible (USFWS, 2011).
- Develop and distribute an information factsheet on hairy rattleweed (USFWS, 2011).
- Share with the local Natural Resource Conservation office information about the distribution and best management practices of hairy rattleweed (USFWS, 2011).

- Contact and cooperatively work with Okefenokee Electric Membership Cooperation/Georgia Department of Transportation regarding rights-of-way management (broadcast spraying along right-of-ways) (e.g., Georgia Power – mowing) (USFWS, 2011).
- Document change in industrial timber management over time and relate the change in management to the change in habitat (USFWS, 2011).
- Work with partners to help secure funding for protection and management efforts (USFWS, 2011).
- Reintroduce fire on select industrial timberland sites to study effects (USFWS, 2011).
- Create demonstration sites to establish effective hairy rattleweed habitat management (reflective of management guidelines that will be established and further researched) (USFWS, 2011).
- Investigate and provide incentives for hairy rattleweed management on private lands (e.g., appropriate mowing regimes or other management options) (USFWS, 2011).
- Prioritize tracts/sites for different purposes – acquisition/conservation, research plots, seedling recruitment, vulnerability to development, etc. (USFWS, 2011).
- Identify safeguarding sites (Sansavilla, others) for reintroduction efforts and potential expansion of the currently recognized distribution within historical area (USFWS, 2011).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS I. Conservation/Management Strategies 1. Secure funding for land acquisition to facilitate permanent protection for the recovery of hairy rattleweed populations. 2. Partner with Georgia Department of Transportation, Georgia Power, and the respective landowners to secure hairy rattleweed populations along rights-of way. 3. Work with timber companies on alternative management strategies that will promote hairy rattleweed populations, such as creating buffers along roadsides where populations occur. 4. Survey unknown populations. 5. Implement conservation easements on private land. 6. Work with public and private schools in Wayne and Brantley Counties to educate the youth about the endangerment of hairy rattleweed and to foster future recovery. 7. Reintroduce fire on select industrial timberland sites. 8. Create demonstration sites to establish effective hairy rattleweed habitat management (reflective of management guidelines that will be established and further researched). 9. Investigate and provide incentives for hairy rattleweed management on private lands (e.g., appropriate mowing regimes or other management options). 10. Collaborate with the Georgia Plant Conservation Alliance to propagate this species at botanical gardens or arboreta along the Coastal Plain of Georgia to help with future reintroduction efforts. II. Research Priorities 1. Re-survey long-term monitoring plots and GPS each site to document status across the range of hairy rattleweed. 2. Determine canopy cover relationships to vigor of plants and reproduction. 3. Characterize the vegetation and habitat requirements of hairy rattleweed. 4. Conduct additional inventory/surveys to more accurately predict the size of occupied polygons and the distribution of the species. 5. Characterize hydrology of hairy rattleweed sites. (USFWS, 2019)

# SPECIES ACCOUNT: *Berberis nevinii* (Nevin's barberry)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/13/1998; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An evergreen shrub, 1-4 m tall. Leaves have 3-5 leaflets with serrated, spine-tipped edges. Produces yellow flowers (March-April), followed by red or yellow-red berries (NatureServe, 2015).

**Taxonomy**

A member of the Berberidaceae (barberry family). Berberis nevinii is distinguished from other members of the genus by its nearly flat, narrow, serrate, pinnately veined leaflets, few flowered racemes, and reddish fruits (Munz 1974, p. 245; Niehaus 1977, p. 1; Williams 1993, pp. 362-363) (USFWS, 2009).

**Historical Range**

Its historical distribution likely consisted of fewer than 30 scattered occurrences in Los Angeles, San Bernardino, and Riverside Counties (Service 1998, p. 54958), and possibly San Diego County (Neihaus 1977, p. 1; Reiser 2001, p. 3; CNDDB 2008, Element Occurrence (EO) 45) (USFWS, 2009).

**Current Range**

Ranges from the foothills of the San Gabriel Mountains of Los Angeles County to near the foothills of the Peninsular Ranges of southwestern Riverside County, California (Fish and Wildlife Service 1998) (NatureServe, 2015).

**Critical Habitat Designated**

Yes; 2/13/2008.

**Legal Description**

On February 13, 2008, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Berberis nevinii (Nevin's barberry) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat units (CHU), in California (73 FR 8412-8440).

**Critical Habitat Designation**

The critical habitat designation for Berberis nevinii includes one CHU (six sub-units) in Rverside County, California. This species critical habitat encompasses approximately six acres (ac) (three hectares (ha)) (73 FR 8412-8440).

Unit 1: Agua Tibia/Vail Lake: Unit 1 comprises approximately 6 ac (3 ha) and is divided into two subunits: Big Oak Mountain Summit (1A) and Agua Tibia Mountain Foothills (1B). The lands in Unit 1 were occupied at the time of listing, contain the physical and biological features essential to the conservation of Berberis nevinii, and may be important for maintaining genetic diversity for the species as they include occurrences in ecologically unique areas. Subunit 1A: Big Oak Mountain Summit: Subunit 1A consists of approximately 5 ac (2 ha) of Federal land managed by the BLM on Big Oak Mountain to the north of Vail Lake in southern Riverside County. Two Berberis nevinii individuals of different sizes (ages) occur in this subunit on the summit of Big Oak Mountain at approximately 2,700 ft (823 m) elevation (i.e., the lower edge of the marine layer) (PCE 1 and 3). One individual is an old plant that is covered in lichens, and the other individual is considerably smaller and at some distance to the northeast of the older plant. This location is considered unusual (i.e., ecologically unique) for the species in that it is at higher elevation and on relatively flat clay lenses consisting of heavy adobe/gabbro type soils with high water-holding capacity, derived from Mesozoic basic intrusive rock (PCE 2) (Soza 2003, unpaginated). Soils in this area are classified primarily as Auld clay, 8 to 15 percent slopes, and Las Posas loam, 8 to 15 percent slopes, eroded (PCE 2) (Service GIS data 2006). This occurrence is located in an open grassland area with chaparral nearby. Associated plant species include Chenopodium californicum, Avena fatua, Harpagonella palmeri, Plantago erecta, Convolvulus simulans, Galium porrigens, and Delphinium sp. We are designating this subunit as critical habitat even though it is occupied by only two Berberis nevinii plants because it represents an ecologically unique site for the species and contains the physical and biological features essential to the conservation of B. nevinii. Additionally, this site contains naturally occurring B. nevinii of different sizes (ages). Because this occurrence is on an ecologically unique site, this subunit may be important in terms of preserving genetic diversity throughout the range of the species. Berberis nevinii occupied this subunit at the time of listing (63 FR 54956; October 13, 1998). Bureau of Land Management land on Big Oak Mountain consists of three small parcels totaling 888 ac (360 ha) surrounded by private land. The primary threats to Berberis nevinii habitat in this area are the indirect effects associated with urban and residential development on private lands adjacent to BLM lands, such as increased human recreation; incursion or spread of invasive, nonnative plants; and changes to the natural fire regime (i.e., increased ignitions and fire frequency, and shortened fire return intervals that can lead to type conversion of shrublands to annual grasslands). The BLM Resource Management Plan indicates that these parcels are closed to motorized vehicles and livestock grazing (BLM 1994, p. 28). However, special management considerations or protection for the physical and biological features may be needed to minimize disturbance to the vegetation and soils within this subunit; control invasive, nonnative plants; and maintain the natural hydrologic and fire regime of the area resulting from urban and residential development. Subunit 1B: Agua Tibia Mountain Foothills: Subunit 1B consists of approximately 1 ac (<1 ha) of federally-owned land managed by the USFS on the CNF near the Agua Tibia Wilderness Area in southern Riverside County, California. Five Berberis nevinii individuals are known from this area and are located at the edge of a stream channel (PCE 1) growing in association with coast live oak and riparian woodland species (PCE 3). Nearby chaparral includes such species as Quercus berberidifolia, Adenostoma fasciculatum, and Haplopappus squarrosus, and nearby desert species include Yucca schidigera (CNDDB 2007). These B. nevinii plants are growing under a canopy of Quercus agrifolia and Platanus racemosa with the following species: Heteromeles arbutifolia, Q. berberidifolia, Elymus condensatus, Mimulus aurantiacus, Lonicera subspicata, Pterostegia drymarioides, and Epilobium canum. Soils in this area are classified as rough broken land and Visalia gravelly sandy loam, with 5 to 9 percent slopes (PCE 2) (Service GIS data 2007). We are designating this subunit as critical habitat because it contains the physical and biological features essential to conservation of Berberis nevinii and it contains a relatively large natural occurrence of the species. Additionally, Service personnel visited this site in June 2006 while B. nevinii was in fruit and found that several of the fruits had three to four seeds, which may be significant for a species that appears to rarely set seed. Berberis nevinii occupied this subunit at the time of listing, as identified in the final listing rule (63 FR 54956, October 13, 1998). The Berberis nevinii occurrence on the CNF is not as well protected as the occurrence on the ANF (USFS 2005, p. 238).

The primary threats to B. nevinii habitat in this area are human recreation (off-highway vehicle use, shooting); wildland fire, including an increased risk of fire ignition due to the proximity of State Highway 79 (USFS 2005, pp. 232, 237); fuels and fire management activities (USFS 2005, p. 237); and invasive, nonnative plants, including potential short-term adverse effects associated with control efforts (USFS 2005, p. 234). This occurrence on the CNF burned in 1996 and vigorously resprouted following the fire (USFS 2005, p. 237). According to the USFS, this location has shown signs of disturbance from road activities, with unauthorized use of off-highway vehicles occurring close to, but not within, the area occupied by the species (USFS 2005, p. 235). Nonetheless, the magnitude of impacts associated with roads and recreational activity in this area appears to be low (USFS 2005, p. 238). Also, the USFS does not anticipate substantial camping and hiking-related impacts to B. nevinii habitat, and intends to avoid or mitigate these impacts through implementation of Forest Plan standards (USFS 2005, p. 234). The February 6, 2007, proposed rule (72 FR 5552) identified the proximity of Highway 79 as a potential threat to the Berberis nevinii occurrence and habitat on the CNF, in part due to proposed highway widening and realignment activities (72 FR 5565). However, we no longer anticipate that these activities will affect Subunit 1B as there currently are no plans for widening or realigning Highway 79 in the section of roadway closest to this subunit. The revised subunit is now more than 525 ft (160 m) south of the highway. As discussed in the Special Management Considerations or Protection section above, the presence of invasive, nonnative plants may impact the B. nevinii occurrence and habitat at this site. However, the CNF anticipates an eradication effort of the nonnative Arundo donax and other invasive grasses (USFS 2005) present in this subunit, which should minimize the impacts of this threat to the species and its habitat. One of the greatest threats to occupied habitat on the CNF and the physical and biological features contained therein is from wildland fire and the management of fire and fuels (i.e., fire suppression and prevention activities). This subunit is within the Wildland-Urban Interface (WUI) Defense Zone (USFS 2005, p. 237; Service 2005, p. 127). Some plants or habitat within the WUI Defense Zone could be removed or degraded under the Revised Land and Resource Management Plan due to fuel removal for fire protection or overly frequent fuel treatments (Service 2005, p. 127). Special management considerations or protection of the physical and biological features may be required to minimize disturbance to the vegetation and soils within this subunit; control invasive, nonnative plants; and maintain the natural fire regime of the area.   Subunit 1C: South Flank Big Oak Mountain:  We are excluding this subunit from the final designation of critical habitat under section 4(b)(2) of the Act (Table 1). See the Relationship of Critical Habitat to Habitat Conservation Plan Lands—Exclusions Under Section 4(b)(2) of the Act section below for a discussion of this exclusion.   Subunit 1D: North of Vail Lake:  We are excluding this subunit from the final designation of critical habitat under section 4(b)(2) of the Act (Table 1). See the Relationship of Critical Habitat to Habitat Conservation Plan Lands—Exclusions Under Section 4(b)(2) of the Act section below for a discussion of this exclusion.   Subunit 1E: South of Vail Lake/ Peninsula:  We are excluding this subunit from the final designation of critical habitat under section 4(b)(2) of the Act (Table 1). See the Relationship of Critical Habitat to Habitat Conservation Plan Lands—Exclusions Under Section 4(b)(2) of the Act section below for a discussion of this exclusion.   Subunit 1F: Temecula Creek East:  We are excluding this subunit from the final designation of critical habitat under section 4(b)(2) of the Act (Table 1). See the Relationship of Critical Habitat to Habitat Conservation Plan Lands—Exclusions Under Section 4(b)(2) of the Act section below for a discussion of this exclusion.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Berberis nevinii critical habitat consists of three components (73 FR 8412-8440):

(i) Low-gradient (i.e., nearly flat) canyon floors, washes and adjacent terraces, and mountain ridge/summits, or eroded, generally northeast to northwest-facing mountain slopes and banks of dry washes typically of less than 70 percent slope that provide space for plant establishment and growth;

(ii) Well-drained alluvial soils primarily of non-marine sedimentary origin, such as Temecula or sandy arkose soils; soils of the CajalcoTemescal-Las Posas soil association formed on gabbro (igneous) or latite (volcanic) bedrock; metasedimentary substrates associated with springs or seeps; and heavy adobe/gabbro-type soils derived from metavolcanic geology (Mesozoic basic intrusive rock) that provide the appropriate nutrients and space for growth and reproduction; and

(iii) Scrub (chaparral, coastal sage, alluvial, riparian) and woodland (oak, riparian) vegetation communities between 900 and 3,000 feet (275 and 915 meters) in elevation that provide the appropriate cover for growth and reproduction.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the areas within the geographical area occupied by the species at the time of listing contain the physical or biological features essential to the conservation of the species, and whether these features may require special management considerations or protection. As stated in the final listing rule (63 FR 54956, October 13, 1998), threats to the species and its physical and biological features include urban development, off-road vehicle use, human recreation (e.g., horseback riding), highway projects, fire management strategies (suppression measures, brush clearing) that alter natural fire processes to which native plant communities are adapted, and the introduction of invasive, nonnative plants that may compete with Berberis nevinii or contribute to combustible fuel loads (63 FR 54961). These threats can directly or indirectly result in the loss, modification, degradation, or fragmentation of B. nevinii habitat, thereby eliminating or reducing potential habitat for seed production and germination, seedling establishment, plant growth and maturation, and population growth. Individually or combined, these threats may require special management considerations or protection of the physical and biological features as addressed here and in more detail within the individual critical habitat unit descriptions that follow. Urbanization, flood control measures, road widening, and habitat degradation from extensive recreational use have contributed to the loss of Berberis nevinii habitat and have apparently resulted in the extirpation of several occurrences, particularly in the San Fernando Valley of Los Angeles County (63 FR 54961). Urban development is currently the primary threat to B. nevinii habitat and occurrences in the vicinity of Vail Lake and Oak Mountain in Riverside County. Urbanization may destroy, degrade, fragment, or otherwise alter the topography, soil, and vegetation community structure in ways that make areas less suitable for B. nevinii. Land grading for residential development and road projects may affect the topography of the site (PCE 1); alter soil composition and structure (PCE 2); change vegetation community composition and structure through clearing or thinning of vegetation and the introduction of nonnative plants (PCE 3); increase erosion potential (PCE 1 and 2); and change hydrological (drainage and water infiltration) patterns, thereby decreasing the quality and extent of available habitat for B. nevinii. Additionally, urban development within or near B. nevinii habitat may increase the frequency of fire on the landscape due to increased combustible fuel loads that may result from the incursion and spread of annual nonnative grasses and an increased potential for fire ignition. In the February 6, 2007, proposed rule (72 FR 5552), we focused primarily on potential indirect impacts of urbanization on Berberis nevinii habitat and occurrences in the vicinity of Vail Lake and Oak Mountain (72 FR 5565– 5567). Urban development is not expected to directly impact the known occurrences of B. nevinii on Federal land in the Vail Lake and Oak Mountain area, although indirect impacts associated with increased urbanization may occur. On the other hand, B. nevinii habitat on private land in this area may be subject to some degree of residential development, as described below in the critical habitat subunit descriptions (see the Critical Habitat Designation section of this final rule). However, these private lands are located within the Criteria Area of the Western Riverside County MSHCP and are targeted, in whole or in part, for acquisition and inclusion in the MSHCP Conservation Area as Additional Reserve Lands. Specifically, the conservation objectives of the MSHCP include conservation and management of at least 8,000 ac (3,238 ha) of suitable habitat, including all known locations of B. nevinii in the Vail Lake area (see the Relationship of Critical Habitat to Habitat Conservation Plan Lands—Exclusions Under Section 4(b)(2) of the Act section below for a detailed discussion of the MSHCP). Recreational activities may also impact the physical and biological features essential to the conservation of the species by destroying, degrading, fragmenting, or otherwise altering the topography, soil, and vegetation community in ways that make areas less suitable for Berberis nevinii. For example, off-highway vehicle use, hiking, camping, horseback riding, and recreational facility development in or near B. nevinii occurrences could alter or destroy surface and subsurface structure through trampling and clearing or thinning of vegetation (PCE 3), the introduction of nonnative plants (PCE 3), soil disturbance or compaction (PCE 2), and increased erosion and changes to hydrological (drainage and water infiltration) patterns that may in turn affect the topography, soil, and vegetation of the site (PCE 1, 2, and 3). Activities associated with fire management, such as fuel treatments, prescribed burns, and wildfire suppression, may also impact the physical and biological features essential to the conservation of the species. The creation of fuel breaks, brush clearing or thinning, and the use of heavy equipment and off-road vehicles for fire management could physically remove or disturb soils and alter soil composition (PCE 2), remove or destroy vegetation (PCE 3), increase erosion, and alter the topography (PCE 1) and hydrologic patterns in or near Berberis nevinii occurrences. Fire management activities could facilitate the incursion or spread of invasive, nonnative plants by potentially dispersing seeds and creating (disturbance) conditions that increase the competitive edge of nonnative species over native species, thereby altering the composition of the vegetation community (PCE 3). As pointed out in the proposed critical habitat rule (72 FR 5552), vegetation community composition and structure could be altered by fire management activities such as prescribed fires that are too frequent or that occur at times of the year atypical of the natural fire regime, or by fire suppression that allows overgrowth of high canopy cover, limiting or eliminating plant species that require full or partial sun from the plant community (72 FR 5563). Berberis nevinii's life history characteristics indicate that it likely recruits into chaparral during fire-free periods and may require long intervals between fires for recruitment and population increases; thus, overly frequent fire is a substantial and immediate threat to this species (White 2007, p. 1). While highway projects were identified in the final listing rule (63 FR 54956, October 13, 1998) and proposed critical habitat rule (72 FR 5552; February 6, 2007) as a threat to Berberis nevinii, we do not anticipate that this activity will affect designated critical habitat in the foreseeable future. Specifically, the proposed critical habitat rule identified the proximity of Highway 79 as a potential threat to the B. nevinii occurrence and habitat on the CNF (Subunit 1B) in part due to proposed highway widening and realignment activities (72 FR 5565). However, we no longer anticipate that these activities will affect Subunit 1B because: (1) There are currently no plans to widen the portion of State Route 79 closest to Subunit 1B, and (2) the revised subunit is now more than 525 ft (160 m) south of the highway, which is far enough away that impacts to the subunit from construction or widening activities are unlikely. Based on information provided for the economic analysis, nonnative Arundo donax (Arundo) and other invasive grasses are present in Subunit 1B, and the CNF anticipates an eradication effort based on the weed management strategy in the USFS' Revised Land Management Plan for the Four Southern California National Forests (USFS 2005). Additional information obtained on water storage at Vail Lake indicates that lake level fluctuations could affect proposed subunits bordering Vail Lake (specifically, proposed subunits 1D and 1E). While we revised proposed critical habitat boundaries for these subunits based on the currently permitted storage capacity of Vail Lake (see the Criteria Used to Identify Critical Habitat section in this final rule), fluctuating water levels that surpass permitted storage levels and lake storage capacity could still affect Berberis nevinii in subunits that border Vail Lake. However, the occurrences that are located closest to Vail Lake have not been inundated or affected by rising water levels and fluctuations in the recent past (Boyd 2007, p. 1), and we do not anticipate that any B. nevinii individuals in this area will be affected.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2009)

**Lifespan**

Adult: > 50 years (USFWS, 2009)

**Breeding Season**

Adult: March - April (USFWS, 2009)

**Reproduction Narrative**

Adult: This species flowers from March through April. Berberis nevinii shrubs are long-lived (more than 50 years) (Mistretta and Brown 1989, p. 5) with low reproductive rates likely due to sporadic production of fertile seed (Mistretta and Brown 1989, p. 5). Several occurrences of B. nevinii consist of only single plants that have existed for years or decades without reproducing sexually (Mistretta and Brown 1989, p. 5), suggesting a self-incompatible breeding system (White 2001, p. 36). Berberis nevinii likely does not reproduce by vegetative means (Mistretta and Brown 1989, p. 5; S. Boyd, Rancho Santa Ana Botanic Garden, in litt. 2006, p. 1) (USFWS, 2009).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Alluvial shrub communities, chaparral (NatureServe, 2015); oak woodland, riparian scrub, riparian woodland (USFWS, 2009)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire (USFWS, 2009)

**Geographic or Habitat Restraints or Barriers**

Adult: 1,400 - 2,700 ft. elevation (USFWS, 2009)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2009)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from USFWS, 2009)

**Habitat Narrative**

Adult: This species is found in 2 habitat types: the margins of dry washes with sandy and gravelly substrates and alluvial shrub communities; and steep slopes with coarse soils and chaparral communities. The presence of groundwater flow may be a habitat requirement (NatureServe, 2015). This species generally grows on sandy soils in low-gradient washes, alluvial terraces, and canyon bottoms, along gravelly wash margins, or on coarse soils on steep, generally north-facing slopes in association with the following plant communities: alluvial scrub, cismontane (e.g., chamise) chaparral, coastal sage scrub, oak woodland, and/or riparian scrub or woodland. Berberis nevinii is a fire-adapted species, where mature individuals may survive and re-sprout following fire (Mistretta and Brown 1989, p. 5; White and Leatherman 2001, p. 36). Most native occurrences of B. nevinii are between 1,400 and 1,700 feet (427 to 518 meters) in elevation (Boyd 1987, p. 2; CNDDB 2008, pp. 1–34), although one native occurrence on the Oak Mountain summit north of Vail Lake is at approximately 2,700 feet (823 meters). Native occurrences are strongly associated with alluvial soils or soils derived from nonmarine sedimentary based substrates, especially sandy arkose (sandstone derived from granitic material) (Boyd 1987, p. 7; Boyd and Banks 1995, p. 24; Soza and Boyd 2000, p. 25). Berberis nevinii is considered a drought-tolerant species, but it will also tolerate large amounts of water in cultivation without apparent damage (Wolf 1940, p. 2; Lenz and Dourley 1981, p. 130; A. Sanders, University of California Riverside, in litt. 1997, p. 2) (USFWS, 2009).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Fruits are adapted for animal dispersal (USFWS, 2009).

***Population Information and Trends***

**Population Trends:**

Declining (inferred from NatureServe, 2015)

**Number of Populations:**

14 native (USFWS, 2009)

**Population Size:**

< 370 (USFWS, 2009)

**Population Narrative:**

Historically, the range of this species probably consisted of fewer than thirty scattered occurrences. At least seven populations of the thirtyish known occurrences have been extirpated (Fish and Wildlife Service 1998) (NatureServe, 2015). Currently, there are 14 extant, native occurrences of Berberis nevinii. The total number of native B. nevinii individuals across its range may be less than 370 (USFWS, 2009).

***Threats and Stressors***

**Stressor:** Urbanization (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A majority of the occurrences and individuals of B. nevinii are on private lands subject to urbanization. Urban development is the primary threat to Berberis nevinii and its habitat in the vicinity of Vail Lake (USFWS 2008a, p. 8423). Land grading for residential development and associated roads may affect the topography of the site; alter soil composition and structure; change vegetation community composition and structure through clearing or thinning of vegetation and the introduction of nonnative plants; increase erosion potential; and change hydrological (drainage and water infiltration) patterns, thereby decreasing the quality and extent of available habitat for B. nevinii. In addition, urban development may increase the frequency of fire on the landscape due to increased combustible fuel loads and potential for fire ignition resulting from the incursion and spread of annual nonnative grasses (USFWS, 2009).

**Stressor:** Recreation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, hiking, camping, and recreational facility development have been included with off-road vehicles and horseback riding as recreational activities that threaten Berberis nevinii (USFWS 2008a, p. 8423). These activities may alter or destroy surface and subsurface structure through trampling and clearing or thinning of vegetation, the introduction of nonnative plants, soil disturbance or compaction, and increased erosion and changes to hydrological (drainage and water infiltration) patterns (USFWS 2008a, p. 8423). Although not discussed in the listing rule, recreational uses associated with the Vail Lake Village Resort and Campground (private) and the Dripping Springs Campground (Cleveland National Forest) were identified as a threat to three Berberis nevinii occurrences (CNDDB 2008, EOs 2, 20, 24). Since listing, hiking and biking along an adjacent fire road was noted as threat to the Cobal Canyon occurrence consisting of a single individual (CNDDB 2008, EO 46). At least 36 percent (5 of 14) of Berberis nevinii occurrences are currently known to be threatened by recreational activities. Seven additional occurrences near urban areas are likely threatened by these activities due to lack of protection from off-road vehicle access and close proximity to roads (USFWS, 2009).

**Stressor:** Proposed road widening (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** A proposal to widen State Route 79 (SR-79) south of Vail Lake was noted as a potential threat as it may directly impact B. nevinii occurrences and promote development in the area (USFWS 1998, p. 54961). An occurrence consisting of two plants in Arroyo Seco Creek (Table 1) is in close proximity to SR-79. According to geographic information system (GIS) data provided by the County of Riverside, planned widening of SR-79 in that area partially overlaps one of the B. nevinii individuals mapped in CNDDB (Dudek 2003a, pp.7-25, 7-26, 7-31; USFWS GIS data 2008) (USFWS, 2009).

**Stressor:** Altered fire regimes (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Activities associated with fire management, such as fuel treatments, prescribed burns, and wildfire suppression, may impact the physical and biological features essential to the conservation of Berberis nevinii. The creation of fuel breaks, brush clearing or thinning, and the use of heavy equipment and off-road vehicles for fire management could physically remove or disturb soils and alter soil composition, remove or destroy vegetation, increase erosion, and alter the topography and hydrologic patterns in or near B. nevinii occurrences. Fire management activities could facilitate the incursion or spread of invasive, nonnative plants by potentially dispersing seeds and creating (disturbance) conditions that increase the competitive edge of nonnative species over native species, thereby altering the composition of the vegetation community (USFWS 2008a, p. 8423). increases in urbanization and human activity in or near B. nevinii habitat are generally accompanied by an increased incidence of accidental fires (USFWS 1998, p. 54964). Overly frequent fire on the landscape could potentially kill young B. nevinii before they reach their reproductive potential and may adversely affect mature B. nevinii by causing repeated resprouting that depletes stored resources faster than they can accumulate during fire-free periods (White 2007, in litt., p. 1). In addition, repeated burnings over short intervals could eventually lead to type conversion (wholesale replacement) of chaparral/shrublands with nonnative annual grassland (Keeley et al. 1999, p. 1831) (USFWS, 2009).

**Stressor:** Small population size and low reproductive output (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since listing, the total number of native Berberis nevinii individuals across its range was reduced from 500 to fewer than 370 because of the reclassification of the San Francisquito Canyon occurrences from native to nonnative. In addition, 57 percent (8 of 14) of B. nevinii occurrences consist of three or fewer individuals, and 29 percent (4 of 14) of occurrences consist of only one individual. Low reproductive output of Berberis nevinii may be evidence of the potential impact of small population size on fitness described above. There appears to be little to no regeneration by seed occurring at most B. nevinii sites (Mistretta 1994, p. 186). Low seed set (including plants bearing fruits that lack seed) and lack of viable seed has been noted by both botanists and horticulturalists trying to obtain seed for propagation, even from within larger occurrences (Wolf 1940, p. 2; Boyd 1987, pp. 3, 44, 56; Mistretta and Brown 1989, pp. 4–5; Mistretta 1994, p. 186; Wall 2009, in litt., p. 5). In addition, several occurrences of B. nevinii consist of only a single plant that has existed for years or decades without reproducing (Mistretta and Brown 1989, p. 5; CNDDB 2008, EO 5). (USFWS, 2009).

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** One study predicted that 5 to 10 percent of California's native plant species would no longer find suitable habitat within the state, and thus be vulnerable to extinction, if average temperatures warmed 5–6° F (Morse et al. 1995, p. 393). Whether or not this would include Berberis nevinii is unknown. While the Service recognizes that climate change is an important issue with potential effects to listed species and their habitats, it lacks adequate information to make accurate predictions regarding its effects to B. nevinii at this time. Any changes in fire frequency resulting from climate change could directly threaten the persistence of the fire-prone occurrences of B. nevinii near Vail Lake in Riverside County (USFWS, 2009).

**Stressor:** Recreational activities (USFWS, 2021)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the 2009 5-year review, we discussed recreational threats to Berberis nevinii at four locations (San Timoteo Canyon, Dripping Springs Campground, Vail Lake, and Cobal Canyon). Off-road vehicles, horseback riding, hiking, camping, and recreational facility development were all listed as threats to B. nevinii (USFWS 2009, p. 14). (USFWS, 2021)

**Stressor:** Urbanization (Residential development) (USFWS, 2021)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the 2009 5-year review for Berberis nevinii, development was considered an immediate threat to the species, due to a proposal to develop the Vail Lake area (USFWS 2009, p. 13). In 2014, the Rancho California Water District (RCWD) acquired the lands encompassing the Vail Lake occurrences of Berberis nevinii, eliminating the immediate threat of residential development. The area is not under permanent conservation (for example, through conservation easement). However, RCWD management objectives for the area include habitat conservation and restoration (RCWD 2016, p. 6). We do not have information about other ownership or conservation status changes at other Berberis nevinii occurrences since 2009. (USFWS, 2021)

***Recovery***

**Reclassification Criteria:**
Not available - this species does not have a recovery plan.

Recovery Priority Number: 8

**Delisting Criteria:**
Not available - this species does not have a recovery plan.

**Recovery Actions:**
- Not available - this species does not have a recovery plan.

- Cooperate with the Western Riverside Regional Conservation Authority to acquire occupied Berberis nevinii habitat around Vail Lake, and to establish land management practices on these lands that will benefit the species (USFWS, 2009).
- Determine causes and remedies of low reproductive output in Berberis nevinii. Investigate its breeding system; pollinators; seed dispersal mechanisms; and seedling requirements and establishment (USFWS, 2009).
- Work with partners to help conserve Berberis nevinii. Identify opportunities through the Service's Partners for Fish and Wildlife Program to seek habitat restoration and enhancement opportunities (USFWS, 2009).
- Identify partners to help support efforts to survey Berberis nevinii occurrences around Vail Lake, including occurrences within or partially within the perimeter of the 2004 Eagle fire (USFWS, 2009).
- Verify presence of the occurrence near the mouth of Scott Canyon in San Bernardino County (USFWS, 2009).
- Determine the genetic origins of cultivated specimens that are successfully reproducing, in particular, the Berberis nevinii in San Francisquito Canyon (USFWS, 2009).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Monitor known occurrences of Berberis nevinii, with a focus on occurrences not monitored by the California Botanic Garden or the Western Riverside County Multiple Species Habitat Conservation Plan. Survey surrounding areas of suitable habitat for additional plants. 2. Collect additional B. nevinii seeds for ex situ storage at a certified Center for Plant Conservation facility. Focus collection efforts on occurrences that are not yet represented in conservation seed collections. 3. Work with the Rancho California Water District to conserve and enhance the Vail Lake occurrences of B. nevinii. For example, census the Vail Lake population, collect seed, and assess threats associated with recreational use. 4. Model B. nevinii habitat under a range of future climate scenarios and evaluate current and future areas of suitable habitat to identify opportunities for assisted migration. 5. Reintroduce B. nevinii to areas of suitable habitat within the species' range. 6. Augment B. nevinii occurrences where occurrence size is small. Increase occurrence size by planting additional B. nevinii. Work with conservation botanists to determine genetic management strategies for small occurrences. 7. Restore and enhance B. nevinii habitat where needed (for example, by controlling nonnative plants). (USFWS, 2021)
- Conservation Efforts As part of the genetics and breeding system study, California Botanic Garden botanists developed a propagation protocol for Berberis nevinii and obtained two conservation collections of B. nevinii seed from SFC (Washburn and Fraga 2017, p. 16). In addition to the two new seed collections from SFC, there are four other conservation collections of Berberis nevinii seed at California Botanic Garden (CBG 2020, unpaginated): 1. In 1990, B. nevinii was collected from SFC (accession number 16285). 2. In 2003, B. nevinii was collected from multiple plants within California Botanic Garden (accession number 21182). 3. In 1989 and 1990, B. nevinii was collected from CNDDB EO 16 (Vail Lake) (accession numbers 16073 and 16284, respectively). California Botanic Garden is working on a project to complete additional conservation activities for Berberis nevinii on the Angeles National Forest. The study includes 1) continued monitoring of B. nevinii at SFC, 2) a habitat suitability model to identify potential outplanting locations within the Copper Fire burn area, 3) a restoration out-planting, which will be documented over 5 years, and 4) additional ex situ seed conservation (Fraga 2019, unpaginated; Fraga 2020, pers. comm.). (USFWS, 2021)

# SPECIES ACCOUNT: *Betula uber* (Virginia round-leaf birch)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 5/27/1978; Northeast Region (R5) (USFWS, 2016)

**Physical Description**

A deciduous, moderate-sized tree, up to 15 m tall, with smooth dark-brown to black, aromatic bark and a compact crown. The alternately arranged, simple leaves are round to slightly oblong in outline, 3.3-5.3 cm long, hearth shaped at the base, rounded to obtuse at the tip, with 4-5 pairs of lateral veins and 21-33 coarse teeth along each margin. The fruiting structures (catkins) are 1.7 - 2.8 cm long and possess nearly smooth, 4.8-6.0 mm long scales with three broadly divergent lobes. At the base of each scale are three winged nutlets (samaras), ranging in length from 1.7-2.0 mm (USFWS, 1990).

**Taxonomy**

Originally described as a variety of the common sweet birch or black birch (Betula lenta L.) by W.W. Ashe (1918). The taxon was subsequently elevated to the species level by M.L. Fernald (1945) and transferred from series Costatae (dark—barked tree birches) to series Humiles because of presumed affinities to the shrub birches (USFWS, 1990).

**Historical Range**

See current range/distribution.

**Current Range**

Known from a 700-m stretch of highly disturbed, second-growth forest less than 100 m wide along the banks of Cressy Creek, near the town of Sugar Grove, in Smyth County, Virginia (USFWS, 1990).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Abiotic (EPA, 2016)

**Breeding Season**

Adult: Flowers in late April to early May with fruiting in September (USFWS, 2016)

**Reproduction Narrative**

Adult: Reproduction is abiotic, with pollination by wind (EPA, 2016). The tree flowers in late April to early May with fruiting in September (USFWS, 2016).

**Habitat Type**

Adult: Terrestrial, Wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Forested riparian (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (USFWS, 2016)

**Habitat Narrative**

Adult: This birch is a subcanopy tree growing in rocky debris that is strongly acidic and very permeable. The natural population is within a narrow strip of second-growth forest that includes many sweet and yellow birches. The band of forest is nearly surrounded by agricultural land (USFWS, 2016).

***Dispersal/Migration***

**Motility/Mobility**

Adult: Abiotic (EPA, 2016)

**Dispersal/Migration Narrative**

Adult: Seed dispersal is by wind (EPA, 2016).

***Population Information and Trends***

**Population Trends:**

Stable (USFWS, 2006)

**Species Trends:**

Stable (inferred from USFWS, 2006)

**Number of Populations:**

1 (USFWS, 2020)

**Population Size:**

1 wild; 926 in progeny plots in 2008 (USFWS, 2020)

**Population Narrative:**

The Virginia round-leaf birch is known from a single natural population, which contains individuals that were originally rediscovered in the wild in 1975 (Service 1990). This population, contained within a fenced plot on USFS land for its protection, has dwindled in the last 15 years, from 8 extant individuals reported in 2006 (Service 2006) to 1 individual in 2017 (Bresowar 2020). Additional individuals of B. uber occur at this location, but are not considered to be natural since they were planted as part of recovery efforts. In addition to the natural population, 20 progeny plots containing planted greenhouse-grown individuals were established on USFS land in the 1980s, to help recover the species. Progeny plots have been periodically monitored by USFS staff, to ensure that they are not damaged by active timber sales occurring in adjacent lands (T. Blevins, USFS, email to A. Irizarry, Service, February 3, 2020). A full inventory of the species has not been conducted since 2008, when a total of 926 individuals of round-leaf birch were reported for all 20 progeny plots (USFS 2008). While the number of extant individuals has not been systematically assessed since 2008, populations informally visited by USFS appear to be stable (T. Blevins, USFS, email to A. Irizarry, Service, February 3, 2020). In addition to the natural population and progeny plots, there is 1 individual located at the Mount Rogers National Recreation Area office yard. Other natural trees are likely to occur on private land, however, the status of those individuals remains unknown (T. Blevins, USFS, email to A. Irizarry, Service, February 19, 2020). The 5-year review from 2012 (Service 2012) indicated the single natural population had been declining due to presumed natural mortality and lack of reproduction. Since then, no seedlings or evidence of reproduction have been observed either at the natural population site or any of the progeny plots. To restore favorable conditions for natural reproduction, all progeny plots require vegetative management. B. uber produces abundant seeds every 3-4 years (known as a mast year) and requires exposed mineral soil and forest openings to establish itself. Natural reproduction is expected to occur when one of these mast years coincide with suitable habitat availability, an event that seems to be rare. (USFWS, 2020) A full inventory of the species has not been conducted since 2008, when a total of 926 individuals of round-leaf birch were reported for all 20 progeny plots (USFS 2008). (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Habitat destruction, modification, or curtailment or its habitat or range (USFWS, 2006)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species needs small forest openings, especially during years that it produces abundant seed. Rarely do these two factors coincide. Thus, natural reproduction is rare; it has only been documented once - in 1981-1982. The natural population is surrounded by agricultural land. Because the species relies on wind for pollination and seed dispersal, opportunities for range expansion are limited (USFWS, 2006).

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2006).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Overcollection for cultivation and research was a problem until the 1990s, when seeds that were germinated in captivity provided ample seedlings. In addition, providing propagated plants to the nursery trade created a supply of commercially available round-leaf birches that has virtually eliminated the demand for the wild plants (USFWS, 2006).

**Stressor:** Disease or predation (USFWS, 2006).
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Disease is not a threat, but herbivory by deer, rabbits, mice, and domestic livestock has been a problem. Cages placed around seedlings have proven effective in reducing herbivory (USFWS, 2006).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2006).

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Plants on U.S. Forest Service property are protected by the ESA, but the plants on private prope1iy are not protected unless an action has Federal involvement (USFWS, 2006).

***Recovery***

**Reclassification Criteria:**
Not available.

Recovery Priority Number: 8

**Delisting Criteria:**
Establishment of 10 self-sustaining populations, defined of the basis of having each produced through natural regeneration 500-1000 individuals > 2 m tall (USFWS, 1990). The recovery objective for B. uber is to delist the species by increasing the number of individuals in the wild and meeting the following condition: “establishment of 10 self-sustaining populations, defined on the basis of having each produced through natural regeneration 500-1,000 individuals > 2 meters tall. The populations may include individuals of sweet birch (Betula lenta) which carry the round-leaf trait in a cryptic (heterozygous) state.” (USFWS, 2020)

**Recovery Actions:**
- Manage existing individuals and habitat for maintenance and expansion of the single wild population. Provide immediate protection for existing habitat. Monitor individuals for general condition and incidence of disease and insect infestations. Expand zone of management adjacent to existing population. Consider purchase of private property should it become available. Determine essential habitat. Encourage natural regeneration (USFWS, 1990).
- Retain existing germplasm through cultivation. Distribute propagated materials to public and private sectors. Establish pollen and seed banks (USFWS, 1990).
- Determine the systematic relationships of round-leaf birch. Conduct morphological. anatomical, and chemical studies on existing individuals of round-leaf birch and closely related taxa. Conduct studies of the reproductive and genetic systems of round-leaf birch and closely related taxa (USFWS, 1990).
- Establish and maintain additional natural populations. Establish several sites containing numerous genotypes. Maintain sites to reduce competition and retain vigor (USFWS, 1990).
- Implement educational programs to facilitate management of round-leaf birch (USFWS, 1990).
- Continue search for additional natural populations (USFWS, 1990).
- The recovery plan should be revised to include required threats-reduction criteria and to focus on actions conducive to achieving in situ reproduction (USFWS, 2006).
- The taxonomy of the birch is not universally agreed upon. Scientific evidence to date has been inconclusive, as some evidence points to the species level and some points to the variety level. If the plant is determined to be a variety, the variety should remain listed under the ESA until revised recovery criteria are met (USFWS, 2006).

- Natural reproduction is the most essential recovery criterion not yet met. The U.S. Forest Service should conduct management activities to expose mineral soil and remove other nearby birch species as they did in 1981. The management actions need to occur until a year when the Virginia round-leaf birch produces abundant seeds. Once ten populations reproduce naturally (in situ), delisting may be warranted (USFWS, 2006).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1) Develop and implement short-term management activities that improve the potential for natural reproduction in the progeny plots and natural population plot. Specifically, competing vegetation should be cleared from all plots in which the species occurs. 2) The Service should continue to work with USFS to identify further management actions that expose mineral soil to create appropriate conditions for seed set. 3) Conduct additional studies to improve understanding of the species' current reproduction conditions and reasons for apparent low-reproductive rates. 4) Perform an inventory of the species within the natural population plot and the 20 progeny plots. Surveys are needed to update current population size and to monitor population trends over time, seed production, and evidence of reproduction within the plots. 5) Conduct additional genetic analyses to clarify whether the birch is a species or a variety. 6) Develop and implement a plan to assess the status of the species on private lands. (USFWS, 2020)

# SPECIES ACCOUNT: *Blennosperma bakeri* (Sonoma sunshine)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 1/2/1992; Pacific Southwest (R8)

**Physical Description**

Blennosperma bakeri plants are less than 30 centimeters (cm) (11.8 inches (in)) tall with alternate, linear leaves (Ornduff 1977a, Baldwin 2012). The leaves have smooth margins and are 5.1 to 15.2 cm (2.0 to 6.0 in) long with zero to five lobes (Baldwin 2012). From March to May, the plants have a butter-yellow, daisy-like flower head at the tip of each branch. Each flower head is less than 1.5 cm (0.6 in) across. The 6 to 15 outer petals are 5 to 7 millimeters (mm) (0.20 to 0.28 in) long. Occasionally the flowers may be white instead of yellow. The pollen is white. The flowers produce tapered achenes (dry, one-seeded fruits) that are 3 to 4 mm (0.12 to 0.16 in) long and have 4 to 6 sharp angles along the sides. The achenes are covered with tiny bumps and become slimy when wet giving the species one of its common names, “Baker’s sticky seed” (Ornduff 1963, Munz and Keck 1968, Ornduff 1977a, Baldwin 2012). (USFWS, 2016)

**Taxonomy**

Blennosperma bakeri is an annual plant in the aster family. It has been known by the scientific name Blennosperma bakeri (Heiser) since it was first described by Heiser (1947). Two other species are recognized in this genus; B. nanum (dwarf blennosperma) grows in California and B. chilense (Chilean blennosperma) occurs in Chile (Baldwin 2012). (USFWS, 2016)

**Historical Range**

Sonoma County, California. (USFWS, 2016)

**Current Range**

Sonoma County, California. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual: cross-pollination (USFWS, 2016)

**Lifespan**

Adult: ~ 1 year (USFWS, 2016)

**Dependency on Other Individuals or Species**

Adult: Pollinators, such as Andrena blennospermatis (USFWS, 2016)

**Breeding Season**

Adult: March - April (USFWS, 2016)

**Key Resources Needed for Breeding**

Adult: Heavy fall rains, insect pollinators (USFWS, 2016)

**Reproduction Narrative**

Adult: Flower from March through April. The flowers of B. bakeri are self-incompatible, meaning that they can set seed only when fertilized by pollen from a different plant (USFWS, 2016). Blennosperma bakeri is an annual; its entire life cycle from seed germination to seed set is completed in a single growing season. In nature, B. bakeri seeds germinate in the fall following heavy rains, and the plants can grow even when submerged (Patterson et al. 1994). The most abundant native pollinator of B. bakeri was the solitary bee, Andrena blennospermatis. Other pollinators that visited B. bakeri included Apis mellifera (European honeybee), four species of generalist native bees, and syrphid flies. Under dry conditions, or in dense populations, B. bakeri may bear only a single flower head per plant (Patterson et al. 1994), thus producing a maximum of 15 achenes. However, when pools dry and fill repeatedly in a single growing season, each plant may produce as many as 20 flower heads (Patterson et al. 1994), with potential for 300 achenes per plant (USFWS, 2016).

**Habitat Type**

Adult: Wetland, aquatic (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Vernal pool, wet grassland (USFWS, 2016)

**Geographic or Habitat Restraints or Barriers**

Adult: Occurs < 330 ft. elevation (USFWS, 2016)

**Environmental Specificity**

Adult: Very Narrow (Inferred from USFWS, 2016)

**Habitat Narrative**

Adult: Occurs predominantly on the Santa Rosa Plain, which is located in central Sonoma County, California, and is characterized by seasonal wetlands, predominately in the form vernal pools, and associated upland grassland habitat. Vernal pools form in depressions having a shallow, impermeable soil layer that restricts the downward movement of water. The pools have an outlet barrier that further causes ponding (CH2M Hill 1995) and may be connected and fed by shallow drainage pathways called “swales.” Vernal pools generally fill during winter rains and dry in late spring or summer. “Natural” vernal pools are those that are found occurring naturally in the landscape. “Created” vernal pools are those that have been constructed in an area that was not a vernal pool in the recent past (within the last 100 to 200 years) and that is isolated from existing vernal pools (Gwin et al. 1999 and Lewis 1989). This species grows only in seasonal wetlands. (USFWS, 2016)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Dispersal mechanisms for the achenes have not been studied. However, seed dispersal of B. nanum var. nanum, a species that occupies similar habitat to B. bakeri, was found by Ornduff

(1964) to be within a small radius of the parent plants based on the area occupied by flower-color variants. (USFWS, 2016)

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2016)

**Species Trends:**

Decreasing (USFWS, 2016)

**Number of Populations:**

19 presumed extant occurrences (USFWS, 2024)

**Population Size:**

Variable among years; < 100 to > 1.5 million (USFWS, 2016)

**Additional Population-level Information:**

Historically, Sonoma sunshine was only known to occur in Sonoma County. At the time of listing, the species was known from 35 sites in the Santa Rosa Plain and seven sites from the Sonoma Valley (Service 1991, p. 61173). The current known distribution of Sonoma sunshine is similar to as described in the previous status review (Diversity Database 2024, entire). The Diversity Database currently reports 24 occurrences (Appendix, Table A; Diversity Database 2024, entire). All of these occurrences, aside from the single occurrence in Mendocino County, are in Sonoma County. Since listing, Sonoma sunshine has been introduced to at least 12 new sites during mitigation activities or to establish conservation banks (Service 2016, p. 5). Populations of Sonoma sunshine exhibit extreme fluctuations in size among years, often varying by one or two orders of magnitude (Diversity Database 2013, as cited in Service 2016, p. 8). Individual occurrence sizes ranged over time from fewer than 100 plants to more than 1.5 million plants (Diversity Database 2024, pp. 1, 3). Collection of annual abundance data has been sporadic; therefore, determination of population trends is difficult. Years of peak abundance are often associated with copious rainfall, especially when storms occur at regular intervals throughout the growing season, whereas years of minimal abundance are typically drought years. The Diversity Database (2024, entire) reports unknown or decreasing trends for the 19 presumed extant occurrences; however, decreasing trends may not be indicative of population status change due to natural fluctuations and sporadic data collection (USFWS, 2024).

**Population Narrative:**

After listing, the number of sites with many individuals decreased, and the number with less than 10 individuals increased. The percentage of sites with fewer than 10 individuals increased by 15 percent between the time of listing and 1994 (USFWS, 2008). The most current occurrence information documents the presence of 18 extant occurrences. Populations exhibit extreme fluctuations in size among years, often varying by one or two orders of magnitude (CNDDB 2013). Individual occurrence sizes ranged over time from fewer than 100 plants to more than 1.5 million plants (CNDDB 2013). Collection of annual abundance data has been sporadic; therefore, determination of population trends is difficult. A 2009 study by Sloop and Ayres found that moderate genetic diversity existed among the occurrences of Blennosperma bakeri on the Santa Rosa Plain (USFWS, 2016).

***Threats and Stressors***

**Stressor:** Development and conversion to agriculture (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Today, the largest continuing threats to this species are urban development and land conversion to agriculture (such as vineyards) and associated agricultural activities and wastewater irrigation. The most recent estimates from the California Department of Conservation (2002) are that about 71,000 acres of Sonoma County have been converted to urban uses (Sonoma County Permit and Resource Management Department 2014). The threat of urban development to these species in the Santa Rosa Plain is expected to continue. In addition to urban development, land conversion to agriculture and associated agricultural activities has reduced occurrences of these plants (CNDDB 2014). In 1991, at the time of the listing, approximately 34,500 acres of land were in wine grape production in Sonoma County (Sonoma County Agricultural Commissioner 1991). As of 2012, the acreage of wine grapes in Sonoma County had increased to approximately 58,400 acres (Sonoma County Agricultural Commissioner 2013). Additionally, irrigation with recycled water, a practice that began in the Santa Rosa Plain in the 1970s, has emerged as a major threat. Although the California Regional Water Quality Control Board regulations (Water Quality Control Plan for the North Coast Region) prohibit discharge of recycled water to surface waters during the summer, the regulations did not contemplate that recycled water would be used to irrigate vernal pools and other types of seasonal wetlands (J. Short, pers. comm., 2007). Recycled water, as opposed to wastewater, is tertiary-treated (City of Santa Rosa, in litt. 2015** [comment letter]). Wastewater, however, can come from many sources including livestock waste ponds and runoff from agricultural fields (City of Santa Rosa, in litt. 2015** [comment letter]). (USFWS, 2016)

**Stressor:** Alteration of hydrology (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some actions, such as runoff from irrigation or irrigation with recycled water, can result in increased water on the landscape. The vernal pool habitat may receive more water than it normally would or receive it at an inappropriate time, resulting in flooding and death of listed plant seedlings. If water from urban or agricultural runoff continues to fill pools during spring and summer months, the listed plants will disappear because they cannot tolerate permanent inundation; invasion by plant species adapted to permanent inundation will occur. Additionally, irrigation with recycled water and runoff from irrigation can contain chemicals, such as herbicides, and other nutrients (Pereira et al. 1996) that can alter the vernal pool plant community, prevent germination, or kill seedlings. Nitrogen deposition from automobile traffic may also modify habitat by increasing soil nutrients, thus posing a continuing threat to remnant habitat that might otherwise be suitable for these species. Weiss and Luth (2003, p. 1) conducted research on the effects of nitrogen deposition along a highway south of the San Franciscan peninsula in San Francisco County. They found that nitrogen deposition within 100 m to 400 m from the highway was correlated with increased nonnative grass cover within these areas, resulting in competition for space with native plants. An increase in nonnative grass cover through changed habitat conditions could threaten the three plant species by competing for soil

moisture and nutrients and inhibiting successful germination. (USFWS, 2016)

**Stressor:** Off-highway vehicles (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Damage by off-highway vehicles was noted as a threat to Blennosperma bakeri. Currently, on Department-owned properties that support the listed plants, some damage to preserves from vehicle trespass does occur, but without damage to the vernal pools. The most significant damage to vernal pools from vehicles has resulted from a Mosquito Vector Control vehicle driving through the vernal pools to spray for mosquitoes during the time when the pools were wet in 2014. Disturbance to the pools included physical damage to the pools and swales from tire ruts and crushing and uprooting the plants (S. Martinelli, CDFW, in litt. 2014). The level of this threat is likely to be variable and is difficult to predict or monitor. (USFWS, 2016)

**Stressor:** Grazing managment and thatch accumulation (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Appropriate levels of grazing may provide some control of weedy plants, reduce competition between native plants and invasive plants, and can provide some bare soil for germination of native plants, all of which may provide opportunities for native plants to germinate. Cessation of cattle grazing has been found to exacerbate the negative effects of invasive nonnative plants on vernal pool inundation period. If grazing is removed, areas of bare soil can be quickly occupied by nonnative, invasive plants. Removal of grazing from vernal pool grasslands where grazing is the traditional land use practice may have devastating impacts on vernal pool habitat, particularly on upland habitat surrounding vernal pools (G. Cooley, in litt., 2014). For example, non-native grasses increased and native grasses decreased in vernal pools when grazing was discontinued at a site in the Southeastern Sacramento Valley, resulting in a 50 to 80 percent reduction in vernal pool inundation (Marty 2005). Since the time of listing, grazing has been removed at many locations and has resulted in thatch build-up. Anecdotal evidence supports the theory that thatch build-up of nonnative vegetation has caused a reduction in the size of extant populations of the listed plants. The Department is re-establishing appropriate grazing practices on some Department-owned lands to reduce thatch build-up and nonnative competitors to the three listed plants (e.g., Todd Road Unit Ecological Preserve). However, reintroduction of grazing may not return a site to its former condition because nonnative plants may continue to occupy the once-vacant niches. For example, harding grass (Phalaris aquatica), a robust, invasive perennial grass, can be present in a grazed field, and not be obvious. If grazing is removed, however, the suppressed harding grass can become vigorous and dominate the entire field within a year or two and grazing will not remove this species once it is established (G. Cooley, in litt. 2014). We recognize that there is disagreement among biologists as to the extent of the threat of inappropriate grazing on the three species. As the final rule concluded, we believe that although the effect of well-managed livestock grazing may be beneficial to vernal pool ecosystem. (USFWS, 2016)

**Stressor:** Loss of Genetic Diversity / Inappropriate Mixing of Populations(USFWS, 2016)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** An additional potential threat to these three plants is the disruption of normal gene flow due to population restoration efforts that may mix populations, which may cause unanticipated adverse effects such as disruption of locally adapted gene complexes and outbreeding depression (when offspring from individuals from different populations have lower health/fitness than progeny from individuals from the same population). Several sites are proposed as Preserves in the Santa Rosa Plain and include proposals to seed/inoculate created or restored vernal pools. Seed from a limited number of donor occurrences has already been used for several years to inoculate multiple created or restored sites, creating a risk of overrepresentation of a small gene pool (swamping). The threat level of this activity is unknown; however, the 2007 Programmatic Biological Opinion (Service 2007) includes measures to reduce this potential threat as well as the requirement to obtain a collection permit from the Department. (USFWS, 2016)

**Stressor:** Climate change (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since the 1950s, the Northern Hemisphere has experienced warmer air temperatures and decreased snowfall (Ackerly et al. 2010, IPCC 2013). By the end of the 21st century, climate change is predicted to result in more intense precipitation events in the form of rain, increased summer continental drying, extreme weather events, and increased wildfire (Ackerly et al. 2010, IPCC 2013). However, current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2013). Climate simulations have shown that California temperatures are likely to increase by 2.7 degrees Fahrenheit (1.5 degrees Celsius) to 8.1 degrees Fahrenheit (4.5 degrees Celsius) depending on the emissions scenario (Cayan et al. 2008). The predicted impacts on California's ecosystems projected with a high certainty include (1) higher sea level and (2) decreased suitable habitat for many terrestrial species as climate change intensifies human impacts [for example isolated patches of vernal pools can be so poorly connected with other patches that migrations required by climate change may be difficult or impossible without human intervention (Field et al. 1999)]. Climate change threatens to increase the loss of pollinators if the abundance of flowers preferred by pollinators decreases. Pollinator emergence times may also be altered by a warming climate. If this occurs, the synchrony of bloom periods and pollinator emergence could be disrupted. The loss of pollinators would further reduce the amount of seed produced by the listed plants because of the plants' limited ability to self-pollinate. Although there currently are no data available regarding changes in plant bloom periods or emergence dates of pollinators in the Santa Rosa Plain in response to climate change, Forister and Shapiro (2003) found that over a period of 31 years, warmer and drier winter conditions were associated with earlier butterfly appearance in the Central Valley of California. Although the loss of seed produced in a single year would not likely lead to the extirpation of the species, the continued reduction of the seed crop or dependence on self-pollination would reduce the seedbank, genetic variation, and the potential for population expansion. Monitoring of vernal pool ecosystems to determine effects from climate change is necessary to determine what adaptive land management practices would be the most appropriate to ensure the sustainability of vernal pool species (Pyke and Marty 2005), including B. bakeri, L. burkei, and L. vinculans. (USFWS< 2016)

**Stressor:** Extirpation due to Stochastic Events, Isolated Occurrences, and Small Size of Occurrences (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Chance events constitute a serious threat to Blennosperma bakeri. Because the known occurrences of B. bakeri are limited in number and in range, the species are vulnerable to stochastic (random) events—natural but damaging environmental perturbations and catastrophes such as droughts, storm damage, disease outbreaks, and fires, from which large wide-ranging populations can generally recover, but may lead to extirpation of small isolated populations (Gilpin and Soule 1986). The majority of the remaining habitat associated with the three species is vernal pools and swales in the Santa Rosa Plain. The nature of the vernal pool and swale habitat associated with the three plants may also increase the effects of drought. Vernal pools and swales are inundated only briefly and may not fill during dry years. As a result, we consider stochastic events to be of significant concern for these species. Isolated, small occurrences may also be at risk from a decrease in reproductive rate resulting from decreasing population density. The correlation of reproductive rate with population density, called the Allee effect, may be the result of either increased density or quality of compatible mates, or increased pollination, or both (Stephens et al. 1999). In small populations, if either the plants or their pollinators decline, consequences on the reproductive output of the other may result in an extinction vortex in which each generation is more likely to go extinct (Gilpin and Soulé 1986, Soulé and Mills1998). (USFWS, 2016)

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Service found that many existing regulatory mechanisms were not sufficient to protect plants, including section 404 of the Clean Water Act, the protections of the California Endangered Species Act, and the California Environmental Quality Act. The 1991 final rule also found that listing the plants under the Federal Endangered Species Act would provide better protection by requiring the Army Corps of Engineers (and other Federal agencies) to consult with the Service prior to final determinations on a proposed activity. (USFWS, 2016)

**Stressor:** Non-native invasive species (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** creating a drier habitat and facilitating the invasion of non-native upland species, may permanently change the plant community and the non-native plants may outcompete the listed species (Bauder 2000, Marty 2005, competition discussed further below). With insufficient water, the distribution of plant species that are normally found higher on the edge of the vernal pools may shift downward along the moisture gradient in response to the introduction of invasive plants that now flourish at pool edges. Non-native grasses maintain dominance at pool edges, sequestering light and soil moisture, promoting thatch build-up, and shortening inundation periods. Species strongly associated with vernal pools may disappear from shallow pools as a result of invasion by upland non-native plants. In addition, the invasive species can further alter the hydrology of the site by reducing the inundation period (Marty 2005). Reduction in

inundation period is thought to be due to increased evapo-transpiration associated with dense cover of nonnative plants at the vernal pools (Marty 2005). Once non-native, invasive plants are introduced to vernal pools, competition with native species can come from several interactions including root competition (roots of one species are more efficient at absorbing moisture and nutrients from the soil) and pollination success (one species will set more seed and produce more plants). Plant size can also confer superiority when competing with smaller plants. A larger plant can shade smaller or shorter plants and seedlings, depriving them of adequate sunlight which is necessary for plant and seedling growth and survival, and in some cases necessary for seed germination (Barbour et al. 1987). (USFWS, 2016)

**Stressor:** Pesticides (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Environmental Protection Agency (Agency) recently released final biological evaluations assessing the effects of labeled uses of three neonicotinoid pesticides on listed species (Agency 2022a, entire; Agency 2022b, entire; Agency 2022c, entire). The three pesticides (clothianidin, imidacloprid, and thiamethoxam) are registered for use on a variety of agricultural crops; there are also some non-agricultural applications. The three pesticides target insect species by acting on their neurotransmitters to cause excessive nervous stimulation, paralysis, and death. The pollinators of Sonoma sunshine are diverse and include the European honeybee (Apis mellifera), four species of generalist native bees, syrphid flies, and most abundantly, the solitary bee (Andrena blennospermatis). The Agency's final biological evaluations determined that all three pesticides are highly toxic to bees, have the potential to result in bee brood and colony reductions, and if affected bee colonies decline near Sonoma sunshine, there is a potential for the three pesticides to indirectly adversely affect the species (Agency 2022a, p. 4; Agency 2022b, p. 2; Agency 2022c, p. 3). The Agency anticipates releasing amended proposed interim decisions and a national consultation with the Agency is currently pending. (USFWS, 2024)

***Recovery***

**Reclassification Criteria:**
A/1: Eighty percent of extant, native occurrences, not protected as of December 2014, within each core area (Windsor Core Area, Alton Lane Core Area, and Blennosperma bakeri Southern Core Area) are permanently protected to maintain the current geographic, elevational, and ecological distribution of the species. Priority should be given to preserve isolated and/or genetically unique occurrences. (USFWS, 2016)

A/2: The following additional habitat is needed in order to downlist B. bakeri. New preserves protect a minimum of 50 ac in the Windsor Core Area, a minimum of 500 ac in the Alton Lane Core Area, and a minimum of 300 ac in the Blennosperma bakeri Southern Core Area. These preserves consist of occupied habitat that is not currently protected. The ecological integrity (e.g., water quality, hydrology, uplands conditions) of these areas is not threatened by adverse habitat modification. Buffers between the protected habitat and incompatible land uses must be sufficient to ensure that there are no significant adverse effects to Blennosperma bakeri, such as changes in hydrology, or contamination by pesticides or herbicides, currently and into the foreseeable future. (USFWS, 2016)

A/3: New preserves (comprised of restored or created habitat) must be 10 ac or greater; however, preserves with native occurrences may be less than 10 ac. The preserves should be as near to new or existing preserves as possible .(USFWS, 2016)

A/4: The total new preserve acreage in core area includes no less than 175 ac of vernal pools and swales in the Alton Lane Core Area, no less than 105 ac in the Blennosperma bakeri Southern Core Area, and no less than 18 ac in the Windsor Core Area. However, new preserves are no more than 35 percent wetland which is based on general wetland to upland percentages. (USFWS, 2016)

A/5: Service-approved conservation and management plans that protect vernal pool habitat and upland habitat and address effects of invasive plants are developed and are being effectively implemented. (USFWS, 2016)

A/6: Service shall work with Mosquito Abatement Districts so that their practices in the core and management areas are implemented to avoid impacts to the species. (USFWS, 2016)

E/1: Native occurrences, extant as of December 2014, in (a) the Windsor Core Area, and (b) the Blennosperma bakeri Southern Core Area are replicated at 1:3 (quadrupled in numbers of occurrences) in permanently protected sites. Extant native occurrences in the Alton Lane Core Area are replicated at 1:2 (tripled) in permanently protected appropriate sites24. Replication is accomplished by collecting seed or inoculum from a natural occurrence and planting it at additional sites. For example: collecting seed or inoculum at one site and planting it at two additional sites increases the original single occurrence to 3 occurrences (1:2); planting it at three additional sites increases the original occurrence to 4 occurrences (1:3). (USFWS, 2016)

E/2: The preserves noted in Factor A are occupied by Blennosperma bakeri seeds at a density of 2,500 seeds per square meter averaged over whole vernal pools and swales when measured on a 25-year moving average which includes at least one above average and one average rainfall year, and a multi-year drought. A multi-year drought is defined as a period of 3 or more years of below average local rainfall. (USFWS, 2016)

E/3: Service-approved conservation and management plans that protect vernal pool habitat and address the effects of small occurrence size, and climate change, among other threats, are developed and are being effectively implemented. (USFWS, 2016)

Recovery Priority Number: 5C

**Delisting Criteria:**
A/1: At least 90 percent of all known native occurrences of Blennosperma bakeri that are extant as of December 2014, have been fully protected in perpetuity. (USFWS, 2016)

A/2: 100 ac of habitat containing Blennosperma bakeri is preserved and appropriately managed in the Sonoma Valley Management Area. (USFWS, 2016)

E/1: In addition to replication noted in E/1 of the downlisting criteria for Blennosperma bakeri, all occurrences in management areas have been replicated at 1:2 at appropriate locations.

Bouverie Preserve, east of the Town of Glen Ellen, may be considered as part of the Sonoma Valley Regional Park Management Area and replicated at 1:2 if Blennosperma bakeri is still found there. This occurrence, if not already lost, could provide important genetic diversity and thus be valuable for the recovery of the species. The occurrences in the Sonoma Valley Management Area should be replicated at 1:3. (USFWS, 2016)

E/2: All replicate occurrences from E/1 have achieved the same rates of seed density (2,500 seeds per square meter), as the core area occurrences. (USFWS, 2016)

E/3: All genetically unique and isolated unprotected sites in management areas are permanently protected in situ including: occurrences in Sonoma Valley Regional Park and the Wood Road area in the northern portion of the Alton Lane core area. Identification of some genetically unique occurrences is not yet known but will be determined during research listed in Table 6 of the Recovery Plan. (USFWS, 2016)

**Recovery Actions:**

- 1. Protect extant occurrences and potential habitat for Blennosperma bakeri. Natural areas that are known to contain species covered in this recovery plan should be protected in perpetuity through land acquisition, conservation easements, or other means. Protection of these areas will need to be followed by identification of threats and application of appropriate and adaptive management to ensure abatement of these threats. In addition to areas that currently support the species, two other types of natural areas also need to be protected or secured: areas where the endangered plants have been found in the past but not been seen recently, and that retain habitat that can be readily restored so that plants can be reintroduced successfully; and areas where the plants have not been found but are appropriate for vernal pool creation, and subsequent introduction of the endangered plants. (USFWS, 2016)
- 2. Develop a central database for survey data from all natural and created occurrences of Blennosperma bakeri including information on protection status. Data should include numbers of plants; area occupied by the species; presence of invasive species; site condition; land ownership; level of management; disturbance; whether the site is natural, restored, or created; and degree of genetic uniqueness. If the site has been seeded, the origin of the seed should be identified by name and location of parcel where seed was collected, location of specific pools where seed was collected, and date of seed collection. Any observations of pollinators, such as species or type of pollinator, should also be recorded. This information will serve as the current baseline for evaluating progress of the Factor A and Factor E comparative downlisting and delisting recovery criteria for each of the three plant species. This database should be updated regularly and should be available to all management agencies (USFWS, 2016). In addition, the database should track the location of source seed for sites with created occurrences (USFWS, 2019).
- 3. Collect and store seed from all occurrences of Blennosperma bakeri. Seed collections for each plant taxon should be representative of both population- and species-level genetic diversity; seeds should be collected from multiple plants at each occurrence. Seed collection guidelines published by the Center for Plant Conservation (1991) should be followed. Seed collection should be conducted with caution to ensure that donor populations are not adversely affected by the collection. No more than 5 percent of the reproductive output should be removed from donor populations. Store seeds at two storage facilities certified by the Center for Plant Conservation. Seeds should be collected every 5 years to ensure that

seeds in storage are viable. Permits will be required for collecting federally-listed plant seed on federal lands. (USFWS, 2016)

- 4. Survey historical locations and other potential habitat (not previously surveyed) where Blennosperma bakeri may occur. (USFWS, 2016)
- 5. Conduct research necessary to develop a population viability analysis for Blennosperma bakeri. Table 2 of the Recovery Plan lists research tasks needed for the development of a population viability analysis for all three species in the Recovery Plan. All research tasks need to be performed for each of the three species. To maximize efficiency, it may be possible to study the effects of an experimental factor on all three species in the Recovery Plan via the same experiment. (USFWS, 2016)
- 6. Conduct necessary biological research on Limnanthes vinculans and use results to guide recovery efforts. Table 6 of the Recovery Plan the needed research tasks for the recovery of Blennosperma bakeri, Lasthenia burkei, and Limnanthes vinculans. All research tasks need to be performed for each of the three species. To maximize efficiency, it may be possible to study the effects of an experimental factor on all three species via the same experiment. (USFWS, 2016)
- 7. Habitat management for Blennosperma bakeri. Develop adaptive management plans and implement appropriate management actions for all protected sites. Work with local agricultural commissions to track conversion of agricultural uses to vineyards or other non-suitable agricultural uses. Decrease acreage of vernal pool habitat within priority preservation and restoration areas that are subjected to altered hydrologic regimes through irrigation practices. Develop treatment protocol with mosquito abatement district to avoid impacts to listed species and vernal pool habitat during treatment. (USFWS, 2016)
- 8. Restore or create vernal wetlands, followed by reintroduction of the species per a restoration techniques white paper and a Reintroduction and Genetic Management Plan. As noted in the Factor A discussion, much of the habitat and occurrences of the three listed plants has been destroyed or fragmented by urban development and conversion to agricultural use. Restoration or creation of habitat, when appropriate, will be necessary to maintain the numbers of plants and occurrences at levels sufficient for survival of the species. Restoration and creation of vernal pool habitat has been conducted for many years in the Santa Rosa Plain for the three plants. To better understand these processes and their rates of success, a white paper and a Reintroduction and Genetic Management Plan should be developed. (USFWS, 2016)
- 9. Monitor all protected occurrences. Monitoring plans should be developed and implemented for all protected natural and replicated occurrences. Protected occurrences should be monitored annually for plant density, area occupied by the listed species, site condition, changes in hydrology, application of recycled water and wastewater, effects of grazing, invasive species, vandalism, and whether management is appropriate for the listed species' needs. The responsible party for monitoring should also keep an ongoing record of management activities and precipitation on the site, so that changes in rare plant populations can be related to changes in management activities. Monitoring efforts for co-occurring species (e.g. Blennosperma bakeri and Limnanthes vinculans at Wright Mitigation Bank) should be coordinated to increase efficiency and reduce costs. (USFWS, 2016)
- 10. Engage and educate the public about Blennosperma bakeri recovery. Public education and outreach is important to inform residents and land managers in the Santa Rosa Plain and other areas that support habitat for the species about the significance of the plants and the importance of management and protection of habitat for their persistence. Education

and outreach activities should include: (1) develop a public outreach plan, (2) outreach to enhance public understanding of vernal wetlands in general and of imperiled vernal wetland species in particular, (3) information on regulatory responsibilities with regard to endangered species, (4) programs to encourage local interest and involvement in site stewardship, and (5) programs including conservation easements and incentive programs that are available to landowners who may have the vernal pool species on their land. (USFWS, 2016)

- 13. Agency coordination. Partner with California Department of Fish and Wildlife, Army Corps of Engineers, Regional Water Quality Control Board, Sonoma County, Marin/Sonoma Mosquito and Vector Control District, and Cities of Santa Rosa, Cotati, Rohnert Park, and Windsor to ensure resource management practices are aligned with species conservation needs. Resource management practices to be addressed include: irrigation of vernal pool habitat with recycled water and wastewater within priority preservation and restoration areas; protection of habitat buffers; stream ordinances, grading ordinances, and water quality regulations; and vineyard conversion or other agricultural conversion of areas adjacent to vernal pool habitat that contribute to hydrologic regime and/or provide upland habitat for sustaining the Sonoma County California tiger salamander. Provide legal assurances to willing landowners who implement projects that provide a net conservation benefit. (USFWS, 2016)
- Recommendation for future action: In response to the recently discovered range expansion of Sonoma sunshine, the Service recommends surveying vernal pools in Mendocino County near the recent observation of Sonoma sunshine to search for additional occurrences. (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations which will aid in the recovery and conservation of the Sonoma sunshine. Some of these recommendations have already been discussed in previous recovery documents (Service 2016, pp. 90–99; Service 2019, p. 5) and remain valid. 1. Habitat Acquisition, Management, and Restoration. All sites with Sonoma sunshine present should be protected, managed, and monitored to address recovery goals. Resource agencies and private partner groups should work to ensure land protection through acquisition or easement, and large unprotected areas currently occupied by the species should be given the highest priority. Large, formerly occupied sites that are unoccupied but have a high restoration potential should also be considered. Protected lands must also be adequately managed or restored based on the best available science. 2. Determine Population Status. Comprehensive, range-wide surveys should be completed for all known occurrences (both extant and extirpated) recorded in the Diversity Database. The site-specific evaluations should include, at minimum, whether the species is present, estimated population/occurrence extent, extent of suitable habitat, and an indepth analysis of threats at that location. Field surveys for the evaluation should be timed for favorable conditions, such as in the first wet year following a drought. Occurrence reports in the Diversity Database should be updated to represent the most accurate, up-todate population data. These results should be used to help inform decision-makers about the acquisition of appropriate sites where Sonoma sunshine occurs but are unprotected, to suggest sites that could be acquired for restoration, and to develop an adaptive management program that will achieve the recovery of Sonoma sunshine. 3. Monitor Occupied Sites. Known populations of Sonoma sunshine should be monitored during multiple precipitation/drought cycles to gain a better understanding of the ecology of the species and impacts of grazing and community composition. 4. Seed Collection, Research, and Planting.

Collect and correctly store Sonoma sunshine seeds from extant populations found during comprehensive surveys. Seed collection results should be compiled into a list that qualitatively describes the environmental conditions of the collection site and the treatment techniques used. Partner groups should conduct further research on the genetic diversity of seedlings from different occurrences, germination success rate, and replanting success rate. 5. Invasive Species Management. A basic inventory of invasive species should be conducted to itemize, describe, and map the current invasive plants that are the highest threat to the Sonoma sunshine. This inventory would be used as a management tool to prioritize and begin targeting the invasive plants and provide a baseline to evaluate the effectiveness of management actions. Non-native, invasive (noxious) plant species should be controlled and eradicated. Use existing management plans or develop and implement management plans that include control of invasive plants for all protected areas (USFWS, 2024)

# SPECIES ACCOUNT: *Boltonia decurrens* (Decurrent false aster)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 11/14/1988; Great Lakes-Big Rivers Region (R3) (USFWS, 2016)

**Physical Description**

A robust, short-lived perennial herb, up to 2 m tall, that produces numerous flower heads with white or pale violet ray flowers surrounding a yellow central disk (NatureServe, 2015).

**Taxonomy**

Formerly classified as Boltonia asteroides var. decurrens or B. latisquama var. decurrens; now recognized as a distinct species (B. decurrens) by Flora of North America (2006) and Kartesz (1994), the U.S. Fish and Wildlife Service, and the Illinois and Missouri Heritage Programs (NatureServe, 2015).

**Historical Range**

Historical collection records reveal that Boltonia decurrens once occurred in almost contiguous populations along a 400 km stretch between LaSalle, Illinois and St. Louis, Missouri within the Illinois and Mississippi River floodplain. A disjunct population, reported in 1976, but not found since, is known from Cape Girardeau, MO, about 195 km down the Mississippi River from St. Louis (Schwegman and Nyboer, 1985) (NatureServe, 2015).

**Current Range**

The species is currently limited to disjunct populations from Woodford County, Illinois to Madison County, Illinois. In some years, ephemeral populations occur in St. Charles County, Missouri, in the area of confluence of the Mississippi and Illinois Rivers (NatureServe, 2015). There is no apparent change in the distribution or range of the species. (USFWS, 2020)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual: vegetative, sexual: self-pollination, cross-pollination (NatureServe, 2015)

**Lifespan**

Adult: 1 - 2+ years (USFWS, 2012)

**Breeding Season**

Adult: August - October (NatureServe, 2015)

**Key Resources Needed for Breeding**

Adult: Unshaded soil surface (NatureServe, 2015)

**Reproduction Narrative**

Adult: Vegetative reproduction occurs through shoots formed from a basal rosette (Smith and Keevin 1998). The species is primarily outcrossing, but some selfing occurs (Smith, 1995). Seed production is prolific with an average of ca. 50,000 seeds produced per plant (Smith & Keevin 1998; Smith, 1990). Seedling survival in the field is < 1%. However, under optimal conditions, the average plant produces 40,000 seedlings but the rate of seedling survival is low (Smith & Keevin 1998). Boltonia decurrens blooms from August through October throughout its range (Schwegman and Nyboer, 1985). Germination and seedling establishment do not occur where the soil surface is shaded, such as in places where natural succession has been uninterrupted for a period of 3 - 5 years. Seed germination is also inhibited by silt deposition (NatureServe, 2015). It is considered a perennial plant but also exhibits annual and biennial lifecycles (USFWS, 2012).

**Habitat Type**

Adult: Riparian, wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Forested wetland, herbaceous wetland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Disturbance regime, preferably flooding (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Successional vegetation (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (USFWS, 1990)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: It colonizes periodically disturbed riverine moist soil habitats (Smith et al. 2005). In general, sites where the species is successful in reproducing sexually and maintaining a self-sustaining population are characterized by moist, sandy soil and regular disturbance, preferably periodic flooding, which maintains open areas with high light levels. Analysis of 19th-century habitat data taken from herbarium sheets indicates that natural habitat was the shores of lakes and the banks of streams, including the Illinois River. In these habitats, regular flooding prevented succession, allowing sunlight to reach the seedlings. Boltonia decurrens is still found in these occasional natural habitats, but it is now primarily restricted to disturbed lowland areas, where it appears to be dependent on human activities (mowing, cultivation) for survival. Although prolonged flooding by extremely turbid water can damage a population (US Fish and Wildlife Service, 1990), the species is extraordinarily flood tolerant (Stoecker, Smith and Melton, 1995) and is known to survive several months of complete inundation by relatively clear groundwater (Smith, 1990). The palustrine habitat is characterized as forested wetland and herbaceous wetland (NatureServe, 2015). As many as 11 plants have been observed to grow from a single stem of the previous year, giving a 2-year-old wild population a definite clumped appearance (USFWS, 1990).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: It appears that one mechanism of long distance dispersal of B .decurrens seeds is by flood waters. There appears to be suitable habitat for the species in many areas on the flood plain of the Illinois River; however, dispersal has been prevented by the extensive levee system that has been constructed to reduce flood damage to agricultural fields. (USFWS, 1990)

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2020)

**Species Trends:**

Unknown (USFWS, 2020)

**Number of Populations:**

43 (USFWS, 2012)

**Population Size:**

1000 - 10,000 individuals (NatureServe, 2015)

**Population Narrative:**

Like the numbers of populations, numbers of individuals of B. decurrens also fluctuate greatly from year to year. Larger stands sometimes have several thousand plants in good years, occasionally exceeding 10,000. Because of the vulnerability of this species to changes in flooding regime, population number is expected to continue to fluctuate in upcoming years. The short term population trend has been relatively stable to a < 30% decline. Preliminary isozyme data developed by Thomas Ranker (University of Colorado, Boulder) from seeds collected from three populations in Illinois in 1994 indicate that there is a high level of genetic diversity (Smith, 1995). This rare species is much more variable, by all the measures examined, than most rare or geographically-restricted plant species, and is even slightly more variable than the average plant species (NatureServe, 2015). Approximately 43 populations have been discovered and monitored intermittently from 1984 to present. Due to the intermittent nature of the available data, long-term trends are not readily apparent but appear to include a periodical expansion and contraction of populations (USFWS, 2012). Specifically, we cannot draw conclusions about individual populations at the site scale, or the population as a whole, at the species-wide scale. We can confidently say, however, that decurrent false aster was found at least once at more than half of the historically documented sites, and that the number of plants at a site often varied drastically, which is consistent with historical data. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Habitat degradation (NatureServe, 2015 and USFWS, 1990)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Boltonia decurrens is threatened primarily by anthropogenic disturbance of natural habitat. Principal threats include flood-control measures; agricultural use of marginal river-bottom land; increased siltation of floodwater, which decreases light availability and prevents germination and seedling establishment; herbicide use for weed control; and marina construction (NatureServe, 2015). Boltonia decurrens populations may also be vulnerable to destruction by discing and herbicide use in low-lying marginal lands for crop weed control. Nearly all stands are in habitats kept open by occasional cropping (USFWS, 1990).

**Stressor:** Hybridization (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Preliminary allozyme research has been conducted on the potential hybridization of B. decurrens and a related species in the genus, B. asteroides. Hybridization could pose a threat to the species through decreased fertility, genetic swamping, and ecological competition from hybrid individuals (DeWoody 2011). DeWoody et.al. (2011) tested for hybridization in sympatric populations using allozyme genetic marker data. The results revealed a very low rate of hybridization and introgression, indicating that cross-pollination and hybridization may not pose an immediate threat to the species. However, higher resolution genetic testing has yet to be performed, and therefore the level of threat posed by hybridization is currently indeterminable (USFWS, 2012).

**Stressor:** Prolonged flooding (USFWS, 1990)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Prolonged flooding during the growing season appears to be a limiting factor. A flood in 1981 inundated most of the unleveed flood plain of the Illinois River with turbid flood water for an extended period during the summer. Shrubs such as Cephalanthus occidentalis were killed by the prolonged total inundation in some areas, and herbs were buried under heavy deposits of silt. Despite intensive searches, no B. decurrens was found for 2 subsequent seasons along the Illinois River. Such conditions severely limit natural reproduction and survival by B. decurrens (USFWS, 1990). The survey records examined for this review (2012-2018) indicate that many known sites were under water during the fall survey season, which precluded both plant survival and surveys. However, decurrent false aster seeds (“achenes”) remain viable even when buried in the soil for long periods (at least 88 months) of time (Baskin and Baskin 2002). Therefore, late season flood events do not necessarily mean that populations are locally extirpated if suitable growing conditions are present in subsequent years. However, as demonstrated by the population records for the species (see Appendix A) late flooding events on the Illinois River across the range of the species continue to appear to affect population growth, at least in the short term. (USFWS, 2020)

***Recovery***

**Reclassification Criteria:**
Not available

Recovery Priority Number: 8

**Delisting Criteria:**
1. A basic research program to determine the requirements of a naturally reproducing population must be completed (USFWS, 2012).

2. Twelve geographically distinct self-sustaining natural or established populations of the species must be protected through purchase in fee, easement, or by cooperative management agreements (USFWS, 2012).

3. Populations must be monitored for a period of five years to determine if they are self-sustaining. Self-sustaining is defined for recovery purposes as a population which is found to be stable or expanding during the five-year monitoring period (USFWS, 2013).

**Recovery Actions:**
- Survey suitable habitat for additional populations (USFWS, 1990).
- Protect existing and established populations (USFWS, 1990).
- Establish new populations (USFWS, 1990).
- Conduct research on the biology of the species (USFWS, 1990).
- Monitor natural and established populations (USFWS, 1990).
- Develop and maintain public support (brochure/display) (USFWS, 1990).
- Continue to monitor known B. decurrens sites and search for new populations annually, collecting GPS location and census data. Include survey efforts for B. decurrens in suitable habitat at the confluence of the Illinois River and Mississippi River to determine the extent of the species' southern range (USFWS, 2012).
- Finalize the draft cooperative management agreement between the ILDNR and the Service (USFWS, 2012).
- Establish a consensus among the workgroup regarding the core sub-populations that are important for the survival of the species during times of adverse hydrologic conditions. Also, normal, expected patterns of expansion and contraction of populations over time should be identified to facilitate the definition of population stability in the context of recovery (USFWS, 2012).
- Based on the results of the genetic primer research by Drs. Romano, explore genetic relationships between sub-populations and refine the metapopulation model for the species. Specifically, dispersal patterns and important source populations could be identified through microsatellite research in combination with spatial analysis (USFWS, 2012).
- Explore the phenomenon of hybridization between B. decurrens and B. asteroides using microsatellite genetic markers. Research should include a confirmation of hybridization between the two species and an analysis of the extent of hybridization in the population (USFWS, 2012).

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS • Continue to monitor known decurrent false aster sites and search for new populations annually, collecting GPS location and census data. Other survey methods, such as remote sensing, should be explored to increase the number of sites that can be surveyed annually. • Establish a consensus among the workgroup regarding the core sub-

populations that are important for the survival of the species during times of adverse hydrologic conditions. Also, normal, expected patterns of expansion and contraction of populations over time should be identified to facilitate the definition of population stability in the context of recovery. • Develop a sampling methodology to ensure comparable annual data (USFWS, 2020).

# SPECIES ACCOUNT: *Bonamia grandiflora* (Florida bonamia)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 12/2/1987; Southeast Region (R4)

**Physical Description**

A perennial vine with appressed hairs and long prostrate stems a meter or more in length. It has a long, relatively slender tap root. The leathery sessile or subsessile leaves are up to 4 cm in length and ovate in shape. The flowers are solitary and sessile in the leaf axils. The funnel-shaped corolla is 7 to 10 cm long and 7 to 8 cm across. It has a deep blue or bluish-purple color with a white throat. The flowers open in the morning and are wilted by early afternoon (G. Romano, University of Florida, personal communication 1996). The fruits are capsules, normally containing four seeds. The seeds are smoothish, pale brown or greenish-brown, 5 to 8 mm long, and oblong (G. Romano, University of Florida, personal communication 1995). The outer face is convex, and the inner two faces are flat, forming an angle (Wunderlin et al. 1980). B. grandiflora is the only morning glory vine found in scrub areas with a large blue flower (Wunderlin et al. 1980), but could be confused with Stylisma villosa. (USFWS, 1999)

**Taxonomy**

Bonamia grandiflora was originally named by Asa Gray in 1880 as Breweria grandiflora. In 1897, Hans Hallier transferred it to the genus Bonamia. There have been no other taxonomic treatments of the species since then (Myint and Ward 1968). (USFWS, 1999)

**Historical Range**

Florida bonamia is found in herbaria with collection locations in Volusia and Marion counties south through Lake, Orange, Polk, Highlands, Hardee, and west to Hillsborough, Manatee, and Sarasota counties (Institute for Systematic Botany 2006). Of these records, three are historical (Sarasota County in 1878, Manatee County in 1916, and Volusia County in 1900) and no recent records exist. (USFWS, 2017)

**Current Range**

The South Florida multispecies Recovery Plan (1999) indicated that Florida bonamia was found in Charlotte, Hardee, Highlands, Hillsborough, Lake, Manatee, Marion, Orange, Osceola, and Polk counties in Florida. (USFWS, 2017)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual, asexual (USFWS, 1999)

**Lifespan**

Adult: 3 or more years (USFWS, 1999)

**Dependency on Other Individuals or Species**

Adult: Insect pollinators (USFWS, 1999)

**Key Resources Needed for Breeding**

Adult: Fire (NatureServe, 2015)

**Other Reproductive Information**

Adult: Seedling survival rates are not known but are currently being investigated (G. Romano, University of Florida, personal communication 1996). Due to the nature of Bonamia's growth, identifying seedlings from older individuals' stems that are actually connected to other stems below-ground can be difficult. However, it is possible to distinguish these two life phases. Hartnett and Richardson (1989) excavated several plants and found that the clumps of prostrate stems seen at the surface are all connected to a "large central and somewhat woody rootstock." They had no difficulty distinguishing such well-established older individuals from young single-stem plants that had grown from seed. According to Hartnett and Richardson (1989), fire stimulates seed production and germination as well as regrowth from clonal stems. The first season after a fire, clonal stem production is the greatest and then declines. However, seed production is greatest during the second season after a fire. The lag is probably due to the increased energy needed for regrowth following fire; seed production is postponed to conserve energy. New seed production replaces the seed banks that are often destroyed by fire. (USFWS, 1999)

**Reproduction Narrative**

Adult: Bonamia grandiflora grows for 3 or more years (50 FR 42068, Wunderlin et al. 1980), flowering from spring to summer (Small 1933). It has a mixed mating system; it is highly self-compatible, it can self-pollinate, and it can produce seeds without fertilization (G. Romano, University of Florida, personal communication 1998). Pollinators are essential, however, to ensure substantial seed production by self- as well as cross-fertilization. Bonamia grandiflora shows some inbreeding depression in selfed fruits and seeds but it does not appear to be enough to hinder the present populations (G. Romano, University of Florida, personal communication 1998). The seeds of Bonamia become dormant, but may not require dormancy to germinate, particularly if the seeds are planted immediately. Hartnett and Richardson (1989) observed that populations of this species have large seed banks of dormant seeds, mostly within 1 cm of the surface, distributed rather homogeneously, with no relation to the distribution of mature plants. The seedlings germinate throughout the summer until September. The necessity of fire for germination has not been studied; however, germination occurs on sites with sparse vegetation that have not burned recently (G. Romano, University of Florida, personal communication 1996). (USFWS, 1999)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Shrubland/chaparral (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Bonamia grandiflora is a scrub endemic of central Florida. All of its known populations occur within or near scrub or on the edge of scrub habitat in the white sands associated with the ancient Pleistocene dune systems of the central ridge system (Ward 1979). These sands are of the St. Lucie-Paola complex, highly porous, acidic (4.5 to 6.0) and containing few nutrients (Wunderlin et al. 1980). This substrate is associated with a sand pine scrub vegetation consisting of evergreen scrub oak (Quercus myrtifolia and Q. germinata) and sand pine (Pinus clausa) with openings between the trees and shrubs occupied by lichens and herbs. The openings are cleared by infrequent fires or by mechanical disturbance. Bonamia grandiflora is also known to live in disturbed areas near roadways and clearings caused by logging operations (50 FR 42068). This species is not found on altered soils such as the clay applied to logging roads (Miller 1989). As the scrub community reaches maturity, encroachment and shading from overstory pines and oaks cause the decline of this species as well as other associated endemics (Wunderlin et al. 1980). It seems that this species prefers an open canopy in full sunlight in order to avoid competition from the surrounding shrubs. For example, in Ocala NF, the Bonamia grows in a variety of growth stages of sand pine, but flowers profusely only in the open, sunny conditions of regeneration stands, and sparsely if at all in older stands. (USFWS, 1999)

***Dispersal/Migration***

**Dependency on Other Individuals or Species for Dispersal**

Adult: Unknown

**Dispersal/Migration Narrative**

Adult: Dispersal occurs via biotic and abiotic factors - specific factors are unknown.

***Population Information and Trends***

**Population Trends:**

Declining (NatureServe, 2015)

**Species Trends:**

Declining (USFWS, 2017)

**Resiliency:**

Bonamia grandiflora is a long-lived perennial and can self-pollinate and produce seeds without fertilization, which affords the species some natural ability to withstand year-toyear variation in conditions. The distribution of the species includes 55 populations over 6 counties on lands that are managed for appropriate habitat. Many of these populations are within contiguous tracts of land that provide for connectedness between populations. In one study habitat disturbance (e.g., fire and mechanical) resulted in greater plant density, stem densities, seedling recruitment, flowering, and seed production than in habitat that had not been disturbed recently and that was considered successionally mature (Hartnett and Richardson 1989). Because of the disturbance-dependence of this species, some level of environmental stochasticity may not be detrimental and may actually be beneficial to the species. We believe these characteristics provide the species with sufficient and inherent resiliency (USFWS, 2023).

**Representation:**

Bonamia grandiflora is a scrub and sandhill endemic of central Florida. Because the species occurs in a limited range of habitats in central Florida, it may limit the species ability to adapt to changing conditions and therefore limit its representation. The species’ ability to seed without fertilization and self-pollinate may also limit genetic diversity. However, the self-pollination and setting seeds without fertilization allows the species to persist during times or in areas where additional plants will be unavailable for crosspollination. Bonamia grandiflora has low genetic variability compared to other plants endemic to scrub in Florida, which is likely the result of a small initial gene pool and/or strong selection in the harsh scrub environment (Romano 1999). Habitat fragmentation and population isolation in some cases may contribute to limitations in genetic diversity (Romano 1999). The mode of dispersal is undocumented for this species, but seeds may be dispersed by animals (e.g., herbivores or insects), wind, or water dispersal as seen in other members of the morning glory family (Convolvulaceae; Austin 1997). In one study seed density in the soil of disturbed site (i.e., site was previously disked or plowed) was closely linked to the proximity of adult plants and in other sites (e.g., undisturbed or burned sites) seed density was not related to proximity to adult plants (Hartnett and Richardson 1989). Some of these characteristics may limit the species’ representation but also allow it to persist when there are few nearby plants for cross-pollination. However, we do not feel that these characteristics will impact the species’ viability in the foreseeable future (USFWS, 2023).

**Redundancy:**

As described in the information above, the species is known to occur in 55 managed, secured populations across six counties in the state. In addition to known, managed populations, there are an additional 16 populations on unsecured or unmanaged lands. In addition to the known populations, the species’ condition in Ocala National Forest was described by USFS personnel as “widespread … it is in every scrub stand essentially” (Jay Garcia, USFS pers. comm.). This indicates to the Service that the species is likely much more widespread than we know and may be similarly more widespread on other protected and private lands. Because of the widespread nature of the species and its general biological characteristic, a single catastrophic event is unlikely to impact all individuals in all populations. and should have sufficient redundancy to be viable in the foreseeable future (USFWS, 2023).

**Number of Populations:**

95 (USFWS, 2023)

**Additional Population-level Information:**

Turner et al.'s (2006) assessment included locality records over the past 20 years and more recent observations and it is not evident from this database whether Florida bonamia is still found at each of the 66 locations. Therefore, without a comprehensive range-wide survey it is not possible to evaluate the spatial distribution and trends in spatial distribution of this species. Nonetheless, it is likely that some of the historic locality records on private lands have been lost due to habitat degradation (fire exclusion) and destruction. As a result, since its listing, the distribution of Florida bonamia has likely become more fragmented. (USFWS, 2017)

**Population Narrative:**

The status of Florida bonamia is largely unknown because repeated surveys have not been conducted at most known populations. However, available monitoring suggests that some populations may be in decline and others may be increasing, but this may be reflective of Florida honmnia's typical boom and subsequent decline following fire. Use of periodic prescribed fire appears to be essential in maintaining suitable habitat. Sixty-six locality records existed for Florida bonamia in 2006, but the number of extant populations is not known because recent range wide surveys have not been conducted. Twenty-five locality records occur on public lands. (USFWS, 2017). Bonamia grandiflora formerly occurred in central Florida peninsula counties from Volusia and Marion south to Highlands and Charlotte as shown in Figure 1. (Wunderlin et al. 1980). The Florida Natural Areas Inventory's (FNAI) Element of Occurrence Records (EO) database listed 95 populations from nine counties in 2022 (e.g., Hardee, Highlands, Hillsborough, Lake, Manatee, Marion, Orange, Osceola, and Polk). An EO is considered a distinct population that is separated from another EO by a distance of 1 kilometer or greater. When assessing the species, there are currently 55 extant populations in six counties where they occur on managed, conservation lands (e.g., Highlands, Lake, Manatee, Marion, Orange, and Polk). Populations (i.e., EOs) in private ownership, historical EOs, extirpated EOs, or failed to find EOs are not included in the following table (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Fire Suppression (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The most pervasive threat to Florida bonamia on public land is habitat degradation due to fire suppression, although off-road vehicle use on the ONF is likely to result in adverse impacts. Florida bonamia on private lands are also threatened long-term with fire suppression, but habitat destruction is a more immediate concern in many locations. Recent range wide surveys have not been conducted for this species so evaluating threats due to fire suppression and habitat destruction is problematic because in many instances we do not know if previously identified populations still exist. Nonetheless, most land managing agencies in Florida are not able to use prescribed fire at the rates, frequency, and/or intensity needed to restore and maintain most of Florida's fire-adapted ecosystems (R. Mulholland, Florida Department of Environmental Protection, personal communication, 2007; Service 2006). Consequently, the difficulties land managing agencies currently face in implementing prescribed fires probably have resulted in the degradation of Florida bonamia habitat in some areas. Except for several privately owned conservation parcels, most other private landowners are unlikely to use habitat management techniques such as prescribed fire to maintain or enhance Florida bonamia habitat. At present, there are no incentives available that would encourage private landowners to undertake prescribed fire, especially for those who own relatively small parcels embedded in urban matrices. As a result, we believe that many locality records for Florida bonamia on nonconservation parcels in private ownership are threatened with habitat modification due to fire suppression. (USFWS, 2017)

**Stressor:** Urban Development (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Florida bonamia that occur on non-conservation private lands also are vulnerable to destruction due to urban development, such as construction of roads; installation of utilities and other infrastructure; and residential, commercial, and industrial construction. Florida bonamia on

each private parcel is vulnerable to this threat at any time, however, we are not aware of any imminent loss of Florida bonamia due to development. (USFWS, 2017)

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Overutlization is not currently thought be a significant risk factor to Florida bonamia; however, TNC reported two occasions of unauthorized plant removal on INC property since 1991 (TNC 2006). (USFWS, 2017)

**Stressor:** Disease or predation (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Florida bonamia may be affected by fungus, but no detailed investigations have been undertaken (Romano 1999). Insect herbivory has been observed, bu t is not thought to be a significant risk to Florida bonamia (Romano 1999). (USFWS, 2017)

**Stressor:** Disease or predation (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Florida bonamia may be affected by fungus, but no detailed investigations have been undertaken (Romano 1999). Insect herbivory has been observed, bu t is not thought to be a significant risk to Florida bonamia (Romano 1999). (USFWS< 2017)

**Stressor:** Inadequacy of existing regulatory mechanisms: Florida (USFWS, 2017)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Existing regulatory mechanisms appear adequate to protect Florida bonamia on State and federally owned lands. Furthermore, we believe Florida bonamia on private conservation parcels are adequately protected because The Nature Conservancy would not authorize removal or destruction of Florida bonamia except for scientific or educational purposes. Even then, we anticipate that TNC would seek research permits from the Service to evaluate potential impacts resulting from proposed research or educational projects involving Florida bonamia. On private properties, Federal or State laws provide little protection for Florida bonamia. Since the majority of extant Florida bonamia populations occur on unprotected private lands, we conclude that existing regulatory mechanisms are inadequate to protect this species. e. Other natural or manmade factors affecting its continued existence: The 1999 South Florida Multi-species Recovery Plan (Service 1999) indicated that competition with non-native vegetation (e.g., cogon grass) may have been a management concern at ONF. Although ONF has an exotic vegetation management program in place, this threat is not entirely controlled and it is possible that unknown bonamia populations within the ONF may be affected by cogon grass or other exotic vegetation. We suspect that there are other locations containing Florida bonamia that also contain exotic vegetation, but we did not find current literature indicating this to be a significant

management problem. (USFWS, 2017)

***Recovery***

**Reclassification Criteria:**
Not applicable.

Recovery Priority Number: 8

**Delisting Criteria:**
1. The species is secure in Ocala National Forest and low-intensity monitoring must continue after delisting (USFWS, 2008).

2. Secure and monitor at least three sites in Highlands county; three sites in Polk county; and at least two sites in other counties (USFWS, 2008).

3. Provide at least five years of demographic monitoring at each of the sites identified in numbers 1 and 2 (USFWS, 2008).

In South Florida: Delisting can be achieved when: (1) sites, within the historic range of B. grandiflora, are adequately protected from habitat loss, degradation, and fragmentation; (2) when these sites are managed to maintain the seral stage of xeric oak scrub communities to support B. grandiflora; and (3) when monitoring programs demonstrate that these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. (USFWS, 1999)

**Recovery Actions:**
- Protect habitat through purchase and other means (including the Habitat Conservation Plan process for threatened animals in the Florida scrub habitat) (USFWS, 1996).
- Manage protected habitats (USFWS, 1996).
- Assess progress and plan post-recovery monitoring (USFWS, 1996).
- S1. Determine current distribution of B. grandiflora. Some portions of B. grandiflora's range have been well surveyed (Ocala NF and the southern Lake Wales Ridge), yet a distribution has not been ascertained for this species. Lack of survey knowledge in much of its range makes defining distribution difficult. (USFWS, 1999)
- S2. Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- S3. Conduct research on life history characteristics of B. grandiflora. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species more specific biological information is needed.
- S4. Monitor existing populations of B. grandiflora. Develop monitoring protocol to assess population trends for B. grandiflora. Develop a quantitative description of the population structure of B. grandiflora. (USFWS, 1999)

- S5. Provide public information about B. grandiflora. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of B. grandiflora and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999) (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)
- Recommendation for Future Action from 2017 5-Year Review: Revise the recovery criteria to establish measureable goals for demographic monitoring, including but not limited to: the number of populations that should be monitored, the demographic parameters that should be measured, and the demographic performance levels/rates that should be met. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: A range wide survey should be conducted to determine the size and location of extant Florida bonamia populations and assessment of historic locality records. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: Demographic monitoring of Florida bonamia populations should be initiated on public lands. Level 2 monitoring (Menges and Gordon 1996) includes sufficient detail to evaluate trends in population status over time. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: Management activities should be implemented on public lands that contain Florida bonamia, including prescribed fire at return intervals and intensities necessary to restore and/or maintain the various xeric vegetative communities that support this species. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: An assessment of mechanical vegetation management (e.g., roller chopping, mowing, gyro-tracking, logging, and chain-saw felling) is needed to evaluate the response of Florida bonamia to various management alternatives. These data should be collected concurrently with level 2 monitoring. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: Future land acquisition or other conservation measures should be taken to protect large Florida bonamia populations on unprotected lands. Protection should target bonamia populations that are sufficiently large, or could be large if adequately managed, as to be self-sustaining and viable long-term. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: Given the relatively large number of unprotected Florida bonamia populations, efforts should be explored to encourage private landowners to conserve and manage property known to contain this species.

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES • Collaboration with conservation land managers to increase habitat suitability of occupied habitat by promoting beneficial management options to increase population persistence wherever additional opportunities present themselves. • Encourage landowners whose populations are under a habitat management plan to monitor occupied habitat for increased data of long-term trends (USFWS, 2023).

# SPECIES ACCOUNT: *Brickellia mosieri* (Florida brickell-bush)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/6/2014; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Brickellia mosieri is a perennial herb. Mature plants are 0.3–1.1 meters (m) (1.0–3.5 feet (ft)) tall, slender, erect, and branching (Chafin 2000, page numbers not applicable). Leaves are 1–3 centimeters (cm) (0.4–1.2 inches (in)) long, alternate, narrow, linear, thick, usually spreading or curved downward, entire or slightly toothed, and resin dotted. The flower heads are in loose, open clusters at the ends of branches. Disk flowers are white in small, dense heads surrounded by hairy, slightly ribbed bracts; there are no ray flowers, although long-style branches (white, sometimes brown) may appear to be rays. (USFWS, 2013)

**Taxonomy**

Brickellia mosieri (Family: Asteraceae) was first described by Small in 1933 as Kuhnia mosieri. In 1970, Long called the species Kuhnia eupatorioides var. floridana, reducing it to a variety of a more widespread species occurring in the eastern United States. In 1971, Shinners included all members of the genus Kuhnia in Brickellia and restored the plant to species status, calling it Brickellia mosieri (USFWS, 2013). Kartesz (1999) lists B. mosieri as a synonym of Brickellia eupatorioides var. floridana. (NatureServe, 2015).

**Historical Range**

Brickellia mosieri is endemic to the pine rocklands of the Miami Rock Ridge in Miami-Dade County. It was historically known from central and southern Miami-Dade County from approximately Coconut Grove to Florida City, a range of approximately 45.0 km (28.0 mi), along the Miami Rock Ridge. (USFWS, 2014). The historical range of Florida brickell-bush is central and southern Miami-Dade County, covering approximately 22.5 miles (36.2 km) from South Miami to Florida City (Bradley and Gann 1999). At present, the northernmost extant population occurs at Ron Ehmann Park (10 miles south of the northernmost historic range) with the southern extent occurring in Florida City at Navy Wells Pineland Preserve (USFWS, 2023).

**Current Range**

Brickellia mosieri is currently distributed from central and southern Miami-Dade County from SW 120 St. to Florida City, suggesting its historical range has contracted at least 13.6 km (8.5 mi), or more than 30 percent. (USFWS, 2014). The historical range of Florida brickell-bush is central and southern Miami-Dade County, covering approximately 22.5 miles (36.2 km) from South Miami to Florida City (Bradley and Gann 1999). At present, the northernmost extant population occurs at Ron Ehmann Park (10 miles south of the northernmost historic range) with the southern extent occurring in Florida City at Navy Wells Pineland Preserve (USFWS, 2023).

**Critical Habitat Designated**

Yes; 9/16/2015.

**Legal Description**

On August 17, 2015, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective September 16, 2015) for Brickellia mosieri (Florida brickell-bush) under the

Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in Florida (80 FR 49846-49886).

**Critical Habitat Designation**

The critical habitat designation for Brickellia mosieri includes six CHUs (40 sub-units) in Miami-Dade County, Florida. This species critical habitat encompasses approximately 2,624 acres (ac) (1,062 hectares (ha)). Brief descriptions are presented below. Maps depicting the CH units are available in the Final Rule. (80 FR 49846-49886).

Unit BM1: Trinity Pineland and Surrounding Areas, Miami-Dade County, Florida: Unit BM1 consists of 18 ha (43 ac) in Miami-Dade County. Within Unit BM1, there are two subunits—BM1A (Countyowned) and BM1B (combination of State, County, and privately owned lands). The unit is comprised of State lands within Trinity Pineland County Park (4 ha (10 ac)); County lands primarily within A. D. ‘‘Doug’’ Barnes Park (6 ha (14 ac)); and parcels in private ownership (8 ha (19 ac)). This unit is bordered on the north by SW 24 Street, on the south by the Snapper Creek Expressway (State Road (SR) 878), on the east by SW 67 Avenue, and on the west by SW 87 Avenue.

Unit BM2: Nixon Smiley Pineland Preserve and Surrounding Areas, Miami-Dade County, Florida: Unit BM2 consists of approximately 108 ha (267 ac) of habitat in MiamiDade County. Within Unit BM2, there are seven subunits (BM2A–BM2G) comprising primarily conservation lands and including four larger areas plus three smaller areas. The unit is comprised of State lands within Camp Matecumbe, Tamiami Pineland Complex Addition, and Rockdale Pineland (49 ha (121 ac)); County/local lands primarily within Nixon Smiley Pineland Preserve, Tamiami #8 (Nixon Smiley Addition) Pineland, Pine Shore Pineland Preserve, Ron Ehman Park, and Rockdale Pineland Addition (59 ha (146 ac)); and small portions of parcels in private or other ownership (less than 1 ha (less than 1 ac)). This unit is bordered on the north by SW 104 Street, on the south by SW 152 Street (Coral Reef Drive), on the east by U.S. 1 (South Dixie Highway), and on the west by SW 177 Avenue (Krome Avenue).

Unit BM3: USDA Subtropical Horticultural Research Station and Surrounding Areas, Miami-Dade County, Florida: Unit BM3 consists of approximately 127 ha (315 ac) of habitat in MiamiDade County. Within Unit BM3, there are eight subunits (BM3A–BM3H), including two larger areas (U.S. Department of Agriculture (USDA) Subtropical Horticultural Research Station, and Deering Estate at Cutler) plus six smaller areas surrounding these. The unit is comprised of Federal lands within the USDA Subtropical Horticultural Research Station (59 ha (145 ac)); State lands within the R. Hardy Matheson Preserve, Ludlam Pineland, Deering Estate at Cutler, and Deering Estate South Addition (45 ha (112 ac)); County/local lands within Coral Reef Park, Ned Glenn Nature Preserve, and Bill Sadowski Park (15 ha (38 ac)); and parcels in private ownership (8 ha (19 ac)). This unit is bordered on the north by SW 112 Street, on the south by the intersection of Old Cutler Road and Franjo Road (County Road (CR) 977), on the east by the Atlantic Ocean, and on the west by U.S. 1 (South Dixie Highway).

Unit BM4: Richmond Pinelands and Surrounding Areas, Miami-Dade County, Florida: Unit BM4 consists of approximately 395 ha (975 ac) in Miami-Dade County. Within Unit BM4, there are eight subunits (BM4A–BM4H), most within the Richmond Pinelands complex (made up of Federal and County-owned lands, as well as land owned by the University of Miami). The unit is comprised of Federal lands owned by the USCG (Homeland Security), U.S. Army Corps of

Engineers (ACOE; Department of Defense), U.S. Prison Bureau (Department of Justice), and the U.S. Department of Commerce/National Oceanic and Atmospheric Administration (NOAA) (75 ha (185 ac)); County/local lands within and adjacent to Larry and Penny Thompson Park, Martinez Pineland, Zoo Miami, and Eachus Pineland (239 ha (590 ac)); and parcels in private or other ownership (81 ha (200 ac)). This unit is bordered on the north by SW 152 Street (Coral Reef Drive), on the south by SW 200 St (Quail Drive/SR 994), on the east by U.S. 1 (South Dixie Highway), and on the west by SW 177 Avenue (Krome Avenue).

Unit BM5: Quail Roost Pineland and Surrounding Areas, Miami-Dade County, Florida: Unit BM5 consists of approximately 96 ha (238 ac) in Miami-Dade County. Within Unit BM5, there are 11 subunits (BM5A–BM5K), including 4 larger areas plus 7 smaller areas surrounding these. The unit is comprised of State lands within Quail Roost Pineland, Goulds Pineland and Addition, and Silver Palm Groves Pineland (39 ha (97 ac)); County/ local lands including Black Creek Forest, Rock Pit #46, and lands owned by the School Board of Miami-Dade County (15 ha (37 ac)); and parcels in private ownership (42 ha (104 ac)), including Porter-Russell Pineland owned by the Tropical Audubon Society. This unit is bordered on the north by SW 200 St (Quail Drive/SR 994), on the south by SW 248 Street, on the east by the Florida Turnpike, and on the west by SW 194 Avenue.

Unit BM6: Camp Owaissa Bauer and Surrounding Areas, Miami-Dade County, Florida: Unit BM6 consists of approximately 112 ha (276 ac) of habitat in MiamiDade County. Within Unit BM6, there are 12 subunits (BM6A–BM6L), composed of 1 larger area (Camp Owaissa Bauer and its addition) and 11 smaller areas to the south. The unit is comprised of State lands within Owaissa Bauer Pineland Addition, Ingram Pineland, West Biscayne Pineland, and Fuchs Hammock Addition (20 ha (50 ac)); County/local lands including Camp Owaissa Bauer, Pine Island Lake Park, Seminole Wayside Park, and Northrop Pineland (63 ha (156 ac)); and parcels in private ownership (28 ha (70 ac)), including the private conservation area, Pine Ridge Sanctuary. This unit is bordered on the north by SW 248 Street, on the south by SW 312 Street, on the east by SW 112 Avenue, and on the west by SW 217 Avenue.

Unit BM7: Navy Wells Pineland Preserve and Surrounding Areas, Miami-Dade County, Florida: Unit BM7 consists of approximately 206 ha (510 ac) of habitat in MiamiDade County. Within Unit BM7, there are eight subunits (BM7A–BM7H), including one larger area (Navy Wells Pineland Preserve) and seven smaller outlying areas. The unit is comprised of State lands within Palm Drive Pineland, Navy Wells Pineland #39, Navy Wells Pineland Preserve (portion), and Florida City Pineland (53 ha (132 ac)); County/ local lands including primarily Sunny Palms Pineland and Navy Wells Pineland Preserve (portion) (125 ha (309 ac)); and parcels in private ownership (28 ha (68 ac)). This unit is bordered on the north by SW 320 Street, on the south by SW 368 Street, on the east by U.S. 1 (South Dixie Highway), and on the west by SW 217 Avenue.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Brickellia mosieri critical habitat consists of three components (80 FR 49846-49886):

(i) Areas of pine rockland habitat that contain: (A) Open canopy, semi-open subcanopy, and understory; (B) Substrate of oolitic limestone rock; and (C) A plant community of predominately native vegetation that may include, but is not limited to: (1) Canopy vegetation dominated by Pinus elliottii var. densa (South Florida slash pine); (2) Subcanopy vegetation that may include, but is not limited to, Serenoa repens (saw palmetto), Sabal palmetto (cabbage palm), Coccothrinax argentata (silver palm), Myrica cerifera (wax myrtle), Myrsine floridana (myrsine), Metopium toxiferum (poisonwood), Byrsonima lucida (locustberry), Tetrazygia bicolor (tetrazygia), Guettarda scabra (rough velvetseed), Ardisia escallonioides (marlberry), Psidium longipes (mangroveberry), Sideroxylon salicifolium (willow bustic), and Rhus copallinum (winged sumac); (3) Short-statured shrubs that may include, but are not limited to, Quercus pumila (running oak), Randia aculeata (white indigoberry), Crossopetalum ilicifolium (Christmas berry), Morinda royoc (redgal), and Chiococca alba (snowberry); and (4) Understory vegetation that may include, but is not limited to: Andropogon spp.; Schizachyrium gracile, S. rhizomatum, and S. sanguineum (bluestems); Aristida purpurascens (arrowfeather threeawn); Sorghastrum secundum (lopsided Indiangrass); Muhlenbergia capillaris (hairawn muhly); Rhynchospora floridensis (Florida white-top sedge); Tragia saxicola (pineland noseburn); Echites umbellata (devil's potato); Croton linearis (pineland croton); Chamaesyce spp. (sandmats); Chamaecrista deeringiania (partridge pea); Zamia integrifolia (coontie); and Anemia adiantifolia (maidenhair pineland fern).

(ii) A disturbance regime that naturally or artificially duplicates natural ecological processes (e.g., fire, hurricanes, or other weather events) and that maintains the pine rockland habitat described in paragraph (2)(i) of this entry.

(iii) Habitats that are connected and of sufficient area to sustain viable populations of Brickellia mosieri in the pine rockland habitat described in paragraph (2)(i) of this entry.

**Special Management Considerations or Protections**

When designating critical habitat, the Service assesses whether the specific areas within the geographic area occupied by the species at the time of listing contain features which are essential to the conservation of the species and which may require special management considerations or protection. The features essential to the conservation of Brickellia mosieri and may require special management considerations or protection to reduce threats related to habitat loss, fragmentation, and modification primarily due to development; inadequate fire management; nonnative, invasive plants; and sea level rise. Destruction of the pinelands for economic development has reduced pine rockland habitat on the Miami Rock Ridge outside of ENP by over 98 percent, and remaining habitat in this area is highly fragmented. Brickellia mosieri occurs on a mix of private and publicly owned lands, only some of which are managed for conservation. Populations of the plants that occur on private land or non-conservation public land are vulnerable to habitat loss, while populations on conservation lands are vulnerable to the effects of habitat degradation if natural disturbance regimes are disrupted (e.g., through inadequate fire management). Prolonged lack of fire in pine rockland typically results in succession to rockland hammock, and displacement of native species by invasive, nonnative plants often occurs. Further development and degradation of pine rocklands increase fragmentation and decrease the conservation value of the remaining functioning pine rockland habitat. In addition, pine rocklands are expected to be further degraded and fragmented due to anticipated sea level rise, which would fully or partially inundate some pine rocklands along the coast and in the southern portion of Miami-Dade County (near Navy Wells Pineland Preserve), and cause increases in the salinity of the water table and soils resulting in vegetation shifts in additional pine rocklands across the Miami Rock Ridge. Many existing pine rockland fragments are also projected to be developed for housing as the human population grows and adjusts to changing sea levels. Special management considerations and protections that will address these threats include increased coordination and conservation of these plants and their habitat on Federal lands, and improved habitat restoration and management efforts (including fire management and nonnative plant treatments) of high-priority and high-elevation sites. (USFWS, 2013)

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2014)

**Breeding Season**

Adult: August - October (USFWS, 2014)

**Key Resources Needed for Breeding**

Adult: Fire (USFWS, 2014)

**Reproduction Narrative**

Adult: While specific pollinators or dispersers are unknown, flower morphology suggests this species may be pollinated by butterflies, bees, or both (Koptur 2013, pers. comm.); wind is one likely dispersal vector (Gann 2013b, pers. comm.). (USFWS, 2014). Reproduction is sexual (Bradley and Gann 1999, p. 12). Flowering takes place primarily in the fall (August–October) (Bradley and Gann 1999, p. 12). Off-season flowering is usually the result of fire, and B. mosieri will flower within 1 to 2 months following a fire, regardless of the time of year (Possley 2013 pers. comm.) (USFWS, 2014).

**Habitat Type**

Adult: Terrestrial (USFWS, 2014).

**Habitat Vegetation or Surface Water Classification**

Adult: Pine rockland (USFWS, 2014)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fire (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Scattered (USFWS, 2014)

**Environmental Specificity**

Adult: Very narrow

**Habitat Narrative**

Adult: Grows exclusively in pine rockland (USFWS, 2014). Pine rockland is characterized by an open canopy of South Florida slash pine (Pinus elliottii var. densa). Subcanopy development is rare in well-maintained pine rocklands, with only occasional hardwoods, such as Lysiloma latisiliquum (wild tamarind) and Quercus virginiana (live oak) growing to tree size in Miami Rock Ridge pinelands (Snyder et al. 1990, p. 253). The shrub/ understory layer is a diverse mix of species including both temperate and tropical shrubs and palms. The pine rocklands where Brickellia mosieri occurs are characterized by an open shrub canopy of Serenoa repens (saw palmetto), Myrica cerifera (wax myrtle), Metopium toxiferum (poisonwood), and Sideroxylon salicifolium (willow bustic) as well as species with more restricted distribution within pine rocklands including Sideroxylon reclinatum ssp. austrofloridense (Everglades bully), Callicarpa americana (beauty berry), Dodonaea angustifolia (varnish leaf), and Ilex cassine (dahoon holly) (Snyder et al. 1990, p. 254; Bradley and Gann 1999, p. 12). Populations are typically sparse and contain a low density of plants even in well-maintained pine rockland habitat (Bradley and Gann 1999, p. 12) (USFWS, 2014). The environmental specificity of this species is very narrow, as it is known only from pine rockland habitat in southern Florida, requiring fire to maintain the openings in which the plant occurs (NatureServe, 2015).

***Dispersal/Migration***

**Dependency on Other Individuals or Species for Dispersal**

Adult: Unknown (USFWS, 2014)

**Dispersal/Migration Narrative**

Adult: Wind is one likely dispersal vector (Gann 2013b, pers. comm.) (USFWS, 2014).

***Population Information and Trends***

**Population Trends:**

50% decline (USFWS, 2013)

**Species Trends:**

50 - 70% decline (NatureServe, 2015)

**Number of Populations:**

55 Historic and 14 Extant populations (USFWS, 2023)

**Population Size:**

All extant populations are estimated to have <1,000 individuals (USFWS, 2023).

**Population Narrative:**

Florida brickell-bush is a perennial herb that is endemic to pine rockland habitat outside of Everglades National Park in Miami-Dade County, Florida. There are 14 known extant populations, all with relatively small population estimates (<1,000). Of the 14 extant populations, one is on federal lands, one is on private lands, eight are Miami-Dade County owned, and four are on State of Florida land managed by Miami-Dade County. The status of 24 historic occurrences is unknown due to inaccessibility. There are 17 known extirpated occurrences of the species. Although the known extant populations occur mostly on county owned lands that are offered some protections, most of the data deficient occurrences are found on privately owned parcels that do not offer sufficient protection to the species (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The pine rockland community of south Florida, to which the species endemic, is critically imperiled globally (FNAI 2012, p. 27). Since the 1800s, residential and commercial development and agriculture have drastically reduced the habitat for these plants throughout pine rocklands in south Florida. Habitat loss continues to occur in its range, and most remaining suitable habitat has been negatively altered by human activity. Another human-related factor that can modify public and private lands alike is the potential for high levels of nutrients from agricultural and urban areas to enter into pine rockland systems. Such chemical alteration of pine rockland soil, which has naturally low amounts of phosphorus and nitrogen, can result in changes to vegetation composition and structure, at the expense of pine rockland endemics such as Brickellia mosieri. Effects of fragmentation on pollinators may include changes to the pollinator community as a result of limitation of pollinator-required resources (e.g., reduced availability of rendezvous plants, nesting and roosting sites, and nectar/pollen); these changes may include changes to pollinator community composition, species abundance and diversity, and pollinator behavior (Rathcke and Jules 1993, pp. 273–275; Kremen and Ricketts 2000, p. 1227; Harris and Johnson 2004, pp. 30– 33). As a result, plants in fragmented habitats may experience lower visitation rates, which in turn may result in reduced seed production of the pollinated plant (which may lead to reduced seedling recruitment), reduced pollen dispersal, increased inbreeding, reduced genetic variability, and ultimately reduced population viability (Rathcke and Jules 1993, p. 275; Goverde et al. 2002, pp. 297–298; Harris and Johnson 2004, pp. 33–34). Exclusion of fire for approximately 25 years will likely result in gradual hammock development over that time period, leaving a system that is very fire resistant if additional pre-fire management (e.g., mechanical hardwood removal) is not undertaken. Now, natural fires are unlikely to occur or are likely to be suppressed in the remaining, highly fragmented pine rockland habitat. The suppression of natural fires has reduced the size of the areas that burn, and habitat fragmentation has prevented fire from moving across the landscape in a natural way. Without fire, successional climax from pine rockland to rockland hammock is rapid, and displacement of native species by invasive nonnative plants often occurs. Understory plants such as Brickellia mosieri are shaded out by hardwoods and nonnatives alike (USFWS, 2013).

**Stressor:** Nonnative plants (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nonnative plants have significantly affected pine rocklands, and threaten all occurrences of Brickellia mosieri to some degree (Bradley and Gann 1999, pp. 15, 72; Bradley and Gann 2005, page numbers not applicable; Bradley 2007, pers. comm.; Bradley and van der Heiden 2013, pp. 12–16). As a result of human activities, at least 277 taxa of nonnative plants have invaded pine rocklands throughout south Florida (Service 1999, p. 3–175). Nonnative invasive plants compete with native plants for space, light, water, and nutrients, and make habitat conditions unsuitable for Brickellia mosieri which responds positively to open conditions (USFWS, 2014).

**Stressor:** Small isolated populations (USFWS, 2013)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Only small and fragmented occurrences of this plant remains. The current range spans such a small area that all populations could be affected by a single event (e.g., hurricane). Although robust population viability analyses (including minimum viable population calculations) have not been conducted for these plants, indications are that most existing populations for this plant are at best marginal (USFWS, 2013).

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Drier conditions and increased variability in precipitation associated with climate change are expected to hamper successful regeneration of forests and cause shifts in vegetation types through time (Wear and Greis 2012, p. 39). Although it has not been well studied, existing pine rocklands have probably been affected by reductions in the mean water table. Climate changes are also forecasted to extend fire seasons and the frequency of large fire events throughout the Coastal Plain (Wear and Greis 2012, p. 43). While restoring fire to pine rocklands is essential to the long-term viability of Brickellia mosieri populations, increases in the scale, frequency, or severity of wildfires could have negative effects on this species considering its general vulnerability due to small population size, restricted range, few colonies, and relative isolation (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
Not available - this species does not have a recovery plan.

Recovery Priority Number: 5

**Delisting Criteria:**
Not available - this species does not have a recovery plan.

**Recovery Actions:**
- Not available - this species does not have a recovery plan.

***Conservation Measures and Best Management Practices:***
- RECOMMENDED FUTURE ACTIVITIES During this status review, we have utilized the recovery outline and also identified additional potential recovery activities which are included below. Recovery Activities • Implement, continue, or increase habitat restoration efforts (exotic species removal and prescribed fire) at all occurrences. • Pursue conservation agreements and/or acquire land where Florida brickell-bush occurs. • Continue to work with Miami Dade County to protect remnant patches of habitat. • Expand work on ex situ propagation and seed banks. • Support and expand upon the Connect to Protect imitative promoting Florida brickell-bush within its historical range. • Develop a reintroduction plan and conduct reintroduction and augmentation of the species in suitable pine rockland habitat and evaluate reintroduction techniques and success. Monitoring/Research Activities • Survey sites that have an undetermined population status if landowners allow access. • Census extant populations every three years. In the event of fire in a

population, conduct quarterly monitoring up to 2 years post-fire, noting any seedling recruitment. • Conduct demographic research including population assessments, such as phenology and lifeclass stage, population trends, and examining growth and establishment rates. • Conduct reintroduction feasibility studies and identify potential recipient sites. • Conduct research to examine the effects of growing season burns versus non-growing season burns on flowering, seed set, and establishment. • Evaluate how climate change may impact the species range. • Conduct genetic studies to examine diversity among sites that may be declining due to isolation and genetic drift. Outreach Activities • Promote additional partnerships to share information, conduct collaborative research on pine rockland and scrub habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. • Attend relevant community events that will create and foster appreciation for endemic species in the pine rockland habitat (USFWS, 2023).

# SPECIES ACCOUNT: *Callirhoe scabriuscula* (Texas poppy-mallow)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 2/12/1981; Southwest

**Physical Description**

A perennial herbaceous plant found in deep, loose, sandy soils near the Colorado River in west Texas. The fleshy taproots extend about 45 centimeters (cm) (18 inches (in)) deep before branching. During the winter, the plants form rosettes of 3 to 8 basal leaves that have 3 to 5 palmately-arranged lobes. Flower stalks emerge in the spring, reaching up to 45 cm (18 in) tall. The stems and leaves have a rough texture due to a covering of stellate pubescence (star-shaped hairs). Flowers have 5 reddish-purple petals, about 3.8 cm (1.5 in) long, arranged in the form of a cup, with dark maroon centers. This species is distinguished from others in the Genus by its linear involucellar bractlets, valvate calyx lobes that form an apiculate or acuminate point in bud (cover photograph), indehiscent mericarps, stiffly erect stems, and 6- to 8-rayed stellate hairs. (USFWS, 2019a)

**Taxonomy**

Robinson (1895–1897, p. 302) described Callirhoe scabriuscula as a new species in the Malvaceae (Mallow Family), based on a single specimen collected by Dr. Sutton Hayes. Robinson distinguished this from other species in the genus by its densely pubescent carpels with short beaks and involucel of 3 linear bractlets (figure 1.e.a). Callirhoe leiocarpa (tall poppymallow) and C. involucrata (winecup) occur near C. scabriuscula. These are distinguished by smaller flowers with white petal bases and the absence of stellate pubescence; additionally, C. leiocarpa is an annual species and lacks an involucel, and C. involucrata has a prostrate rather than erect habit. (USFWS, 2019a)

**Historical Range**

Historically known from Runnels County, Texas.

**Current Range**

In four counties in Texas: Runnels, Coke, Mitchell, and Scurry. (USFWS, 2019a)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: short-lived perennial (USFWS, 2019a)

**Breeding Season**

Adult: Flowers from late April to mid-June (USFWS, 2019a).

**Key Resources Needed for Breeding**

Adult: Insects for pollination (USFWS, 1985).

**Reproduction Narrative**

Adult: Texas poppy-mallow flowers from late April until mid-June (Amos 1979, pp. 8–10; USFWS 1985, pp. 7–9). Flowers open 2 to 3 hours after sunrise and close before sunset. If pollinated, flowers close within 30 to 90 minutes. Un-pollinated flowers continue to open for 6 to 8 days. Anthers of individual flowers mature prior to stigmas (figure 1.d), releasing their pollen about 36 hours before stigmas emerge. Less than 1 percent of flowers from which insects were excluded produced seeds. Conversely, 85 percent of open-pollinated flowers produced seeds; therefore, Texas poppy-mallow is a predominantly out-crossing species. Plants produced an average of 41.4 fruits per plant per year, and fruits averaged 19 seeds each; thus, individuals produced an average of 878 seeds per year. Three species of bees, Diadasia afflicta, Melissodes intorta, and M. tepanica, forage for nectar and pollen in Texas poppy-mallow flowers and use the staminal column as a landing and take-off platform; the foraging behaviors of these bees indicates that they are likely to be effective pollinators. D. afflicta and M. intorta are oligolectic species that forage primarily within the genus Callirhoe. Seeds mature and dehisce from 10 to 18 days after flowering and fertilization. Flowering ceases by late June, as the weather becomes increasingly hot and dry, and the stems die by late July. New rosettes emerge from the taproots in late August and September. (USFWS, 2019a)

**Habitat Type**

Adult: Terrestrial (USFWS, 2019a)

**Habitat Vegetation or Surface Water Classification**

Adult: Grasslands, shin oak shrublands, or open oak or mesquite woodlands (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Deep sandy soil blown from alluvial deposits along the Colorado River (USFWS, 2019a)

**Environmental Specificity**

Adult: Very Narrow (USFWS, 2019a)

**Habitat Narrative**

Adult: Texas poppy-mallow occurs in deep, loose sands of the Tivoli and Brownfield Soil Series (USFWS 1985, pp. 3–4). These sands are carried by wind from alluvial formations in the Colorado River flood plain and deposited on the lee (north and east) side of the river (USDA Soil Conservation Service 1970, p. 26). The difference between Tivoli and Brownfield soils is that the former lacks a distinct B horizon, while the latter has a sandy clay subsoil at a depth of about 0.51–1.02 m (20–40 in). Dunes up to 9 m (30 ft) high and 61 m (200 ft) wide form to the lee of cultivated fields. These soils have very rapid rainfall infiltration rates, very little runoff, and low water holding capacity. Cruze (1991, pp. 12, 15) found 159 Texas poppy-mallow plants within an area of 225 m2 (2,422 ft2) at the study site at EO3. About 80 percent of Texas poppy-mallow plants occurred on 1-m2 (10.76 ft2) plots that had from 3 to 16 percent cover of forbs and grasses; 79 percent of plots were within this range of vegetative cover (p. 12). This demonstrates that occupied habitats have sparse vegetative cover . (USFWS, 2019a)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Cruze (1991) investigated the soil seed reserve of the Runnels County population mentioned above (EO3). She recovered 325 seeds from 6,583 soil samples totaling 1.7 m3 (60.0 ft3 ) of soil (pp. 6, 9). Seed distribution was uneven, with 91 percent of recovered seeds in the uppermost 5 cm of the soil; 85 percent of seeds were found within 1 m (3.28 ft) in horizontal distance of an established individual (pp. 9–11), indicating that seeds have very limited dispersal. Seed viability, tested with tetrazolium chloride, was 16.3 percent (p. 12); on this basis, the author concluded that seed viability declines rapidly in the soil (p. 19). (USFWS, 2019a)

***Population Information and Trends***

**Population Trends:**

Not available.

**Species Trends:**

Not available.

**Number of Populations:**

10 (USFWS, 2019a)

**Population Size:**

Approximately 2800 individuals (USFWS, 2019a)

**Minimum Viable Population Size:**

1,300 mature, reproductive individuals (USFWS, 2019a)

**Population Narrative:**

The Texas Natural Heritage Program conducted extensive surveys for Texas poppy-mallow from 1987 through 1989 at 143 sites in 37 counties (Poole (1990). This project documented 9 new populations at 6 sites in Runnels, Coke, and Mitchell counties, totaling 2,817 individuals, and reported an additional population discovered in Coke County in 1990 by an environmental consultant (Poole 1990, pp. 1, 3). All populations were found in areas of intact native vegetation on deep, loose, sandy soils of the Tivoli and Brownfield Series near the Colorado River (note that Likes and Heatly are alternate names for the Tivoli and Brownfield soil map units, respectively). The species has now been documented in four counties—Runnels, Coke, Mitchell, and Scurry (Amos 2008, 2019). The most recent censuses (TXNDD 2019) for all known EOs totals less than 3,000 individuals; however, we have no survey data more recent than 2001. All known populations of Texas poppy-mallow occur in Tivoli (Likes) and Brownfield (Heatly) fine sands (NRCS 2019c) in Runnels, Coke, Mitchells, and Scurry counties. Although we do not have geographic data for populations in Scurry County, Amos (2008, 2019) confirmed that at least one population extends from northern Mitchell County into southern Scurry County. The known populations span a linear distance of about 155 km (96 mi) from northwest to southeast. Within the counties mentioned, NRCS (2019c) classifies 16,987 ha (41,975 ac) as Tivoli (Likes) or Brownfield (Heatly) fine sands. (USFWS, 2019a)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 1981)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Much of the natural habitat of Callirhoe scabriuscula has been disturbed. The present-range is limited to one Texas county, much of which is no longer suitable habitat for the plant. The actual area covered by the plant is very small. The range is dissected by a four-lane divided highway (Highway 67) and two frontage roads. All of the land on which the plants now occur is in private ownership. Cultivation, establishment of rural residences, and development of roads and a railway have reduced the range and the size of the populations. An imminent threat to all existing populations is commercial sand mining within the plant's habitat (USFWS, 1981).

**Stressor:** Overutilization (USFWS, 1981)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** If exact localities were published, the plant’s conspicuous and showy blooms could cause it to be threatened by amateur gardeners wildflower enthusiasts, and commercial horticultural collecting. Since all the populations occur on privately owned land, taking of these attractive plants could not be prohibited (USFWS, 1981).

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2019a)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The ESA does provide some legal protection for federally-listed plants on land under federal jurisdiction; however, the known populations of Texas poppy-mallow occur almost entirely on privately-owned land (as well as a small amount of state highway ROW). Federally-listed plants occurring on private lands have limited protection under the ESA, unless they are protected by state laws; the State of Texas also provides very little protection to listed plant species on private lands. It is reasonable to assume that any undiscovered populations are also likely to be privately owned. Therefore, none of the species’ populations and habitats are subject to federal protection unless there is a federal nexus, such as provisions of the Clean Water Act, or a federally-funded project, for example, a new highway or water treatment plant. Chapter 88 of the Texas Parks and Wildlife Code lists plant species as state-threatened or endangered once they are federally listed with these statuses. The State of Texas listed Texas poppy-mallow as endangered on April 29, 1983. The State prohibits taking and/or possession for commercial sale of all or any part of an endangered, threatened, or protected plant from public land. Texas Parks and Wildlife Department requires permits for the commercial use of listed plants collected from private land. Scientific permits are required for collection of endangered plants or plant parts from public lands for scientific or educational purposes. In addition to state endangered species regulations, other state laws may apply. For example, state law prohibits the destruction or removal of any plant species from state lands without a Texas Parks and Wildlife Department permit. (USFWS, 2019a)

**Stressor:** Demographic and genetic consequences of small population sizes (USFWS, 2019a)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Small populations are less able to recover from losses caused by random fluctuations in recruitment (demographic stochasticity) or variations in rainfall (environmental stochasticity) (Shaffer and Stein 2000, pp. 308-310). In addition to population size, it is likely that population density also influences population viability, since successful sexual outcrossing—necessary to maintain genetic diversity in populations—requires genetically distinct individuals to be in sufficiently close proximity for cross-pollination to occur. Small, reproductively isolated populations are also susceptible to the loss of genetic diversity, to genetic drift, and to inbreeding depression. The combined demographic and genetic consequences of small population sizes may reduce population recruitment, leading to an extinction vortex of even smaller populations, greater isolation, decreasing genetic diversity, and loss of viability. These factors may already have contributed to the restriction of Texas poppy-mallow to its current state of extreme endemism in the Tivoli (Likes) and Brownfield (Heatly) sands along the Colorado River of Texas. (USFWS, 2019a)

***Recovery***

**Reclassification Criteria:**
1. Texas poppy-mallow is documented in 10 or more protected, viable populations, with at least 3 viable populations in each of 3 recovery units. Populations and metapopulations are delineated by unpopulated gaps of at least 1 km (0.6 mi). However, viable populations that expand and merge with other populations may be counted as separate populations for the specific purpose of meeting this criterion. (USFWS, 2019b)

2. Viable populations have 1,600 or more mature individuals. Mature individuals have flowered at least once or are judged capable of flowering. Population surveys should be conducted during the peak of flowering and fruiting, from April through June. (USFWS, 2019b)

3. Protected populations occur on lands that are legally protected and managed to conserve the Region's native flora and fauna, including Texas poppy-mallow, its habitats, and its pollinators. Examples include, but are not limited to, conservation easements on private lands, lands owned and managed for conservation by non-profit organizations, publicly-owned land managed for conservation purposes, and legally binding long-term management agreements with private landowners. (USFWS, 2019b)

Recovery Priority Number: 5C

**Delisting Criteria:**
1. Periodic monitoring indicates that the downlisting criteria have been met, and that demographic trends have subsequently remained stable or have increased over a period of 25 years. Ideally, monitoring (censuses) of each protected population should be conducted during years of above-average April–May rainfall; trend detection should be based on the largest populations observed during each 5-year period. (USFWS, 2019b)

**Recovery Actions:**
- Manage presently known individuals and habitat for maintenance and expansion of existing wild populations.. A crucial step in recovery is to protect existing populations and the habitat upon which they depend. All populations are threatened by expansion of commercial sand mining and development. The land presently inhabited by the Texas

poppy-mallow is under private ownership. The Endangered Species Act is most effective in protecting populations on Federal lands. Immediate protection of the habitat and cooperation with landowners is essential to recovery of the species. (USFWS, 1985)

- Sustain healthy populations in their natural habitat at existing sites. In order to develop management plans for sustaining healthy populations, it may be necessary to learn more about the Texas poppy-mallow. (USFWS, 1985)
- Search potential habitat for additional populations. Other windblown sand deposits similar to the habitat presently occupied by Texas poppy—mallow exist on the upper Colorado River between Ballinger and Colorado City (a distance of about 80 miles). These areas need to be thoroughly searched for new populations. Additionally, deep sands are extensive in Jones, Haskell, Knox, Foard, Hardeman, and adjacent counties north of the presently known populations. Suitable habitat may exist in some of these counties and they should also be searched for presence of the species structure. (USFWS, 1985)
- Establish additional populations within the historic range. If searches fail to locate enough new populations to ensure safety for the species, expanding present populations within the essential habitat and introducing the species into new areas within its historic range would diminish the risk of extinction. (USFWS, 1985)
- Develop public awareness, appreciation, and support for presentation of the Texas poppy-mallow. Education and cooperation of the public is a vital part of the recovery process. Enlist the support of public interest groups such as the Texas Organization for Endangered Species, The Nature Conservancy, and local garden clubs. The visibility of this support can be instrumental in shaping public opinion. Useful tools in this endeavor would include talks and slide presentations to local interest groups and articles on the Texas poppy-mallow in newspapers and nature magazines. (USFWS, 1985)
- Recommendation for Future Action (USFWS, 2019a): Revise the recovery plan and recovery criteria to incorporate updated guidance and specific, measurable recovery criteria (U.S. Fish and Wildlife Service 2017). Use the MVP level and population delimitation distances described in this review as components of recovery criteria that address resilience and redundancy. Adopt the provisional recovery units discussed in this review to develop recovery criteria that address the species' ecological and genetic representation.
- Recommendation for Future Action (USFWS, 2019a): Promote awareness and conservation of Texas poppy-mallow in Runnels, Coke, Mitchell, and Scurry counties.
- Recommendation for Future Action (USFWS, 2019a): Seek permission to survey and monitor populations on private land.
- Recommendation for Future Action (USFWS, 2019a): Conduct up-to-date censuses of the accessible populations and revise the TXNDD EO records.
- Recommendation for Future Action (USFWS, 2019a): Work cooperatively with private landowners who are interested in conserving and managing the species on their lands. Consider voluntary measures to confer long-term protection for populations on private lands, such as conservation agreements and conservation easements.
- Recommendation for Future Action (USFWS, 2019a): Propagate the species, using seeds in the Lady Bird Johnson Wildflower Center seed bank, to establish seed production plots, renew the seed bank, and reintroduce populations in appropriate sites that can be protected.
- Recommendation for Future Action (USFWS, 2019a): Recommendation for Future Action (USFWS, 2019a): Obtain support for conservation actions from the Cooperative Endangered Species Conservation Fund (Section 6) or other grant sources.

- Not available.

# SPECIES ACCOUNT: *Calystegia stebbinsii* (Stebbins' morning-glory)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 11/18/1996; Pacific Southwest (R8)

**Physical Description**

A leafy herbaceous perennial (persisting or living for several years with a period of growth each year) in the morning-glory family (Convolvulaceae). Its stems, which range up to 1 meter (3.3 feet) in length, generally lie flat on the ground. The leaves are palmately lobed (lobing radiating from a common point) with the two outermost lobes (major expansion or bulge) being divided again. The leaf lobes are narrow and lance-shaped. White flowers are on stalks 3 to 13 centimeters (1 to 5 inches) long and bear two leaf-like bracts. The fruit is a slender capsule. Calystegia stebbinsii flowers from May through June. Calystegia occidentalis (chaparral false bindweed) and C. purpurata ssp. saxicola (Pacific false bindweed) also occur on gabbro-derived soils in the Pine Hill area (Wilson 1986). Calystegia stebbinsii can be distinguished from other California morning-glories by its distinctively shaped leaves, each having 7 to 9 narrow lance-shaped lobes. (USFWS, 2002)

**Taxonomy**

Brummitt (1974) described Calystegia stebbinsii (Stebbins’ morning-glory) from the type collection made by G. Ledyard Stebbins in 1970, 17 kilometers (10 miles) west of Placerville in El Dorado County, California. (USFWS, 2002)

**Historical Range**

In western El Dorado County that includes the Pine Hill formation (northern and southern portions). (USFWS, 2002)

**Current Range**

The species is found in El Dorado County within the immediate vicinity of the Pine Hill Preserve (though it is not found on Pine Hill itself) and sites near Grass Valley in Nevada County. Ongoing research indicates it may also occur in Shasta County, but this is not confirmed (USFWS, 2024).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

<u>Adult:</u> Lives for several years (USFWS, 2002).

**Breeding Season**

<u>Adult:</u> May through June (USFWS, 2002)

**Key Resources Needed for Breeding**

<u>Adult:</u> Insect pollinators; disturbance (USFWS, 2002)

**Reproduction Narrative**

Adult: The fruit is a slender capsule. Calystegia stebbinsii appears to emerge from a dormant seed bank or rootstock after disturbance. The plants grow and begin to flower in the year following germination or re-emergence. While an above-ground shoot may appear in the same spot for only several years, other portions of this plant’s extensive root system might survive much longer (L. Eng in litt. 1999). Pollination studies showed that animal vectors were needed for successful seed set. Observations showed that Calystegia stebbinsii is only pollinated by insects. Eighty percent of all visits were made by Hymenoptera, the Halictidae (solitary bees) and Apidae (honey bees) being the most important families (Nosal 1997). Seedproduction ranged from an average of 20.6 seeds per square meter (1.9 seeds per square foot) at Grass Valley to 380 seeds per square meter (35.3 seeds per square foot) at Salmon Falls. (USFWS, 2002)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Barrens, Shrubland/ chaparral (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Seeds require heat or scarification for germination. (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Well-burned areas; shade intolerant (USFWS, 2002)

**Spatial Arrangements of the Population**

Adult: Discontinuously scattered (USFWS, 2002)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from USFWS, 2002)

**Habitat Narrative**

Adult: Calystegia stebbinsii prefers mixed chaparral communities on gabbro-derived and serpentine-derived soils (NatureServe, 2015). Most occurrences of C. stebbinsii are discontinuously scattered within two population centers in the northern and southern portions of the Pine Hill formation. Calystegia stebbinsii produce fire adapted: seeds need heat or scarification for germination; plants grow well in burned-over areas, but are eliminated when surrounding chaparral grows tall enough to shade them. (NatureServe, 2015). Calystegia stebbinsii seems to be shade intolerant and does not occur beneath a closed canopy of vegetation (Baad and Hanna 1987). (USFWS, 2002)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2019)

**Number of Populations:**

3 known extant; 8 presumed extant; 3 possibly extirpated; 1 extirpated. (USFWS, 2019)

**Population Size:**

Greater than 9800 individuals (USFWS, 2019)

**Additional Population-level Information:**

At the time of listing Stebbins' morning-glory, Pine Hill ceanothus, Pine Hill flannelbush, El Dorado bedstraw, and Layne's butterweed occurred primarily on the Pine Hill formation, an area of approximately 10,400 hectares (25,700 acres) in western El Dorado County, California, ranging in elevation from 138 to 628 meters (453 to 2,060 feet) (Service 1996, p. 54346). In addition, Stebbins' morning-glory and Layne's butterweed had "a few known isolated occurrences in El Dorado, Nevada and/or Tuolumne counties" (Service 1996, p. 54346). Between the listing of the species and the 2019 review, additional occurrences were discovered or introduced outside of Pine Hill Preserve (Service 2019, p. 6). Most notably, a few occurrences of Stebbins' morning glory were identified in Nevada County near Grass Valley, two occurrences of Layne's butterweed were found in Yuba and Placer counties, and two additional occurrences of Layne's butterweed were identified in Tuolumne County (Service 2019, p. 6). The 2019 review also noted that occurrences of Pine Hill flannelbush (Diversity Database occurrences 8, 9, 13, 14, 15) had been recorded in Nevada and Yuba counties but that the species identification had not yet been verified (Service 2019, p. 6). Recent morphological studies suggest that the flannelbush plants in Nevada and Yuba counties are unique from Pine Hill flannelbush (USFWS, 2024)

**Population Narrative:**

At the time of listing Stebbins' morning-glory occurred primarily on the Pine Hill formation an area of approximately 10,400 hectares (ha) (25,700 acres (ac)), in western El Dorado County, California, ranging in elevation from 138 to 628 m (453 to 2,060 ft). In addition, Stebbins' morning-glory had "a few known isolated occurrences in El Dorado, Nevada and/or Tuolumne Counties" (Service 1996). Today, the species continue to occur primarily at the Pine Hill Preserve, but Stebbins' morning-glory has a few known occurrences in Nevada County near Grass Valley. (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Historically, gold rush activities and clearing for agriculture reduced and fragmented habitat in western El Dorado County. More recently, vegetation on the Pine Hill formation has changed significantly due to commercial and residential development, road construction, and fragmentation. Commercial or residential developments have partially or completely destroyed occurrences of the species (California Natural Diversity Data Base 1998; California Department of Fish and Game 1990a, 1990b; G. Clark in litt. 1993). Proposed residential or commercial

development within the Pine Hill formation threatens most of the remaining sites within the Pine Hill formation and adjacent serpentine in western El Dorado County, and either directly or indirectly will adversely affect most of the range of this species. Additionally, habitat fragments may be too small to support viable populations of animals serving as pollinators or seed dispersal agents for the species. Edge effects, which occur at the interfaces of any two or more habitat types, typically increase with habitat fragmentation and are more pronounced for natural communities bordered by human disturbances. (USFWS, 2002)

**Stressor:** Other species-specific threats (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Calystegia stebbinsii is threatened by altered periodicity of fire (either too frequent or fire suppression), competition with invasive alien vegetation, herbicide spraying, and unauthorized dumping. There is an increased risk of extinction due to environmental, demographic, or genetic random events due to habitat fragmentation (USFWS, 2002).

**Stressor:** Alteration of the natural fire regime (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary overall threat is encroachment of native vegetation due to succession, even on lands in conservation ownership, in the absence of the natural fire regime. The long fire return interval due to fire suppression is preventing the formation of necessary clearings for Stebbins’ morning-glory  establishment and possibly the scarification of seeds needed for germination. (USFWS, 2019)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The State’s authority to conserve rare wildlife and plants is comprised of four major pieces of legislation: the California Endangered Species Act, the Native Plant Protection Act, the California Environmental Quality Act, and the Natural Community Conservation Planning Act. The State may authorize permits for scientific, educational, or management purposes, and to allow take that is incidental to otherwise lawful activities. Landowners are exempt from the prohibition for plants to be taken in the process of habitat modification. Protection of listed species through California Environmental Quality Act isdependent upon the discretion of the lead agency involved. The National Environmental Policy Act (NEPA) does not require that adverse impacts be fully mitigated, only that impacts be assessed and the analysis disclosed to the public. More details about existing protections are provided in the 2019 5-Year Review. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
1. Secure and protect specified recovery areas from incompatible uses: (a) Cameron Park preserve north of Highway 50; (b) Cameron Park preserve south of Highway 50; (c) Salmon Falls/Martel Creek preserve; (d) occurrences in Nevada County; along with sufficient adjacent

unoccupied habitat for fire management and a 150-meter (500-foot) buffer. (USFWS, 2002)

2.Management plan approved and implemented for recovery areas, including survival and recovery of the species as the objective for all populations recommended for protection and any adjacent areas identified as necessary for continued survival and recovery. (USFWS, 2002)

3. Monitoring in all recommended preserves shows: (a) Populations stable or increasing over one fire cycle (about 30 years) (subject to modification depending on results of fire management studies). (b) Habitat monitoring shows a mosaic of multiage -class stands and habitat fragmentation has not appreciably increased (less than 5 percent) within any preserve over current (2000) conditions. (c) Spatially and temporally, the establishment of occurrences must be greater than the extirpation of occurrences. (USFWS, 2002)

4. Other actions: (a) Ameliorate or eliminate threats; (b) Fire management studies; (c) Research on genetics of Nevada County population; (d) Seeds of disjunct populations stored in at least two Center for Plant Conservation certified facilities; (e) Research on propagation techniques if repatriation, enhancement, or restoration are determined to be necessary (f) Maintain metapopulation dynamics of at least 2 very large, 7 medium, and 4 small occurrences throughout the northern and southern portions of the Pine Hill formation; and of at least 1 medium and 5 small occurrences near Grass Valley in Nevada County. (USFWS, 2002)

Recovery Priority Number: 5C

**Delisting Criteria:**
1. Management plan approved and implemented for recovery areas, including survival and recovery of the species as the objective: For all occurrences and any adjacent areas identified as necessary for continued survival and recovery. (USFWS, 2002)

2. Monitoring in all recommended preserves shows: (d) No population decline after downlisting during two additional fire cycles (about 60 years); if declining, determine cause and reverse trend. (e) Habitat monitoring continues to show a mosaic of multi-age class stands and habitat fragmentation has not appreciably increased (less than 5 percent) within any preserves over current (2000) conditions. (f) Spatially and temporally, the establishment of occurrences must continue to be greater than the extirpation of occurrences. (USFWS, 2002)

3. Other actions: (g) Ameliorate or eliminate threats. (USFWS, 2002)

**Recovery Actions:**
- 1. Develop and implement a cooperative program and participation plan. A cooperative program is needed to coordinate local public and private land use planning with State and Federal land use and recovery planning for gabbro species. A cooperative program needs to be developed focusing on western El Dorado County. A participation plan produced from this program will increase the chances of recovery for listed species. (USFWS, 2002)
- 2. Protect and secure existing populations. Natural lands that contain this species need to be protected in perpetuity. Protection of these lands includes identification and minimization of threats in perpetuity and application of appropriate and adaptive management (see Task 3) to ensure species survival and recovery. Natural lands that need protection can be categorized into two types: (1) blocks of land that contain occupied or potential habitat for

two or more this species and (2) blocks of land that contain occupied or potential habitat for one this species. All potential preserve areas should be evaluated based on current mapping information and ground-truthed prior to purchase to confirm their value for recovery. (USFWS, 2002)

- 3. Manage Habitat Managing habitat is essential to the recovery of the listed species. Habitat management includes preparation and implementation of management plans for all areas inhabited by special status species being proposed for preservation, and periodic monitoring of populations in each of these areas. Within western El Dorado County, a multi-constituent committee should be formed to oversee the management of preserves located on the Pine Hill formation. The preserve management committee should include, at a minimum, representatives from the California Department of Fish and Game, U.S. Fish and Wildlife Service, Bureau of Land Management, El Dorado County, California Department of Forestry and Fire Protection, California Native Plant Society, American River Conservancy, and a private landowner representative. (USFWS, 2002)
- 4. Survey historical locations and other potential habitat where this species may occur. Recovery of listed species may often require relocating historic populations or locating new populations of these species. Historical locations should be surveyed to determine whether suitable habitat remains, the species persists at the sites, and/or the sites may be suitable for repatriation. Suitability of historical locations for repatriation would depend upon: (1) whether potential habitat exists, (2) the presence and magnitude of threats, and (3) whether the sites can be secured and managed for the long-term protection of the species. Surveys should also include other potential gabbro or serpentine habitat to determine whether undiscovered populations may exist. If new populations are discovered, they need to be protected and managed as discussed above. During the surveys, potential introduction sites should also be identified. (USFWS, 2002)
- 5. Conduct necessary biological research and use results to guide recovery/conservation efforts. - Develop propagation techniques for listed plant species for which enhancement, repatriation, or introductions would be appropriate. Geographic area research is outlined in the Recovery Plan. Species-specific research is described as follows: Habitat Survey Research: Nevada County on gabbro and serpentine soils. Reproduction and Demography Research: Including determining limiting life stages, seed production, and survival in soil to determine appropriate fire return period. Genetics research. Other Research Needs: Propagation techniques; fire management techniques; metapopulation analysis; determine efficacy of other types of disturbance regimes for species and habitat management; feasibility of habitat restoration/ enhancement. Management Actions Needed: Burning; general surveys; baseline monitoring; monitoring for trends of populations, success of management actions, and threats at all populations identified for protection; monitoring for habitat fragmentation, major shifts in vegetation type, and tracking of occurrence establishment, and extirpation; seed banking for disjunct populations. (USFWS, 2002)
- 6. Undertake artificial enhancement, repatriation, or introduction efforts where necessary. Where it is deemed necessary, artificial enhancement, repatriation, or introduction efforts for sensitive plants should be undertaken. Prior to repatriation or introduction of sensitive plants, genetics studies are needed (see Task 5) to ensure that new populations will not disrupt unique local gene complexes. Plant repatriation or introduction efforts should be undertaken using collected seeds or plant propagules. (USFWS, 2002)
- 7. Determine possible prescribed burning management strategies and incorporate the strategies into the management plans (Priority 1). Possible prescribed burning management strategies need to be evaluated, peer reviewed, and incorporated into management plans.

(USFWS, 2002)

- 8. Perform metapopulation-type analyses for this species (Priority 2). The results of a metapopulation-type analysis may be useful in clarifying uncertainties, data needs, and research, management priorities, and delisting criteria. Metapopulation-type analyses should be based on the results of monitoring and research. (USFWS, 2002)
- Preserves must include sufficient habitat to allow for expansion or shifts in occupied habitat.
- In addition to securing and protecting habitat, maintenance of the metapopulation dynamics will be important for survival and recovery.
- Unless the metapopulation analysis shows otherwise, at least two very large occurrences each greater than 128 hectares (315 acres); seven medium occurrences each between 4 and 40 hectares (10 and 100 acres); and four small occurrences each smaller than 4 hectares (10 acres), are to be maintained at any given time throughout the northern and southern portions of the Pine Hill formation. In addition at least one medium and five small occurrences are to be maintained at any given time at the metapopulation near Grass Valley in Nevada County.
- In addition to securing and protecting habitat, directed surveys for Calystegia stebbinsii should be conducted on gabbro and serpentine soils in Nevada County. If plants (or additional populations) are discovered in Nevada County, they should be secured through land acquisition, conservation easements, or other means. (USFWS, 2002)
- In addition, unoccupied habitat that might provide space for expansion of the populations and habitat for pollinators and seed dispersers must be protected along with sufficient adjacent unoccupied habitat for fire management, and a 150-meter (500-foot) buffer for fire safety. (USFWS, 2002)
- Dedicate more resources toward the investigation of best management approaches for the Pine Hill listed plant species, even at the cost of a temporary hiatus in land acquisition efforts. Investigation should be made into fire-related and non-fire related methods of disturbance to maintain listed plant species habitat. (USFWS, 2019)
- Once the best management strategy (in terms of technique, frequency, timing, and intensity) is determined at each site, implement these management practices to achieve and maintain a habitat mosaic that enables the attainment of recovery criteria for the species. (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- Stebbins' morning-glory 1. Verify the identity of the possible occurrence at Whiskeytown National Recreation Area. (USFWS, 2024)

# SPECIES ACCOUNT: *Campanula robinsiae* (Brooksville bellflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/28/1989; Southeast Region (R4)

**Physical Description**

Campanula robinsiae is an annual herb, with stems 1-15 cm2 (0.5-6 in.) tall, very slender, simple or branched, faintly winged or 4-angled. The stems are glabrous except for a few trichomes in the angles (Morn 1987). The plant may be submerged for part of its life, which may affect its growth. Some stems root at the nodes (Morn 1987). The leaves are alternate, the blades varying in size and shape on different parts of the plant and from plant to plant (Morn 1987). Open flowers are solitary, 3-10 mm long, bell-shaped, “deep purple” (Morn 1987). Steven Leonard (under contract to The Nature Conservancy; report at Florida Natural Areas Inventory) discovered in 1983 that the plant has cleistogamous (closed, self-pollinating) flowers, which are quite small. This is the only North American Campanula with cleistogamous flowers (Morn 1987). The fruit is a subglobose capsule about 2 mm in diameter (Wunderlin et al. 1 980a). The seeds are about 1 mm long, the smallest of any North American member of the genus (Shetler and Morn 1986; description adapted from Wunderlin et al. [1980a] and other sources as noted). Leonard observed only cleistogamous flowers on February 8 and 11, 1983, and did not see a chasmogamous flower until February 23 (letters from Leonard to Morn in Morn 1987). Flowering specimens have also been collected March 11, 1983; April 13, 1983; and April 26, 1958. Seed production proceeds while flowering continues. Campanula robinsiae may be confused with Campanula floridana, but the latter species has very different seeds and leaves that are “much firmer than those of C. robinsiae” (Morn 1987). (USFWS, 1993)

**Taxonomy**

Small (1926) formally published the species, but later (Small 1933) transferred the species to his new genus Rotantha, along with Campanula floridana, based on the shared character of their rotate corollas’ (Small 1933). Later workers (Shetler 1963, Wunderlin et al. 1 980a) determined that these two species are not closely related, so Rotantha is an artificial genus; the two species are retained in Campanula (USFWS, 1993).

**Historical Range**

All historically known sites of C. robinsiae occurred within approximately 2-3 square miles centered on Chinsegut Hill, which is located 5 miles north of Brooksville, in Hernando County, Florida. (USFWS, 2019)

**Current Range**

Hernando and Hillsborough Counties, Florida. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from EPA, 2016); asexual (EPA, 2019)

**Breeding Season**

Adult: March - April (EPA, 2016)

**Key Resources Needed for Breeding**

Adult: rainfall (USFWS, 2010)

**Reproduction Narrative**

Adult: Flowering specimens have been collected March-April. Capable of self-pollination.Seeds germinate in winter or spring. Seed production occurs while flowering continues (USFWS, 2019). It was determined that water levels from rainfall rather than time of year may be a critical factor controlling germination (Williams 1998) (USFWS, 2010).

**Habitat Type**

Adult: Palustrine, terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Herbaceous wetland, forest (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Campanula robinsiae was originally found in a seepage area on the north facing slope of Chinsegut Hill surrounded by pasture used for animal husbandry. It has since been found within an oak/palm hydric hammock along the edge of an elongated maidencane (Panicum hemitomom) marsh at Burns Prairie (Laundry 1996). Typically this species is found along the margins of ponds and marshes with fluctuating water levels and moist seepage areas, both surrounded by pastures. C. robinsiae is associated with other wetland plants, such as mosquito fern (Azolla carolinaiana), hair sedge (Bulbostylis spp.), coinwort (Centella asiatica), button snakeroot (Eryngium spp.), pennywort (Hydrocotyle spp.), rush (Juncus spp.), pimpernel (Anagallis minima), pearlwort (Sagina decumbens), and maidencane (Panicum hemitomom). (USFWS, 2019)

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Not available

**Species Trends:**

Stable (USFWS, 2019)

**Number of Populations:**

7 (USFWS, 2024)

**Population Size:**

~5,000 individuals (USFWS, 2024)

**Population Narrative:**

Seven populations. All extant populations occur on publicly-owned lands, not necessarily conservation lands. The Brooksville Sec 24 (EO 1) and Chinsegut Hill (EO 3) populations occurred on private lands. The former population no longer has suitable habitat present and the latter population’s marginal habitat has degraded to what appears unsuitable. Surveys performed at this location have not detected species presence for many decades (USFWS, 2024).

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is threatened by habitat destruction and degradation on its six extant sites due to the lack of habitat management and development of the land surrounding protected sites. Previously, conversion of existing sites to residential and agriculture was determined to be the primary threat and resulted in the need to list the species (USFWS 1994). Since all six known extant populations now occur on public land, the threat of conversion of known sites to residential land use has been significantly reduced. The lack of habitat management has resulted in the disappearance of the Chinsegut Hill and Young populations and may be affecting other populations, such as the introduction and Burns Prairie. At Chinsegut Hill and the Young site, C. robinsiae was likely outcompeted by dense vegetation due to lack of disturbance, which was previously created by mowing or trampling by cattle. In addition, at Chinsegut Hill, the death of an oak tree that provided shade to C. robinsiae likely affected moisture levels (Service 2010). It is important to consider overstory composition when managing habitat. The introduction at the Blackwater Creek Preserve failed due to lack of habitat management that would have allowed cattle to graze the site. In 2012, Burns Prairie lost its grazing cattle and the only management that has taken place is that overgrown competing vegetation was removed in 2015 (Peterson, BTG pers. comm. 2019a). It is possible that this population will disappear if grazing or other habitat management is not continued. More research is needed to determine which methods are effective at managing habitat. Development of the land surrounding protected lands may alter hydrology by increasing runoff to C. robinsiae sites. This runoff may also contain fertilizers and herbicides that may affect growth and germination of the plants. C. robinsiae occurs in the Central Region of Florida, which is projected to experience the greatest population growth in the state in the near future. By 2070, the percentage of developed land is expected to double from 25% in 2010 to almost 50% (Carr and Zwick 2016). Due to modeling efforts (Lewis 2010, 2011), unknown populations and suitable habitat for introductions likely exist on private land and may be at risk to development. It is likely that agricultural lands will be converted to residential land uses in the near future (Carr and Zwick 2016). This conversion may negatively affect C. robinsiae habitat because cattle may benefit the species by providing the disturbance necessary to reduce competition from other plants. (USFWS, 2019)

***Recovery***

**Reclassification Criteria:**
Not developed

Recovery Priority Number: 8

**Delisting Criteria:**
Not developed - Plausible criteria for recovery might include securing at least 10 viable and self-sustaining populations of Brooksville bellflower in pond margin habitats, consisting of approximately 10,000 individuals during prolific years (USFWS, 1993).

**Recovery Actions:**

- Develop management and protection criteria for populations on current managed areas (includes collection of biological/systematic data and control of exotic plants) (USFWS, 1993).
- Acquire additional habitat, or protect habitat through conservation easements and/or regulation. Sufficient information is available to proceed immediately (USFWS, 1993).
- Conduct additional surveys for new populations of the species (USFWS, 1993).
- Augment existing cultivated populations, including establishment of a germ plasm bank (USFWS, 1993).
- Develop plans for possible (re)introduction of plants into suitable habitats (includes 10-year monitoring of existing and/or reintroduced populations) (USFWS, 1993).
- Enforce protective legislation (USFWS, 1993).
- Revise the current recovery plan to include updated objective and measurable recovery criteria for reclassifying this species to threatened status and delisting that are related to reducing the threats identified in the recovery plan, as well as updated information on the species distribution and biology (USFWS, 2010).
- Support further research on: a. Effects of cattle grazing on this species. b. Life history needs. c. Microhabitat requirements of this species. d. Effect of severe changes in temperatures (freezing) on germination. e. Drought and fluctuating water levels and their effect on germination. f. Transplant experiments, long-term seed viability trials, and optimizing germination protocols (USFWS, 2010).
- Continue working with public land managers to increase management efforts to benefit C. robinsiae. No management plans have been developed for this species but are necessary. Minimal management has been taking place at some sites. Once disturbance has been removed from some sites, populations have disappeared. Burns Prairie especially needs additional management because competing vegetation has taken over since grazing cattle were removed from the site. (USFWS, 2019)
- Continue conducting surveys at known sites of occurrence and expand surveys to other suitable areas in Hillsborough and Hernando Counties. This information is necessary to determine where plants currently exist and to prioritize recovery actions such as reintroductions at suitable sites. BTG has continued conducting surveys at known sites of occurrence. This work has been made possible through annual grants from the State of Florida, Department of Agriculture and Consumer Services, Division of Plant Industry, which funds the basic operations of BTG’s Rare Plant Conservation Program. Surveys have been expanded to other sites determined by a GIS model to have suitable habitat. However, due to either flood or drought conditions during the survey periods, no plants were found. One introduction took place in 2013, but no plants were found the following year due to

overgrowth of competing vegetation. No plants have been found at the introduction site since. Habitat management is necessary to control competing vegetation. (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES The same future recommendation from previous 5-year reviews remain valid. The following recommendations are a brief summary from those prior reports. A. Support research on: • Effects of cattle grazing, • Life history needs, • Microhabitat requirements, • Temperature effects on germination, • Drought and fluctuating water levels on germination. B. Transplant experiments, long-term seed viability trails, and optimizing germination protocols. C. Collaborating with land managers to increase beneficial habitat management. D. Continue conducting surveys at known locations and expand surveys to included potential suitable areas (USFWS, 2024).

# SPECIES ACCOUNT: *Cardamine micranthera* (Small-anthered bittercress)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/23/1989; Southeast Region (R4)

**Physical Description**

It is an erect slender perennial herb with fibrous roots and one (or rarely more) simple or branched stem(s) growing 2 to 4 decimeters tall. Basal leaves are 1 to 5 centimeters long (occasionally longer), 0.5 to 2.0 centimeters wide, crenate, with one (or rarely two) pairs of small lateral lobes or leaflets. The stem leaves are alternate and mostly unlobed, 1 to 1.5 centimeters long, crenate and cuneate. Flowering and fruiting occur in April and May. The flowers, subtended by leafy bracts, have four white petals, six stamens, and small, round anthers. The fruit is a silique, 0.8 to 1.2 centimeters long and approximately 1 millimeter in diameter, with a beak 1 to 1.2 millimeters long. The brown seeds are approximately I millimeter long. Cardamine micranthera can be distinguished from its most similar relative, Cardamine rotundifolia, by its much smaller, nearly orbicular (instead of oblong) anthers, smaller flowers, and more angulate and nonclasping leaves. In Cardamine micranthera, the anthers are about 0.5 millimeter long, and the petals are 1.2 to 2 millimeters wide. Stem leaves of Cardamine micranthera are typically broadly cuneate (rarely narrowly cuneate, oblique, or cordate) and never cordate-clasping. Cardamine micranthera is typically erect, or occasionally has decumbent stems, but these do not develop proliferating branches. C. micranthera has only one to two pairs of lateral leaflets (or none), with the terminal leaflet being nearly one-half the total length. Cardamine micranthera has pedicels 9 to 15 mm long and siliques 14 to 22 mm (pods only one and one-fourth to one and one-half times the length of the stalks). The beak of the fruit corresponds to the style in the flower and is that portion of the pod extending beyond the seed-bearing part. Cardamine micranthera's beak is about 2 mm long and can be readily seen as a sharp, spindle-like tip on the pod (T. Wieboldt, personal communication, 1991). (USFWS, 1991)

**Taxonomy**

Cardamine micranthera was first described by R. C. Rollins (1940) from material collected in North Carolina in 1939. (USFWS, 1991)

**Historical Range**

Native to the Dan River drainage of the North Carolina and Virginia piedmont. Historically found in Stokes and Forsyth Counties (USFWS, 1991).

**Current Range**

Stokes County, North Carolina and Patrick County, Virginia. (USFWS, 2016)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Ants have been observed visiting the flowers (USFWS, 1991).

**Habitat Type**

Adult: Palustrine, terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Riparian, forest (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Full to partial shade (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Seepages, wet rock crevices, streambanks, sandbars, and wet woods along small streams (Murdock and Weakley 1991). The environmental specificity of this specie is narrow; C. micranthera occupies moist soils of the upper Piedmont that are fully to partially shaded (Murdock and Weakley 1991). More specifically, it is typically found in wet, boggy soils of deciduous woodlands and moist to wet soils along the edge of small to intermediate sized streams (NCA 1996). Within the stream bed plants also inhabit sand and gravel bars and wet rock crevices (Murdock and Weakley 1991) (NatureServe, 2015).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Unknown (NatureServe, 2015)

**Species Trends:**

Declining (NatureServe, 2015)

**Number of Populations:**

29 (13 North Carolina. 16 Virginia) (USFWS, 2023).

**Population Size:**

Annual fluctuation; < 23,000 (USFWS, 2016)

**Population Narrative:**

Cardamine micranthera was federally listed in 1989, the listing rule described four populations all confined to the Dan River basin in North Carolina. In 1991 a recovery plan was developed for the species and by then five additional populations had been discovered in Patrick County, Virginia totaling nine extant populations (four in North Carolina and five in Virginia) (Service 1991). At the time of the 2016 5-year review, the number of known extant populations had increased from 9 to 32 (Service, 2016). New populations remained in the narrow range of the

Dan River system of Stokes County, North Carolina and Patrick County, Virginia. Estimates of abundance for the 32 extant populations of the species ranged from one plant (North Fork of South Mayo River, VA) to 8,000 – 10,000 plants (Peters Creek, VA) (Appendix A). Since the 2016 5-year review, three populations (Service populations 1, 25, and 32, Appendix A have been moved from a D-ranking (poor viability) to F (failed to find). Therefore, the current species range remains confined to 29 populations in the Dan River system in Stokes County, NC and Patrick County, VA. The 29 extant populations (13 in NC and 16 in VA) represented by current (within the last 5 years) population surveys ranged from 10 to 3,000 plants. New occurrences were identified in Patrick County, VA (Van Alstine 2018). One hundred and fifty-two new plants were found within Peters Creek and Little Peters Creek and one new plant in Russell Creek (Van Alstine, N.E. 2018). One new discrete site has been added to the Dan River, NC (NCNHP 2021). The EOs have been expanded to represent these increases. These 29 populations represent some 124 sites (28 in NC and 96 in VA). A historical review of extant populations and more current information is provided below (Tables 1 and 2). The number of populations in North Carolina has remained stable at 13 since 2016. Of these 13 populations, five were surveyed in 2013 and eight were surveyed in 2018 (NCNHP 2021). The number of extant populations in Virginia has declined from 20 to 16 (Van Alstine 2016, 2018). Of these 16 populations, 2 were surveyed in 2004, 6 in 2014, 4 in 2015, 2 in 2017 and 2 in 2020. Current estimates of abundance for the 29 populations range from ten plants (Dan River, NC) to 3,000 – 5,000 plants (Peters Creek, VA) (Appendix A). Nine of the 29 populations are in a decline, 4 are stable, 8 are increasing, and 8 are unknown. Survey data which post-dates the 2016 5-year review has been provided by the VADCR which completed population counts of C. micranthera in the area surrounding Patrick County, VA. This effort was accomplished with funds provided under Section 6 of the Act, and data includes both extant and extirpated populations. This monitoring revealed population sizes from 11 known sites. Six of the 11 populations declined, ranging from 19.29% to 100% population loss, two sites had a population increase of 68% and 90%, and three populations are extirpated. In North Carolina, nine surveys post-date the previous 2016 5-year review and include both extant and failed to find populations. Four populations declined, ranging from 28.26% to 90.38% population loss; one remains stable; and three have increased by an average of 217 plants and one population is considered a 'failed to find.' A summary of the current survey data is provided in Appendix A. Recent survey efforts find that the number of documented C. micranthera populations has decreased since the last 5-year review in 2016. Inconsistent and infrequent monitoring increases uncertainties associated with the species' status and trends and the status of individual populations cannot be adequately assessed at this time (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Beaver dams (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Beaver dams have been observed to constitute a significant threat to Cardamine micranthera at some locations, with one knowledgeable observer regarding this as perhaps the most immediate threat to the species (Bridle 2009, pers. comm.). Bridle notes that beaver activity (especially in drought years) within main stream channels has flooded entire colonies of the species (USFWS, 2016).

**Stressor:** Habitat destruction and modification (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat alteration remains the primary threat to Cardamine micrantera, with impoundment, channelization, conversion associated with agriculture or silviculture, flooding, and encroachment of exotic species as threats affecting the species. Cattle trampling and downstream beaver impoundments have also been noted as threatening C. micranthera habitat (USFWS, 2016).

**Stressor:** Inadequacy of regulatory mechanisms (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** State statutes primarily regulate collection and trade in listed species, and do not prohibit land owners from neglecting or otherwise impacting such species on their own properties or in conjunction with otherwise legal activities (USFWS, 2016).

**Stressor:** Timber Harvest/Invasive species (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Disturbances to the floodplain, tributaries, and river basins due to timber harvesting further support erosion and sedimentation loss while also removing the canopy over stream banks where C. micranthera is often located. Additionally, these disturbances present a risk of common invasive species which were found in the Gilbert Mills, Peters Creek North, and Peters Creek Central Sites of Virginia. Microstegium vimineum (Japanese stiltgrass) was commonly found on the silt/sand bars, Lonicera japonica (Japanese honeysuckle) and Rosa multiflora (multiflora rose) were occasionally present on streambanks and Murdannia keisak (marsh dewflower) was also noted (VanAlstine, 2018). Three site records, Gilbert Mills, Peters Creek North, and Peters Creek Central Sites of Virginia, specifically note that one or more of these threats are either ongoing or imminent, further noting the need for active intervention to address them (USFWS, 2023)

***Recovery***

**Reclassification Criteria:**
Not defined (USFWS, 1991)

Recovery Priority Number: 5

**Delisting Criteria:**
1. It has been documented that at least six populations are self-sustaining and that necessary mangement actions have been undertaken by the landowners or cooperating agencies to ensure their continued survival (USFWS, 1991).

2. All of the above populations and their habitat are protected from present and foreseeable human-related and natural threats that may interfere with the survival of any of the populations

(USFWS, 1991).

**Recovery Actions:**

- Protect existing populations and essential habitat. Only nine populations of small-anthered bittercress are currently known to exist, all in the piedmont of North Carolina and Virginia. Until more is known about the species' biology and specific habitat requirements, and about the measures necessary to protect occupied sites, all existing populations should be protected. The long-term survival of six populations is believed to be essential to the recovery of the species as a whole. (USFWS, 1991)
- Determine and implement management necessary for long-term reproduction, establishment, maintenance, and vigor. Protection of the species' habitat is the obvious first step in ensuring its long-term survival, but this alone may not be sufficient. Since very little is known about this species, information on its population biology and ecology is necessary before effective management guidelines can be formulated and implemented.
- Develop a cultivated source of plants and provide for long-term seed storage. There are presently no cultivated sources of this species. Techniques for seed storage, germination, and maintenance of cultivated specimens must be developed. (USFWS, 1991)
- Enforce laws protecting the species and/or its habitat. The Endangered Species Act prohibits taking of Cardamine micranthera from Federal lands without a permit and regulates trade. Section 7 of the Act provides additional protection of the habitat from impacts related to federally funded or authorized projects. In addition, the 1988 amendments to the Act prohibit (1) the malicious damage or destruction of listed plants on Federal lands and (2) the removal, cutting, digging, damaging or destroying of such plants in knowing violation of any State law or regulation, including State criminal trespass law. The State of North Carolina prohibits taking of the species without a permit and the landowner's written permission and regulates trade in the species (North Carolina General Statute 19-B, 202.12-202.19). The State of Virginia prohibits taking and trade of listed species without a permit (Code of Virginia 39:3.1-1020 to 31-030). Federal and State enforcement agents whose jurisdiction includes the known range of small-anthered bittercress should be made aware of the threats to the species and be able to identify specimens. (USFWS, 1991)
- Develop materials to inform the public about the statu of the species and the recovery plan objectives. Public support for the conservation of small-anthered bittercress could play an important part in encouraging landowner assistance and conservation efforts. Information materials should not identify the plant's locations so as not to increase the threat of taking or vandalism. Annually assess success of recovery efforts for the species. Review of new information, evaluation of ongoing actions, and redirection, if necessary, is essential for assuring that full recovery is achieved as quickly and efficiently as possible. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: Continue to pursue follow-up information from stream restoration project on Snow Creek (involving a portion of one population of this species) from appropriate state, federal and private parties. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: Communicate existing habitat protection priorities (VDCR 2007, Boyer 1996) to state agencies, local land trusts, and other conservation partners, to assess current and future options for protection. Encourage land protection strategies focused on headwater occurrences likely to serve as a seed source for recolonization of sites further downstream (Bridle 2009, pers. comm.). (USFWS, 1991)

- Recommendation for Future Action from 2016 5-Year Review: Identify sites which have experienced recent disturbance, and evaluate the effects of ongoing and prior habitat disturbance upon the species. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: Utilize information obtained from assessments of prior or ongoing habitat disturbance to devise and implement appropriate habitat management guidelines. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: 5. Conduct site visits to determine if Boyer's (1996) long-term monitoring transects can be relocated and resurrected. If so, reinitiate monitoring efforts to learn more about the longevity and relative stability of populations of this short-lived species. If Boyer's (1996) monitoring transects cannot be resurrected, work to establish comparable monitoring (using Boyer's protocol or modifications thereof) at priority sites using standardized monitoring methods. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: 6. Use monitoring data and other information to draft objective, measurable criteria for "selfsustaining" populations . (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: 7. Determine the status of genetic material held in botanical gardens and other institutions, and work to ensure that the species is adequately represented in long-term storage. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: 8. Pursue development of habitat predictability models for this species, and iteratively refine and use these to search for new populations and guide land protection efforts. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: 9. Identify landowners, obtain permission to visit populations, and provide information to landowners about voluntary protection measures that may be implemented to protect the species (including best management practices, NHP Registry programs, conservation easements, and fee simple purchase by cooperating land protection agencies). (USFWS, 1991)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES The following activities are recommendations to improve recovery of the species. 1. Continue to pursue follow-up information from stream restoration projects on Snow Creek (involving a portion of one population of this species) from appropriate state, federal and private parties. (Recovery Task 4). 2. Communicate existing habitat protection priorities (VDCR 2007, Boyer 1996) to state agencies, local land trusts, and other conservation partners, to assess current and future options for protection. Encourage land protection strategies focused on headwater occurrences likely to serve as a seed source for recolonization of sites further downstream (Bridle 2009, pers. comm.) (Recovery Task 1.4). 3. Identify sites which have experienced recent disturbance and evaluate the effects of ongoing and prior habitat disturbance upon the species (Recovery Task 2.4). 4. Utilize information obtained from assessments of prior or ongoing habitat disturbance to devise and implement appropriate habitat management guidelines (Recovery Tasks 2.5 and 2.6). 5. Conduct site visits to determine if Boyer’s (1996) long-term monitoring transects can be relocated and resurrected. If so, reinitiate monitoring efforts to learn more about the longevity and relative stability of populations of this short-lived species. If Boyer’s (1996) monitoring transects cannot be resurrected, work to establish comparable monitoring (using Boyer’s protocol or modifications thereof) at priority sites using standardized monitoring methods (Recovery Tasks 2.1, 2.2, and 2.3). 6. Use monitoring data and other information to draft objective, measurable criteria for “self-sustaining” populations (Recovery Tasks

2.3, 2.4, and 2.5). 7. Determine the status of genetic material held in botanical gardens and other institutions, and work to ensure that the species is adequately represented in longterm storage (Recovery Task 3). 8. Pursue development of habitat predictability models for this species, and iteratively refine and use these to search for new populations and guide land protection efforts (Recovery Tasks 1.2 and 1.3). 9. Identify landowners, obtain permission to visit populations, and provide information to landowners about voluntary protection measures that may be implemented to protect the species (including best management practices, NHP Registry programs, conservation easements, and fee simple purchase by cooperating land protection agencies) (Recovery Tasks 1.1, 1,2, 1.3, and 1.4) (USFWS< 2023)

# SPECIES ACCOUNT: *Castilleja affinis ssp. neglecta* (Tiburon paintbrush)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 3/6/1995; Pacific Southwest (R8)

**Physical Description**

Castilleja affinis ssp. neglecta (Figure II- 5) is a semi-woody perennial of the snapdragon family (Scrophulariaceae), with erect, branched stems 30 to 60 centimeters (1 to 2 feet) tall and a sparse covering of soft, spreading hairs (Munz and Keck 1959). The lance-shaped leaves are 20 to 40 millimeters (0.8 to 1.6 inches) long and have 0 to 5 lobes (Hickman 1993). The conspicuous floral bracts are yellowish and sometimes red-tipped; the flowers are yellow to red and 18 to 20 millimeters (0.7 to 0.8 inch) long. (USFWS, 1998)

**Taxonomy**

Transferred to varietal rank by Egger (2008). Treated as Castilleja affinis ssp. neglecta by Kartesz (1999 Synthesis), by The Jepson Manual (Hickman, 1993) and by the U.S. Fish and Wildlife Service. Originally named as a species (Castilleja neglecta), and treated at that level by Kartesz (1994). Kartesz notes (pers. comm. to Larry Morse, 25Nov99) that his treatment of this as a subspecies is based on a 1992 personal communication with Chuang. (NatureServe, 2015)

**Historical Range**

Never widespread;  in 1998, locations were on the Tiburon Peninsula in Main County, one population in Napa County, and one population in Santa Clara County (USFWS, 1998)

**Current Range**

Known from Marin, Napa, Santa Clara counties in California (USFWS, 2012)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2012)

**Dependency on Other Individuals or Species**

Adult: The yellow flowers of Castilleja affinis ssp. neglecta are pollinated by hummingbirds (County of Santa Clara et al. 2010). (USFWS, 2012)

**Breeding Season**

Adult: April to June (USFWS, 1998)

**Key Resources Needed for Breeding**

Adult: Low temperatures and leaching (USFWS, 1998)

**Reproduction Narrative**

Adult: Castilleja affinis ssp. neglecta is a root parasite on other angiosperm (flowering plant) species. Castilleja affinis ssp. neglecta is a perennial, flowering from April to June (Munz and Keck 1959). The yellow flowers of Castilleja affinis ssp. neglecta are pollinated by hummingbirds (County of Santa Clara et al. 2010). Seed germination occurs in January or February and seems to be induced by leaching and low temperatures (5 to 15 degrees Celsius or 45 to 59 degrees Fahrenheit) (Martin 1989). The mean number of inflorescences per plant was 2.3, the mean number of capsules per inflorescence was 8.8, and the mean number of seeds per capsule was 82.3. Based on these figures, seed production for 1 year was calculated to be 1,666 seeds per plant (Martin 1989). The plant dies back to its woody base after seed dispersal and new growth occurs after the first winter rain. Heckard (1968) observed evidence that polyploidy leads to patterns of variation that can lead to hybridization while plants maintain differences in their appearance. (USFWS, 1998; USFWS, 2012)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Serpentine grasslands (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Leaching and low temperatures (USFWS, 1998)

**Geographic or Habitat Restraints or Barriers**

Adult: Grows at elevations between 75 and 400 meters (USFWS, 2012)

**Spatial Arrangements of the Population**

Adult: Scattered colonies (USFWS, 2012)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2012)

**Site Fidelity**

Adult: High (inferred from USFWS, 2012)

**Dependency on Other Individuals or Species for Habitat**

Adult: The primary advantage of the parasitic attachment in Castilleja and related plants in the figwort family is reportedly an increased water and mineral supply. Though the parasitic relationship is not obligate (hemiparasitic), benefits to species of Castilleja from the parasitic habit are manifested in increased vigor with more branching, greater height, and earlier flowering (Heckard 1962). Heckard (1962) showed that a host plant is beneficial to Castilleja affinis spp. neglecta and increases the species' chance for survival. (USFWS, 1998)

**Habitat Narrative**

Adult: Three scattered colonies of the occurrences of Castilleja affinis ssp. neglecta in Marin County occur on the Tiburon peninsula. Castilleja affinis ssp. neglecta occurs in serpentine bunchgrass communities typically on north to west facing slopes. Castilleja affinis ssp. neglecta grows on open, rocky, serpentine slopes within the serpentine grassland communities, between about 75 and 400 meters in elevation in Napa, Marin, and Santa Clara Counties (Service 1998, Safford et al. 2005, LSA 2007, CDFG 2010). Seed germination occurs in January or February and seems to be induced by leaching and low temperatures (5 to 15 degrees Celsius or 45 to 59 degrees Fahrenheit) (Martin 1989). Castilleja affinis ssp. neglecta parasitic attachment increases water and mineral supply. Though the parasitic relationship is not obligate (hemiparasitic), benefits to species of Castilleja from the parasitic habit are manifested in increased vigor with more branching, greater height, and earlier flowering (Heckard 1962). Heckard (1962) showed that a host plant is beneficial to Castilleja affinis spp. neglecta and increases the species' chance for survival. (USFWS, 1998; USFWS, 2012)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seed dispersal occurs from June to October. (USFWS, 2012)

**Additional Life History Information**

Adult: Seed dispersal occurs from June to October. (USFWS, 2012)

***Population Information and Trends***

**Number of Populations:**

8 (USFWS, 2012)

**Population Size:**

Approximately 2,000 plants (USFWS, 2012)

**Population Narrative:**

The distribution of C. affinis ssp. neglecta has never been widespread. Seven occurrences are described: five in Marin County (three of which occur on the Tiburon Peninsula), one near American Canyon in Napa County, and one in Santa Clara County (Service 1998, CDFG 2010). The CNDDB reports one additional occurrence in Santa Clara County (CDFG 2010) and one occurrence from Stinson Beach in Marin County that was last observed at 1965 with the exact location and number of plants listed as unknown (CDFG 2010). The range of C. affinis ssp. neglecta is approximately 50 kilometers (30 miles) from east to west, and 112 kilometers (70 miles) from north to south (Service 1995). (USFWS, 2012)

***Threats and Stressors***

**Stressor:** Residential Development (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** When Castilleja affinis ssp. neglecta was listed as endangered in 1995, residential development was identified as a primary threat to Marin County populations. It remains a significant threat today. At the time of listing, the St. Hilary's church occurrence on the Tiburon peninsula was threatened by a proposed residential development. A portion of the land supporting this population was purchased by the Marin County Open Space District and Town of Tiburon in 1997 as an open space preserve (the Old St. Hilary's Open Space Preserve), however, a

portion of the population remains on private land where residential development has been proposed on multiple occasions. Residential development on the Middle Ridge adjacent to Tiburon paintbrush habitat is anticipated to occur in the near future (S. Anderson personal communication 2009). (USFWS, 2012)

**Stressor:** Mining/Landfill (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Both Santa Clara County occurrences of Castilleja affinis ssp. neglecta occur on private land associated with the Kirby Canyon Landfill. However, both are located in areas currently managed as mitigation sites for landfill impacts. Both occurrences are monitored and managed by the Kirby Canyon Butterfly Trust, but neither site is permanently protected (County of Santa Clara et al. 2010). At the time of listing, the Napa County occurrence was threatened by the potential expansion of the American Canyon Quarry. In 1999 private landowners donated land supporting 5 to 10 percent of the Castilleja affinis ssp. neglecta occurrence to the City of American Canyon in order to create the Newell Preserve; the Land Trust of Napa County holds a conservation easement on the preserve land (Napa County Land Trust website). Currently, there are no active plans for quarry expansion on the land that supports the majority of this occurrence and quarry reclamation which was initiated in 2007 is not anticipated to affect this occurrence (D. Barrella personal communication 2011). However, the quarry property is in an area zoned for agriculture and low density residential and could potentially be developed in the future. (USFWS, 2012)

**Stressor:** Recreation (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time Castilleja affinis ssp. neglecta was listed, we cited pedestrian traffic associated with recreation activities as a Factor A threat for the Middle Ridge and Ring Mountain populations of C. affinis ssp. neglecta on the Tiburon peninsula. Currently, wayward trails continue to crisscross Ring Mountain Preserve resulting in a small reduction in available habitat. C. affinis ssp. neglecta is most likely to be negatively affected by hikers, cyclists, and equestrians if they stray from designated and social trails and trample plants or if new trails are established. C. affinis ssp. neglecta plants on the Middle Ridge of the Town of Tiburon faces threats from hikers and their dogs that trample plants and habitat despite posted signs warning sensitive plant habitat (E. Buxton personal communication 2009). (USFWS, 2012) Currently, visitors are only allowed to visit Newell Preserve in Napa County during docent-led tours. Therefore, trampling and habitat destruction from recreational hikers, dogs, cyclists, and equestrians is currently not a threat to this Castilleja affinis ssp. neglecta occurrence. However, a master plan is being developed for the preserve that will likely include allowing public access without docent supervision. (USFWS, 2012)

**Stressor:** Landslide/Erosion (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** At the time of listing, soil slumping was identified as a threat to the Castilleja affinis ssp. neglecta occurrence at Ring Mountain Preserve (Service 1995). The toe of the slope that supports the population was removed to accommodate residential development in Corte Madera in the 1960s and soil from the slope slips onto the street below. Some Town of Tiburon Open space parcels are mapped as being prone to landslides and erosion occurs along some trails and watercourses on open space parcels, but neither appears to be a major threat to C. affinis ssp. neglecta at this time (LSA 2010). (USFWS, 2012)

**Stressor:** Grazing (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Cattle grazing was cited as a factor C threat to Castilleja affinis ssp. neglecta at the time of listing. Improper grazing may remain a potential threat to the species, however, grazing can also be used as a management tool to reduce biomass of non-native vegetation and may actually be beneficial to the species if managed appropriately (County of Santa Clara et al. 2010). (USFWS, 2012)

**Stressor:** Herbivory (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mammal herbivory by mule deer (Odocoileus hemionus) and black-tailed jackrabbits (Lepus californicus) may pose a threat to Castilleja affinis ssp. neglecta on the Ring Mountain Preserve. Results from 2007 monitoring showed that approximately 25 percent of the inflorescence branches in the 53 plants evaluated were removed by herbivory (LSA 2007). However, side branches developed when tips of branches were removed, so this type of herbivory may not pose a substantial threat. Disturbance from feral pig (Sus scrofa) rooting poses a threat to the Paintbrush Hill occurrence in Santa Clara County (County of Santa Clara et al. 2010). Cameras placed at the Santa Clara occurrences have documented rabbits and deer in the area and sharp incisions on the plants suggest that rabbits may be eating some C. affinis ssp. neglecta flowers and fruit at this location (C. Niederer personal communication 2011). It is not known whether any diseases threaten the species. (USFWS, 2012)

**Stressor:** Non-native Invasive Plant Species (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Competition from non-native invasive plant species continues to pose a serious threat to Castilleja affinis ssp. neglecta on the Tiburon peninsula. At the Ring Mountain Preserve, the Marin County Open Space District has been working to eradicate or control non-native invasive species for several years. The Ring Mountain Preserve Sensitive Resource Monitoring Plan (LSA Associates, Inc. 2007) provides a list of non-native invasive species that currently occur on Ring Mountain and describes treatment recommendations. Similarly, the Town of Tiburon has an Open Space Resource Management Plan (LSA 2010) that addresses invasive species that affect the Middle Ridge occurrence of C. affinis ssp. neglecta. Bull thistle (Cirsium vulgare), French broom (Genista monspessulana), and wild oats (Avena spp.), are problematic on parcels supporting C. affinis ssp. neglecta. Weed abatement is an ongoing activity that will likely need to

occur in perpetuity at these locations. (USFWS, 2012) Non-native invasive plant species occur to some extent in association with occurrences of Castilleja affinis ssp. neglecta outside the Tiburon peninsula as well. Point Reyes National Seashore is working to control an invasion of distaff thistle (Carthamus lanatus) in the vicinity of the Nicasio Ridge occurrence of C. affinis ssp. neglecta within the GGNRA and hand removal of tocolote (Centaurea melitensis) is conducted on Nicasio Ridge once or twice a year as funding allows. At this time, however, these non-native species do not appear to pose a serious threat to the Nicasio Ridge C. affinis ssp. neglecta occurrence (M. Chasse personal communication 2011). Treatments for barbed goatgrass (Aegilops triuncialis) have taken place on the Kirby Canyon Butterfly Preserve that supports Paintbrush Hill occurrence of C. affinis ssp. neglecta in Santa Clara County (Niederer 2008) and a number of non-native species occur in low densities within the North Canyon occurrence in Santa Clara County (C. Niederer personal communication 2009). At these two locations, efforts to control non-native plant species are necessary to keep them in control, but at this 14 time cattle grazing and current efforts appear to have prevented severe encroachment of non-native species (C. Niederer personal communication 2009). (USFWS, 2012)

**Stressor:** Nitrogen Deposition (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Air pollution and the resultant deposition of reactive airborne nitrogen has become a significant threat to many native California plants, in particular to those that occur in nutrient poor soils such those in serpentine areas (Weiss 1999). Increased nitrogen deposition allows nutrient-poor serpentine soils to be invaded by non-native annual grasses that displace the native forbs (Weiss 1999). Nitrogen deposition is especially high near urban areas where combustion sources produce substantial concentrations of nitrogen oxides (Weiss 1999). All occurrences of Castilleja affinis ssp. neglecta occur within or adjacent to urban areas with elevated levels of nitrogen deposition with particularly high nitrogen deposition levels occurring in Santa Clara County near San Jose (Weiss 2006). (USFWS, 2012)

**Stressor:** Stochasticity (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The limited number and small sizes of Castilleja affinis ssp. neglecta occurrences increase this species vulnerability to chance events such as fire, flood, drought, disease, and other natural and human-caused disasters (Brook et al. 2002). The occurrences of C. affinis ssp. neglecta on the Tiburon peninsula in particular are located in close proximity to dense, residential development placing them at risk of catastrophic events associated with human activity such as fire or vandalism. In addition, small populations are subject to inbreeding (mating between closely related individuals) resulting in a subsequent loss of genetic diversity (Spielman et al. 2004). Small populations are also more likely to experience extinction as a result of “stochastic” demographic fluctuations or other density-dependent effects (Avise 2004). (USFWS, 2012)

**Stressor:** Climate Change/Drought (USFWS, 2012)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). However, climatic conditions for smaller sub-regions such as California remain uncertain (Pyke 2005). It is unknown at this time if climate change in California will result in a localized, relatively small cooling and drying trend, or a warmer trend with higher precipitation events (Pyke 2005). A modeling study completed by Loarie et al. (2008) provides an evaluation of potential trends to California's floristic communities under climate change scenarios. The models suggest that shifts in species ranges may break up local floras, resulting in new species combinations, with new patterns of competition and biotic interactions (Loarie et al. 2008). While it appears reasonable to assume that Castilleja affinis ssp. neglecta will be affected by climate change, we lack sufficient certainty regarding how and how soon climate change will affect the species. Because C. affinis ssp. neglecta is restricted to limited and patchily distributed serpentine soils, however, the species will likely have difficulty shifting its range to adjust to changing conditions. (USFWS, 2012)

***Recovery***

**Reclassification Criteria:**
1. Six (6) populations of Castilleja affinis ssp. neglecta are fully protected and managed with the primary intention of preserving the populations in perpetuity (USFWS, 1998)

2. Six (6) populations of Castilleja affinis ssp. neglecta are shown to be stable or increasing with evidence of recruitment over a minimum of 20 years that include the normal precipitation cycle (or longer if suggested by the results of demographic monitoring) (USFWS, 1998)

3. Seed collected from natural populations throughout the range of the species is stored at a minimum of two Center for Plant Conservation certified botanic gardens (USFWS, 1998)

4. Reliable seed germination and propagation techniques for the species are understood (USFWS, 1998)

Recovery Priority Number: 9C

**Delisting Criteria:**
1. Ten (10) populations throughout its range are shown to be fully protected and managed with the primary intention of preserving the populations in perpetuity. At least 2 of the 10 should occur in Santa Clara County. (USFWS, 1998)

2. Ten (10) populations of Castilleja affinis ssp. neglecta are shown to be stable or increasing with evidence of recruitment over a minimum of 20 years that include the normal precipitation cycle (or longer if suggested by the results of demographic monitoring) (USFWS, 1998)

3. Seed collected from natural populations throughout the range of the species is stored at a minimum of two Center for Plant Conservation certified botanic gardens (USFWS, 1998)

4. Reliable seed germination and propagation techniques for the species are understood (USFWS, 1998)

**Recovery Actions:**

- Protecting and managing the known populations. Protection and management of populations on public lands will involve working with Main Open Space District, the town of Tiburon, and the Golden Gate National Recreation Area to ensure the long-term survival of the species on their lands. The populations, or portions of populations, occurring on private lands should be protected by land acquisition, conservation easements, or other mechanisms. Among populations on private land, protection of the only known population in Santa Clara County is a particularly high priority because it is geographically disjunct from other populations. In general, the largest possible block of serpentine habitat should be protected at each site. Protection should, at least, involve securing the populations themselves as well as a 150-meter (500-foot) buffer around each population, where possible, to reduce external influences and allow expansion of populations. In addition, other unoccupied habitat at the sites that might provide space for expansion of the populations and habitat for pollinators and seed dispersers must be protected. Management plans emphasizing Castilleja affinis ssp. neglecta and other special status species in each location must be developed and implemented. The plans should include provisions for standardized monitoring of Castilleja affinis ssp. neglecta populations every other year to determine demographic trends. The plans should also include strategies to minimize known threats (e.g. foot traffic) at the sites as well as to identify new threats should they appear. Removal of nonnatives should be a high priority for management of sites on the Tiburon Peninsula such as those on Middle Ridge and in Main County Open Space near Old St. Hilary's Church. In addition, soil slumping at the Ring Mountain Preserve needs to be minimized. If new threats are identified or other new information becomes available, management plans need to be reevaluated and revised. For populations on public lands, any management plan developed should include an educational outreach program. (USFWS, 1998)
- Collection and banking of seed in Center for Plant Conservation certified botanic gardens. Seed banking guards against extinction of populations from chance catastrophic events and provides potential material for enhancement efforts in existing populations, repatriations, and/or introductions to new sites. In the absence of genetic data for Castilleja affinis ssp. neglecta, seed collection efforts should represent populations throughout the range of the species, including the Santa Clara County population that is at least 100 kilometers (62 miles) south of the other known populations (Elam in prep). Care should be taken to ensure that seed collection does not adversely affect the donor populations. (USFWS, 1998)
- Other potential serpentine habitat throughout the range of the species should be surveyed to determine if other populations exist. Santa Clara County, in particular, contains habitat that should be surveyed (e.g. to the south of the known occurrence and in Henry Coe State Park east of Anderson Reservoir) (California Department of Fish and Game 1 997a). If new populations are discovered, they should be protected and managed as discussed above. During these surveys, potential introduction sites might also be identified. (USFWS, 1998)
- The effect of various vegetation management techniques (e.g. grazing, mowing, and burning) on Castilleja affinis ssp. neglecta needs to be evaluated, because (1) Castilleja affinis ssp. neglecta occurs approximately 100 to 250 meters (328 to 820 feet) from relatively good quality bay checkerspot butterfly habitat (N. McCarten, in litt., 1998) in Santa Clara County, and (2) bay checkerspot butterfly habitat benefits from vegetation management,. Although cattle and deer grazing of Castilleja affinis ssp. neglecta has not been observed (N. McCarten, in litt., 1998), evaluation of these techniques will ensure that

managers select management strategies that maintain bay checkerspot butterfly habitat while not adversely affecting Castilleja affinis ssp. neglecta. Research on the effects of grazing are also important in recovery efforts for Castilleja affinis ssp. neglecta because grazing is a concern at the Golden Gate National Recreation Area in Main County. In addition, because other Castilleja species appear to benefit from fire (R. Raiche. cited in California Department of Fish and Game 1997b, small scale experimental burning (e.g. using burn boxes) may reveal another possible management strategy. Any experimental burning should initially be limited to a very small area (e.g. 1 square meter [10.8 square feet]). (USFWS, 1998)

- Other research needs include germination and propagation techniques, taxonomic, demographic, and genetic studies as well as mating system and pollination studies. Demographic studies should include field studies of Castilleja affinis ssp. neglecta's hemiparasitic nature, the frequency of seed germination and seedling recruitment in nature. and identification of limiting life history stages. Martin (1989) observed no seedlings in the field during a 2-year study. Genetic studies should focus on whether, and to what extent, populations throughout the range of the species are genetically different from one another. These genetic data would be valuable guides as to which populations should be chosen as sources for enhancement of existing populations or introduction of new populations. (USFWS, 1998)
- Control and eradicate non-native, invasive plant species: continue to control non-native plant species at Ring Mountain Preserve and Town of Tiburon Open Space parcels according to existing management plans. Amend the Town of Tiburon Open Space Management Plan to include the Old Saint Hilary's Church Open Space parcel. Develop and implement management plans for controlling non-native invasive plant species in the area supporting the two Castilleja affinis ssp. neglecta occurrences on GGNRA land in Marin County, on the Newell Preserve in Napa County, and for the mitigation lands supporting the two C. affinis ssp. neglecta occurrences in Santa Clara County. (USFWS, 2012)
- Locations that should be targeted for protection in cooperation with willing landowners: in Santa Clara County, establish a conservation easement on the 250 acre Bay checkerspot butterfly reserve that supports the Paintbrush Hill C. affinis ssp. neglecta occurrence and on the entire mitigation parcel that supports the North Canyon occurrence. In Napa County, pursue opportunities to acquire or incorporate land supporting C. affinis ssp. neglecta in the former quarry area into Newell Open Space Preserve. In Marin County, establish a conservation easement on all remaining undeveloped serpentine habitat in the Old St. Hilary's Church area as mitigation for any development that takes place on private parcels in this location. (USFWS, 2012)
- Monitoring: Continue to monitor Castilleja affinis ssp. neglecta on the Ring Mountain Preserve using the 24 established 1m2 monitoring plots for three years using the same parameters as those used in 2007 thereafter, every two years as recommended by the 1998 Recovery Plan (Service 1998). Add a monitoring protocol for Castilleja affinis ssp. neglecta to the Town of Tiburon Open Space Management Plan. In Marin County on GGNRA land, continue monitoring Castilleja affinis ssp. neglecta at Nicasio Ridge and initiate monitoring at CNDDB occurrence 6. Include monitoring of grazing effects at these locations. (USFWS, 2012)
- Seeds from Castilleja affinis ssp. neglecta should be collected from populations throughout the range and banked in Center for Plant Conservation certified gardens. (USFWS, 2012)

- Other serpentine habitats with the potential to support Castilleja affinis ssp. neglecta should be surveyed to determine whether undiscovered populations exist. New populations should be noted with the appropriate County, California Department of Fish and Game, the Service and the California Native Plant Society. (USFWS, 2012)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: In this section we propose recommendations which will aid in the recovery and conservation of Tiburon paintbrush. Some of these recommendations have already been discussed in previous recovery documents (Service 1998; Service 2012) and have been carried over into this status review. 1) Continue to control and eradicate non-native, invasive plant species. Use existing management plans or develop and implement management plants including controlling nonnative invasive species for all protected areas. 2) In cooperation with willing landowners, target protection of Tiburon paintbrush occurrences on unprotected lands. Continue to work with partners to protect occurrences on private lands, including buffers around them when possible. In particular, pursue opportunities to permanently protect land supporting Tiburon paintbrush in the former quarry area adjacent to the Newell Open Space Preserve in Napa County, and the area immediately east of the Golden Gate National Recreation Area land at Nicasio Ridge in Marin County. 3) Monitor or continue to monitor all existing Tiburon paintbrush occurrences using a consistent protocol. Implement survey protocols carefully to minimize damage to plants (e.g., if attempting to distinguish individual plants) or trampling from group visits. 4) Survey additional serpentine habitats with the potential to support Tiburon paintbrush to determine whether undiscovered populations exist. Habitat suitability studies or iterative niche modeling could be used to identify potential habitat areas. New populations should be noted with the appropriate County, California Department of Fish and Wildlife, the Service, and the California Native Plant Society. 5) Seeds from Tiburon paintbrush should be collected from populations throughout the range and banked in Center for Plant Conservation certified gardens. Priority should be placed on populations that do not yet have seeds banked. 6) Conduct or continue research on Tiburon paintbrush. Continue research on host plants, including testing additional species and host plant preference, and on seed germination. Identify environmental factors that might influence suitability of the habitat in occupied areas (and that might explain absence from other areas). Continue evaluation of exclosures to prevent grazing/rooting and, depending on results, consider additional exclosures or a fence around the Paintbrush Hill population. (USFWS, 2021)

# SPECIES ACCOUNT: *Castilleja campestris ssp. succulenta* (Fleshy owl's-clover)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 03/26/1997; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

A hemiparasitic annual herb, mostly 5-25 cm tall, with fleshy, somewhat brittle leaves. Produces dense inflorescences of yellow to white flowers subtended by green bracts. (NatureServe, 2015)

**Taxonomy**

Both Kartesz and the Fed. Reg. agree on the nomenclature of this element and now recognize it as part of the genus Castilleja (as opposed to Orthocarpus). (NatureServe, 2015)

**Historical Range**

The historical distribution between 1937 and 1986 was reported from 33 occurrences (Hoover 1937, 1968, CNDDB 2005), all in the Southern Sierra Foothills Vernal Pool Region (Keeler-Wolf et al. 1998). Sixteen of those occurrences, including the type locality, were in eastern Merced County. Six occurrences each were in Fresno and Madera Counties and five others were in Stanislaus County (CNDDB 2003). (USFWS, 2011)

**Current Range**

Succulent owl's-clover is geographically distributed in vernal pool complexes that are primarily along the lower foothill grasslands of the eastern San Joaquin Valley. Within the San Joaquin Valley, the succulent owl's-clover is distributed throughout five counties: San Joaquin, Stanislaus, Merced, Madera, and Fresno Counties. The species is also found in the southeastern Sacramento Valley within San Joaquin County. The current species range is approximately 50 kilometers (31 miles) wide from east to west, and 243 kilometers (151 miles) long from north to south. While the range of succulent owl's-clover has expanded since it was described at listing, the current species distribution is similar to what we described in our 2011 review (USFWS, 2023)

**Critical Habitat Designated**

Yes; 2/10/2006.

**Legal Description**

On August 6, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Castilleja campestris ssp. succulenta (Fleshy owl's-clover) (and other vernal pool species) under the Endangered Species Act of 1973, as amended (Act) (68 FR 46684 - 46867). On August 11, 2005, the Service issued a Final Rule that excluded some lands addressed in the 2003 rule from the final designation for economic reasons (70 FR 46924 - 46999). On February 10, 2006, the Service issued administrative revisions to the Final Rule (71 FR 7118-7316). The critical habitat designation for Castilleja campestris ssp. succulenta includes six critical habitat units (CHUs) in California.

**Critical Habitat Designation**

The critical habitat designation for Castilleja campestris ssp. succulenta includes six CHUs (some with multiple parts) in Fresno, Madera, Mariposa, Merced, San Joaquin, Stanislaus, and Tuolumne Counties, California. This species critical habitat encompasses approximately 175,873 acres (68 FR 46684 - 46867; 70 FR 46924-46999; 71 FR 7118-7316).

Unit 1: Sacramento and San Joaquin Counties, California. From USGS 1:24,000 scale quadrangles Clay and Lockeford.

Unit 2: Tuolumne and Stanislaus Counties, California. From USGS 1:24,000 scale quadrangles Keystone, La Grange, Cooperstown and Paulsell.

Unit 3: Mariposa and Merced Counties, California. (i) Unit 3A: Mariposa and Merced Counties, California. From USGS 1:24,000 scale quadrangles Merced Falls and Snelling.

Unit 3B: Mariposa and Merced Counties, California. From USGS 1:24,000 scale quadrangles Merced Falls, Snelling, Indian Gulch, Haystack Mountain, Yosemite Lake, Winton, Owen's Resevoir, Planada and Merced.

Unit 4: Madera and Merced Counties, California. (i) Unit 4A: Madera and Merced Counties, California. From USGS 1:24,000 scale quadrangle Raynor Creek.

Unit 4C: Madera and Fresno Counties, California. From USGS 1:24,000 scale quadrangles Millerton Lake West, Little Table Mountain, Daulton, Friant, Lanes Bridge and Gregg.

Unit 5: Fresno County, California. (i) Unit 5A: Fresno County, California. From USGS 1:24,000 scale quadrangles Friant and Round Mountain.

Unit 5B: Fresno County, California. From USGS 1:24,000 scale quadrangle Clovis.

Unit 6: Fresno County, California. (i) Unit 6A: Fresno County, California. From USGS 1:24,000 scale quadrangles Millerton Lake East and Academy.

Unit 6B: Madera County, California. From USGS 1:24,000 scale quadrangles North Fork and Millerton Lake East.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The primary constituent elements of critical habitat for Castilleja campestris ssp. succulenta (Fleshy owl's-clover) are the habitat components that provide:

(i) Topographic features characterized by isolated mound and intermound complex within a matrix of surrounding uplands that result in continuously, or intermittently, flowing surface water in the depressional features including swales connecting the pools described in paragraph (c)(8)(ii) of this section, providing for dispersal and promoting hydroperiods of adequate length in the pools; and

(ii) Depressional features including isolated vernal pools with underlying restrictive soil layers that become inundated during winter rains and that continuously hold water or whose soils are saturated for a period long enough to promote germination, flowering, and seed production of predominantly annual native wetland species and typically exclude both native and nonnative upland plant species in all but the driest years. As these features are inundated on a seasonal basis, they do not promote the development of obligate wetland vegetation habitats typical of permanently flooded emergent wetlands.

**Special Management Considerations or Protections**

Existing manmade features and structures, such as buildings, roads, railroads, airports, runways, other paved areas, lawns, and other urban landscaped areas do not contain one or more of the primary constituent elements. Federal actions limited to those areas, therefore, would not trigger a consultation under section 7 of the Act unless they may affect the species and/or primary constituent elements in adjacent critical habitat.

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (annuals) (USFWS, 2011)

**Breeding Season**

Adult: April and May (USFWS, 2011)

**Reproduction Narrative**

Adult: Castilleja campestris ssp. succulenta is an annual plant. Seeds of the C. campestris ssp. succulenta do not require the presence of a host to germinate, as they form root connections only after reaching a seedling stage.

**Habitat Type**

Adult: Vernal pools (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Small, seasonal pools. (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Occur at elevations of 24 m (80 feet) to 700 m (2,300 feet). (USFWS, 2011)

**Spatial Arrangements of the Population**

Adult: Widely scattered (USFWS, 2011)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2011; NatureServe, 2015)

**Habitat Narrative**

Adult: Castilleja campestris ssp. succulenta is found primarily in vernal pools, and only in the lower rolling foothill areas of the eastern San Joaquin Valley in the Southern Sierra Foothills

Vernal Pool Region (Service Recovery Plan 2005). Soil textures at those sites range from extremely stony loam to loamy clay. At the U.C. Merced site and the surrounding community planning area, 81.4% of the individual pools where this taxon was found were on Redding gravelly loam, 9.5% were on Corning gravelly sandy loam, 6.4% were on Corning gravelly loam, 1.7% were on Keyes gravelly loam, 0.7% was on Keyes gravelly clay loam, and 0.3% was on Pentz loam (EIP Associates 1999). Self-pollinating species of Castilleja typically occur as widely scattered individuals, rather than dense colonies (Atsatt 1970). Populations of Castilleja campestris spp. succulenta have been reported from elevations of 24.0 m (80 feet) at the San Joaquin County site to 700.0 m (2,300 feet) at Kennedy Table in Madera County (CNDDB 2003). (USFWS, 2011; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Number of Populations:**

99 presumed extant occurrences (USFWS, 2023)

**Adaptability:**

Low (inferred from USFWS, 2011)

**Population Narrative:**

The Department (2020, pp. 9–10) defines an element occurrence (also known as an EO and hereafter, occurrence) in the Diversity Database as a specific location where a special status species has been known to occur. A single occurrence can contain multiple distinct sites (i.e., multiple interconnected pools within a single pool complex) where the species occurs. Generally, populations, individuals, or colonies located within a quarter mile of each other constitute a single occurrence. Geographic boundaries or polygons associated with each occurrence can change as additional data is received (Department 2020, p. 10). At the time of listing, the succulent owl's-clover was distributed over 36 extant occurrences throughout Merced, Fresno, Madera, Stanislaus, and San Joaquin Counties (Service 1997, p. 14349). The 2011 5-year review reported 99 occurrences throughout the same counties as those at listing but also included Mariposa County. Nine of those occurrences, which were not identified by occurrence number, were reported as extirpated and 90 were presumed extant (Service 2011, p. 6). The increase in occurrences was attributed to an increase in the number of surveys following listing (Service 2011, p. 8). In 2023, there are 99 reported occurrences that are presumed extant, two of which are possibly extirpated (occurrence numbers 1 and 7) (Diversity Database 2023, pp. 1, 8). None of the current occurrences are described as extirpated and it is unclear which occurrences were previously described as extirpated or why their status was changed. Since the previous 5-year review, 12 new occurrences have been reported for succulent owl'sclover to the Diversity Database (occurrence numbers 100–111) and additional locations have been identified that are not currently in the Diversity Database. However, these additional occurrences are located within the existing range of the species and do not change our understanding of the species' distribution. Furthermore, three previous occurrences reported in 2011 (occurrence numbers 63, 81, and 82) have been added to nearby occurrences in the Diversity Database.

Number 63 has been added to occurrence number 27, number 81 has been added to occurrence number 79, and number 82 has been added to occurrence number 80 (Diversity Database 2023, pp. 25, 72, 73). Again, it is unclear why there is a discrepancy between the number of occurrences reported during the 2011 5-year review and the number of occurrences reported currently. Abundance: At the time of listing, there were 24 occurrences of succulent owl's-clover that had associated plant number estimates and approximately 10 of these occurrences contained fewer than 100 plants each at their peak size (Service 2011, p. 14). Occurrence data was not used in the 2011 5- year review to determine plant population trends due to inconsistently documented plant numbers recorded during surveys and fluctuations of data from year to year (Service 2011, p. 14). However, the 2011 5-year review noted that as of 2009, Diversity Database records showed that 35 occurrences contained plant number estimates with 16 occurrences having fewer than 100 plants and 17 occurrences with more than 100 plants (Service 2011, p. 14). According to the Diversity Database (2023) and additional sources (identified in Table 1), 17 out of 99 presumed extant succulent owl's-clover occurrences have been surveyed since the last 5-year review. Survey data for these occurrences are detailed below in Table 1 and summarized by county in the following subsections (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat degradation
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The 1997 final rule stated that nearly half of the extant Castilleja campestris ssp. succulenta occurrences are threatened by man-made activities such as urbanization, agricultural land conversion, discing, trampling due to overgrazing, mining, and a proposed road expansion project. The threats presented in the listing rule are still relevant. The habitat of this species has been reduced and fragmented throughout its range and vernal pools continue to be removed by the factors previously noted. Lands on the Central Valley floor are closer to existing cities and agricultural lands than the valley rim, which is steeper, less fertile and more removed from cities. As a result, valley floor vernal pools, along with open rangeland, have been and continue to be favored for urban and agricultural development. (USFWS, 2011)

**Stressor:** Stressor
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** According to a University of California, Berkeley study, the native plants unique to California are vulnerable to global climate change and that two-thirds of these endemics could suffer more than an 80% reduction in geographic range by the end of the century (U.C. Berkeley Press Release, June 2008). Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). It is unknown at this time if climate change in California specifically will result in a warmer trend with localized drying, higher precipitation events, or other effects. (USFWS, 2011)

**Stressor:** Small population size
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Since the final listing rule, an additional threat to Castilleja campestris ssp. succulenta is that many of its populations are small in number. A small population size makes a population more vulnerable to extirpation from chance events as noted in the 2005 Recovery Plan. Among the 24 occurrences of C. campestris ssp. succulenta for which size estimates had been documented, ten consisted of fewer than 100 plants each at their peak size (J. Stebbins in litt. 2000b, CNDDB 2003). According to the 2009 CNDDB occurrences, 35 have population size estimates documented with approximately 16 occurrences with fewer than 100 plants and approximately 17 occurrences with more than 100 plants.

**Stressor:** Rainfall
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This taxon is very cyclical and is somewhat scarce in normal or below normal rainfall years but large populations may be evident in wet years at the known sites (J. Stebbins, pers. comm. 2009). (USFWS, 2011)

**Stressor:** Habitat Loss (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Of the three counties analyzed in the Vollmar et al. (2013, p. 28) study, vernal pool grassland habitats in Merced County have experienced the lowest loss of predicted extant habitat for succulent owl's-clover. This lower loss of predicted habitat is likely due to the relatively protected nature of the succulent owl's-clover's primary preferred habitat in high terrace terrain that is not as conducive to conversion for agriculture or development, such as the secondary preferred habitat in lower terrace terrain (Vollmar et al. 2013, p. 28). As of 2010, a total of 54,971 acres of extant succulent owl's-clover habitat was predicted to remain within the core recovery areas in Merced County, and a total of 5.6% (3,198 acres) of extant habitat is predicted to have been lost between 2005–2010 (Vollmar et al. 2013, p. 31). The primary cause of vernal pool habitat loss in Madera and Merced Counties is a result of conversion for agricultural uses and development (Vang et al. 2012, p. 30; Witham 2021, p. 8). However, outside of vernal pool preservation, there are some lesser-degree protections in place for the extant vernal pool habitat that lies within portions of the Great Valley. For example, while most private lands that contain high-quality vernal pool habitat adjacent to the Madera and Friant-Kern canals are not associated with conservation easements or other protections, most extant rangeland along the canals is under contracts with local government under the California Land Conservation Act of 1965 (also known as the Williamson Act), which means land use is restricted to agricultural or open space use and such restrictions can help to limit development and habitat loss (USFWS, 2023).

**Stressor:** Climate Change (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** As described in the 2011 5-year review, climate change has the potential to alter the timing and synchronicity of ecosystem processes, including the germination, growth, and pollination of succulent owl's-clover. The core areas in the Recovery Plan were developed, in part, using current known habitat boundaries for the species; however, possible new areas of suitable habitat may eventually arise because of worsening climate change and altered weather patterns (Service 2005, p. I-25). This could in turn contribute to shifts in the abundance or composition of vernal pool plant communities. Over the 21st century, global climate models predict higher temperatures, increasing potential evapotranspiration from plants and soils, longer and more severe droughts, declining snowpack, more intense precipitation events, more frequent and extensive wildfires, and sea level rise (Fernandez-Bou et al. 2021, p. 17). Worldwide, plants with less static ecosystem requirements are generally responding to climate change patterns by redistributing to higher altitudes, cooler areas of higher latitudes, and areas with higher precipitation, to seek refuge from rising temperatures and drought conditions (Shay et al. 2021, p. 2). Data is limited on how vernal pool plant communities and distributions may respond to increasing threats from global climate change. However, studies have begun to expand focus to identify the possible effects to plant phenology and species ranges that could arise from climate change. Historical data in the San Joaquin Valley from 1961 to 1990 show an increase in average maximum temperatures by about 1 degree Fahrenheit (0.5 degree Celsius); temperatures in the Valley are projected to continue to increase 4 to 5 degrees Fahrenheit (2.2 to 2.7 degrees Celsius) by 2050, and 5 to 8 degrees Fahrenheit (2.7 to 4.4 degrees Celsius) by the end of the century, depending on what level of emissions are actively reduced over time (Fernandez-Bou et al. 2021, p. 18). Recent research was conducted using the creation of hydrology and vegetation models to predict how climate change will impact volcanic vernal pools in northern California (Montrone et al. 2019, pp. 9–23). Simulation output suggests that higher localized seasonal temperatures would contribute to increased evaporation and shorter hydroperiods in vernal pools. This effect could lead to declines of the long-term inundated plant community, and conversely, edge and shallow-tolerant plant communities would increase (Montrone et al. 2019, p. 27). Within the warmer San Joaquin Valley, shorter hydroperiods in vernal pools could lead to competition and encroachment on succulent owl's-clover from nonnative invasive annual grasses and forbs that are less adapted to periodic inundation (Rains et al. 2006, p. 20; Javornik and Collinge 2016, pp. 65–66). Restoration and conservation efforts conducted over the next century in the San Joaquin Valley will need to be sited (and timed within the growing season) to focus on how changes in local precipitation and temperature patterns can impact the success of these efforts (USFWS, 2023).

**Stressor:** Pesticide Use (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Because the agriculture industry is so prevalent throughout the southern Sierra foothills, research is becoming increasingly important to analyze potential effects of pesticide use on vernal pool grassland ecosystems and pollinators. The Environmental Protection Agency recently released final biological evaluations assessing the effects of labeled uses of three neonicotinoid pesticides on listed species (EPA 2022a, entire; EPA 2022b, entire; EPA 2022c, entire). The three pesticides (clothianidin, imidacloprid, and thiamethoxam) are registered for use on a variety of agricultural crops; there are also some non-agricultural applications. All three pesticides were determined likely to adversely affect succulent owl's-clover, primarily due to expected indirect effects to pollinators. The three pesticides target insect species by acting on

their neurotransmitters to cause excessive nervous stimulation, paralysis, and death. The three pesticides are highly toxic to bees and available data suggest that all three pesticides are likely to affect honeybee and bumblebee colonies through brood reduction and declines in numbers of adults. However, the overall importance of pollinating insects for succulent owl's-clover is poorly understood. Some aspects of succulent owl's-clover biology suggest that it may be selfpollinating, but many species related to this taxon are pollinated by generalist bees (Superfamily Apoidea) (Chuang and Heckard 1991, p. 648). Analysis of these insecticides' effects to vernal pool habitat and species is ongoing (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
1. Habitat protection - Accomplish habitat protection that promotes vernal pool ecosystem function sufficient to contribute to population viability of the covered species. Suitable vernal pool habitat within each prioritized core area for the species is protected. Species occurrences distributed across the species geographic range and genetic range are protected. Protection of extreme edges of populations protects the genetic differences that occur there. Reintroductions must be carried out and meet success criteria established in the Recovery Plan. Additional occurrences identified through future site assessments, GIS and other analyses, and status surveys that are determined essential to the recovery are protected. Any newly found occurrences may count towards recovery goals if the occurrences are permanently protected as described in the Recovery Plan. Habitat protection results in protection of hydrology essential to vernal pool ecosystem function, and monitoring indicates that hydrology that contributes to population viability has been maintained through at least one multi-year period that includes above average, average, and below average local rainfall as defined above, a multi-year drought, and a minimum of 5 years of post-drought monitoring. (USFWS, 2011)

2. Adaptive habitat management and monitoring: Habitat management and monitoring plans that ensure maintenance of vernal pool ecosystem function and population viability have been developed and implemented for all habitat protected. Mechanisms are in place to provide for long-term management and monitoring. Monitoring indicates ecosystem function has been maintained in the areas protected. Seed banking actions have been completed for species that would require it as insurance against risk of stochastic extirpations or that will require reintroductions or introductions to contribute to meeting recover criteria. (USFWS, 2011)

3. Status surveys, 5-year status reviews, and population monitoring show populations within each vernal pool region where the species occur are viable (e.g., evidence of reproduction and recruitment) and have been maintained (stable or increasing) for at least one multi-year period that includes above average, average, and below average local rainfall, a multi-year drought, and a minimum of 5 years of post-drought monitoring. Status surveys, status reviews, and habitat monitoring show that threats identified during and since the listing process have been ameliorated or eliminated. Site-specific threats identified through standardized site assessments and habitat management planning also must be ameliorated or eliminated. (USFWS, 2011)

4. Research actions necessary for recovery and conservation of the covered species have been identified (these are research actions that have not been specifically identified in the recovery actions but for which a process to develop them has been identified). Research actions (both specifically identified in the recovery actions and determined through the process) on species

biology and ecology, habitat management and restoration, and methods to eliminate or ameliorate threats have been completed and incorporated into habitat protection, habitat management and monitoring, and species monitoring plans, and refinement of recovery criteria and actions. Research on genetic structure has been completed (for species where necessary – for reintroduction and introduction, seed banking) and results incorporated into habitat protection plans to ensure that within and among population genetic variation is fully represented by populations protected in the Habitat Protection section. Research necessary to determine appropriate parameters to measure population viability for each species has been completed. (USFWS, 2011)

5. Participation and outreach: recovery implementation team is established and functioning to oversee range-wide recovery efforts. Vernal pool regional working groups are established and functioning to oversee regional recovery efforts. Participation plans for each vernal pool region have been completed and implemented. Vernal pool regional working groups have developed and implemented outreach and incentive programs that develop partnerships. (USFWS, 2011)

**Delisting Criteria:**
Same as the reclassification criteria.

**Recovery Actions:**
- Conduct standardized vernal pool habitat site assessments for both the Southeastern Sacramento Valley and Southern Sierra Foothills vernal pool regions. (USFWS, 2011)
- Establish management and monitoring plans which include criteria for frequent surveys in order to capture the blooming period for this species. The Castilleja campestris ssp. succulenta population numbers vary widely from year to year depending on habitat conditions and rainfall (Vollmar 2002). Therefore, the Service should encourage bank owners and preserve managers to perform surveys on a frequent schedule in order to gather additional data which will increase knowledge. The additional information will be utilized for future 5-year reviews. (USFWS, 2011)
- The Vernal Pool Regional working group should formulate a plan to reach out and educate private landowners as to the value of federally-listed species on their lands, with a particular focus on plants. The Vernal Pool Regional group also should provide guidance to assist landowners on how to better manage their lands for the overall benefit of this species. (USFWS, 2011)
- The Service should encourage collection of seeds and storage in approved seed banks from extant occurrences, in each core area, to aid in the establishment of a seed bank. (USFWS, 2011)
- The Service should encourage County and local governments to consider developing Habitat Conservation Plans (HCPs) to include vernal pool species. Take of a federally listed invertebrate species would be permitted on private land, and any habitat acquisition to compensate for invertebrate species could include the Castilleja campestris ssp. succulenta if appropriate. Fresno County has been awarded Federal funds for the development of an HCP and additional funds may be available in the future for counties who apply for them. (USFWS, 2011)
- Efforts to protect vernal pool species should include conservation efforts on a landscape scale (Vollmar 2002). Landscape Conservation Cooperatives provide Federal scientific and technical support for conservation on a landscape scale which is the entire range of an

identified priority species. These cooperatives also have a role in helping partners identify common goals and priorities to target the right science for efficient and effective conservation. (USFWS, 2011)

- Not available

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation and ecological research recommendations that will aid in the recovery and conservation of the succulent owl’s-clover. Some of these recommendations have already been discussed in previous recovery documents (Service 2005, p. ix–xii) and the previous 5-year review (Service 2011, pp. 22–23) and remain valid. 1. Research. Research is needed to determine whether succulent owl’s-clover is insectpollinated. If insects are found to be important to pollination and therefore to seed production, pollinator habitat must be protected in each core area to contribute to the recovery of the species (Service 2005, p. III-13). 2. Invasive plant management. Continue to control and eradicate non-native, invasive (noxious) grass and forb species. Use existing management plans or develop and implement management plans that include control of invasive plants for all protected areas. 3. Expand survey effort for succulent owl’s-clover to determine whether undiscovered populations exist. Conduct standardized vernal pool habitat site assessments for both the Southeastern Sacramento Valley and Southern Sierra Foothills vernal pool regions. A standardized monitoring plan should be used to assess hydrology at the known extant occurrences throughout the species’ range. Federal and State agencies, partners, and a San Joaquin Valley recovery team should create a forum of discussion with a prioritized goal of identifying updated conservation issues and potential incentives for private landowners to become more willing to participate in conservation and surveying efforts. 4. In cooperation with willing landowners, target protection of succulent owl’s-clover occurrences on unprotected lands. Apply updated study methods for identification of key areas of remaining habitat and conduct floristic surveys in core areas of the succulent owl’s-clover range. Develop predicted habitat maps for the entire range of succulent owl’s-clover to aid in conservation planning and species recovery of this species. 5. Seed Banking. The Service should encourage collection of seeds and storage in approved ex situ seed banks (such as the Santa Barbara Botanic Garden) from extant occurrences, in each core area in each vernal pool region, to aid in the establishment of a seed bank (USFWS, 2023).

# SPECIES ACCOUNT: *Castilleja mollis* (Soft-leaved paintbrush)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 07/31/1997; California/Nevada Region (R8) (USFWS, 2015)

**Physical Description**

A shrubby, hemiparasitic, perennial herb with soft-woolly, grayish-green foliage. The highly branched plants are somewhat prostrate, usually reaching only 3+ dm high. Inflorescences (April-August) have yellow bracts (the bracts much more conspicuous than the flowers). (NatureServe, 2015)

**Taxonomy**

This species was described by Pennell as Castitteja moltis in 1947, based on material collected on Santa Rosa Island in 1939 (Ingram 1990, Heckard et at. 1991). Hoover (1970) and Munz and Keck (1973) included plants of coastal sand dunes of San Luis Obispo County in the description of this taxon. (USFWS, 2000). Upon review and in agreement with available systematic and floristic literature and consultation with species experts, we intend to propose amending part 17, subchapter B of chapter I, title 50 of the Code of Federal Regulations to reflect the transfer of Castilleja taxa including C. mollis from the family Scrophulariaceae to the family Orobanchaceae. (USFWS, 2007)

**Historical Range**

See current range/distribution.

**Current Range**

Castilleja mollis (Orobanchaceae) is a perennial herb that occurs only on Santa Rosa Island in Santa Barbara County, California, about 25 miles (40 kilometers) from the mainland. Santa Rosa Island is owned by CINP and is managed primarily for natural resource conservation (USFWS, 2023).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (hybridization) NatureServe, 2015)

**Breeding Season**

Adult: April to August (NatureServe, 2015)

**Other Reproductive Information**

Adult: This plant occasionally hybridizes with Castilleja affinis. (NatureServe, 2015)

**Reproduction Narrative**

Adult: This plant occasionally hybridizes with Castilleja affinis. Inflorescences (April-August) have yellow bracts (the bracts much more conspicuous than the flowers). (NatureServe, 2015)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Sand/dune, Shrubland/chaparral (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Dependency on Other Individuals or Species for Habitat**

Adult: Soft-leaved paintbrush is dependent on a host plant for water and dissolved resources. Some leaves have reduced chlorophyll and the plant compensates by parasitizing the roots of nearby vascular plants (Chuang and Heckard 1993). The most likely host is goldenbush (Isocoma menziesii var. sedoides) (E. Painter in titt. 1995, M. Wetherwax in titt. 1995). (USFWS, 2000)

**Habitat Narrative**

Adult: It is well established that Castilleja mollis requires the coastal scrub bluff community, which includes goldenbush, to establish and survive (USFWS, 2000). Castilleja mollis requires stabilized and partially stabilized coastal dunes (NatureServe, 2015). Castilleja mollis is dependent on a host plant for water and dissolved resources. Some leaves have reduced chlorophyll and the plant compensates by parasitizing the roots of nearby vascular plants (Chuang and Heckard 1993). The most likely host is goldenbush (Isocoma menziesii var. sedoides) (E. Painter in titt. 1995, M. Wetherwax in titt. 1995). (NatureServe, 2015; USFWS, 2000)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Fluctuating populations (USFWS< 2023)

**Population Growth Rate:**

Slow decline (NatureServe, 2015)

**Number of Populations:**

2 (USFWS, 2023)

**Population Size:**

>1000 (NatureServe, 2015)

**Population Narrative:**

Historically and currently, C. mollis has been found in two populations on the north side of Santa Rosa Island which are separated by about 10 miles (16 kilometers): Carrington Point and Jaw Gulch (Table 2). Identification by California Natural Diversity Database Element Occurrence Number (CNDDB EO #) has never been used by staff at CINP or USGS to identify the populations. The species has been extirpated from San Miguel Island, and two other locations reported by CNDDB are in error (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Decline of plant host (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** We have information that indicates the direct dependency of Castilleja mollis on the coastal goldenbush scrub community (McEachern, pers. comm. 2006a). Before 1998, cattle grazing and ungulates rutting caused large gaps in the coastal goldenbush community. These gaps were then invaded by non-native grasses, inhibiting Castilleja mollis from making root connections with the goldenbush host plant. (USFWS, 2007)

**Stressor:** Non-native plants (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Competition with non-native plant taxa was also identified as a threat to Castilleja mollis in the final recovery plan (U.S. Fish and Wildlife Service 2000). Castilleja mollis is forced to compete with the invasive annual grasses for water and nutrients. This competition weakens the paintbrush, which may contribute to the failure of seedlings to make root connections with the goldenbush host plant (McEachern 2004a). (USFWS, 2007)

**Stressor:** Soil disturbance and trampling (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although all cattle have been removed from Santa Rosa Island and deer numbers have decreased, elk numbers have increased since 2001 (see Figures 2 and 3). This is believed to be a continuing factor hindering Castilleja mollis recovery on the island (McEachern 2003). (USFWS, 2007)

**Stressor:** Habitat fragmentation (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Past habitat fragmentation that occurred as a result of grazing and trampling is still considered a major threat to the species. (USFWS, 2007)

**Stressor:** Predation (USFWS, 2007)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** The listing rule also noted cattle herbivory as a problem for the species, but cattle were removed from Santa Rosa Island in 1998. Cattle removal and the reduction in the number of deer have, so far, not resulted in substantial improvements in Castilleja mollis. (USFWS, 2007)

**Stressor:** Soil disturbance and trampling (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Trends in the number of inflorescences and percent cover suggest that a large-scale event, such as weather, may also influence flowering and growth (McEachern, in litt. 2006b; McEachern, pers. comm. 2006c). (USFWS, 2007)

**Stressor:** Stochastic events (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Due to the small population size of this species, the listing rule noted that Castilleja mollis would be vulnerable to stochastic events (including variable weather patterns such as drought), reduced genetic integrity of the species, and depressed reproductive vigor (62 FR 40957). (USFWS, 2007)

**Stressor:** Climate change (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Changes in climate could threaten C. mollis in several ways. First, as vegetation shifts with climate change, the species might not be able to disperse to suitable germination or recruitment habitat, as is predicted to happen to island annuals (Levine et al. 2008 p. 796). Second, the proper combination of environmental cues for germination could occur less frequently or not at all, decreasing germination and causing declines in abundance and possible extirpations (Levine et al. 2008 pp. 800–805; Levine et al. 2011 pp. 2241–2246). Expected climate change for the geographic region of the islands predicts both rising annual temperatures (Langridge 2018 pp. 13–15) and less frequent, more episodic rainfall (Langridge 2018 pp. 16–17). Preliminary analysis of demography and environmental data (HasenstabLehman et al. 2022) show that the C. mollis individuals have lower survival in hotter years, with Jaw Gulch plants more negatively affected by higher temperatures than are Carrington Point plants, so climate change induced temperature rise is a threat to the species. Additionally, the species is found at less than 20 meters or 66 feet elevation. Sea level may rise by about 0.25 m (1 ft) by 2050 (Sweet et al. 2022 p. 19) and 1.0 m (3 ft) by 2100 (Sweet et al. 2022 p. 23). The low elevation habitat in which C. mollis is found is largely unprotected from the effects of rising sea level, and at least the lowest elevation plants might be threatened by inundation or removal by wave action in the future. Another prediction with increasing annual temperature in California is an increasing dominance by non-native annual grasses (Sandel and Dangremond 2012, entire) in certain situations. If nonnative grass cover increases further, the presumed competitive effects of increased grass cover would further threaten C. mollis. (USFWS, 2023)

**Stressor:** Increased visitor use (USFWS, 2023)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Implementation of the preferred alternative in the Channel Islands General Management Plan (2015, pp. 165–173) would facilitate easier visitor access to the backcountry of Santa Rosa Island. If this results in increased hiker use of the relatively level and scenic marine terraces of the Jaw Gulch area, the genetically distinct and possibly declining population of C. mollis there could be detrimentally impacted by trampling by hikers or unauthorized camping in the area. Additionally, at Carrington Point the species has been recently found on both sides of a popular hiking trail (K. McEachern pers. comm.), and could be trampled by hikers. The final impact of increased visitor use will likely be determined by the CINP Backcountry Wilderness Management Plan, which is under development, and until it is finalized, the magnitude of the threat of increased visitor use to the species is unknown (USFWS, 2023).

**Stressor:** Insect damage to inflorescences (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since introduced in the 2007 5-year review, no further work has been done on the effects of insect damage to C. mollis inflorescences, and the magnitude of this threat remains (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
1. Maintain the existing distribution with multiple colonies in each population on Santa Rosa Island. (USFWS, 2000)

2. Maintain stable or increasing population trends with evidence of natural recruitment for a period of 15 years that includes the normal precipitation cycle. (USFWS, 2000)

3. Damage from normative mammals significantly reduced. (USFWS, 2000)

Recovery Priority Number: 2

**Delisting Criteria:**
1. Expansion of individuals into potential habitat within population boundaries. (USFWS, 2000)

2. No decline after downlisting for 10 years. (USFWS, 2000)

3. All potential habitat surveyed.

**Recovery Actions:**
- Provide protection and adaptive management of currently known (and in some cases historic) sites. (USFWS, 2007)
- Provide evidence that the populations at these sites are stable or increasing over a number of years, which is determined by the life history of the individual species. (USFWS, 2007)

- Support and intensify active control programs where herbivory or habitat alteration by alien animals exists. (USFWS, 2007)
- Develop and implement a plan to achieve the goals and standards of the Conservation Strategy. (USFWS, 2007)
- Seed is stored in Center for Plant Conservation cooperating facilities. (USFWS, 2007)
- Seed germination and propagation techniques are understood. (USFWS, 2007)
- Successful outplanting techniques are developed. (USFWS, 2007)
- Host plant and weed management plan are developed and implemented. (USFWS, 2007)
- Life history research is conducted that aids in the conservation and recovery of the species. (USFWS, 2007)
- Hybridization with Castilleja affinis is understood. (USFWS, 2007)
- If declining, determine the cause and reverse trend. (USFWS, 2007)
- Because the removal of cattle and the reduction in deer have had a positive effect on seedling recruitment, the program to eliminate ungulates from the island by 2011 should continue as planned. (USFWS, 2007)
- During the time that the special use permits are in effect, if targeted hunting of deer and elk is no longer effective, the NPS should consider other actions to reduce the threats of these animals to the species. (USFWS, 2007)
- Based on the reports produced by the Scientific Panel, indeterminate threats, in addition to ungulate herbivory, scraping and general presence are contributing to the decline in the amount of inflorescence and percentage cover of Castilleja mollis. Therefore, other parameters that influence the species' ability to recover should be tracked at both locations where the species is found. In particular, the following monitoring actions are recommended: (a) monitor community species composition and cover to indicate whether the habitat is improving; (b) monitor rate of hybridization with Castilleja affinis to understand the level of threat this poses on recovering the species; (c) monitor damage to inflorescence, stems, and leaves caused by insects; (d) monitor the number of plants, or seedlings and juveniles within the populations; and (e) monitor the rate of erosion using soil depth/amount of litter. (USFWS, 2007)
- The following downlisting measures outlined in the recovery plan should be implemented: (1) seed storage in a Center for Plant Conservation facility, and (2) development and implementation of host plant and weed management actions. (USFWS, 2007)
- To secure several populations of Castilleja mollis containing a minimum of 2,000 plants each, efforts should focus on restoring coastal goldenbush scrub habitat so that there is reduced fragmentation within populations of Castilleja mollis on the island. (USFWS, 2007)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Continue demographic monitoring of the two populations of C. mollis, and analyze longterm demographic and environmental monitoring data to determine trends. 2. Use morphological characters from the genetic study to define the geographic edges of the C. mollis populations. 3. Map the distribution of plants within the populations, including plants outside of the demography plots. 4. Augment current populations, especially Jaw Gulch, expand current populations, and establish new populations in areas above sea level rise effects. 5. Collect confirmed C. mollis seed from both populations for accession in conservation seed banks. 6. Ensure that visitor use does not impact C. mollis at the Jaw Gulch and Carrington populations (USFWS, 2023).

# SPECIES ACCOUNT: *Castilleja ornata* (swale paintbrush)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered

**Physical Description**

Herbs, annual, 1.7–3.5(–5) dm; with a thin taproot or fibrous root system. Stems solitary or few to several, erect or ascending, often branched low on stem, unbranched distally, hairs appressed or retrorse, medium length, soft, eglandular, mixed with shorter stipitate-glandular ones. Leaves green or purple-tinged, proximal forming a rosette, linear-lanceolate to oblong or oblanceolate, 2–4 cm, not fleshy, clasping, margins wavy, sometimes plane, involute, 0-lobed, apex acuminate, acute, or obtuse. Inflorescences 3–24 × 1.5–3 cm; bracts proximally green, distally white, sometimes very pale yellow, often aging dull pink or dull redpurple, spatulate, 0-lobed, sometimes seeming lobed due to wavy margins, apex obtuse to rounded. Calyces green throughout or distal margin white aging pink, 15– 17 mm; abaxial and adaxial clefts 6–14 mm, 35–45% of calyx length, deeper than laterals, lateral 0(–0.7) mm, 0(–5)% of calyx length; lobes short-triangular, abaxial segments longer than adaxials, apex acute to obtuse or rounded. Corollas slightly curved, 22–24 mm; tube 10–13 mm; beak exserted, adaxially green, 5–10 mm; abaxial lip pale greenish, reduced, pouches 3, 0.5–1.5 mm, 5–10% as long as beak; teeth slightly incurved, reduced, pale greenish to white, 0.3–0.7 mm. 2n = 24 (Figure 2-1) (Egger et al., 2019, “Castilleja ornata”). Elevations of the known habitats for the species range from approximately 1,500–2,300 meters (m) (4,920–7,550 feet (ft)). Precipitation follows a bimodal pattern throughout the range, with approximately two-thirds of annual precipitation occurring during the summer monsoon period (June–August) and the remainder occurring primarily in winter (NatureServe 2021a, unpaginated). The historically documented range extent of C. ornata is approximately 587 kilometers (km) (365 miles (mi)). (USFWS, 2023).

**Taxonomy**

astilleja ornata is a member of the Orobanchaceae (broomrape) family. This is a family of parasitic plants, and the Castilleja genus is hemi-parasitic (Freeman et al. 2019, “Orobanchaceae”; Egger et al. 2019, “Castilleja”), meaning that Castilleja species can survive, but usually not thrive, without acquiring nutrients and/or other chemicals from the roots of host plants (Granados-Hernández et al. 2020, pp. 152–153). The genus Castilleja includes over 200 species (approximately 170 species are perennial) that occur in North America, Andean South America, Central America, and northern Asia (Tank et al. 2009, pp. 182–183, 186; Egger et al. 2019, entire). Within the genus, C. ornata belongs to a unique assemblage of Mexican Castilleja species, known as the Macrostigma group, which also includes C. sphaerostigma, C. macrostigma, C. angustata, and C. hidalgensis. Except for C. ornata, which also occurs in portions of the United States, each of the five species is endemic to different portions of central and northern Mexico and is unique in morphology, ecology, and distribution (Egger 2002, pp. 193, 195). The currently accepted classification is (Integrated Taxonomic Information System 2022, unpaginated): Domain: Eukaryota Kingdom: Plantae Division: Tracheophyta Class: Magnoliopsida Order: Lamiales Family: Orobanchaceae Genus: Castilleja Mutis ex L.f. Species: Castilleja ornata (Eastwood 1909) Common name: swale paintbrush, Glowing Indian paintbrush, or ornate paintbrush (USFWS, 2023)

**Historical Range**

The Swale Paintbrush was historically documented from 13 sites in the United States and Mexico, spanning a range extent of approximately 587 kilometers (km) (365 miles (mi)): 2 sites in the Animas Valley of Hidalgo County, New Mexico, and 11 sites in the eastern Sierra Madre Occidental of Chihuahua and northern Durango in Mexico. Currently, only one site—the Gray Ranch site in the Animas Valley of Hidalgo County, New Mexico—is known extant; the species was last observed at this site in 2021. The status of historically collected sites at the Cowan Ranch in New Mexico and in the eastern Sierra Madre Occidental of Mexico is unknown. The last observations of these historical sites were 1993 in New Mexico and 1985 in Mexico. (USFWS, 2024).

**Current Range**

Currently, only one site—the Gray Ranch site in the Animas Valley of Hidalgo County, New Mexico—is known extant; the species was last observed at this site in 2021. The status of historically collected sites at the Cowan Ranch in New Mexico and in the eastern Sierra Madre Occidental of Mexico is unknown. The last observations of these historical sites were 1993 in New Mexico and 1985 in Mexico. (USFWS, 2024).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Cross-pollination (Likely insect pollinated)

**Lifespan**

Adult: Annual plant

**Breeding Season**

Adult: Earliest flowering specimens are from late May to early June (USFWS, 2023)

**Other Reproductive Information**

Adult: Swale Paintbrush relies on cool season precipitation, monsoon precipitation, and a suitable surface/subsurface hydrology to complete its life cycle and maintain its seedbank. Thus, this species is sensitive to natural or artificial drought. Artificial drought may occur when upslope obstacles to, or diversions of, surface and near-surface flows starve downslope areas that would have otherwise received those flows (Raiter et al. 2018, pp. 445–446; Roth 2020, p. 5; Nichols and Degginger 2021, entire). (USFWS, 2024)

**Reproduction Narrative**

Adult: Since C. ornata is an annual plant and Castilleja seed longevity is not documented at greater than two years in the wild, frequent replenishment of seedbanks is essential to population persistence. Replenishment of viable seed requires flower production, ovule fertilization, ovule maturation, and seed dispersal. Flower production and ovule maturation require adequate growing conditions (see section 2.4.2 – Establishment and Growth), and ovule fertilization likely requires pollinators (Sun Kim et al. 2019, p. 11; Clark 2015, pp. 43–44; Kaye and Lawrence 2003, p. 11). Further, seed fitness—which increases with increased genetic diversity— requires population abundance in addition to pollinators for outcrossing (Clark 2015, p. 44; Paschke et al. 2002, pp. 1252, 1255–1257). Castilleja ornata's breeding system has not been studied. While the genus Castilleja includes both self-incompatible and self-compatible species, the majority of studied Castilleja taxa are mostly to entirely self-incompatible and reliant on insects and/or birds to transport pollen between genetically unique plants (Sun Kim et al. 2019, p. 11; Clark 2015, pp. 43–44; Kaye and Lawrence 2003, p. 11). While autogamous Castilleja species (species with flowers capable of fertilizing themselves) tend to be pale-bracted, not all pale-bracted species are autogamous; since C. ornata has an exserted stigma (a stigma physically separated from its anthers), it is likely also self-incompatible. Castilleja ornata's pollinators are unknown, and potential pollinators include bumblebees (Bombus spp.), sweat bees (family Halictidae), hummingbirds (family Trochilidae), and thrips (order Thysanoptera) (Duffield 1972, pp. 110–111; Clark 2015, pp. 27–28, 65). Hummingbirds are thought to primarily pollinate Castilleja species with red floral bracts, so insects are presumed to be the primary pollinators for Castilleja species with yellow floral bracts (Duffield 1972, pp. 110–111, 113). Wind pollination is unlikely because stamens are protected from wind by floral tubes. Successful reproduction is supported by healthy populations of local native pollinators. Pollinators, in turn, must be sustained by abundant, diverse, and reliable sources of native nectar and pollen plants (USFWS, 2023).

**Habitat Type**

Adult: Grasslands (USFWS, 2023)

**Environmental Specificity**

Adult: Elevations of the known habitats for the species range from approximately 1,500–2,300 meters (m) (4,920–7,550 feet (ft)) (USFWS, 2023).

**Habitat Narrative**

Adult: Castilleja ornata is native to grassland ecosystems (plains and great basin grassland biotic communities) of southwest New Mexico in the United States and of the eastern Sierra Madre Occidental of Chihuahua and Durango in Mexico (Figure 2-2; McIntosh 1994, p. 329; Brown 1994, pp. 115–121). Elevations of the known habitats for the species range from approximately 1,500–2,300 meters (m) (4,920–7,550 feet (ft)). Precipitation follows a bimodal pattern throughout the range, with approximately two-thirds of annual precipitation occurring during the summer monsoon period (June–August) and the remainder occurring primarily in winter (NatureServe 2021a, unpaginated). The historically documented range extent of C. ornata is approximately 587 kilometers (km) (365 miles (mi)). (USFWS, 2023)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Information about seed dispersal for C. ornata is incomplete. Most seeds are likely shaken from seed capsules by wind and settle to the ground within a short distance of the parent plant (Godt et al. 2005, p. 88). The seeds are light (averaging 0.052 milligrams [mg] per seed, or 19,200 seeds per gram) and could possibly be dispersed short to moderate distances by wind (Service 2021, unpaginated). Additionally, insects and small mammals likely contribute to local seed dispersal (Kolar and Fessler 2006, in litt.). While rare, long-distance dispersal events are also possible for Castilleja species (Tank and Olmstead 2009, p. 1917), natural colonization of new sites likely primarily occurs as the result of a series of short dispersals over time (USFWS, 2023)

***Population Information and Trends***

**Resiliency:**

low resiliency (USFWS, 2023)

**Representation:**

Limited representation (USFWS, 2023)

**Redundancy:**

Lack of redundancy (USFWS, 2023)

**Number of Populations:**

1 Extant (USFWS, 2024)

**Population Narrative:**

Currently, only one site—the Gray Ranch site in the Animas Valley of Hidalgo County, New Mexico—is known extant; the species was last observed at this site in 2021. The status of historically collected sites at the Cowan Ranch in New Mexico and in the eastern Sierra Madre Occidental of Mexico is unknown. The last observations of these historical sites were 1993 in New Mexico and 1985 in Mexico (USFWS, 2024).

# SPECIES ACCOUNT: *Caulanthus californicus* (California jewelflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 07/19/1990; California/Nevada Region (R8) (USFWS, 2015)

**Physical Description**

Caulanthus californicus is a glabrous decumbent to erect often branched annual, with whitish petals and spherical seeds. Leaves are less than 11 millimeters (mm) (0.4 inch (in.)) in length and are shallowly cut to wavy-dentate and tapered. Calyx petals (outer whorl) are generally spreading, 4–10 mm (0.15–0.4 in.) in length, maroon, keeled, and darker in bud stage. Corolla petals (inner whorl) are 6–11 mm (0.2–0.4 in.) long and whitish, with wavy margins (Buck 1993). (USFWS, 2013)

**Taxonomy**

USFWS tracks as synonym 01 - Caulanthus Californicus (8/93). (NatureServe, 2015)

**Historical Range**

Originally in San Joaquin and adjacent valleys. Once fairly abundant in appropriate habitat in Fresno, Kern, King, Santa Barbara, San Luis Obispo and Tulare counties. (NatureServe, 2015)

**Current Range**

Appears to be currently extant in Fresno, Kings, Kern, and Santa Barbara Counties (CalFlora Occurrence Database website Feb. 2, 2000). Extirpated from Kings County, but present in San Luis Obispo County (CNPS Inventory, 2001). (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 1998)

**Habitat Narrative**

Adult: Extant populations of California jewelflower occur in Nonnative Grassland, Upper Sonoran Subshrub Scrub, and Cismontane Juniper Woodland and Scrub(E. Cypher unpubl. data). Historical records suggest that California jewelfiower also occurred in the Valley' Saltbush Scrub community in the past (CDFG 1995).  Herbaceous cover was dense at most California jewelfiower sites studied in 1993 (Cypher 1994a). Native plant species, such as annual fescue (Vulpia microstachys), clovers (Trifolium spp.), red maids (Calandrinia ciliata), and goldfields (Lasthenia californica) comprised a high proportion of the vegetation at many' of the known locations over several years. The exotic grass red brome (Bromus madritensis ssp. rubens) was a significant component of the vegetation only at the Carrizo Plain sites (Taylor and Davilla 1986, Lewis in litt. 1993, Cypher 1994a, E. Cypher unpubl. data). On the Carrizo Plain. California jewelfiower occurred primarily on the burrow systems of giant kangaroo rats (Dipodamvs ingens), another endangered species (Cypher 1994a). Populations of California jewelflower have been reported from elevations of approximately 75 to 900 meters (240 to 2,950 feet) and from level terrain to 25 percent slopes. Soils at known sites are primarily subalkaline, sandy loams (CDFG 1995, Taylor and Davilla 1986, Lewis in litI. 1993) (USFWS, 1998).

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**
Decline (NatureServe, 2015)

**Population Growth Rate:**
Slowly declining (NatureServe, 2015)

**Number of Populations:**
37 (USFWS, 2020)

**Population Narrative:**
At the time of listing (1990), California jewelflower was known from three localized areas: the mouth of Santa Barbara Canyon in Santa Barbara County, the southern portion of the Carrizo Plain in San Luis Obispo County, and the Paul Paine Preserve (owned by The Nature Conservancy) in Kern County (Service 1990). At the time of our 2013 status review, there were 34 presumed extant occurrences: one introduced occurrence in Kern County; 7 occurrences in Santa Barbara County; 22 occurrences in San Luis Obispo County; 3 occurrences in Fresno County; and 1 occurrence in Kings County. A summary of past and current distribution can be found in Table 1 below. Four occurrences (numbers 81, 82, 83, and 84) have been added to the Diversity Database since our 2013 review (Diversity Database 2020). All four of these occurrences are in Kern County and do not extend the range of the species. The status of the one remaining extant occurrence in Kings County (occurrence number 5) has been changed to “possibly extirpated” since our last review. Table 1 in Appendix A summarizes the number of occurrences over time. Currently, there are 37 Diversity Database occurrences that are presumed extant. (USFWS, 2020)

***Threats and Stressors***

**Stressor:** Urbanization (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing the primary threats to C. californicus were the ongoing and threatened destruction and adverse modification of habitat due to agricultural land conversion and urbanization on the San Joaquin Valley floor (Service 1990). Non-urbanized or non-converted lands, which largely occurred in the neighboring foothills and valleys, were subject to livestock grazing, oil and gas exploration and development, off-road vehicle use, and mining (Service 1990). (USFWS, 2013)

**Stressor:** Agriculture (USFWS, 2013)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The CVP supplies water to more than 250 long-term water contractors in the Central Valley, Santa Clara Valley, and eastern San Francisco Bay Area. Agricultural conversions and related operations either directly or indirectly facilitated by the CVP include: conversion of native habitats to agricultural fields; conversion of land use to more water intensive purposes; disposal of agricultural drain water; application of pesticides; and other mowing and harvesting operations. Agricultural conversion and related operations have contributed to the loss and degradation of several habitat types, including grasslands and alkali scrub associated with declines of multiple listed species (Service 1998). (USFWS, 2013)

**Stressor:** Mining (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mining presented a threat to C. californicus (Service 1990). On the Carrizo Plain National Monument (Monument), only valid leases, claims and other rights that existed as of the date of the Proclamation, January 17, 2001, may see mineral development on federal lands within the Monument (BLM 2010). (USFWS, 2013)

**Stressor:** Oil and Gas Exploration and Development (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, oil and gas exploration and development presented a threat to C. californicus (Service 1990). Adverse effects of oil and gas development on C. californicus include the loss of habitat, changes in habitat quality, destruction of individuals or populations and their seed bank, habitat fragmentation, and increased competition from nonnative plant species due to habitat degradation. (USFWS, 2013)

**Stressor:** Off-road Vehicle Use (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, off-road vehicle use presented a threat to C. californicus (Service 1990). Off road vehicle use has been reported as a minor threat potentially affecting 7 occurrences on the Carrizo Plain National Monument where no off-road motorized or mechanized travel is legally permitted (BLM 2010). (USFWS, 2013)

**Stressor:** Solar Power Development (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, solar power development did not present a threat to C. californicus. Solar power development projects pose potential threats to and may impact large amounts of habitat. These projects can destroy, fragment, or impact C. californicus habitat by: altering landscape topography, vegetation, and drainage patterns; and reducing habitat quality

through interception of solar energy normally reaching the ground surface, affecting ambient air temperatures through habitat shading, and altering soil moisture regimes (Smith 1984; Smith et al. 1987 as cited in J.R. Single 2010). Moreover, recently proposed solar projects tend to be large contiguous blocks of disturbance in undeveloped habitat lands, ranging from hundreds to several thousand acres. (USFWS, 2013)

**Stressor:** Predation (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, domestic livestock predation was thought to have extirpated colonies of C. californicus (Service 1990). On the Carrizo Plain, C. californicus is known to occur within and around the precincts or burrows of the endangered giant kangaroo rat (Dipodomys ingens). Giant kangaroo rats apparently seek out C. californicus, because stems of this species were clipped with equal frequency both on precincts (circular areas with a concentration of giant kangaroo rat burrows) and in interspaces of giant kangaroo rat burrows; however, directed research exploring interactions of plant and animal species in the community should be completed (Cypher 1994). (USFWS, 2013)

**Stressor:** Grazing (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Domestic livestock grazing has been used to reduce grass and forb competitors in endangered plant habitats; however, the use of domestic livestock grazing to benefit native plant species has had mixed results (Vesk and Westoby 2001; Floyd et al. 2003; Kimball and Schiffman 2003). Direct effects from cattle grazing are reported to be detrimental because cattle seek out and show preference for eating the plant (Service 1998). The habitat of C. californicus in Fresno County is grazed after the dispersal of its seeds in late spring and prior to the new growth of its basal rosettes in late winter. (USFWS, 2013)

**Stressor:** Competition from Nonnative Grasses (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The southern San Joaquin Valley of California, as with much of western North America, has been invaded by nonnative plant species during the past 100 to 200 years. These include the following species: Bromus rubens (red brome), Vulpia myuros (mouse tail fescue), Schismus arabicus (Arabian grass), Hordeum murinum ssp. glaucum (known locally as foxtail and elsewhere as smooth barley), Bromus diandrus (ripgut brome), and Bromus hordeaceus (soft chess) (Biswell 1956; Germano et al. 2001). Individual invasive species could modify ecosystem properties (Gordon 1998). (USFWS, 2013)

**Stressor:** Competition from Nonnative Plant Species Due to Fire Retardant Application (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Another threat to California jewelflower is invasion and competition from nonnative plant species; this threat could be exacerbated by the application of fire retardant, which can act as a nutrient source for nonnative invasives. California jewelflower habitat includes slightly alkaline sandy loams; the low nitrogen levels of these soil conditions are unfavorable for nonnative, which in turn provides a competitive advantage to species, such as the jewelflower, which have adapted to the nutrient-poor environment. Nitrogen and phosphorus could be increased in the soil through the application of ammonium-based retardants. (USFWS, 2013)

**Stressor:** Nitrogen Deposition (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Nitrification of soil was not considered a threat at the time of listing C. californicus, but should currently be considered a threat. There is little information regarding C. californicus and soil nitrogen levels in which it occurs (B. Delgado, BLM pers. comm. 2011), however some adverse soil conditions (low nutrients, low water holding capacity) exert stress on plant species and can reduce competition, particularly for species that are not tolerant of the soil stress factors (R. O'Dell pers. comm. 2011). Human activities have increased nitrogen availability throughout terrestrial systems (Suding et al. 2005). Three major producers of nitrogen emissions are transportation, agricultural production, and industrial activities including electricity production (Spiegel 2003). (USFWS, 2013)

**Stressor:** Pollinators (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, the declines in the pollinators of all descriptions were not considered a threat to C. californicus. Since that time, the reduction to the population of the non-native honeybee (Apis mellifera), often referred to as colony collapse disorder, has been well documented. Native insects may pollinate the C. californicus, however a reduction in their abundance has been observed as well (United States 2007). (USFWS, 2013)

**Stressor:** Genetic Diversity (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Loss of genetic diversity was not considered a threat at the time of listing C. californicus. However, considering the reduction of the range of the C. californicus and fragmentation of habitat, lack of cross pollination between populations of the remaining localities may be a future threat. This may result in the loss of genetic diversity, which may reduce the adaptability of the plant to current and future environmental conditions and also increases the threat of inbreeding depression. Loss of genetic diversity and adaptability is likely to reduce the long-term survival of plant species (Huenneke 1991). (USFWS, 2013)

**Stressor:** Climate Change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Climate change was not considered a threat to C. californicus at the time of listing; however, climate change is a potential threat to the species. Projected California temperature rise estimates range from an increase of 1.7° Celcius to 5.8° Celcius (3.0° Fahrenheit to 10.4°Farhenheit) for years 2000 - 2100 (Cayan et al. 2006). Climate change has the potential to alter the timing and synchronicity of ecosystem processes. The interactions between flower production and insect availability for pollination may be altered (Field et al. 1999; Cayan et al. 2006). Changes in temperature and precipitation likely will alter the structure, composition, and productivity of vegetation communities and wildfire may become more frequent and intense (Lenihan et al. 2006). (USFWS, 2013)

***Recovery***

**Reclassification Criteria:**
1. Secure and protect specified recovery areas from incompatible uses on ninety-five percent of occupied habitat on public lands; 75 percent of population and occupied habitat in Santa Barbara Canyon. (USFWS, 2013)

2. Management Plan approved and implemented for recovery areas that include survival of the species as an objective for all protected areas identified as important to continued survival. (USFWS, 2013)

3. Population monitoring for specified recovery areas shows that the populations are stable or increasing through the normal precipitation cycle. (USFWS, 2013)

**Delisting Criteria:**
Delisting criteria is not available.

**Recovery Actions:**
- Surveys will be necessary to determine whether natural populations remain in all target areas. (USFWS, 1998)
- Unoccupied habitat within metapopulations also should be protected to facilitate movement of pollinators and seed dispersers. (USFWS, 1998)
- The top-priority action for recovery of California jewelflower is to protect the plants on private land in Santa Barbara Canyon. (USFWS, 1998)
- Buffer zones of 150 meters (500 feet) or more should be protected beyond the population margins to reduce external influences and to allow for population expansion. (USFWS, 1998)
- Additional tasks are required to achieve recovery goals. These tasks include developing management plans, surveying for additional populations, banking seed, conducting research, and modeling population demographics using matrix projection modeling. (USFWS, 1998)
- Protection of extant populations and reintroductions as described in the 1998 Recovery Plan should be completed. Management on public lands should include provisions for suitable levels of sheep and cattle grazing. Protection of colonies on private lands or those to be re-established on private lands could result from partnering with landowners or offering conservation easements. (USFWS, 2013)
- Regular yearly surveys utilizing a standardized methodology should be conducted over the next five years at the Santa Barbara Canyon area in the Cuyama Valley in Santa Barbara

County, at the Carrizo Plain National Monument in San Luis Obispo County, and at the Kreyenhagen Hills in Fresno County so that the determination of what constitutes a sustainable population can be defined and environmental variables affecting abundance, such as precipitation and temperature, can be monitored. (USFWS, 2013)
- Successful re-establishment of populations will require an adequate understanding of the biology of the species and a robust seed collection. Studies should be conducted that advance the understanding of the species' propagation requirements, knowledge of the physical and chemical elements of the soil required for successful re-establishment, the presence and role of mutualistic soil fungi, the species and role of pollinators, genetics, and seed dispersal mechanisms. Seeds should be collected from each of the three sites and banked at an appropriate depository. (USFWS, 2013)
- Threats such as loss and degradation of habitat should be eliminated, reduced, or ameliorated. The potential for habitat degradation due to nitrogen deposition and threats to pollinators from regional pesticide use should be analyzed and appropriate measures to ameliorate these threats should be implemented. (USFWS, 2013)

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS: The following recommendations for future actions are from the 2013 5-year review (Service 2013), scientific literature, and as a result of discussions with species experts. 1. Protect existing habitat in the San Joaquin Valley for the California jewelflower. 2. A comprehensive evaluation should be completed for all known occurrences (both extant and extirpated). The site-specific evaluation should include, at minimum, whether the species is present, the estimated population/occurrence size, and an in-depth analysis of threats at that location. 3. Implement and/or continue yearly surveys utilizing a standardized methodology to determine trends in the range-wide status of the species as well as population/occurrence abundance. 4. Conduct studies that advance the understanding of the species' propagation requirements, knowledge of the physical and chemical elements of the soil required for successful reestablishment, the presence and role of mutualistic soil fungi, the species and role of pollinators, genetics, and seed dispersal mechanisms. 5. Analyze the potential for habitat degradation due to climate change and nitrogen deposition, as well as threats to pollinators from regional pesticide use. Appropriate measures to ameliorate these threats should be implemented. (USFWS, 2020)

# SPECIES ACCOUNT: *Ceanothus ferrisae* (Coyote ceanothus)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 02/03/1995; California/Nevada Region (R8) (USFWS, 2015)

**Physical Description**

An evergreen shrub, 1-2 m tall. Leaves are < 3.2 cm long, rounded, tapering towards the base. The leaves are opposite and round with a dark green, hairless upper surface and a lighter green undersurface with minute hairs (Schmidt 1993). Leaf margins have short teeth or sometimes lack teeth; the leaf base is abruptly tapering or rounded. Small white flowers are borne in clusters 1.3 to 2.5 centimeters (0.5 to 1.0 inch) in length (McMinn 1933; Schmidt 1993). (NatureServe, 2015; USFWS, 2011)

**Taxonomy**

USFWS and CAHP tracks as synonym 01 - Ceanthous ferrisiae (9/93). (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

At the time of listing and our 2011 5-year review, coyote ceanothus was only known from three locations in Santa Clara County, all within 6 km (4 miles) of each other (Service 1995, p. 6675; Service 2011). The current species distribution is similar to what was previously described, with three extant populations (Anderson, Llagas Road, and Kirby) distributed within an approximately 3-mile radius of Anderson Reservoir near the City of Morgan Hill (Vasey 2013, p. 1; CDFW 2021; Valley Water 2021, p. 4). The Kirby population and Anderson population are located on the eastern side of the Santa Clara Valley while the Llagas Road population occurs on the western side of the Santa Clara Valley. The 2011 5-year review further divided the Anderson population into two small subpopulations and one large population that are fragmented by Anderson Dam (Service 2011, p. 7). However, a genetic analysis conducted on all three extant populations did not support the dividing of the Anderson population into subpopulations (see Genetics subsection in the Coyote Ceanothus Population Creation Pilot Study section) (J. Hillman, Valley Water, in litt. 2013, p. 3; J. Hillman, Valley Water, in litt. 2021d; Potter 2012, p. 3; Honeycutt 2012, p. 5). There is an estimated 482 acres of occupied coyote ceanothus habitat range-wide: 400 acres in the Anderson population, 75 acres in the Llagas Road population, and 7 acres in the Kirby population (USFWS, 2023).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2011)

**Lifespan**

Adult: 20 to 50 years (USFWS, 2011)

**Breeding Season**

Adult: January to March (USFWS, 2011

**Key Resources Needed for Breeding**

Adult: Possibly fire; require multiple, large populations within close proximity to allow genetic migration to occur via pollination (USFWS, 2011)

**Reproduction Narrative**

Adult: Ceanothus ferrisae is a perennial, flowering from January to May (Munz and Keck 1959). Ceanothus reach reproductive maturity after 5- 6 years. Will hybridize with other species or sub-species in situations where only one plant exists or there is genetic incompatibility with surrounding plants of the same species. (USFWS, 2011). The role of fire in the ecology of this plant remains unclear. Fire appears to destroy all mature and older plants, and stimulate regeneration from soil seed banks. C. ferrisae require multiple, large populations within close proximity to allow genetic migration to occur via pollination. The average lifespan for this species is estimated to range from 20 to 50 years (Keeley 1975; T. Parker, pers. comm., 2010; D. Wilken, pers. comm., 2010). (USFWS, 2011)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Barrens, Shrubland/chaparral (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Possibly fire (USFWS, 2011)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations < 300 m (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Colonial (USFWS, 2011)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from USFWS, 2011)

**Dependency on Other Individuals or Species for Habitat**

Adult: Rare species associated with Ceanothus ferrisae include the federally listed bay checkerspot butterfly (Euphydryas editha bayensis), Santa Clara Valley dudleya (Dudleya setchellii), and most beautiful jewelflower (Streptanthus albidus ssp. peramoenus) (Evens and San 2004). It is also associated with bigberry manzanita (Arctostaphylos glauca), California coffee berry (Rhamnus californica), California sagebrush (Artemesia californica), common yarrow (Achillea millefolium), foothill pine (Pinus sabiniana), leather oak (Quercus durata), and toyon (Heteromeles arbutifolia) (Corelli 1991; Evens and San 2004). Fire appears to destroy all mature and older plants, and stimulate regeneration from soil seed banks. (USFWS, 2011)

**Habitat Narrative**

Adult: Ceanothus ferrisae grows on arid slopes in mixed serpentine chaparral, valley, and foothill serpentine bunchgrass grasslands below 300 meters (about 1,000 feet) (Munz and Keck 1959; Hickman 1993). C. ferrisae is found in colonies at the Llagas Road location (CNDDB, 2010). Rare species associated with C. ferrisae include the federally listed bay checkerspot butterfly (Euphydryas editha bayensis), Santa Clara Valley dudleya (Dudleya setchellii), and most beautiful jewelflower (Streptanthus albidus ssp. peramoenus) (Evens and San 2004). It is also associated with bigberry manzanita (Arctostaphylos glauca), California coffee berry (Rhamnus californica), California sagebrush (Artemesia californica), common yarrow (Achillea millefolium), foothill pine (Pinus sabiniana), leather oak (Quercus durata), and toyon (Heteromeles arbutifolia) (Corelli 1991; Evens and San 2004). (USFWS, 2011)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2011)

**Number of Populations:**

4 (USFWS, 2011)

**Population Size:**

>188,000 (USFWS, 2023)

**Minimum Viable Population Size:**

5000 (USFWS, 2011)

**Adaptability:**

Low (inferred from USFWS, 2011)

**Population Narrative:**

Two of the four existing occurrences of Ceanothus ferrisae have population sizes greater than 2,000 individuals (3,600 and > 100,000, respectively). Information available to the Service suggests a minimum population size of 5,000 may be necessary to maintain 95 percent fitness for plants (Reed 2005). A genetic Allee effect may occurring as a result of limited availability of genetically suitable pollen mates in small populations of plants, thereby decreasing reproductive rates and increasing the risk of extinction (Berec et al. 2006; Wagenius et al. 2007). The survival and recovery of existing C. ferrisae populations may be threatened by limited genetic diversity as a result of small or declining population size, habitat loss and fragmentation, and geographic isolation that may limit insect-mediated gene flow. (USFWS, 2011). At the time of listing fewer than 6,000 coyote ceanothus plants were known to exist, with the largest population (Anderson) estimated at approximately 5,000 plants (Service 1995, p. 6675). The 2011 5-year review estimated the Anderson population consisted of over >100,000 plants, the Kirby population at

150 plants, and the Llagas Road population at 600 to 650 plants (CDFW 2021; Service 2011, pp. 7–8) (Table 1). A 2011 survey of the Llagas Road population estimated the size at 1,000–2,000 plants (Table 1) (CDFW 2021). No additional surveys have been conducted to estimate the size of three populations of coyote ceanothus (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat destruction (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Destruction and modification of habitat, and development on recreational and private lands continues to be a threat for Ceanothus ferrisae. Construction of a commercial landfill at Kirby Canyon beginning in 1986 (prior to the listing of C. ferrisae in 1995) may have resulted in the undocumented loss of thousands plants, as evidenced by the decline of this population from 5,000 in 1987 to about 100 individuals observed in 1992 (Freas, pers. comm. 1993; LSA Associates 1992). The remaining population is currently threatened by altered fire regime and lack of recruitment. Proximity to the commercial landfill and urban development may limit or prevent the use of fire for regeneration. The Llagas Road population exists on private land that is nearly surrounded by residential development. Future development could result in increased encroachment upon existing habitat necessary for expansion of the Llagas Road population to meet recovery goals. The proximity of urban development may limit or prevent the use of fire to regenerate this population as well. (USFWS, 2011)

**Stressor:** Cattle grazing (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Cattle have been grazing on the property for many years and may be negatively affecting the habitat and limiting recruitment for the Llagas Road population. The unprotected portion of the property where cattle grazing is permitted is nearly denuded of native chaparral vegetation with large areas of exposed soil and serpentine rocks evident (F. Gardipee pers. obs., 2010; T. Willsey, pers. obs., 2010; J. Hillman, pers. obs., 2010). The cattle have gained access into the existing conservation easement through broken fencing thereby allowing them to browse on inflorescences of young C. ferrisiae plants before seed production can occur (F. Gardipee pers. obs., 2010; T. Willsey, pers. obs., 2010; J. Hillman, pers. obs., 2010). Heavy browsing by cattle and wild ungulates was observed among young, reproductive-age, plants during the fall 2010 survey at all sites (F. Gardipee pers. obs., 2010; T. Willsey, pers. obs., 2010; J. Hillman pers. comm., 2010). (USFWS, 2011)

**Stressor:** Dam activities (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The population located at Anderson Dam is threatened by loss and modification of habitat as a result of activities associated with the dam, actions to protect against damage from potential seismic activity, and un-regulated land management practices. Anderson Dam was constructed upon unstable materials and is positioned on a seismically active fault line (SCVHP

2010). (USFWS, 2011)

**Stressor:** Predation (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Several insect species have been noted to infest Ceanothus species in California and predation in the form of herbivory by native ungulates and seed consumption by small mammals, insects, and birds is common (Deveny and Fox 2006). The western tent caterpillar (Malacosoma californicum) is known to construct large web-like tents on the branches of Ceanothus species (USDA 2006). Larvae feed on the leaves within the tent, often defoliating entire branches (USDA 2006). The western tussock moth (Orgyia vetusta) has been reported on Ceanothus species (USDA 2006). Large masses of cocoons may be observed on branches in late spring. Western tussock moth larvae feed on leaves and young growth, sometimes causing substantial defoliation and branch dieback. The western sycamore borer (Synanthedon resplendens) may attack Ceanothus species (USDA 2006). Adults emerge in May through early August and lay eggs within cracks, depressions, and injured tissues in the bark of old or slow-growing plants (USDA 2006). After hatching, larvae tunnel into the inner bark, creating winding tunnels that extend over 100 square centimeters (about 15.5 square inches). The amount of Herbivory may retard plant growth, destroy plants, and often reduces seed production (Boyd 2003; Deveny and Fox 2006). Black-tailed deer (Odocoileus hemionus columbianus) are primary browsers of C. ferrisae (Deveny and Fox 2006). Herds of black-tailed deer make their home in the Anderson Dam area. Evidence of browsing on fresh shoots, inflorescences, and leaves of young C. ferrisae plants was observed among all populations surveyed in mid-July and fall 2010 (F. Gardipee, pers. obs., 2010; T. Willsey, pers. obs., 2010; J. Hillman, pers. obs., 2010). Damage caused by western sycamore borers is generally considered to be insignificant (USDA 2006). (USFWS, 2011)

**Stressor:** Genetic Allee effect (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A genetic Allee effect may occur as a result of limited availability of genetically suitable pollen mates in small populations of plants, thereby decreasing reproductive rates and increasing the risk of extinction (Berec et al. 2006; Wagenius et al. 2007). Habitat loss and fragmentation, small population size, and genetic isolation may increase the risk of a genetic Allee effect for self-incompatible species, such as Ceanothus ferrisae, and ultimately result in a subsequent loss of long-term population viability (Willi et al. 2005; Berec et al. 2006: Leimu et al 2006; Honnay and Jacquemyn 2007; Wagenius et al. 2007; Pickup and Young 2008). The subdivision of this population has resulted in possible isolation and reduced connectivity, thus increasing the risk of genetic Allee effects and decreased population viability. (USFWS, 2011)

**Stressor:** Fire management (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The proximity of Ceanothus ferrisae to residential development may preclude or limit the use of fire that may be necessary for stand regeneration. Further research regarding the role of fire for C. ferrisae is warranted to insure effective use of this management tool can be applied

to benefit the long-term conservation of this species. (USFWS, 2011)

**Stressor:** Global climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, altered fire regimes, and increased summer continental drying (Field et al. 1999; Cayan et al. 2005; IPCC 2007). However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. However, climate change may exacerbate the effects of altered fire regimes on population viability of Ceanothus species endemic to California (Lawson et al. 2010). (USFWS, 2011)

**Stressor:** Fungal Pathogens (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** As mentioned previously, diseases were not considered a threat to the coyote ceanothus at the time of listing or the 2011 5-year review (Service 1995; Service 2011, p. 12). However, Fusarium oxysporum, a widespread taxa of fungus with both pathogenic and non-pathogenic strains, was identified as a potential weak root pathogen of nursery-grown coyote ceanothus as was observed during a wound inoculation test on terminal shoots for the coyote ceanothus population creation pilot study (Table 1) (Valley Water 2021, pp. 21–22). Although Fusarium proliferatum, another common fungal pathogen, was detected on the roots of coyote ceanothus that died at the introduction site along Coyote Ridge in the summer 2020 (Table 1), this taxa was not thought to be the cause of the die off based on the low virulence observed in a wound inoculation test on terminal shoots for the coyote ceanothus (Valley Water 2021, pp. 21–22). There is not sufficient data available to determine whether F. oxysporum or F. proliferatum is a threat to the health of coyote ceanothus in the wild (Valley Water 2021, p. 22). Botrytis, a common fungal pathogen that can be a problem under cool and moist conditions, was detected on coyote ceanothus container plants prior to outplanting at the introduction site on Coyote Ridge in late 2017 (Table 1); these infected seedlings exhibited leaf necrosis and wilted shoot tips (Valley Water 2021, p. 22). There is not sufficient data available to determine whether Botrytisis a threat to the health of coyote ceanothus in the wild; however, Valley Water is implementing measures to reduce the risk of spread (USFWS, 2023).

**Stressor:** Fire (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, fire was not considered to play an important role in the ecology of the coyote ceanothus and was considered a potential threat to the persistence of the species (Service 1995). However, the Recovery Plan and the 2011 5-year review identified an altered fire regime as a threat to the coyote ceanothus and reported the lack of natural recruitment without fire (Service 1998, pp. II-36, II-38, and II-39; Service 2011, pp. 17–18). An altered fire regime due to fire suppression continues to be a significant threat to the coyote ceanothus and a lack of fire is considered one of the biggest threats to the Llagas Road population (J. Hillman, Valley Water, in litt. 2021f). Valley Water observed the senescence of larger coyote ceanothus shrubs with a lot

of old, woody growth and dead branches on many of the larger plants in the Llagas Road population and recommended prescribed burning to remove dead wood and grass thatch, and promote the recruitment of new plants (J. Hillman, Valley Water, in litt. 2021f). Germination experiments at Stanford University demonstrated that under the right conditions coyote ceanothus can germinate without fire, but recruitment is less frequent and less abundant without fire (Service in litt. 2020a; J. Hillman, Valley Water, in litt. 2021c; Service 1998, p. II-36). As stated previously, there has been some natural recruitment of coyote ceanothus observed in the absence of fire above a perennial stream in the Kirby population, commonly along the exposed areas of the reservoir shoreline in the Anderson population, and many times over the years in the Llagas Road population (Valley Water 2021, pp. 29–30; J. Hillman, Valley Water, in litt. 2021d). In addition to a lack of fire, the species could also be threatened if fires occurred too frequently and increasing summer aridity is predicted to increase wildfire frequency and severity in the San Francisco Bay Area (see the Climate Change section below) (Williams et al. 2019, p. 892; Westerling 2018; Ackerly et al. 2018, p. 30, Figure 10). Additionally, the accumulation of biomass from invasive grasses in coyote ceanothus habitat facilitated by atmospheric N deposition increases the frequency and severity of wildfires (Rao et al. 2010 cited in Fenn et al. 2010, p. 2409; S. Weiss, Creekside Science Center for Earth Observation, in litt. 2021) (USFWS, 2023).

**Stressor:** Climate Change (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of the 2011 5-year review, climate change was identified as a potential threat to the coyote ceanothus, but due to the uncertainty in predictions of climatic conditions for smaller subregions such as California, the Service lacked adequate information to make accurate predictions regarding its effects on the coyote ceanothus (Service 2011, p. 18). There is consensus that the increase in greenhouse gas emissions during the 20th century resulted in global climate change characterized by: warming atmospheric and ocean temperatures, diminishing snow and ice, and rising sea levels (Intergovernmental Panel on Climate Change 2014, pp. 2–3). While the influence of climate change on these highly localized features of the San Francisco Bay Area climate is poorly understood at this time, there is general agreement about increasing temperatures and increasing interannual variability of precipitation (Ackerly et al. 2018, pp. 6, 13). Further, warming near the San Francisco Bay Area coast will be affected by changes in fog and sea breeze (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
1. Protection and management of the four known occurrences of Ceanothus ferrisae by working with Santa Clara County, the SCVWD, and private landowners to ensure long-term survival of the species on their lands. (USFWS, 2011)

2. Survey of other potential serpentine habitats to identify potential habitat. (USFWS, 2011)

3. Seed collection and research. Collection and banking of seed in Center for Plant Conservation certified botanic gardens is prudent to guard against extinction of the species from catastrophic events and to provide potential material for enhancement efforts in existing populations,

repatriations, and/or introductions to new sites. All known populations should be represented in seed collections. Care should be taken to ensure that seed collection does not adversely affect the donor populations. (USFWS, 2011)

4. Research on demography, fire ecology, and effects of grazing. Important research questions include how grazing impacts the reproduction, recruitment, and survival of the species, and why so little recruitment is observed in natural populations. (USFWS, 2011)

5. Establishment of new populations to meet recovery goal of eight populations representing the entire historic range. Ceanothus ferrisae should not be considered for delisting unless eight populations, consisting of at least, 2,000 individuals, within its historic range and representing its entire historic range. (USFWS, 2011)

Recovery Priority Number: 14

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**
- Recovery actions are not available.
- Habitat conservation to support the survival and recovery of Ceanothus ferrisae should be accomplished through land acquisition and establishment of conservation easements where possible. Protection of C. ferrisae populations on private lands through additional conservation easements and land purchases, and restoration of additional populations within the historic range should be prioritized to minimize the likelihood of extinction. (USFWS, 2011)
- Research that will inform management decisions, conservation planning, and restoration efforts for Ceanothus ferrisae should be conducted. (USFWS, 2011)
- Establishment of additional Ceanothus ferrisae populations where appropriate serpentine chaparral habitat has been identified in the proposed SCVHP. Restoration efforts should target habitat sites that can support a minimum population of at least 5,000 individuals. (USFWS, 2011)
- Enhancement and regeneration of existing populations of Ceanothus ferrisae to achieve minimum populations of 5,000 plants through various strategies. For example, implementation of an optimal fire regime (determined through research) to stimulate seedling production from the soil seed bank may prove to be a successful strategy to increase small population sizes. Fire applied to small areas over several years may yield large, sustainable populations, consisting of a mosaic of age classes and genotypes, which may be less vulnerable to stochastic events and senescence. Translocation efforts may prove successful as well. (USFWS, 2011)

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several habitat conservation, restoration, and Phytophthora avoidance recommendations that will aid in the recovery and conservation of the coyote ceanothus. 1. Research should further analyze the cause of the decline of the Kirby population. A restoration effort including the introduction of new genotypes should be conducted for the Kirby population since it has the lowest genetic diversity and shows evidence of

inbreeding (Honeycutt 2012; J. Hillman, Valley Water, in litt. 2013). 2. Public access should be restricted and trails rerouted away from all coyote ceanothus populations in order to prevent the introduction and spread of the plant pathogen Phytophthora. Specifically, public access should be prohibited near the Kirby population due to the detection of Phytophthora in a stream downhill from the Kirby population near the public entry point. 3. All work within or near coyote ceanothus habitat should follow the best management practices and updated guidance provided by the Working Group for Phytophthoras in Native Habitats available at https://www.suddenoakdeath.org/welcome-to-calphytos-orgphytophthoras-in-native-habitats/(e.g., Working Group for Phytophthoras in Native Habitat 2016). Any revegetation efforts within coyote ceanothus habitat should use only direct seeding instead of installing container plants unless the nursery can prove that the container plants are free of Phytophthora and all necessary best management practices are being implemented at the nursery to prevent the introduction and spread of Phytophthora consistent with the “Guidelines to Minimize Phytophthora Pathogens in Restoration Nurseries” (https://www.suddenoakdeath.org/wpcontent/uploads/2020/08/Restoration.Nsy_.Guidelines.final_.092216_rv_8.20.20.pdf, Working Group for Phytophthoras in Native Habitat 2020). 4. Efforts should continue to preserve the Anderson and Kirby populations of the coyote ceanothus with a minimum 1,000-foot buffer around the occurrences. 5. Any additional introduction or population creation efforts for coyote ceanothus should occur on the western side of Santa Clara Valley near the Llagas Road population, where the climate is more mesic and population genetic diversity is highest.The created population should be planted annually over a series of years from seed collected regularly from the Llagas Road population in order to mimic natural recruitment and allow the establishment of multiple age classes.Both direct seeding and installation of container plants following strict phytosanitary measures should be used for the population creation. 6. Coyote ceanothus seedlings and young plants should be caged in wide cages in the Llagas Road population to reduce browse/herbivory and set up wildlife cameras in extant occurrences of the coyote ceanothus to examine browse pressure and herbivory. A study should also be conducted comparing the abundance of rodents and rates of seed predation under browsed and unbrowsed coyote ceanothus. Vegetation cover (e.g., non-native grasses, sagebrush) near coyote ceanothus should be reduced if it is determined that the vegetation supports a high abundance of rodents that prey on the seeds and seedlings. 7. The Llagas Road population should be tested for the presence of Phytophthora pathogens. 8. Prescribed burning should be investigated as a management tool for regeneration in the Llagas Road population because it facilitates the removal of dead wood and grass thatch and promotes natural recruitment. 9. Research should further explore the soil microsymbiotic relationships such as Frankia and mycorrhizae in managed and created populations of the coyote ceanothus. 10. Research should further explore plant pathogen introductions and potential impacts on managed and created populations of the coyote ceanothus. This should include not just Phytophthora, but also Fusarium and Botrytis, which are known to affect seedlings. 11. Identify additional habitat suitability needs and potential locations for another population creation site for the coyote ceanothus while taking into consideration climate change and atmospheric N deposition. 12. An additional seed banking effort should be conducted for all three extant populations (USFWS, 2023).

# SPECIES ACCOUNT: *Ceanothus ophiochilus* (Vail Lake ceanothus)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 10/13/1998; California/Nevada Region (R8) (USFWS, 2015)

**Physical Description**

A rounded shrub, usually 1.2-1.5 m (4-5 feet) tall. The flat, dull green leaves are opposite, with knob-like stipules, narrowly oblanceolate (broadest above the middle and tapering toward the base) to obovate (eggshaped) in shape, glabrous (smooth), with obscure veins and blades 3 to 7 mm long and 1 to 3 mm wide; fruits are 3 to 3.5 mm wide, and without horns (Wilken 2012, p. 1158). Flowers are pale blue, occasionally pink, in bloom from mid-February to March. (NatureServe, 2015)

**Historical Range**

See current range/distribution.

**Current Range**

Ceanothus ophiochilus is a narrow, edaphic endemic plant found only within 20 acres in Southwestern Riverside County, California (Fish and Wildlife Service 1998). (NatureServe, 2015)

**Critical Habitat Designated**

Yes; 9/27/2007.

**Legal Description**

On September 27, 2007, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Ceanothus ophiochilus (Vail Lake ceanothus) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes obe critical habitat unit (CHU), in California (72 FR 54984-55010).

**Critical Habitat Designation**

The critical habitat designation for Ceanothus ophiochilus includes one CHU (2 sub-units) in Riverside County, California. This species critical habitat encompasses approximately 283 acres (ac) (115 hectares (ha)) (72 FR 54984-55010).

Unit 1: Western Riverside County Unit 1 is located near Vail Lake in southern Riverside County, California. The area was occupied at the time of listing and contains all of the primary constituent elements essential to the conservation of the species that may require special management considerations or protection for Ceanothus ophiochilus. Below, we present a brief description of subunit 1B, reasons why it meets the definition of critical habitat for C. ophiochilus, and our rationale for our final designation of critical habitat. Subunit 1B, Agua Tibia Mountains, Riverside County, California Subunit 1B (Agua Tibia Mountains) consists of 203 ac (82 ha) of land which is managed by the USFS. Subunit 1B contains two of the three CNDDB element occurrences (2 and 3) of Ceanothus ophiochilus, both known at the time of listing. The PCEs within this subunit may require special management considerations or protection to address the threats posed by short-interval fires, competing nonnative species, impacts to ridge tops (PCE 1) from grading associated with the creation of fuel breaks and impacts to the associated vegetation community (PCE 3) resulting from unnatural fire regimes. Subunit 1B is entirely within the Agua Tibia Wilderness of the Cleveland National Forest. Recently the USFS completed the LMP for the Four Southern California National Forests. Implementation of the LMP was analyzed by the Service to address potential impacts to Ceanothus ophiochilus. This analysis found that impacts to C. ophiochilus would be minor or negligible upon implementation of appropriate minimization measures due to the lowimpact nature of activities planned (e.g., dispersed recreation, non-motorized trails) (Service 2005 p. 129–132). However, the LMP does not identify specific management measures to address the threat posed by shortinterval fires and by competing nonnative species (Keeley 2006, p. 367; Merriam et al. 2007, p. vi, v, 48, 61). Because the USFS does not have a management plan specific to C. ophiochilus that provides the same or better level of protection from adverse modification or destruction than that provided through a consultation under section 7 of the Act, we have determined that exclusion of these lands from the final designation of critical habitat pursuant to section 4(b)(2) of the Act is not appropriate for these Federal lands (please see ''Exclusions under Section 4(b)(2) of the Act'' for a detailed discussion). Therefore, we are designating the USFS lands containing features essential to the conservation of C. ophiochilus as critical habitat for this species.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Ceanothus ophiochilus critical habitat consists of three components (72 FR 54984-55010):

(i) Flat to gently sloping north to northeast facing ridge tops with slopes in the range of 0 to 40 percent slope that provide the appropriate solar exposure for seedling establishment and growth.

(ii) Soils formed from metavolcanic and ultra-basic parent materials and deeply weathered gabbro or pyroxeniterich outcrops that provide nutrients and space for growth and reproduction. Specifically in the areas that Ceanothus ophiochilus is found, the soils are: (A) Ramona, Cienaba, Las Posas, and Vista series in the Agua Tibia Wilderness; and (B) Cajalco series in the vicinity of Vail Lake.

(iii) Chamise chaparral or mixed chamise-ceanothus-arctostaphylos chaparral at elevations of 2,000 feet to 3,000 feet (610 meters to 914 meters) that provide the appropriate canopy cover and elevation requirements for growth and reproduction.

**Special Management Considerations or Protections**

As stated in the final listing rule, threats to Ceanothus ophiochilus include habitat destruction, alteration, fragmentation, and degradation from urban development, as well as hybridization and fire at too frequent intervals to allow for sufficient seed bank replenishment in the soil (63 FR 54956, October 13, 1998). Threats to Fremontodendron mexicanum as cited in the final listing rule include altered fire regimes, indirect impacts from nearby urbanization, and increased competition from nonnative species (63 FR 54965, October 13, 1998). These threats could impact the PCEs determined to be essential for conservation of C. ophiochilus and F. mexicanum. Urban development near Ceanothus ophiochilus critical habitat units may alter the habitat characteristics required by the species. Land grading in and around occurrences of C. ophiochilus may affect the topography of the habitat and change the soil composition (PCEs 1 and 2) rendering the habitat unsuitable for species growth and reproduction. Urban development may also encourage invasion by nonnative plant species, changing the vegetation community and/or directly impacting the vegetation community (PCE 3). In addition, urban development near this species may increase the frequency of fire. All identified private land is covered by the Western Riverside County MSHCP (MSHCP), and those lands have been excluded from the final designation (see ‘‘Relationship of Critical Habitat to Habitat Conservation Plan Lands—Exclusions Under Section 4(b)(2) of the Act’’ section for a detailed discussion). No urban development is expected to directly impact the occurrences of C. ophiochilus on land owned by the USFS. Therefore, we do not believe threats from urban development would require special management considerations or protection of the PCEs on designated critical habitat for this species. The management of both fire frequency and the placement of fuel breaks is important for the conservation of Ceanothus ophiochilus, and special management considerations or protection of the PCEs for C. ophiochilus may be required on USFS lands to address potential threats posed by fire management activities. In the past, fuel breaks have been placed on the ridgelines (PCE 1) in C. ophiochilus habitat and have caused soil disturbance (PCE 2). Studies of fuel breaks in the Cleveland National Forest near the critical habitat designation have demonstrated an increase in the density of competing nonnative species (Merriam et al. 2007, p. 48), and it has been hypothesized that fuel breaks promote the introduction and spread of nonnative plants (Merriam et al. 2007, p. vi). These nonnative invasive plants alter local fuel conditions and change fire behavior and frequency (Merriam et al. 2007, p. 61). Ceanothus ophiochilus is very sensitive to short-interval fires, which may extirpate the species from a site entirely (Keeley 2006, p. 367). Soil disturbance, caused by the creation of fuel breaks, has also led to increased hybridization between Ceanothus ophiochilus and C. crassifolius. However, the degree to which hybridization is impacting C. ophiochilus and its habitat is not yet known.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (hybridization) (USFWS, 2013)

**Breeding Season**

Adult: Mid-February to March (NatureServe, 2015)

**Key Resources Needed for Breeding**

Adult: Fire (USFWS, 2013)

**Reproduction Narrative**

Adult: Flowers are pale blue, occasionally pink, in bloom from mid-February to March (NatureServe, 2015). Hybridization is common among Ceanothus species (Wilken 2012, p. 1153; Fross and Wilken 2006, pp. 132–133). Ceanothus ophiochilus generally requires a firereturn interval between 10 to 20 years to adequately replenish the seed bank (Keeley and Davis 2007, p. 350). Ceanothus ophiochilus is an obligate seeder and therefore does not resprout following fire, but instead recovers through the germination of seeds stored in the soil (Boyd and Banks 1995, p. 28; Keeley 2006, p. 367). (USFWS, 2013)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2013)

**Habitat Vegetation or Surface Water Classification**

Adult: Shrubland/chaparral

**Dependencies on Specific Environmental Elements**

Adult: Fire (USFWS, 2013)

**Spatial Arrangements of the Population**

Adult: Isolated patches (USFWS, 2013)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Habitat Narrative**

Adult: Ceanothus ophiochilus is restricted to isolated patches of gabbro and pyroxenite-rich outcrops (Vail Lake), or within a mix of gabbro and sedimentary deposits (Agua Tibia Wilderness) (Boyd and Banks 1995, p. 15). It is generally found within chamise chaparral habitats on ridge tops and north- to northeast-facing slopes (USFWS, 2013). Ceanothus ophiochilus generally requires a firereturn interval between 10 to 20 years to adequately replenish the seed bank (Keeley and Davis 2007, p. 350). (USFWS, 2013)

***Dispersal/Migration***

**Motility/Mobility**

Adult: Low (USFWS, 2013)

**Dispersal/Migration Narrative**

Adult: Many plant species with refractory seeds (i.e., seeds that need a fire-related stimulus, alone or in conjunction with other conditions; Keeley 1991, p. 87) have propagules that are not specialized for widespread dispersal and therefore have a relatively short dispersal distance (Keeley 1991, p. 105). Ceanothus plants have capsules that eject seeds and studies on two Sierra Nevadan Ceanothus species, C. cuneatus and C. leucodermis, found that most seeds fall beneath the canopy vegetation (Evans et al. 1987, p. 288); even on open sites, few seeds (less than 2 percent) reached a distance of 29.5 ft (9 m) (Evans et al., 1987, pp. 288–289). (USFWS, 2013)

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

3 (USFWS, 2013)

**Population Size:**

~10,000

**Population Narrative:**

One populations consists of about 3,000-5,000 individuals and occupies about 8 hectares; the remaining two populations comprise over 4,000 individuals in a 12 hectare area (Fish and

Wildlife Service 1998). Known from only three occurrences near Vail Lake, California (Skinner 1997). (NatureServe, 2015).

***Threats and Stressors***

**Stressor:** Urban development (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, the Service indicated that much of southwestern Riverside County was expected to become more urbanized based on development trends and planned developments on private lands in the Vail Lake area (USFWS 1998, p. 54961). In the 2008 5-year review, the Service reevaluated the proposed developments for this area and stated that the most recently proposed, large-scale development (Specific Plan No. 324) for this area had not been acted upon and the project was inactive (USFWS 2008, p. 8). However, the Service concluded that urban development in the Vail Lake area remained a significant threat to the Vail Lake occurrence of Ceanothus ophiochilus since no assurances of the conservation of this species have been made (USFWS 2008, p. 8). In summary, the Service believes that urban development represents a potential threat to Ceanothus ophiochilus at two of the three occurrences. (USFWS, 2013)

**Stressor:** Recreational activities (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Dispersed recreation (e.g., camping, hiking, mountain bike activity) is an occasional, ongoing use at the Agua Tibia Wilderness occurrences (USFS 2012b, p.41). The use of exiting trails or the creation of new trails within the Agua Tibia Wilderness occurrences located on CNF lands represents a potential threat to Ceanothus ophiochilus primarily from soil compaction of habitat, although trampling of individual plants may also result from these activities. However, no designated USFS trails currently intersect with habitat occupied by C. ophiochilus (USFS 2012b, p. 41) and the recreational use, although allowed in or near the two Agua Tibia Wilderness occurrences within CNF by the public, is limited because access is controlled by adjacent private lands (USFS 2012b, pp. 40–41). (USFWS, 2013)

**Stressor:** Invasive non-native plants (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive nonnative plants have been identified by the USFS as a threat to habitat quality for Ceanothus ophiochilus, particularly in those areas within the Agua Tibia Wilderness occurrences where recent wildland fire has exposed bare soils and created unclassified trails as a result of fire suppression activities (USFS 2005a, p. 259). Roads and road construction from grading of fuel breaks facilitate the introduction and establishment of invasive nonnative plants (discussed above) by creating open, continually disturbed habitat. Invasive nonnative plants can also be transported along these corridors by equipment and other vehicles, as well as recreational uses, and can become more readily established on exposed cut-and-fill slopes of roads than native plants (USFS 2005e, Volume 1, p. 114). Activities conducted by the USFS

associated with the removal of invasive plants may have short-term adverse effects to Ceanothus ophiochilus. (USFWS, 2013)

**Stressor:** Wildland fire and fire Management (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the USFWS listing rule, the Service identified the change in fire cycle regimes (or fire frequency) as a threat to Ceanothus ophiochilus and other plants adapted to specific fire frequencies (USFWS 1998, p. 54964). Changes occurred from increased incidence of local accidental fires and less frequent natural fires resulting from human activity in fire prone areas (e.g., Vail Lake occurrence). The Service also highlighted fire management practices including grading of C. ophiochilus habitat for fire or implementation of fuel breaks as an important threat to this species for all three occurrences (Boyd 1991, pp. 2, 8; Boyd and Banks 1995, p. 16; USFWS 1998, p. 54961). Fire management and suppression activities including fire line construction, fire retardant and water drops, establishment of temporary fire camps, staging areas, parking sites, safety zones, helipads, and post-fire rehabilitation can affect Ceanothus ophiochilus habitat (USFWS 2005, p. 27). (USFWS, 2013)

**Stressor:** Hybridization and introgression (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Service identified hybridization and genetic introgression with C. crassifolius as a major threat to C. ophiochilus where the two species co-occur in our 2008 5-year review (USFWS 2008, p. 14). Without genetic evaluations and comprehensive surveys within the three occurrences, it is difficult to assess the nature and extent of hybrid individuals; thus, it is unclear if hybridization or introgression represents a current threat to C. ophiochilus at this time. Continued monitoring of disturbance to all three occurrences is needed in conjunction with additional genetic viability studies to better evaluate these two related threats to C. ophiochilus. (USFWS, 2013)

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Based on the best available information contained in model predictions for this general region of California, a change in temperature conditions resulting from climate change is considered a rangewide threat to Ceanothus ophiochilus due to predicted changes to its habitat. Climate model predications also indicate a slight increase in fire risk to the geographical range of C. ophiochilus, which, when combined with anthropogenic facilitation, can produce a shortening of the fire return interval and affect its ability to recover and maintain its viability in the chaparral ecosystem. (USFWS, 2013)

**Stressor:** Climate Change - New Information (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** TEMPERATURE Temperature across southern California has increased over the past century. He and Gautam (2016) analyzed 1896–2015 temperature records for the region. They reported that annual average, maximum, and minimum temperature all increased by around 0.16 degree Celsius per decade (p. 11). Projected temperature increases differ spatially across southern California. The ocean buffers warming near the coast, so coastal areas are projected to experience relatively smaller temperature increases (Hall et al. 2018, p. 11). But inland areas—such as the range of Ceanothus ophiochilus in western Riverside County—are projected to have relatively larger temperature changes under both emissions scenarios (Hall et al. 2018, p. 11). Extremely hot days are also projected to become more frequent and intense, with the largest changes in interior regions (Hall et al. 2018, p. 11). For the range of Ceanothus ophiochilus in Western Riverside County, annual average maximum temperatures under RCP 4.5 are projected to increase from an observed historical (1961–1990) average of 77.2 degrees Fahrenheit (F) [25.1 degrees Celsius (C)] (range 75.8–80.0 degrees F, 24.3–26.7 degrees C), to a projected future (2070–2099) average of 82.9 degrees F (28.3 degrees C) (range 79.8 –86.0 degrees F, 26.5–30.0) (Cal-Adapt 2020). Under RCP 8.5, end-of-century (2070–2099) annual average maximum temperatures are projected to rise to 85.7 degrees F (29.8 degrees C) (range 81.4–90.6 degrees F, 27.4–32.5 degrees C). For projections of future temperature, RCP 4.5 and 8.5 scenarios are similar in the early and mid-21st century. Projections diverge in the second part of the century, as emissions continue to rise under RCP 8.5 (Hall et al. 2018, p. 10). PRECIPITATION Precipitation in southern California is highly variable from year to year (Kalansky et al. 2018, p. 24; Hall et al. 2018, p. 12). Models of future precipitation generally project small mean changes relative to the historical variability, and the overall direction of future precipitation is unclear (Hall et al. 2018, p. 13). Models do project increases in extreme precipitation frequency and intensity (Polade et al. 2017, p. 7; Swain et al. 2018, p. 428), including increases in the frequency of atmospheric-river storms, which deliver intense precipitation and can cause severe flooding (Dettinger 2011, p. 519). However, droughts are also projected to become more frequent and intense, and will be exacerbated by higher temperatures (Kalansky et al. 2018, p. 25). ATMOSPHERIC CO2 CONCENTRATION Since 1750, the atmospheric concentrations of greenhouse gasses (including carbon dioxide, methane, and nitrous oxide) have increased because of human activity (IPCC 2013, p. 11). In 2011, the concentration of carbon dioxide ($CO_2$) was 391 parts per million (ppm), 40 percent higher than pre-industrial levels (IPCC 2013, p. 11). In 2018, the global average atmospheric carbon dioxide ($CO_2$) concentration was 407.4 parts per million (ppm) (Lindsey 2020). Plants use $CO_2$ and water to synthesize carbohydrates. Therefore, elevated $CO_2$ concentrations can directly affect photosynthesis. FIRE California has a Mediterranean climate with cool, wet winters and hot, dry summers. Fire is an important part of California ecosystems. Fire behavior is influenced by topography, weather, fuel characteristics, and ignition sources (van Wagtendonk 2006, pp. 38–46). Santa Ana winds—strong, dry, and hot winds occurring mostly in September through December (Hughes and Hall 2010, p. 847; Jin et al. 2015, pp. 1–2)—are one feature of the southern California climate which can influence wildfire behavior and size. Wildfires driven by Santa Ana winds (Santa Ana fires) spread more quickly, and have higher intensity, than fires that occur outside the Santa Ana season (Jin et al. 2015, pp. 5–6). For California's Fourth Climate Assessment, Pierce et al. (2018) projected an increase in the driest of Santa Ana days (daily wind speeds greater than or equal to 8 meters per second, and less than or equal to 20 percent relative humidity), although the number of Santa Ana days and the days with the strongest wind speeds were projected to decrease (Pierce et al. 2018, p. 36; Kalansky et al. 2018, p. 27). There is uncertainty in future wildfire projections for southern California (Hall et al. 2018, p. 18), but wildfire risk will likely increase as climate warms (Kalansky et al. 2018, p. 6). Under RCP 8.5, Westerling (2018, p. 19) projected an increasing tendency towards extreme wildfire events, rapidly accelerating after the mid-21st century. Statewide, the greatest increases in burned area were projected to be in forested areas of the state (Westerling 2018, p. 14). For southern California under RCP 8.5, Jin et al. (2015, p. 9–10) projected increases in burned area, number of fires, and fire size for both Santa Ana and non-Santa Ana fires. (USFWS, 2020)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 8C

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**

- Recovery actions are not available.
- Continue to work with the CNF to ensure that USFS guidelines and directives are being implemented for activities that might directly or indirectly impact Ceanothus ophiochilus habitat. This should include providing comment on biological assessments for proposed fire suppression activities and assistance in designing fuel breaks to protect populations of C. ophiochilus. (USFWS, 2013)
- Conserve or preserve Ceanothus ophiochilus occurrences on private lands, especially at Vail Lake. Pursue opportunities to purchase parcels through the Act’s section 6 funding and other conservation partnership programs (i.e., Western Riverside County MSHCP) with willing sellers. (USFWS, 2013)
- Develop outreach or educational activities with the primary landowner adjacent to the Agua Tibia Wilderness–North occurrence to enlist their assistance in ensuring the survival and recovery of Ceanothus ophiochilus. (USFWS, 2013)
- Develop a monitoring plan for populations of Ceanothus ophiochilus, the quality of chamise chaparral habitats, and threats at the three C. ophiochilus occurrences. This monitoring plan should include surveys to detect abundance, habitat conditions, and potential threats to the taxon, particularly those related to the effects of fire and fire management activities. (USFWS, 2013)
- Determine the current level and pattern, extent, and impact of introgression of Ceanothus ophiochilus with C. crassifolius at all three occurrences. (USFWS, 2013)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: 1. Work with the Rancho California Water District to conserve and enhance the Vail Lake occurrence of Ceanothus ophiochilus. 2. Survey suitable habitat for new occurrences of C. ophiochilus. 3. Survey for nonnative invasive plants in the vicinity of C. ophiochilus occurrences. 4. Model C. ophiochilus habitat under a range of future climate scenarios, and evaluate assisted migration or translocation as a management strategy. 5. Determine the current level and extent of introgression of C. ophiochilus with C. crassifolius, and reexamine putative hybrids. 6. Collect additional C. ophiochilus seeds for ex situ storage at a certified Center for Plant Conservation facility. (USFWS, 2020)

# SPECIES ACCOUNT: *Ceanothus roderickii* (Pine Hill ceanothus)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 11/18/1996; California/Nevada Region (R8)

**Physical Description**

A prostrate evergreen shrub of the buckthorn family (Rhamnaceae) that generally grows to 3 meters (9.8 feet) in diameter. The smooth gray-brown branches radiate from a central axis and root when they come into contact with the ground. Its leaves are semi-erect with entire (smooth-edged) margins. Small whitish flowers tinged with blue appear from May through June. Its fruit is an inconspicuously horned, globe-shaped capsule. Ceanothus roderickii can be differentiated from its congeners (other species of the same genus, other related species) by a combination of its blue-tinged flowers, prostrate habit, and inconspicuously horned fruit. (USFWS, 2002)

**Taxonomy**

Walter Knight (1968) described Ceanothus roderickii as Ceanothus rodericki, naming it after Wayne Roderick, who first recognized the horticultural value of this endemic shrub. Due to an orthographic change, the correct spelling is Ceanothus roderickii. Knight (1968) considered C. roderickii to be most closely related to C. cuneatus (buckbrush), which also grows throughout the area. Ceanothus roderickii is suggested to resemble the sprawling C. fresnensis (Fresno mat), which grows a considerable distance to the south at higher elevations; plants of the two species grown in a regional park flowered at different times (Knight 1968). (USFWS, 2002)

**Historical Range**

Endemic to western El Dorado County, California. (USFWS, 2002)

**Current Range**

On the Pine Hill formation in western El Dorado County, California.(USFWS, 2019). The species is restricted to the Pine Hill Preserve and the immediate vicinity (USFWS, 2024).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Dependency on Other Individuals or Species**

Adult: The pollination of Ceanothus roderickii is primarily by insects from the orders Diptera (flies and gnats) and Hymenoptera (bees and wasps). (USFWS, 2002)

**Breeding Season**

Adult: May to June (USFWS, 2002)

**Key Resources Needed for Breeding**

Adult: Fire/heat (USFWS, 2002)

**Reproduction Narrative**

Adult: Flower/fruit development in this species is negatively affected by canopy shading (James 1996). Unlike most chaparral shrub species, Pine Hill ceanothus will not resprout from a caudex (woody axis comprising the stem and root) after a fire, and therefore, depends on nearby plants connected via branch layering for survival or the seedbank for re-establishment (Boyd 2007). There is reason to believe that seeds can survive at least 80 years in the seedbank (Ayres 2011; Boyd 2007). Hot/cold stratification, but not necessarily fire (Boyd 2007), seems to be required for germination (James 1996; Boyd 2007). Because juvenile plants do not begin flowering until 5-6 years after fire, populations need a fire-free period of at least six years to replenish the seed bank (Marsh and Ayres 2002; Ayres 2011), otherwise populations may be permanently lost. (USFWS, 2019)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Barrens, Shrubland/chaparral (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Combination of heat and cold (USFWS, 2002)

**Geographic or Habitat Restraints or Barriers**

Adult: Shading limits flower production (USFWS, 2002)

**Spatial Arrangements of the Population**

Adult: Scattered (USFWS, 2002)

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2002; NatureServe, 2015)

**Habitat Narrative**

Adult: Ceanothus roderickii is found in openings in chaparral communities on gabbro- or serpentinite- derived soils (NatureServe, 2015). Most occurrences are discontinuously scattered within two population centers in the northern and southern portions of the Pine Hill formation. The seeds treated with a combination of heat and cold have the best germination rate. Canopy shading was shown to negatively affect flower and fruit production in C. roderickii. (USFWS, 2002)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2019)

**Number of Populations:**

2 known extant ; 7 presumed extant (USFWS, 2019)

**Population Size:**

Greater than 55,000 individuals (USFWS, 2019)

**Additional Population-level Information:**

Botanical surveys were conducted around the perimeter of Pine Hill in conjunction with a fuels reduction project that created a 20–25-meter firebreak around the reserve between 2017–2019 (Klip et al. 2020, p. 59). Ten new patches of Pine Hill ceanothus were found during these surveys (Klip et al. 2020, p. 65). These new patches of plants are within proximity to other areas occupied by the species on Pine Hill and thus do not change our overall understanding of the distribution of the species. In addition, germination and survival of Pine Hill ceanothus on the reserve was monitored in plots with three different treatments: burned piles, hand-cleared and unburned, and intact chaparral (Klip et al. 2020, pp. 59, 61). Pine Hill ceanothus seedlings were found at higher densities in plots where piles had been burned, suggesting that pile burning could be used by land managers to promote germination of Pine Hill ceanothus (Klip et al. 2020, pp. 74–75). Purple false brome (Brachypodium distachyon), an exotic grass which thrives in mature chaparral and is eliminated by neither fire nor clearing, has been noted on Pine Hill in the two treatments within the ongoing studies on post-fire regeneration conducted by the El Dorado Chapter California Native Plant Society (See further discussion in Threats section; Klip et al. 2020, pp. 67, 73). (USFWS, 2024)

**Population Narrative:**

It is restricted to one localized area of approximately 10 occurrences discontinuously scattered in the Pine Hill formation in the north, central, and south areas (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat loss (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Proposed residential or commercial development within the Pine Hill formation threatens most of the remaining sites within the Pine Hill formation and adjacent serpentine in western El Dorado County, and either directly or indirectly will adversely affect most of the range. (USFWS, 2002)

**Stressor:** Habitat fragmentation (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The subsequent induced growth from water acquisitions would affect all six species on the Pine Hill formation and adjacent serpentine, either by further fragmenting the habitat or by directly destroying habitat. Habitat fragmentation and edge effects significantly affect gabbro plants. Habitat fragments are more susceptible to being burned in their entirety, with shorter than natural intervals between fires, relative to larger tracts of habitat. If an entire preserve

burns more often than the natural fire frequency, the seed bank of certain chaparral shrub species may not be adequate to replace the population. Fragmentation splits habitat into smaller, more isolated units and has two primary effects. First, habitat fragmentation may alter the physical environment, changing the amount of incoming solar radiation, water, wind, or nutrients for the remnant vegetation (Saunders et al. 1991). Second, most of these fragmented natural areas are subject to influences from external factors (e.g., additional development, lawn and garden watering, herbicide drift, and off-road vehicular use) that disrupt natural ecosystem processes. (USFWS, 2002)

**Stressor:** Fire management (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Changes in fire frequency threaten Ceanothus roderickii. C. roderickii occur within a fire-adapted plant community, either within chaparral or on the ecotone between chaparral and woodland. Before the advent of fire suppression policies, chaparral stands may have burned at a frequency of roughly 3 to 5 times per 100 years (Boyd 1985). Longer than normal fire frequencies lead to the loss of some plant species from the chaparral plant community. (USFWS, 2002)

**Stressor:** Hydrologic changes (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** El Dorado Irrigation District, is attempting to get additional water from the South Fork of the American River through purchase of PG&E’s Hydroelectric Project 184 and a storage contract with the Bureau of Reclamation utilizing Folsom Reservoir. This water is most likely to be used for developments in the extreme western part of El Dorado County, where the gabbro soil plants are found (A. Howard in litt. 1999). (USFWS, 2002)

**Stressor:** Development (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mitigation for development often is by small "set asides" (small natural areas within the development), which increase habitat fragmentation, are difficult to manage for fire, and are subject to edge effect problems. Land development and multiple ownership complicate the planning and implementation of controlled burns at the appropriate fire frequency necessary for maintenance of chaparral. (USFWS, 2002)

**Stressor:** Road widening and maintenance (USFWS, 2002)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Road widening occurs near development within El Dorado County threatens the habitat of Ceanothus roderickii at one site (California Natural Diversity Data Base 1994). (USFWS, 2002)

**Stressor:** Recreation (USFWS, 2002)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Off-road vehicle use has adversely affected the habitat of Ceanothus roderickii at three sites in the northern part of the Pine Hill formation. Several hills are scarred with off-road vehicle tracks. Erosion promoted by scarring adversely modifies the habitat. (USFWS, 2002)

**Stressor:** Invasive plants (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive plants continue to present a minor threat to gabbro plant species. Populations within the Pine Hill Preserve are not significantly threatened by invasive plants and any small infestations identified are largely reduced or eliminated by mechanical means (BLM 2008). (USFWS, 2019)

**Stressor:** Alteration of the natural fire regime, herbicide spraying, unauthorized dumping, invasive species, and shading via succession (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Alteration of the natural fire regime, herbicide spraying, unauthorized dumping, invasive species, and shading via succession were also listed as threats to Stebbins' morning-glory, Pine Hill ceanothus, Pine Hill flannelbush, and Layne's butterweed in the listing rule (USFWS, 2024)

***Recovery***

**Reclassification Criteria:**
1. Secure and protect specified recovery areas from incompatible uses: (a) Cameron Park preserve north of Highway 50; (b) Cameron Park preserve south of Highway 50; (c) Pine Hill preserve; Salmon Falls/Martel Creek preserve; (d) sufficient adjacent unoccupied habitat for fire management and a 150- meter (500-foot) buffer. (USFWS, 2002)

2. Management plan approved and implemented for recovery areas, including survival and recovery of the species as the objective: For preserves and any adjacent occupied or unoccupied habitat identified as necessary for continued survival and recovery (USFWS, 2002).

3. Monitoring in all recommended preserves shows: (a) populations stable or increasing over one fire cycle (about 30 years), (b) habitat monitoring of recommended preserves shows a mosaic of multiage class stands and habitat fragmentation has not appreciably increased (less than 5 percent) within any preserves over current (2000) conditions, (c) spatially and temporally, the establishment of occurrences must be greater than the extirpation of occurrences. (USFWS, 2002)

4. Other actions: (a) Ameliorate or eliminate threats; (b) Fire management studies; (c) Research on propagation techniques if repatriation, enhancement, or restoration are determined to be necessary; (d) Maintain metapopulation dynamics of at least 2 very large, 2 large, 6 medium,

and 7 small occurrences throughout the range of the species. (USFWS, 2002)

Recovery Priority Number: 5C

**Delisting Criteria:**
1. Management plan approved and implemented for recovery areas, including survival and recovery of the species as the objective: For all occurrences and any adjacent areas identified as necessary for continued survival and recovery. (USFWS, 2002)

2. Monitoring in all recommended preserves shows: (a) no decline after downlisting during two additional fire cycles (about 60 years); if declining, determine cause and reverse trend, (b) habitat monitoring of recommended preserves shows a mosaic of multiage class stands and habitat fragmentation has not appreciably increased (less than 5 percent) within any preserves over current (2000) conditions, (c) spatially and temporally, the establishment of occurrences must be at least 10 percent greater than the extirpation of occurrences. (USFWS, 2002)

3. Ameliorate or eliminate threats; research on propagation techniques if repatriation, enhancement, or restoration are determined to be necessary. (USFWS, 2002)

**Recovery Actions:**
- 1. Develop and implement a cooperative program and participation plan. A cooperative program is needed to coordinate local public and private land use planning with State and Federal land use and recovery planning for gabbro species. A cooperative program needs to be developed focusing on western El Dorado County. A participation plan produced from this program will increase the chances of recovery for listed species. (USFWS, 2002)
- 2. Protect and secure existing populations. Natural lands that contain this species need to be protected in perpetuity. Protection of these lands includes identification and minimization of threats in perpetuity and application of appropriate and adaptive management (see Task 3) to ensure species survival and recovery. Natural lands that need protection can be categorized into two types: (1) blocks of land that contain occupied or potential habitat for two or more this species and (2) blocks of land that contain occupied or potential habitat for one this species. All potential preserve areas should be evaluated based on current mapping information and ground-truthed prior to purchase to confirm their value for recovery. (USFWS, 2002)
- 3. Manage Habitat Managing habitat is essential to the recovery of the listed species. Habitat management includes preparation and implementation of management plans for all areas inhabited by special status species being proposed for preservation, and periodic monitoring of populations in each of these areas. Within western El Dorado County, a multi-constituent committee should be formed to oversee the management of preserves located on the Pine Hill formation. The preserve management committee should include, at a minimum, representatives from the California Department of Fish and Game, U.S. Fish and Wildlife Service, Bureau of Land Management, El Dorado County, California Department of Forestry and Fire Protection, California Native Plant Society, American River Conservancy, and a private landowner representative. (USFWS, 2002)
- 4. Survey historical locations and other potential habitat where this species may occur. Recovery of listed species may often require relocating historic populations or locating new populations of these species. Historical locations should be surveyed to determine whether suitable habitat remains, the species persists at the sites, and/or the sites may be suitable

for repatriation. Suitability of historical locations for repatriation would depend upon: (1) whether potential habitat exists, (2) the presence and magnitude of threats, and (3) whether the sites can be secured and managed for the long-term protection of the species. Surveys should also include other potential gabbro or serpentine habitat to determine whether undiscovered populations may exist. If new populations are discovered, they need to be protected and managed as discussed above. During the surveys, potential introduction sites should also be identified. (USFWS, 2002)

- 5. Conduct necessary biological research and use results to guide recovery/conservation efforts. - Develop propagation techniques for listed plant species for which enhancement, repatriation, or introductions would be appropriate. Geographic area research is outlined in the Recovery Plan. Species-specific research is described as follows: Reproduction and Demography Research: Including determining limiting life stages, seed production, and survival in soil to determine appropriate fire return period. Systematics research and genetic studies if repatriation is determined to be necessary. Other Research Needs: Propagation techniques; fire management techniques; metapopulation analysis; determine efficacy of other types of disturbance regimes for species and habitat management; feasibility of habitat restoration/ enhancement. Management Actions Needed: Burning; general surveys; baseline monitoring; monitoring for trends of populations, success of management actions, and threats at all populations identified for protection; monitoring for habitat fragmentation, major shifts in vegetation type, and tracking of occurrence establishment, and extirpation. (USFWS, 2002)
- 6. Undertake artificial enhancement, repatriation, or introduction efforts where necessary. Where it is deemed necessary, artificial enhancement, repatriation, or introduction efforts for sensitive plants should be undertaken. Prior to repatriation or introduction of sensitive plants, genetics studies are needed (see Task 5) to ensure that new populations will not disrupt unique local gene complexes. Plant repatriation or introduction efforts should be undertaken using collected seeds or plant propagules. (USFWS, 2002)
- 7. Determine possible prescribed burning management strategies and incorporate the strategies into the management plans (Priority 1). Possible prescribed burning management strategies need to be evaluated, peer reviewed, and incorporated into management plans. (USFWS, 2002)
- 8. Perform metapopulation-type analyses for this species (Priority 2). The results of a metapopulation-type analysis may be useful in clarifying uncertainties, data needs, and research, management priorities, and delisting criteria. Metapopulation-type analyses should be based on the results of monitoring and research. (USFWS, 2002)
- Dedicate more resources toward the investigation of best management approaches for the Pine Hill listed plant species, even at the cost of a temporary hiatus in land acquisition efforts. Investigation should be made into fire-related and non-fire related methods of disturbance to maintain listed plant species habitat. (USFWS, 2019)
- Once the best management strategy (in terms of technique, frequency, timing, and intensity) is determined at each site, implement these management practices to achieve and maintain a habitat mosaic that enables the attainment of recovery criteria for the species. (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- Pine Hill ceanothus 1. Further investigate the prevalence and survival of Pine Hill ceanothus/buck brush hybrids in disturbed and undisturbed conditions (USFWS, 2024)

# SPECIES ACCOUNT: *Cereus eriophorus var. fragrans* (Fragrant prickly-apple)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 12/2/1985; Southeast Region (R4)

**Physical Description**

Cereus eriophorus var. fragrans is a solitary tree cactus that may have from one to eight, spiny, cane-like, stout, and succulent stems. The columnar stems are 2.5 to 5.0 cm in diameter, and have 10 or 12 ridges alternated with deep, sharp grooves (Benson 1982). Stems may be erect, or for longer stems, the plant may recline over neighboring vegetation. The branching can be extensive, and the roots of this cactus are coarse, fibrous, and shallow (Small 1920). The spine-bearing regions (areoles) are aligned along its ridges about 2 cm apart. Each areole bears 9 to 13 spines, which are mostly grayish and yellowish at the tip, with one spine longer (2 to 4 cm) than the rest. Cereus eriophorus var. fragrans has initial flower buds that are 1 cm long, white, and exceedingly hairy. Buds often appear on the plant one to two months prior to flower growth. About 9 days after initiation of flower growth, the flower opens (Rae 1995). The flowers are fragrant, showy, solitary, and open only at night. The buds are 12 to 20 cm long when about to open and 7.5 to 10 cm in diameter when open. The ovary bears many lanceolate scales while the flower tube has only a few scattered scales. A tuft of long white hairs (10 to 15 mm long) protrudes from the axil beneath each scale. The sepals are narrowly linear, with green outer sepals and nearly white inner ones. There are numerous spatulate petals, white or pinkish, with unevenly toothed margins. The stamens are numerous and are composed of white filaments and yellow anthers. The style is elongate with 9 to 12 stigmas (FWS 1988). The fruits are attached at the narrower end. They average 4 to 6 cm in diameter and are a dull red. The fruit does not split and has long tufts of white hairs that remain persistent with the scale bases (Leon and Alain 1953). The fruits are swollen at the base and finely pitted; each contains approximately 1,500 black seeds that are about 3 mm long (Rae 1995). (USFWS, 1999)

**Taxonomy**

The type specimen was collected by John K. Small in 1917 along sand dunes approximately 6 miles (mi) south of Ft. Pierce, Florida, and treated as Harrisia fragrans (Britton and Rose 1920). It was separated from other species partly on the basis of having one longer spine than the other 9 to 13 spines per areole (Britton and Rose 1920). Austin (1984) followed the treatment of Lyman Benson (1982) in which Harrisia and other cacti were joined together in the genus Cereus. Since then, fragrant prickly-apple has consistently been referred to by its former name, Harrisia, in references to the flora of the United States and Florida (Chafin 2000; Gann et al. 2002; Flora of North America 2003; Wunderlin and Hansen 2003). The Integrated Taxonomic Information System (2010) was also checked while conducting this review and indicated that the accepted name is Harrisia fragrans. Because Harrisia fragrans is the name used in peer-reviewed literature and is accepted by the scientific community, we concur with this nomenclature. (USFWS, 2010)

**Historical Range**

Historically occurred on the east coast of Florida in St. Lucie, Indian River, Brevard, and Volusia Counties (USFWS, 2010)

**Current Range**

In Florida, in Volusia and St. Lucie Counties, projected to include Brevard and Indiana River Counties. (USFWS, 2010)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexually and by regeneration by vegetative reproduction

**Breeding Season**

Adult: Plants flower from April to September with two distinct peaks. (USFWS, 2016)

**Reproduction Narrative**

Adult: Fragrant prickly-apple reproduces sexually and by regeneration by vegetative reproduction. Plants flower from April to September with two distinct peaks. The first peak is in the spring with flowering starting in April and reaching a peak in May. Some sporadic flowering occurs in the summer. In September and October, another minor peak in flowering occurs. Flowering is uncommon in the late fall, and no flowering occurs from January through March. Fruit set follows flowering with a major peak in May and a minor peak in September. A large standing crop of fruit remains on plants for approximately 8 months of the year. According to Rae (1995), mature plants are greater than 41 cm in length. The smallest plant to flower was 14.5 cm in stem length and the smallest plant to set fruit was 41 cm in length. In his study, 63 percent of the mature plants flowered. At two sites in the Savannas State Preserve, in St. Lucie County, 38 and 60 percent of flowers successfully produced fruits and 44 and 61 percent of mature plants successfully set fruit. A positive relationship was observed between total length of the stems and branches of a plant and the total annual production of fruit. The means of seed dispersal are uncertain, but there is evidence that birds consume the fruit of fragrant prickly-apple. Additionally, most individuals of this species are found within the drip line of other plants, suggesting avian seed dispersal. Rodents or gopher tortoises may also distribute the seeds. In addition to sexual reproduction, long stems will occasionally snap off of existing plants. After falling to the ground, stems may re-root at several places creating a small group of genetically identical plants (Rae 1994a). Vegetative growth of this perennial species is slowest from November to March. Growth accelerates in April and May, with the fastest growth occurring from July through September. The growth rate drops off rapidly after September (Rae 1994a, 1995). The fragrant prickly-apple is characterized as a long-lived species with late maturity, low fecundity, and low adult mortality (Rae and Ebert 2002). Larger plants tend to have higher fecundity and lower mortality rates (Rae and Ebert 2002); therefore, the larger individuals in the population are extremely important to overall population health (Rae and Ebert 2002). (USFWS, 2016)

**Habitat Type**

Adult: Sand pine scrub habitat

**Environmental Specificity**

Adult: Narrow (USFWS, 2016)

**Habitat Narrative**

Adult: Fragrant prickly-apple occurs in a clumped distribution and prefers early-successional sand pine scrub habitat (Rae 1994b, 1995). The known sites are limited to St. Lucie sand which is excessively well drained (Watts and Stankey 1980), where the water table is normally deeper than 3 m. Water capacity, fertility, and organic matter content are all very low. The most common plant species in this community include sandhill jointweed (Polygonella fimbriata), hairy jointweed (P. ciliata), tall jointweed (P. gracilis), sand live oak (Quercus geminata), myrtle oak (Q. myrtifolia), cabbage palm (Sabal palmetto), and pricklypear (Opuntia humifusa). Much of the Atlantic Coastal Ridge was cleared in the 1880s for pineapple plantations, but commercial pineapple cultivation was abandoned by 1920. The vegetative community has yet to regain its previous level of diversity or productivity. The vegetative succession has been arrested and the plant community has not succeeded to the climax sand pine habitat type (Rae 1994a, 1995). This cactus prefers partial shade, which is often provided by surrounding plants that shelter it from sun for a portion of the day (Rae 1994b). Surrounding vegetation is often used for support by fragrant prickly-apple for its long stems. Other plants may serve as nurse plants for the seedlings, protecting them from direct sun, but this has not been studied. As the plant grows, the nursery plant may die, leaving the cacti exposed to a greater intensity of sunlight. Overgrowth and shading by sand live oaks and other species may cause reproductive failure and premature death. Growth and productivity seems to be greater for plants in areas that are partially shaded. (USFWS, 2016)

***Dispersal/Migration***

***Population Information and Trends***

**Number of Populations:**

7 (six natural and one introduced) (USFWS, 2021)

**Population Size:**

Less than 1,200 individuals (USFWS, 2021)

**Population Narrative:**

Fragrant prickly-apple was listed as endangered on November 1, 1985, following substantial losses of suitable habitat (50 FR 45621). At the time of listing, fragrant prickly-apple was only known from St. Lucie County (Service 1985). Historically, fragrant prickly-apple occurred in coastal hammock habitats on the east coast of Florida in St. Lucie, Indian River, Brevard, and Volusia Counties, although some accounts in other areas were erroneously reported due to misidentification with Simpson's prickly-apple (Cereus gracilis var. simpsonii) (Service 1985; Service 1999; Woodmansee et al. 2007). Fragrant prickly-apple was reportedly collected in Everglades National Park (ENP), but this is not confirmed (NPS 2007; Sadle 2009). Because Simpson's prickly-apple commonly occurs in ENP, there is much confusion over identification of these two species, there is no voucher specimen available in herbarium collections for confirmation, the fragrant prickly-apple is limited in distribution, and ENP lacks the habitats believed to support fragrant prickly-apple, it is thought that the species was misidentified (NPS 2007; Sadle 2009). The species is now known to occur on only 10 confirmed sites in Volusia and

St. Lucie Counties, primarily on or around Savannas Preserve State Park (SPSP) where the site covers an area approximately 10.0 mi long and 0.5 mi wide and is bisected by the Florida East Coast railway (Bradley et al. 2002; Bradley and Gann 2002; Woodmansee et al. 2007; Florida Natural Areas Inventory [FNAI] 2009). These cacti are often found to occur in distinct clusters (Bradley et al. 2002; Woodmansee et al. 2007). The occurrence of fragrant prickly-apple in Indian River County is yet unconfirmed because only a single sterile plant was observed on a coastal berm when surveys were conducted in 2006 (Woodmansee et al. 2007; FNAI 2009). Although only confirmed in Volusia and St. Lucie Counties, it is possible that the current range of the species includes Brevard and Indian River Counties, as these counties occur between confirmed locations and appropriate habitat is available (Woodmansee et al 2007).(USFWS,2016). Fragrant prickly-apple is a narrow-ranging species, occurring in just four Florida counties along the Atlantic Coastal Ridge (St. Lucie, Indian River, Brevard, and Volusia). There are currently only seven extant populations (six natural and one introduced) (Table 1). With the recent discoveries of the cacti in Indian River and Brevard counties, the number of known populations has increased; however, the sites where it occurs are fragmented, disjunct, and isolated from each other. Despite newly identified populations and a reintroduction effort, the total number of fragrant prickly-apples has declined from an estimated 3,000 individuals in 2007 (Service 2010) to fewer than 1,200 in 2020 (Table 1; Woodmansee et al. 2007; Kneifl 2020a; Moore 2020a, 2020b; Rogers 2020; van den Ende 2020a; Service unpublished data record). (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat destruction or modification (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Continued habitat loss, fragmentation, and changes in land use threaten the existence of fragrant prickly-apple. Where plants occur on private sites, development has led to both direct destruction of habitat as a result of land clearing and habitat degradation from lack of management. For example, Woodmansee et al. (2007) suggested that the two extirpated sites in Brevard County were probably lost due to habitat alteration or destruction and severe freezes. Moore (2009) stated that another private site known to contain fragrant prickly-apple was to be sold for development a few years ago. After obtaining permission to salvage the cactus from the property, he returned to find that it had already been removed (Moore 2009). - Threats from development and habitat degradation on private sites are expected to continue and increase. Within the range of fragrant prickly-apple, the human population is predicted to grow from just below 500,000 to nearly 1,000,000 in Volusia County and from approximately 193,000 to more than 563,000 in St. Lucie County between 2005 and 2060 (Zwick and Carr 2006). - Even though 63 percent of the sites around SPSP containing fragrant pricklyapple are publicly owned and not at risk of being developed, the plants on these sites may still be vulnerable to habitat degradation from encroachment of exotic plant species and lack of fire or other mechanical treatment. If sites are not properly managed, ecosystem health may deteriorate. Because the sites are fragmented on a developed landscape, fire management may not always be feasible and encroachment by exotic plant species from neighboring properties is likely. Because population densities tend to vary over time, even those sites with high population densities may be vulnerable if not monitored carefully (Rae in litt. 2010). Therefore, habitat loss, degradation, and fragmentation due to increasing development and lack of management in coastal scrub habitat and the

encroachment of exotic plants continue to threaten fragrant prickly-apple. (USFWS, 2010)

**Stressor:** Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing, overutilization was identified as a potential threat for fragrant prickly-apple, but indiscriminate collecting was not known to occur. Because it is limited in distribution and population sizes are relatively small, indiscriminate collecting could adversely affect the species. Like many other species of cacti, fragrant prickly-apple is vulnerable to unlawful exploitation and collection due to the activities of some collectors and hobbyists. Enforcement is difficult due to insufficient resources and the remoteness of the plants. There is minor horticultural interest in this species (Bradley and Gann 2002). During the 5 years of monitoring that took place at SPSP, there was no evidence of poaching (Bradley and Gann 2002). However, the salvage of a fragrant prickly-apple from a property slated to be sold for development was planned but never occurred because the plant was mysteriously removed before the rescue could be implemented (Moore 2009). The Service believes that there is a continuing threat from overutilization for commercial or recreational purposes. (USFWS, 2010)

**Stressor:** Disease or predation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** When the fragrant prickly-apple was listed as endangered, disease and predation were not known to be threats. However, insects may damage cacti. Moore (2009) noted that young seedlings were damaged when unidentified caterpillars ate the sprouts. A native scale insect, Diaspis echinocacti, has been found to destroy stems of the fragrant pricklyapple in SPSP; however, it does not appear to kill the host plant (Bradley et al. 2002a; Bradley and Gann 2002). Root parasitism may occur when fragrant 10 prickly-apple grows in association with tallow wood (Ximenia Americana) or graytwig (Schoepfia chrysophylloides) but has not been directly observed (Bradley and Gann 2002). Fragrant prickly-apple may also be parasitized by love-vine. There is evidence that birds eat the fruit and serve as a mechanism to disperse seeds (Service 1999). It is also thought that rodents or gopher tortoises may distribute seeds (Service 1999). These occurrences of predation and parasitism are not known to constitute serious threats to the fragrant prickly-apple. (USFWS, 2010)

**Stressor:** Inadequacy of existing regulatory mechanisms (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The ESA provides limited protection for the species and its habitat. Existing Federal regulations prohibit the removal or destruction of listed plant species on Federal lands. The fragrant prickly-apple is also listed by the Florida Department of Agriculture and Consumer Services (FDACS) as endangered (5B-40.0055 Regulated Plant Index), but this legislation does not provide any direct habitat protection. State regulations require both written permission from the owner or legal representative and a permit issued by FDACS to collect or remove plants listed as endangered on the Florida Regulated Plant Index. Title 62D2.013 of the Florida Administrative

Code prohibits the removal, destruction, or damage of plants from FDEP, Division of Recreation and Park properties. This regulation provides protection for much of the population where it occurs on SPSP. - Existing regulatory mechanisms do not appear to be adequate, as several properties with fragrant prickly-apple on private lands have been developed. Fragrant prickly-apple was potentially impacted in 2005 when heavy equipment was used to push debris into habitat where the species was presumed to occur along the railroad right-of-way (Kaufmann 2005). Multiple portions of potential habitat along the railroad tracks are being purchased and used to dump dredged material from the Intracoastal Waterway along the Indian River. - Because this plant occurs in habitat along the Atlantic coastal ridge, which is desirable for development and other uses due to its elevation, it remains vulnerable to development pressures where it occurs on private property. Where the species occurs on public land, there is protection from development but not necessarily from habitat degradation. (USFWS, 2010)

**Stressor:** Prescribed fire (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Land management practices such as prescribed fire are important to maintaining the scrub ecosystem. However, the fragrant prickly-apple is intolerant of fire (Bradley and Gann 2002). Because it is thought that the species was historically located along the perimeter of scrub habitat in xeric hammocks, it may not have been affected as frequently by fires that were occurring in adjacent scrub (Bradley and Gann 2002). (USFWS, 2010)

**Stressor:** Invasive nonnative plant species (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A large source of habitat degradation is the establishment of invasive plant 11 species such as Brazilian pepper (Schinus terebinthifolius), rosary pea (Abrus precatorius), white cypress pine (Callitris glaucophylla), golden trumpet (Allamanda cathartica), cathedral bells (Kalanchoe pinnata), chandelier plant (K. tubiflora), swamp mahogany (Eucalyptus robusta), guinea grass (Panicum maximum), and Crow's foot grass (Dactyloctenium aegyptium) (Bradley and Gann 2002; Bradley et al. 2002b). These invasive species may impact fragrant prickly-apple growth, reproductive potential, and recruitment by competing for space and nutrients and blocking sunlight (Bradley and Gann 2002). The species frequently grows beneath the canopy of these invasives to take advantage of partial shade and also can be crushed beneath falling limbs or trees not able to withstand hurricane winds (Bradley and Hines 2007). However, herbicides used to control overgrowth, if not properly applied, also pose a threat to the fragrant prickly-apple. Bradley and Hines (2007) noted mortality as a result of off-target herbicide application at SPSP. (USFWS, 2010)

**Stressor:** Feral hogs, tortoise, and inadequate land management (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Degradation to habitat can also occur from damage by feral hogs (Engeman et al. 2003, 2004). Bradley and Hines (2007) recorded an incident in which feral hog damage killed a fragrant prickly-apple plant. Gopher tortoises may also bury small cacti at the mouth of burrows

(Bradley and Gann 2002). Vegetation restoration and management programs are costly, and the availability of funding is never assured; therefore, habitat modification from inadequate management even on protected lands remains an imminent, though moderate, threat. (USFWS, 2010)

**Stressor:** Climatic events (USFWS 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The species' restriction to specialized habitat, its limited distribution, and its limited reproductive capacity also renders it vulnerable to random natural events, such as freezes and hurricanes. Sea level rise may also threaten cacti on sites with low elevation, such as those at Canaveral National Seashore (Woodmansee et al. 2007). Woodmansee et al. (2007) suggested that freezing temperatures may have led to the extirpation of the species at one location in Brevard County. Although the species did well through the Category 1 hurricane in 2000 and the Category 2 and 3 storms in 2004 and 2005 (Bradley and Gann 2002; Woodmansee et al. 2007), specific conditions such as storm surge and amount of debris dumping following the event vary greatly with each hurricane and may render sites with few plants vulnerable to destruction. Hurricanes have the potential to adversely affect fragrant prickly-apple populations in other ways. High winds can bring surrounding vegetation crashing down on top of individual cacti, injuring or killing them. Bradley and Hines (2007) found that mortality rates more than tripled at SPSP as a result of hurricane impacts. One colony that was particularly affected was located beneath invasive white cypress pine trees which were not equipped to handle hurricane winds and either fell or lost numerous branches that crushed the cacti below (Bradley and Hines 2007). However, hurricanes also open hammock canopies, allowing light to penetrate and stimulating flowering activity, thus providing conditions that may be favorable to cactus regeneration (Bradley and Gann 2002; Woodmansee et al. 2007). (USFWS, 2010)

***Recovery***

**Reclassification Criteria:**
Not defined; 1999 Recovery Plan provided only "stabilization" criteria. (USFWS, 1999)

Recovery Priority Number: 3

**Delisting Criteria:**
1. When at least 15 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)

2. When populations (as defined in criterion 1) in coastal sand pine scrub habitat are distributed across the historical range of the species. (Factors A and E) (USFWS, 2019)

3. When populations (as defined in criterion 1) must be protected via a conservation mechanism and managed (e.g., appropriate burn intervals) such that enough suitable habitat is present for the species to remain viable for the foreseeable future. (Factors A, B, D, and E) (USFWS, 2019)

**Recovery Actions:**

- 1. Determine distribution of C. e. var. fragrans. Known C. e. var. fragrans populations occuron well-drained soils indicative of xeric upland plant communities. Much of the xeric upland habitat of Indian River and St. Lucie counties remains botanically unsurveyed and threatened with destruction. Efforts to survey and assess the xeric vegetative communities for C. e. var.fragrans are needed to ensure the survival of this species. (USFWS, 1999)
- 2. Protect and enhance existing populations. Of the three populations known, one occurs on private land in residential areas and two occur in Florida's Savannas State Preserve. Additional protection at each of these sites is needed. (USFWS, 199)
- 3. Conduct research on the biology of C. e. var. fragrans. Much of the basic biology and ecology of this species remains poorly understood. If we are to effectively recover the species, more specific biological information will be needed. (USFWS, 1999)
- 4. Monitor C. e. var. fragrans populations. Maintain an inventory of naturally reproducing populations to help determine habitat characteristics and natural environmental changes affecting C. e. var. fragrans. (USFWS, 1999)
- 5. Provide public information about the fragrant prickly-apple cactus. It is important, and perhaps crucial, to the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and landowners be appropriately informed about this species. Informing the conservation organizations such as the Cactus and Succulent Society is appropriate, but care is needed to avoid unnecessarily revealing localities and to avoid stimulating demand for the species. Efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of C. e. var. fragrans and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- 6. Establish delisting criteria. Once reclassification is achieved, research and monitoring results may provide data necessary to develop delisting criteria. (USFS, 1999)
- Habitat-level Recovery Actions: - Protect, manage and enhance habitat. None of the habitat for C. e. var. fragrans on private land is secure at this time. Efforts to protect these sites are essential since many of the remaining plants occur on private land. - Monitor habitat and ecological processes. Little is known regarding response of C. e. var. fragrans to land management actions used in coastal xeric communities. The effects of fire, vegetative cutting, or other measures must be monitored to determine biological and ecological consequences. - Continue public information efforts about xeric vegetative communities and their unique biota. Educational efforts, especially those conducted by private conservation organizations, have been successful in providing important information about xeric plant communities to the public. (USFWS, 1999)
- Surveys: • Continue monitoring the SPSP and Volusia County populations on an annual basis and after stochastic events, such as fires. 13 • Conduct additional surveys on other parts of Hutchinson Island South in St. Lucie County, Sebastian Inlet State Park in Brevard and Indian River Counties, spoil islands in Indian River and St. Lucie Counties, Pelican Island National Wildlife Refuge and the southern end of Pine Island in Indian River County, and other potential locations within the historic range. • Re-survey the Pine Island location to confirm the identity of the plant in question. (USFWS, 2010)
- Management: • Continue management actions to remove invasive species with particular care in using mechanical means and herbicide application that may damage cacti; control public access to these areas to avoid human disturbance and to improve habitat conditions.

• Continue application of prescribed fire to habitats that support the species while maximizing the number of burn units rather than applying fire to large expanses of habitat. • Consider reducing the canopy in areas where cacti are impacted by too much shade. • Restore coastal hammocks along the eastern slope of the Atlantic Coastal Ridge. • Where unable to restore coastal hammocks, maintain the threeawn (Aristida gyrans)/ Sabal palm (Sabal palmetto) habitat that fragrant prickly-apple now occupies for the long-term existence of the species. • Control public access and eliminate dumping in areas where fragrant prickly-apple occurs. • Focus conservation efforts on marginal and small sites to preserve the genetic diversity of the species. • Evaluate the feasibility of acquiring private property in Brevard County for reintroduction of the species, identify suitable habitat for additional reintroduction sites in protected areas, and establish reintroduced populations. • Increase the genetic diversity of the species at existing and reintroduced locations. (USFWS, 2010)

- Research: • Conduct demographic studies using a metapopulation approach to understand spatial and temporal variation. Incorporate surveys to evaluate flower and fruit production. • Develop a model to evaluate long-term population growth in relationship to microhabitat conditions (i.e., shade, partial shade, and sun). • Develop mechanisms to improve seedling survival and continue to study seed germination to determine habitat preferences of the species. Evaluate the role of nurse plants that provide shade in the early development of seedlings. • Conduct research on recruitment, mortality, seed bank characteristics, and soil moisture. • Conduct parallel studies on the other two similar cacti in Florida, Simpson's pricklyapple and Aboriginal pricklyapple (Harrisia aboriginum), to gain additional insight into fragrant prickly-apple biology and to delineate these species. • Continue genetic research and appropriately apply these results to listing status of all Harrisia species in Florida. • Conduct a population-level genetic study using microsatellite markers to determine genetic variation within the species and gene flow in and among sites and to better understand the reproductive mode at low population densities. • Conduct research on the response of fragrant prickly-apple to fire and fire prescriptions necessary to benefit the species. • Identify pollinators and evaluate impacts to insect pollinators from aerial mosquito spraying. • Continue propagation efforts and collect germ plasm from the remaining sites not currently represented in the CPC's National Collection of Endangered Plants, primarily from the Volusia County population. • Evaluate the effects of climate change on the species, including those that result from precipitation pattern changes and temperature rise. (USFWS, 2010)
- Other: • Pursue conservation agreements/implement management recommendations and/or acquire land and investigate incentives to encourage land managers to manage habitat for ecosystem health and listed species. • Acquire private inholdings within the SPSP when willing sellers are identified. • Consider acquiring the Pine Island tract in Indian River County and determine the status of Fairchild Tropical Botanic Garden's ex situ population of plants from this site. • Promote partnerships to share information, conduct collaborative research on coastal scrub habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. • Consider nomenclatural changes to officially designate the name of the fragrant pricklyapple as Harrisia fragrans. • Conduct an ad hoc meeting to compile new information, discuss recovery actions, share land management strategies, and set and prioritize 5- and 10-year goals. • Seek opportunities to include the media in conservation efforts to provide information about this species to the public. (USFWS, 2010)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIVITIES A detailed discussion of recovery actions and criteria are presented in the Recovery Plan and amendment (Service 1999 and 2019, respectively). In the course of this status review new and/or targeted potential recovery activities were identified and are included below. Recovery Activities • Continue management actions to remove invasive species at CNS, ACNWR, SPSP with particular care when using mechanical means and herbicide application that may damage cacti. • Control public access to populations on public lands to avoid human disturbance. • Continue application of prescribed fire to pyric habitats that support the species at SPSP and ACNWR while using protection measures (e.g., clearing leaf litter away from cacti, creating more burn units for small, patchy fires, etc.) to prevent harming these populations. • Reduce the canopy cover only when the cacti become impacted by too much shade, but leave enough vegetation to protect from desiccation. • Move fallen trees and woody debris away from fragrant prickly-apples to reduce chances of termite damage. • Restore coastal hammocks along the Atlantic Coastal Ridge for potential introduction sites. • Identify suitable areas of protected xeric and coastal hammock for introductions and establish new populations. • Focus conservation efforts (habitat management, augmentations, etc.) on small populations (CNS, ACNWR, Central SPSP) to reduce inbreeding depression and preserve the genetic diversity of the species. • Consider translocating the CNS population to a higher elevation to prevent further decline due to sea level rise and storm surge. • Continue propagation efforts and collect and bank germplasm and seed from the remaining sites not currently represented in the CPC's National Collection of Endangered Plants, primarily from the Volusia, Brevard, and Indian River County populations. • Acquire private inholdings within the SPSP when willing sellers are identified. • Acquire the Pine Island tract in Indian River County if the species is still present. • Work with private land owner(s) (Roseland population) and Indian River County staff to translocate individuals in undeveloped lots as that portion of the property is developed. Monitoring/Research Activities • Conduct a scientific review (e.g., SSA) of the new entity and evaluate its listed status under provisions of the ESA. • Continue monitoring the SPSP and CNS populations on an annual basis and after stochastic events, such as freezes, fires, and hurricanes. • Begin annual monitoring efforts for the ACNWR, Roseland, and HBOI populations to assess status and trends. • Re-survey the Pine Island (Indian River County) location to confirm the identity and status of the plant in question. • Conduct additional surveys on other parts of the barrier and spoil islands along Brevard, Indian River, and St. Lucie counties, as well as other potential locations on the mainland within the historical range. • Conduct surveys in suitable habitat within Martin, Palm Beach, and Broward counties to look for fragrant prickly-apple populations that may occur between the fragrant pricklyapple and populations formerly known as Simpson's prickly-apple. • Assess the status of the populations formerly known as Simpson's prickly-apple in Miami-Dade and Monroe counties in preparation for evaluating the status of and threats to the synonymized species. • Conduct research on the response of fragrant prickly-apple to fire and fire prescriptions necessary to benefit the species. • Identify pollinators and evaluate impacts to insect pollinators from aerial mosquito spraying. • Evaluate the effects of climate change on the species, including those that result from precipitation pattern changes and temperature rise. • Increase outreach efforts to raise awareness of this native species, the natural scrub, xeric hammock, coastal strand, and coastal hammock habitats, and the work needed to recover the species. (USFWS, 2021)

# SPECIES ACCOUNT: *Chamaesyce deltoidea pinetorum* (Pineland sandmat)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 11/6/2017; Southeast Region (R4) (USFWS, 2017)

**Physical Description**

Chamaesyce deltoidea ssp. pinetorum is an ascending to erect perennial herb. The stems are hairy and often reddish. The leaf blades range from kidney-shaped or triangle-shaped and elliptic to oval. The fruit is a 2-mm broad, pubescent capsule. The seeds are 1 mm long, transversely wrinkled, and yellowish in color. Fruit production is year-round, with a peak in the fall. (USFWS, 2017)

**Taxonomy**

Chamaesyce deltoidea ssp. pinetorum was first described by Small in 1905, based on specimens collected in eastern Miami-Dade County. Initially, Small referred to these specimens as C. pinetorum but recognized that it was closely related to Chamaesyce deltoidea. Herndon (1993, included C. pinetorum within the C. deltoidea complex, which is composed of three other taxa, two occurring farther north on the Miami Rock Ridge, and one occurring on Big Pine Key in the lower Florida Keys (Monroe County). The three taxa on the Miami Rock Ridge have distinct, but adjacent, ranges. Subsequently, Herndon (1993) has placed all four taxa at the same taxonomic level, treating each as a distinct subspecies under Chamaesyce deltoidea (C. deltoidea ssp. pinetorum, C. deltoidea ssp. serpyllum, C. deltoidea ssp. adhaerens, and C. deltoidea ssp. deltoidea). Chamaesyce deltoidea ssp. deltoidea and C. deltoidea ssp. adhaerens occur north of known C. deltoidea ssp. pinetorum populations, while Chamaesyce deltoidea ssp. serpyllum is endemic to Big Pine Key. Wunderlin and Hansen (2016) follow Herndon's treatment in using C. deltoidea ssp. pinetorum. Some modern authors place the genus Chamaesyce into the genus Euphorbia sensu lato. If placed into the genus Euphorbia, the correct name of pineland sandmat is Euphorbia deltoidea ssp. pinetorum. The online Atlas of Florida Vascular Plants uses the name Chamaesyce deltoidea ssp. pinetorum (Small) Herndon (Wunderlin and Hansen 2016, p. 1). NatureServe (2016, p. 1) and FDACS (Coile and Garland 2003, p. 11) indicate that C. deltoidea ssp. pinetorum is accepted. However, the Integrated Taxonomic Information System (ITIS 2016, p. 1) accepts Euphorbia deltoidea ssp. pinetorum as the scientific name for the subspecies (Gann 2015, p. 168). We have carefully reviewed all taxonomic data to determine that C. deltoidea ssp. pinetorum is a valid taxon. (USFWS, 2017)

**Historical Range**

Chamaesyce deltoidea ssp. pinetorum occurred historically only with the southern portion of the Miami Rock Ridge, from Homestead to the Long Pine Key region of Everglades National Park, a range of approximately 42 mi (67.6 km). (USFWS, 2017)

**Current Range**

The current range of Chamaesyce deltoidea ssp. pinetorum is similar to the historical range, although 98 percent of the pine rocklands (the species' only habitat) outside of the Everglades National Park has been lost to development. (USFWS, 2017)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2017)

**Lifespan**

Adult: Somewhat long-lived; 88 percent of plants survived more than 3 years. Extensive root system (USFWS, 2017)

**Dependency on Other Individuals or Species**

Adult: Pollinators may include bees, flies, ants, and wasps (USFWS, 2017)

**Breeding Season**

Adult: year-round

**Other Reproductive Information**

Adult: This species is known to flower and fruit year round. Peaks in fruiting for C. deltoidea ssp. pinetorum occur in the fall and are stimulated by fire. (USFWS, 2017)

**Reproduction Narrative**

Adult: Reproduction is sexual, but little is known about the reproductive biology and ecology of the subspecies. Some of the plants recorded as dead during surveys may have instead been in a cryptic phase . Pollinators are unknown; some other species of Chamaesyce are completely reliant on insects for pollination and seed production, while others are self-pollinating. Pollinators may include bees, flies, ants, and wasps. (USFWS, 2017)

**Habitat Type**

Adult: Pine rockland in pockets of clayey marl or on oolitic limestone

**Dependencies on Specific Environmental Elements**

Adult: Fire is an important element in maintaining the pine rockland habitat.

**Environmental Specificity**

Adult: Narrow (inferred from USFWS, 2017)

**Tolerance Ranges/Thresholds**

Adult: The plants can stand partial inundation with fresh water for a portion of the year, but do not tolerate salinity. (USFWS, 2017)

**Habitat Narrative**

Adult: Chamaesyce deltoidea ssp. pinetorum occurs in pine rocklands. Pine rocklands are maintained by regular fire, and are prone to annual flooding for several months during the wet season. However, C. deltoidea ssp. pinetorum generally occurs in higher elevation pine rocklands at Long Pine Key in Everglades National Park, in areas rarely subject to flooding. See detailed description of Pine Rockland habitat in Additional Habitat Information (USFWS, 2017)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Dispersal is unknown for Chamaesyce deltoidea ssp. pinetorum; however, many seed capsules in similar Chamaesyce species are explosively dehiscent, a form of dispersal that flings seeds far from the parent plant. Chamaesyce deltoidea ssp. pinetorum is thought to have a similar, but reduced, level of dispersal (USFWS, 2017)

***Population Information and Trends***

**Number of Populations:**

3 extant populations (2 wild, 1 reintroduced) (USFWS, 2023)

**Population Size:**

>313,000 (USFWS, 2023)

**Population Narrative:**

The total population size of Chamaesyce deltoidea ssp. pinetorum is estimated to be 14,500-146,000 individuals, with the majority of the population occurring on Long Pine Key. However, while Chamaesyce deltoidea ssp. pinetorum is most abundant within Everglades National Park, pine rockland fragments outside of the Everglades represent about half the subspecies' extant range. (USFWS, 2017). Though it was historically known from five islands (No Name Key, Big Pine Key, Ramrod Key, Cudjoe Key, and Lower Sugarloaf Key), only two populations were extant at the time of listing (Big Pine Key and Cudjoe Key; Service 2016). The Cudjoe Key population was not found during recent surveys despite habitat remaining in the area (Lange 2022) and is now considered potentially extirpated since seeds may persist in the soil seed bank for up to three years (Liu and Menges 2005). A translocation of plants and seeds sourced from Big Pine Key were used to reestablish a population on No Name Key in 2019 (Lange et al. 2019; Cuni et al. 2020; Figure 1). The species was extirpated from this area due to lack of habitat management, but restoration with mechanical treatment and prescribed fire occurred prior to reintroduction (Lange et al. 2019). In 2019, 48 individuals were transplanted to No Name Key (Cuni et al. 2020). Within a year after transplanting, over 300 first generation seedlings had recruited, and 220 seedlings were documented three years after transplanting (Fairchild unpublished data). Also in 2019, 720 seeds were sown in 36 seed plots at No Name Key (Cuni et al. 2020). One and half years after sowing, average emergence rates ranged from 31 to 53 percent and average survival rates ranged from 24 to 48 percent (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Present or Threatened Destruction, Modification, or Curtailment of Its Habitat or Range
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat loss, fragmentation and degradation, and associated pressures from increased human population are major threats this species. These threats are expected to increase as

remaining pine rocklands and other habitats are lost to development, placing these plants at greater risk. This species may be impacted when pine rocklands are converted to other uses or when lack of fire causes the conversion to hardwood hammocks or other unsuitable habitats. On public lands, including National Park Service lands and Miami-Dade County-owned lands, implementation of prescribed fire has not been sufficient because of legal constraints (permitting requirements) and inadequate funding. Any populations of this species found on private property could be destroyed due to development. Although efforts are being made to conserve natural areas and apply prescribed fire, most pine rocklands remain in poor fire condition, and the long-term effects of large-scale and wide-ranging habitat modification, destruction, and curtailment will last into the future, while ongoing habitat loss due to population growth, development, and agricultural conversion continues to pose a threat to this species outside of conservation lands.

**Stressor:** Inadequacy of Existing Regulatory Mechanisms
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** This species is found on Federal, State and County lands. NPS regulations provide protection at Everglades National Park and Big Cypress National Preserve. These two sites continue to support the largest and best managed populations. State regulations provide protection against trade, but allow private landowners or their agents to clear or remove species on the Florida Regulated Plant Index. State Park regulations provide protection for plants within Florida State Parks. The Natural Forest Communities program in Miami is designed to protect rare and important upland (non-wetlands) habitats in south Florida; however, this regulatory strategy has several limitations that reduce its ability to protect this plant and its habitat. Although many populations of this species are afforded some level of protection because they are on public conservation lands, especially Federal lands, existing regulatory mechanisms vary in strength and scope, and do not provide substantive protection of habitat at this time. They have not led to a sufficient reduction of threats posed to these plants by a wide array of sources. (USFWS, 2017)

**Stressor:** Other Natural or Manmade Factors Affecting Its Continued Existence
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats from other natural or manmade factors to this species include nonnative, invasive plants; management practices (such as mowing); recreation (including off-road vehicle use), effects from small population size and isolation; limited geographic range; and stochastic events including hurricanes, storm surges, and wildfires. Additionally, this plant is particularly vulnerable to the effects of climate change, including sea level rise, as changes in the water table, increased soil salinity from partial inundation, and storm surge will likely result in vegetation shifts in the decades prior to the fully anticipated sea level rise. Some of these threats (e.g., nonnative species) may be reduced on public lands due to active programs by Federal, State, and County land managers. Many of the remaining populations of this plant are small and geographically isolated, and genetic variability is likely low, increasing the inherent risk due to overall low resilience of these plants. The threats act together to impact populations of this species. (USFWS, 2017)

***Recovery***

**Reclassification Criteria:**
Not defined.

Recovery Priority Number: 9

**Delisting Criteria:**
Not defined.

**Recovery Actions:**
- Not defined.
- Conserve pine rocklands and suitable habitat through purchase or conservation easements (Wendelberger 2003, p. 182).
- Remove exotic plants or hardwoods. Use manual labor, herbicides, and prescribed fire, and once cleared, use proper management to reduce costs of control and to maintain the site free of exotics (Bradley and Gann 1999, p 26.). Control seed sources in small, fragmented areas surrounded by urban development (Bradley and Gann 1999, p. 26).
- Implement regular, prescribed burns to create or maintain suitable habitat conditions. In general, a mosaic of burns should be used, and the recommended burning regime is 3 to 7 years with summer burns generally preferred to winter burns (Bradley and Gann 1999, p. 26). Where fire has been suppressed for long periods of time, reintroduce fire in a step-wise manner (Bradley and Gann 1999, p. 26; Wendelberger 2003, p. 182). Include a monitoring program to determine effectiveness of the fire prescription (Bradley and Gann 1999, p. 26).
- Monitor and manage pine rockland fragments in Miami-Dade County.
- Continue monitoring rare plants at Long Pine Key (Gann et al. 2006, p. 2). It is important to determine effects (positive or negative) from Everglades restoration and other hydrologic manipulations and changes.
- Resurvey known locations and compare those data with current location data to better understand the stability and size of the population (Wendelberger 2003, p. 183; Maschinski et al. 2005, p. 163).
- Consider ex situ collections (Maschinski et al. 2005, p. 163).
- Assess the need for studies to determine current level of genetic variation remaining in extant occurrences.
- Assess the need to augment the population (Wendelberger 2003, p. 183).

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIVITIES This species does not have a final recovery plan. While completing this status review, we have identified the following potential recovery activities which are included below. Recovery Activities • Conduct or continue to conduct habitat maintenance or restoration at occupied areas, including removal of native hardwoods and non-native invasive plants and prescribed burns every 5-7 years. • Protect parcels on Big Pine Key that are occupied by the species. • Continue monitoring the reintroduction on No Name Key and augment as needed, until population is established. • Develop a translocation/reintroduction plan to identify other potential recipient sites for reintroducing or establishing populations. Any future introductions in the Lower Keys should include deer exclusions to protect plants, at least during the establishment phase, and potentially in the longer-term as well. Monitoring and Research Activities • Conduct regular monitoring and assessments of the status of the Big Pine Key population. •

Conduct research on viability of seeds in long-term cold storage to determine storage lifespan and the rate at which stores should be replenished. • Collect and bank wild seeds at an appropriate ex situ facility at least once per decade, or more often if indicated by results of research on viability in storage. • Identify the best management regimes for Big Pine partridge pea along roadsides. • Research the effects of Key deer browsing on Big Pine partridge pea abundance and fitness. • Continue research on the effects of mosquito spraying on Big Pine partridge pea fruit set and plant fitness. Outreach Activities • Increase public education and outreach about native plants and habitats in the Lower Keys community, involve local schools and residents in habitat conservation and restoration efforts geared toward Big Pine partridge pea and other rare species and habitats. • Conduct public outreach on Big Pine Key and No Name Key aimed at improving residents' opinions about prescribed fire and its ecological importance (noting that poststorm-surge recovery of the Big Pine partridge pea is greater in areas that have recently burned) (USFWS, 2023).

# SPECIES ACCOUNT: *Chamaesyce deltoidea ssp. deltoidea* (Deltoid spurge)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 8/19/1985; Southeast Region (R4)

**Physical Description**

Chamaesyce deltoidea ssp. deltoidea is a small, monoecious, prostrate to decumbent herb occurring in mats over exposed limestone. The stems are terete (circular although slightly oblong) in cross section, brown, and 0.3 to 0.6 mm in diameter. The leaves are smooth above to slightly hairy below, with an obtuse apex, cordate base, margins entire; stipules laciniate, brown to reddish brown with light tips, and smooth. The inflorescence is found singly, in leaf axils, with a short peduncle (1 mm long). The cyathium is 1.2 mm long, 1.0 mm wide and smooth (glabrous). It is green and ovate in shape with four glands and minute appendages. The fruit is a capsule, 1.0 mm long and 1.0 mm wide, and completely glabrous. The pedicel is also glabrous. It is fully exerted at maturity. There are three seeds, 1.0 mm long and 0.5 mm wide, ovate in shape and glabrous. The seeds are laterally four-ridged and yellowish-white (Remus 1979). The leaves and stems of the subspecies Chamaesyce deltoidea ssp. adhaerens are appressed to the ground surface and the plants form mats. In some cases the stems will ascend and form tufts (Herndon 1993). The inflorescence is solitary, terminal, pedunculate (1.5 mm long), and glabrous proximally to pilose distally. The main distinction between the two subspecies is their pubescence. The pubescence of the subspecies C. deltoidea ssp. adhaerens is appressed on the leaves and on the stems it is spreading or appressed (Herndon 1993). The pubescence for C. deltoidea ssp. deltoidea is sparse, appressed on the leaves and the stems are glabrous or thinly pubescent (Herndon 1993). (USFWS, 1999)

**Taxonomy**

Deltoid spurge was first described as Euphorbia deltoidea by Engelman (Chapman 1883). In 1903, Small transferred the species to the genus Chamaesyce, a natural genus distinguished from Euphorbia by having the main stem abortive just above the cotyledons, making the aerial portion of Chamaesyce homologous to the inflorescence of Euphorbia subgenus Esula (Webster 1967). Burch (1966) treated C. deltoidea as a complex of three taxa endemic to South Florida: C. deltoidea, C. adhaerens Small, and C. serphyllum Small, treating deltoid spurge as C. deltoidea (Engelman ex Chapman) Small subsp. deltoidea var. deltoidea without comment. In Herndon's (1993) revision of the C. deltoidea complex, he recognized four subspecies endemic to South Florida: ssp. deltoidea, ssp. adhaerens, ssp. pinetorum, and ssp. serphyllum. The taxonomy of this complex is difficult and some follow Burch's 1966 treatment and others follow Herndon's 1993 treatment. The final rule as listed in the Federal Register applies to the taxa deltoidea and adhaerens, which are restricted to Miami-Dade County, Florida. According to this, all members of the C. deltoidea complex that are restricted to Miami-Dade County are considered endangered species by the FWS. For purposes of clarity, Herndon's treatment will be used for this recovery plan. Synonyms: Euphorbia deltoidea Engelman ex Chapman; Chamaesyce deltoidea (Engelman ex Chapman) Small ssp. deltoidea var. deltoidea; Chamaesyce adhaerens Small; Chamaesyce deltoidea (Engelm. ex Chapman) ssp. deltoidea var. adhaerens (Small) Burch. (USFWS, 1999)

**Historical Range**

In Florida, endemic that was historically known to occur in pine rocklands from the Goulds area north to the center of the city of Miami (USFWS, 1999)

**Current Range**

In Florida, from south Miami to the Homstead area (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: Flowers from April through November, peaking in July. (USFWS, 1999)

**Reproduction Narrative**

Adult: Studies into the life history of the deltoid spurge have only recently begun and little is known about its reproduction. It is a perennial that flowers from April through November, peaking in July. Its extensive root system gives evidence that it is a long-lived plant (DERM 1994). The reproductive ecology in Chamaesyce has been poorly studied but it is known to be highly variable (Ehrenfeld 1976, 1979; Webster 1967). Some species are completely reliant on insects for pollination and seed production, while others are self-pollinating. Pollinators may include bees, flies, ants, and wasps (Ehrenfeld 1979). Seed capsules of many Euphorbiaceae are explosively dehiscent, ejecting seeds a short distance from the parent plant. The seeds of some species are dispersed by ants (Pemberton 1988). (USFWS, 1999)

**Habitat Type**

Adult: Pine rocklands (USFWS, 1999)

**Environmental Specificity**

Adult: Moderate (inferred from USFWS, 1999)

**Habitat Narrative**

Adult: The deltoid spurge tends to occur in areas with an open shrub canopy, exposed limestone (oolite), and minimal litter (pine needles, leaves, and other organic materials). It is most often found growing at the edges of sand pockets with plants growing both in sand (sometimes in association with the endangered Polygala smallii) and on oolitic limestone. The soils in which it grows are classified as Opalocka-Rock Outcrop soils. The subspecies C. deltoidea ssp. adhaerens occurs in fine, reddish sandy loam over limestone. Dense colonies are sometimes found in pinelands that have undergone a slight mechanical disturbance, where little or no topsoil is formed and where productivity is low. The shrub canopy in this disturbed habitat is often poorly developed providing high light levels and low organic litter accumulation rates. The pine rocklands are often considered a fire subclimax, and are maintained with periodic fires (3 to 7 years). These periodic fires keep the shrub canopy down and eliminate the litter accumulations. (USFWS, 1999)

### *Dispersal/Migration*

**Dispersal/Migration Narrative**

Adult: Seed capsules of many Euphorbiaceae are explosively dehiscent, ejecting seeds a short distance from the parent plant. The seeds of some species are dispersed by ants (Pemberton 1988).

### *Population Information and Trends*

**Population Trends:**

Unknown

**Number of Populations:**

15 sites (USFWS, 2023)

**Population Size:**

~16,000 to 20,000 individuals (USFWS, 2019)

**Population Narrative:**

The current known populations of deltoid spurge include 13 public and 2 private sites (Table 1). The largest populations of this subspecies were recorded at Zoo Miami with 10,000 plants, followed by Larry and Penny Thompson Park with 5,300 plants and 808 plants at Ludlam Pineland (Appendix A). These three locations account for over 80 percent of the total known density of the deltoid spurge plant population. Eight populations have been extirpated due to habitat fragmentation, degradation, and fire suppression (Service 2019). Seven of the extirpated populations occurred on public conservation lands. The Bill Sadowski Park population had three plants in a 2016 population estimate (Bradley, pers. comm 2010, Lange pers comm 2017, and Possley pers. comm 2017a). However, a Fairchild survey in 2023 could not find any deltoid spurge at this location, and it is now presumed extirpated (Possley pers. comm 2023). Fairchild reintroduced seeds in one known extirpated location (Trinity Pineland) in summer 2023 (Possley, pers comm 2023). It is too early at the time of this review to determine successful reestablishment, and therefore we continue to assume extirpation at this location (USFWS, 2023).

### *Threats and Stressors*

**Stressor:** Habitat loss and fragmentation
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The pine rockland community of south Florida is critically imperiled globally (FNAI 2010b). In Miami-Dade County, development and agriculture have reduced pine rockland habitat by 90 percent. Continued habitat loss (Factor A) and fragmentation threaten the existence of this species, and less than 1 percent of the original acreage of pine rockland habitat remains outside of ENP (Herndon 1998). Populations on private sites remain threatened with destruction or habitat modification due to improper or lack of management (Factors A and E). (USFWS, 2019)

**Stressor:** Nonnative invasive plants

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasion by exotic plant species continue to affect this species (Factor E)Nonnative invasive plants compete with native plants for space, light, water, and nutrients, and make habitat conditions unsuitable for this species, which prefers open conditions (Factor E). Bradley and Gann (1999) indicated that the control of nonnative plants is one of the most important conservation actions for the pine rockland species and a critical part of habitat maintenance. Nonnative plants have significantly affected pine rocklands and negatively impacted all occurrences of this species to some degree. (USFWS, 2019).

**Stressor:** Inadequate fire management
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Fire suppression continues to affect this species (Factor E). Historically, frequent (approximately twice per decade), lightning-induced fires were a vital component in maintaining native vegetation and ecosystem functioning within south Florida pine rocklands. A period of just 10 years without fire may result in a marked decrease in the number of herbaceous species due to the effects of shading and litter accumulation (FNAI 2010b). The majority of extant populations of these species are affected by some degree of inadequate fire management, with the primary threat being shading by hardwoods (Bradley and Gann 1999; Bradley and Gann 2005). (USFWS, 2019)

**Stressor:** Inadequacy of existing regulatory mechanisms
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Regulatory mechanisms (Factor D) provide limited protections for this species. The Florida Department of Agriculture and Consumer Services designated this species as endangered under Chapter 5B-40, Florida Administrative Code. This law regulates the taking, transport, and sale of listed plants. This law does not prohibit private property owners from destroying listed plants nor does it require them to manage habitats to maintain populations. The Natural Forest Communities (NFC) program was established by Miami-Dade County to encourage but notrequire private landowners to protect forested lands by making it necessary to apply for a permit with the County prior to working in designated NFCs (i.e., pinelands, hammocks). (USFWS, 2019)

**Stressor:** Climate Change (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Climate change will impact pine rockland habitat through sea level rise, variability in precipitation and temperature that can cause shifts in vegetation types, increases in freezing conditions, and increase in intensity and frequency of storm and fire events (Wanless et al. 2008, Wear and Greis 2012, Intergovernmental Panel on Climate Change 2021, Runkle et al. 2022). By 2100, direct losses of pine rockland plant populations are expected due to habitat loss and successions caused by sea level rise (Vargas-Moreno and Flaxman 2010, Zhang et al. 2011, Park and Sweet 2015, Rahmstorf et al. 2015, University of Florida Geoplan Center 2015, Sweet et al.

2022). Additionally, changes in regional hydrology may have impacts on the pine rockland habitats. Increased and longer-duration hydroperiods in the areas inhabited by endangered pine rockland species may lead to a reduction in the amount of suitable habitat, a potential reduction in the area occupied, and a reduction in the number of deltoid spurge individuals found (USFWS, 2023).

**Stressor:** land modification for development (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Extensive land modification for development throughout the species historic range has led to habitat loss, fragmentation, and alterations that render the habitat unsuitable for deltoid spurge (Factor A). Due to land modifications of pine rocklands, suitable habitat for deltoid spurge outside of protected areas is limited, severely fragmented, isolated, and degraded. These characteristics contribute to the species low resiliency (ability to withstand stochastic events), low redundancy (ability to recover from catastrophic events), and low representation (low genetic dispersal) (USFWS, 2023)

***Recovery***

**Reclassification Criteria:**
1. Enough demographic data are available to determine the appropriate numbers of self sustaining populations required to ensure 20 to 90 percent probability of persistence for 100 years (USFWS, 2010)

2. When these populations, within the historic range of deltoid spurge are adequately protected from further habitat loss, degradation, exotic plant invasion, and fire suppression (USFWS, 2010)

3. When these sites are managed to maintain the pine rocklands to support deltoid spurge (USFWS, 2010)

4. When monitoring programs demonstrate that populations of deltoid spurge on these sites support sufficient populations sizes, are distributed throughout the historic range, and are sexually or vegetatively reproducing at sufficient rates to maintain the population. (USFWS, 2010)

Recovery Priority Number: 6C

**Delisting Criteria:**
1. Existing natural populations achieve and maintain a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factors A and E) (USFWS, 2019)

2. A network of 6 new populations are either discovered or reintroduced that exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factors A and E) (USFWS, 2019)

3. All populations (criteria 1 and 2) are protected by a conservation mechanism. (addresses Factors A, D, and E) (USFWS, 2019)

4. Threats have been reduced or eliminated to the degree that this species will remain viable for the foreseeable future. (addresses Factors A, D, and E) (USFWS, 2019)

**Recovery Actions:**

- Conduct surveys to determine distribution of pine rockland plants. Pine rockland plants were thoroughly surveyed in Miami-Dade County; however, the status of C. deltoidea is not known over its entire range. (USFWS, 1999)
- Protect and enhance existing populations. It is imperative for the recovery of pine rockland plants that additional populations not be lost. (USFWS, 1999)
- Collect biological information important to species recovery. Additional information on the ecology and life history of pine rockland plants needs to be collected. The size and viability of known populations of C. deltoidea needs to be evaluated. (USFWS, 1999)
- Monitor C. deltoidea populations. Use existing standardized monitoring protocols developed by the Florida Natural Areas Inventory to record baseline data regarding the biology and ecology of C. deltoidea. Determine the effects of management actions on C. deltoidea. Initiate quarterly monitoring programs. (USFWS, 1999)
- Continue implementation of the fire education program and modify as necessary any fire management education program that has been developed. Future modifications to this program may include tri-lingual distribution (Spanish, English, and Haitian Creole). (USFWS, 1999)
- Habitat-Level Recovery Actions: Continue to protect pine rockland plant habitat in order to prevent degradation. Restore areas to suitable habitat. Conduct habitat-related research. (USFWS, 1999)
- Habitat degradation continues to be a moderate threat because vegetation restoration and management programs are costly and depend upon availability of funding (Service 2006).

***Conservation Measures and Best Management Practices:***

- RECOMMENDED FUTURE ACTIVITIES A detailed discussion of recovery actions and criteria are presented in the Recovery Plan (Service 1999) and the Recovery Plan amendment (Service 2019). In the course of this status review new and/or targeted potential recovery activities were identified and are included below. Recovery Activities • Implement, continue, or increase habitat restoration efforts (exotic species removal and prescribed burns/similar disturbance) where deltoid spurge is located (recovery criteria 4). • Identify and pursue conservation agreements or other agreements that protect pine rocklands and deltoid spurge populations (recovery criteria 2 and 3). • Identify and restore patches of pine rocklands that have been historically occupied by deltoid spurge (recovery criteria 1). • Additional partnerships should be promoted to share information, conduct collaborative research, and provide land managers and interested public with information (recovery criteria 1 & 4). • Develop a translocation/reintroduction plan to identify potential recipient sites for reintroducing or establishment of populations within the historical range (recovery criteria 2). Monitoring and Research Activities • Evaluate ‘unknown’ population locations to determine number of individuals or extirpation of the species at those locations (recovery criteria 1). • Monitor extant populations annually and document individual number estimates to determine population trends (recovery criteria 1). • Survey areas that have suitable habitat for the species to identify new populations and/or translocation sites (recovery criteria 2). • Research ex situ propagation and seed bank viability (recovery criteria 2). • Examine the demography and reproductive biology of the deltoid spurge to determine population trends and growth and establishment rates (recovery criteria 1). • Study individual populations to determine genetic diversity (recovery criteria 1). • Research management techniques and impacts particularly with prescribed fire impacts on the biology and life history of deltoid spurge (recovery criteria 4). Outreach Activities • Increase public awareness and appreciation for native plants and habitats. • Attend public events when appropriate to improve the communities understanding of management techniques and policies, such as prescribed fire, in pine rockland habitats (USFWS, 2023).

# SPECIES ACCOUNT: *Chamaesyce garberi* (Garber's spurge)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 7/18/1985; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

A prostrate herb with pubescent stems. Leaves are ovate and 4-9 mm long. Flowers are conspicuous. (NatureServe, 2015)

**Taxonomy**

The treatment of the clade to which Garber's spurge belongs has historically been a subject of disagreement among botanical authorities. While many (Burch 1965; Hassall 1977; Herndon 1993) have recognized Chamaesyce as a distinct and separate genus within the Euphorbiaceae family based on morphological characters, more recent molecular phylogenetic evidence suggests that this taxon is more appropriately treated as a subgenus within Euphorbia (Yang and Berry 2011; Horn et al. 2012). The Integrated Taxonomic System (2022), the Flora of North America (2022), the Atlas of Florida Plants (Wunderlin et al. 2022), and the Flora of the Southeastern United States (Weakley 2022) all accept this treatment. This represents a change in nomenclature for the species compared to its listing name in 1985 from Chamaesyce garberi to Euphorbia garberi but does not change the circumscription of the species or its status as a distinct, threatened taxon (USFWS, 2022).

**Historical Range**

Garber's spurge is endemic to South Florida (USFWS, 1999). It formerly occurred in Dade and Monroe counties, Florida, from Miami to the lower Florida Keys. Has disappeared from much of its historical range. (NatureServe, 2015)

**Current Range**

The current range of Garber's spurge has decreased compared to its historic range due to a few extirpations on the peripheries. Notably, the species was previously known to occur in Collier County (although from only one collection) but was not found there or in surrounding suitable habitat in more recent surveys and is presumed extirpated at this location (Green at al. 2008). Additionally, in MiamiDade County the species had formerly occurred from the vicinity of the City of Miami south of the Miami River to the Cutler area. However, three populations are now extirpated and only two Garber's spurge populations are known to be extant in Miami-Dade County. The Everglades Garber's spurge populations at Long Pine Key (Pine Blocks B and C) and Northwest Cape Sable were estimated to have over 1,000,000 individuals each in 2007, though the latter has declined dramatically since this time (Lange et al. 2020) and the former has not been resurveyed. In the Keys, Garber's spurge still occurs throughout its entire historical range since populations are extant at the western and eastern boundaries, from Key Largo to the Marquesas Keys. Extant populations are known from at least 21 islands in the Florida Keys though this range characterization may be an overestimation considering that most populations have not been revisited in 10-15 years and some of the smaller populations would be especially vulnerable to stochastic change and extirpation. Twelve populations in the Keys have been extirpated from 9 islands (5 of which had no other Garber's spurge populations) (Green et al. 2008; FNAI 2022). Although these extirpations don't represent a decrease in range for Garber's spurge (i.e., they occur within the interior of its range), they do represent a decrease in area of occupancy and an increase in fragmentation. See Figure 1 for a map of both extant and extirpated populations throughout this species' range (USFWS, 2022).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Habitat Type**

Adult: Terrestrial, palustrine (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Herbaceous wetland, barrens, forest, grassland, dune, shrubland (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Periodic fires (NatureServe, 2015)

**Environmental Specificity**

Adult: Moderate (NatureServe, 2015)

**Habitat Narrative**

Adult: Dry, sandy soil in ecotones between hammocks and pinelands or coastal hammocks and sea-oats dunes. Requires periodic burning or is shaded out as succession occurs (NatureServe, 2015). Garber's spurge occurs at low elevations either on thin sandy soils composed largely of Pamlico sands or directly on limestone. It is found in a variety of open to moderately shaded habitat types. In pine rocklands, it grows out of crevices in oolitic limestone. On Cape Sable, Everglades NP, it has been reported from hammock edges, open grassy prairies, and backdune swales. In the Florida Keys, it grows on semi-exposed limestone shores, open calcareous salt flats, pine rocklands, calcareous sands of beach ridges, and along disturbed roadsides. Soils are composed largely of Pamlico sands or directly on limestone.

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Declining (inferred from USFWS, 2007)

**Species Trends:**

Unknown (USFWS, 2007)

**Number of Populations:**

~31 (USFWS, 2022)

**Population Size:**

Unknown (NatureServe, 2015)

**Population Narrative:**

Garber’s spurge is estimated to occur in 31 populations in Monroe and MiamiDade Counties, though many of them (24) have not been surveyed for 10-15 years. The previous status review (Service 2007) reported 17 populations, but only two new populations have been discovered since then. The main difference in the number of populations is how they were grouped together in the previous review. Some islands in the Keys have more than one population, or clusters of plants more than 1.0 kilometers (0.62 miles) from other clusters (NatureServe 2020), but the previous review counted them as one population since they occurred on one island. Also, the previous review grouped all the Cape Sable populations into one instead of counting each Cape as a separate population. General population abundance, trends, and demography are unknown since no population has been monitored consistently on an annual or semi-annual basis to track this information. The current status of many populations of Garber’s spurge is also unknown due to a lack of surveys since Green’s extensive range-wide status survey in 2006-2007. Population sizes for most occurrences are still based on Green’s work and presume that these populations are still extant, though updated surveys are needed to confirm this. Green’s report revealed that Garber’s spurge population sizes vary widely, ranging from over 1,000,000 plants in two locations (at the time) to less than 10 plants at other sites (Green et al. 2008). For populations that have been monitored more recently, only two are estimated to be stable, one may be increasing, and two are likely decreasing (Table 1). Twentyfour are presumed extant with an unknown trend due to lack of recent surveys. Approximately 16 have been extirpated and 2 have an unknown status (no plants observed in 2006-2007 surveys but had potential to re-appear) (Green et al. 2008; FNAI 2022). Only two populations occur in Miami-Dade County (the Long Pine Key area of ENP and CDE). In Monroe County extant or presumed extant Garber’s spurge populations are reported from the mainland in the Cape Sable area of ENP, as well as 21 islands in the Florida Keys (Table 1). In mainland Monroe County, the species was historically known from all three Capes on Cape Sable (ENP), representing three distinct populations (though grouped as one population in the previous review [Service 2007]). In 2006, it was found on only the Middle and Northwest Capes (Green et al. 2008). Although it was thought to be extirpated in the previous status review (Service 2007), the population on East Cape was only temporarily eliminated by hurricane damage incurred in 2005. In 2013, a small population of Garber’s spurge was discovered on East Cape Sable by the ENP botanist, but it is unknown if this is the same location where it was documented in 2005 (Gann 2015).   One of the largest documented populations was that in Northwest Cape Sable where over 1,000,000 plants were estimated to occur in 2007 (Green et al. 2008; Lange 2017). This is the only population where a thorough, updated survey has taken place which showed an approximate 86 percent decrease in the number of plants observed along transects used in both the 2007 and 2017 surveys (Lange et al. 2020). Extrapolated out to the whole population, this means that there may be about 90,000 plants remaining at this location. While this still represents one of the largest and most robust populations of this species, the rapid and steep decline in abundance is still great cause for concern. The decline is most likely due to a lack of fire on the landscape, as evidenced by a significant increase in tree and shrub cover in what should be open habitat (Lange et al. 2020). Within Long Pine Key there may still be over 1,000,000 plants (Green et al. 2008; Lange 2017), but an updated survey is needed. The sub-populations at this location have apparently undergone a large expansion since previous reports did not indicate large population numbers (Bradley 2007; Green et al. 2008). The surveys in 2006 estimated 600-700 individuals in Deer Hammock (Pine Block A) and approximately 1,250,000 in Pine Blocks B and C (Green et al. 2008). Because of the number of plants, geographic size, favorable management activities at ENP, and, for the interior Long Pine Key site - distance from the coast, the populations within ENP may be the most secure of the known extant Garber's spurge populations. However, careful surveys have not been completed here since 2006 and only continued presence of the populations has been noted (Sadle 2022). At the CDE, Miami-Dade County's Department of Environmental Resource Management (DERM; 1993) reported a population size of 250-500 plants based on four days of searches specifically for this species. Herndon (2002) estimated a population size of 600-6,000 plants. In contrast, Possley (2007) suspected that only 100-200 plants were present in 2004, but estimated approximately 50-100 plants at this site in 2017 and 2021 (Possley 2017, 2022a), but emphasized the important caveat that dedicated species-specific surveys have not been completed for Garber's spurge in many years and this is only an approximate number based on site visits for monitoring of other species. The largest populations occurring in the Keys are located on Vaca, Bahia Honda, Big Torch, Woman, and Marquesas Keys (Table 1), but updated population estimates were not available for this review. Similar to the largest mainland populations, these mostly occur in protected areas or on remote islands. Many smaller populations occur throughout the Keys and some of them were observed to still have plants within the last 6 years (Long Key State Park, No Name Key, Big Munson, and Boca Grande), but have not been thoroughly surveyed since 2006-2007. Additional populations may occur in the Keys on private properties with fragments of suitable habitat where botanists have not yet been able to obtain access. For example, Boot Key is mostly privately owned and was noted for having suitable habitat, but permission was not granted to conduct a thorough survey of the island (Green et al. 2008). However, plants were found along an accessible right-of-way and so it is entirely plausible that additional Garber's spurge exists within the privately-owned areas. Other islands with intact habitat may harbor additional populations as well (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Habitat destruction and modification (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Development is a concern for this species mainly in the Keys. Without intervention, areas on private land that may contain Garber's spurge will most likely be altered. Some sites are threatened by fire suppression and/or exotic plants that have been managed insufficiently (USFWS, 2007).

**Stressor:** Key deer (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Dooley (1975) reported Garber's spurge as a food plant of Key deer. The Key deer population increased 240% between 1971 and 2001 (Lopez et al. 2004), and this increase has probably had a significant impact on the vegetation in the deer's range (USFWS, 2007).

**Stressor:** Recreation (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Populations on dunes have the potential to be threatened by trampling from beach goers (USFWS, 2007).

**Stressor:** Small population size (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Because populations are very small, they are subject to extirpation as a result of human or natural stochastic events. Sea level rise may become a significant threat in coming decades. Populations typically occur at elevations less than 0.50 meters; recent estimates for sea level rise through 2100 range from 0.28 - 0.34 meters (Church and White 2006) (USFWS, 2007).

***Recovery***

**Reclassification Criteria:**
1. Enough demographic data are available to determine the appropriate numbers of self-sustaining populations required to ensure 95% probability of persistence for 100 years (USFWS, 2007).

2. When these populations within the historic range of Garber's spurge are adequately protected from further habitat loss, degradation, exotic plant invasion, and fire suppression (USFWS, 2007).

3. When these sites are managed to maintain the pine rocklands to support Garber's spurge (USFWS, 2007).

4. When monitoring programs demonstrate that populations of Garber's spurge on these sites support sufficient population sizes, are distributed throughout the historic range, and are sexually or vegetatively reproducing at sufficient rates to maintain the population (USFWS, 2007).

Recovery Priority Number: 8

**Delisting Criteria:**
Not available

**Recovery Actions:**
- Determine the distribution of the species in South Florida (USFWS, 1999).
- Protect and enhance populations (USFWS, 1999).
- Conduct research on biology/ecology (USFWS, 1999).
- Monitor populations (USFWS, 1999).
- Inform and involve stakeholders and the general public in the recovery process (USFWS, 1999).
- Acquire privately owned properties where the species occurs, including coastal rock barrens on Long Key and Crawl Key (USFWS, 2007).
- Where present on roadsides, maintain an infrequent mowing regime to allow plants sufficient time to flower and disperse seeds. Do not plant turf grasses in or next to roadside

populations. Trim hardwoods from edges of population to prevent shading. Communicate these road maintenance guidelines with road maintenance crews (USFWS, 2007).

- Implement a prescribed fire program at the Deering Estate at Cutler with a fire return interval of 3 - 7 years (USFWS, 2007).
- Ensure that Monroe county regulators can identify Garber's spurge to ensure that developers pay proper mitigation fees when applying for building permits (USFWS, 2007).
- Continue or initiate exotic plat control at all sites where populations occur (USFWS, 2007).
- Initiate long-term monitoring of presence or population sizes of all populations, or at a minimum, at a subset which includes the geographic range of the species and a variety of habitat types (USFWS, 2007).
- Initiate long-term, detailed demographic studies in a subset of populations which includes the geographic range of the species and a variety of habitat types, including pine rockland, coastal habitats, and disturbed areas (USFWS, 2007).
- Reintroduce populations to stations where formerly present (USFWS, 2007).
- Conduct studies of coastal rock barren habitat to determine successional processes and management needs of the ecosystem (USFWS, 2007).
- Remove hardwoods from disturbed area where Garber's spurge occurs at Crocodile Lake National Wildlife Refuge, and use this population as a source of germplasm for reintroductions into natural habitats in the Key Largo area (USFWS, 2007).
- Conduct genetic studies to clarify relationships with C. porteriana, determine if patterns of morphological variation reported by Herndon (1993) are genetically based, and determine if inbreeding depression is occurring within any populations (USFWS, 2007).
- Develop population viability and risk assessments for all populations, based on monitoring and demographic studies (USFWS, 2007).
- Conduct seed bank studies to determine longevity of seed bank and viability under different conditions (USFWS, 2007).
- Study relationship of fire to population demography of Garber's spurge to determine potential impacts of sea level rise (USFWS, 2007).
- Search recently burned pine rocklands in the lower Florida Keys for Garber's spurge (USFWS, 2007).
- Study impacts of hurricanes on Garber's spurge populations in coastal habitats (USFWS, 2007).
- One recovery criteria that should be modified states that sites must be managed to maintain pine rocklands to support Garber's spurge. Because pine rockland is not the primary habitat for the species in much of its range, this criterion should be updated to additionally require that dunes, coastal grasslands, and coastal rock barrens be managed to support the species (USFWS, 2007).
- Determine if Key deer forage significantly on Garber's spurge (USFWS, 2007).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS A detailed discussion of recovery actions and criteria are presented in the Recovery Plan (Service 1999). During this status review, new and/or targeted potential recovery activities were identified and are included below. Recovery Activities • Implement prescribed fire at sites with Garber’s spurge where needed (ENP, CDE, NKDR). Consider manual hardwood removal/thinning if prescribed burning is not possible based on landscape context. • Continue invasive species removal at conservation areas with Garber’s spurge. Apply herbicides carefully to reduce risk of non-target damage. • Reintroduce/augment populations to sites where the species is extirpated (Green et al. 2008) or has low numbers (Crocodile Lake NWR, Lignumvitae Key Botanical State Park, Long Key State Park, Big Pine Key, Wells Key, Boca Chica Key, Marquesas Key – Short Beach,) and habitat remains or can be restored. • Acquire or pursue conservation agreements for privately-owned properties where the species occurs (Vaca Keys, Boot Key, Big Munson Island). Where present on roadsides, maintain an infrequent mowing regime to allow plants sufficient time to flower and disperse seeds. Do not plant turf grasses in or next to roadside populations. Apply herbicides carefully to reduce non-target damage. Trim hardwoods from edges of population to prevent shading. Communicate these road maintenance guidelines with road maintenance crews. • Expand ex situ propagation and seed banking. Specifically, seeds should be stored within at least one more seed bank in addition to NLGRP for safety duplication. Additionally, seeds have only been collected from one population for long-term storage, but more populations should be safeguarded in ex situ collection for sufficient genetic representation. Seed collections for long-term storage should be made on a regular basis since it is unknown how long Garber's spurge seeds retain viability. Monitoring/Research Activities • Initiate long-term, detailed demographic studies in a subset of populations which includes the geographic range of the species and a variety of habitat types, including pine rockland, coastal habitats, and disturbed areas. • Conduct monitoring to document presence on protected lands at least every five years. • Develop population viability and risk assessments for all populations, based on monitoring and demographic studies. • Determine the condition of populations on private land whose status is currently unknown. • Survey potential habitat within the species historic range on both public and private lands (where access is permitted) for presence of Garber's spurge. • Conduct studies of Keys tidal rock barren habitat to determine successional processes and management needs of the ecosystem. • Conduct genetic studies to clarify relationships with C. porteriana, determine if patterns of morphological variation reported by Herndon (1993) are genetically based, and determine if inbreeding depression is occurring within any populations. • Conduct seed bank studies to determine longevity of seed bank and viability under different conditions, such as presence/absence or intensity of fire. • Conduct research to evaluate reproductive biology, including potential pollinators, insect visitation rates, etc. • Examine the effects of fire (growing season versus non-growing season, various firereturn intervals, etc.) on Garber's spurge flowering, seed set, establishment, reestablishment, etc. • Study impacts of stochastic events (hurricanes, storm surge, tidal flooding, wildfires) on Garber's spurge populations (USFWS, 2022).

# SPECIES ACCOUNT: *Chamaesyce hooveri* (Hoover's spurge)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 03/26/2016; California/Nevada Region (R8) (USFWS, 2015)

**Physical Description**

Chamaesyce hooveri forms gray-green mats from a few inches to a few feet across. The flowering structure is a small, highly simplified cup-like "cyathium," as in all other spurges (Chamaesyce and Euphorbia). The flowering structure in C. hooveri has petallike glands that are red to olive in color. Flowers bloom in July. (USFWS, 2009)

**Taxonomy**

This plant was originally named Euphorbia hooveri, based on a specimen collected by Hoover in Yettem, Tulare County (Wheeler 1940). At that time, the genus Euphorbia was viewed as comprising several subgenera, including Chamaesyce and Euphorbia. Webster (1975) subsequently elevated the subgenus Chamaesyce to the rank of genus based on growth patterns and physiology. The currently accepted scientific name, Chamaesyce hooveri, was validated when Koutnik (1985) published the new combination. (USFWS, 2009)

**Historical Range**

For decades, Chamaesyce hooveri was known from only three localities: near Yettem and Visalia in Tulare County, and near Vina in Tehama County. Collections were made from these three areas in the late 1930s and early 1940s (Wheeler 1941, Munz and Keck 1959, Stone et al. 1988). From 1974 through 1987, 21 additional occurrences of C. hooveri were reported. The majority of these (15) were in Tehama County. One to three occurrences were discovered during this period in each of Butte, Merced, Stanislaus, and Tulare Counties (Stone et al. 1988). The historical localities for this species were in the Northeastern Sacramento Valley, San Joaquin Valley, Solano-Colusa, and Southern Sierra Foothills Vernal Pool Regions (Keeler-Wolf et al. 1998). (USFWS, 2005)

**Current Range**

Of the 26 occurrences presumed to be extant, only 3 have been observed within the past decade (California Natural Diversity Data Base 2003). The main remaining area of concentration for Chamaesyce hooveri is within the Northeastern Sacramento Valley Vernal Pool Region. The Vina Plains of Tehama and Butte Counties contain 14 (53.8 percent) of the 26 known extant occurrences for C. hooveri (California Natural Diversity Data Base 2003) in an area of about 91 square kilometers (35 square miles; Stone et al. 1988). One other site in the same region is near Chico in Butte County. Seven of the extant occurrences are in the Southern Sierra Foothills Vernal Pool Region, including five in the Visalia-Yettem area of Tulare County and two in the Hickman-La Grange area of Stanislaus County. Three other occurrences are on the Sacramento National Wildlife Refuge in Glenn County, which is in the Solano-Colusa Vernal Pool Region. The one other extant occurrence is on the Bert Crane Ranch in Merced County, which is within the San Joaquin Valley Vernal Pool Region (Keeler-Wolf et al. 1998, California Natural Diversity Data Base 2003). (USFWS, 2005)

**Critical Habitat Designated**

Yes; 2/10/2006.

**Legal Description**

On August 11, 2005, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Chamaesyce hooveri (Hoover's spurge) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes seven critical habitat units (CHUs), in California (71 FR 7118-7316).

**Critical Habitat Designation**

The critical habitat designation for Chamaesyce hooveri includes seven CHUs in Merced, Stanislaus, Tehama, Tulare, and Tuolumne Counties, California. This species critical habitat encompasses approximately 114,713 acres (71 FR 7118-7316).

Unit 1: Tehama County, California. From USGS 24,000 topographic quad Acorn Hollow, Richardson Springs NW

Unit 2: Butte County, California. From USGS 24,000 topographic quad Hamlin Canyon

Unit 4: Stanislaus and Tuolumne Counties.

Unit 5: Stanislaus and Merced Counties. (i) Unit 5A: Stanislaus and Merced Counties. From USGS 24,000 topographic quads Paulsell, Cooperstown, Le Grange, Montpelier, Turlock Lake, Snelling, Merced Fall. (ii) Unit 5B: Merced County. From USGS 24,000 topographic quad Turlock Lake. USGS 24,000 topographic quads Paulsell, Montpelier.

Unit 6: Merced County. (i) Unit 6A: Merced County. USGS 24,000 topographic quads Stevinson, San Luis Ranch. Unit 6B: Merced County. From USGS 24,000 topographic quad Stevinson, Arena, San Luis Ranch, Turner Ranch. Unit 6C: Merced County. From USGS 24,000 topographic quad Arena, Turner Ranch. Unit 6D: Merced County. USGS 24,000 topographic quad Turner Ranch, Sandy Mush. Unit 6E: Merced County. USGS 24,000 topographic quad Turner Ranch, Sandy Mush.

Unit 7: Tulare County. (i) Unit 7A: Tulare County. From USGS 24,000 topographic quads Stokes Mtn., Ivanhoe. Unit 7B: Tulare County. From USGS 24,000 topographic quads Ivanhoe. (iii) Unit 7C: Tulare County. From USGS 24,000 topographic quads Stokes Mtn., Auckland, Ivanhoe, Woodlake. Unit 7D: Tulare County. From USGS 24,000 topographic quad Woodlake. Unit 7E: Tulare County. From USGS 24,000 topographic quad Monson. Unit 7F: Tulare County. USGS 24,000 topographic quad Monson. Unit 7G: Tulare County. USGS 24,000 topographic quad Monson.

Unit 3: Glenn and Colusa Counties, California. This unit was excluded from the designation pursuant to Section 4(b)(2) of the Act (see Exclusions under 4(b)(2) in the final critical habitat rule (70 FR 46924).

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Chamaesyce hooveri critical habitat consists of two components (70 FR 46924-46999):

(i) Topographic features characterized by isolated mound and intermound complex within a matrix of surrounding uplands that result in continuously, or intermittently, flowing surface water in the depressional features including swales connecting the pools described below in paragraph (2)(ii), providing for dispersal and promoting hydroperiods of adequate length in the pools;

(ii) Depressional features including isolated vernal pools with underlying restrictive soil layers that become inundated during winter rains and that continuously hold water or whose soils are saturated for a period long enough to promote germination, flowering, and seed production of predominantly annual native wetland species and typically exclude both native and nonnative upland plant species in all but the driest years. As these features are inundated on a seasonal basis, they do not promote the development of obligate wetland vegetation habitats typical of permanently flooded emergent wetlands;

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the areas determined to be essential for conservation may require special management considerations or protections. As we undertake the process of designating critical habitat for a species, we first evaluate lands defined by those physical and biological features essential to the conservation of the species for inclusion in the designation pursuant to section 3(5)(A) of the Act. Secondly, we then evaluate lands defined by those features to assess whether they may require special management considerations or protection. In designating critical habitat, we also have considered how this designation highlights habitat that needs special management considerations or protection. For example, we have many regional HCPs under development, and this designation will be useful in helping applicants determine what vernal pool habitat areas should be highest priority for special management or protection, and where there may be more flexibility in conservation options. This designation will guide them and us in ensuring that all local habitat conservation planning efforts are consistent with conservation objectives for these species. Once a vernal pool habitat has been protected from direct filling, it is still necessary to ensure that the habitat is not rendered unsuitable for vernal pool species because of factors such as altered hydrology, contamination, nonnative species invasions, or other incompatible land uses. Many of the factors that cause the decline and localized extirpation of vernal pool species can be avoided. Actions that should be avoided include the following: (1) Actions that increase competition from invasive species as many of the species addressed in this rule are threatened by invasion of nonnative species (CNDDB 2001). (2) Alteration of natural hydrology such as construction of dams or other structures that artificially increase the length of vernal pool inundation or construction of ditches that artificially drain vernal pools. (3) Human degradation of vernal pools such as off-road vehicle use, dumping, and vandalism that threatens many of the species addressed in this rule.

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (annual) (USFWS, 2005)

**Dependency on Other Individuals or Species**

Adult: Beetles (order Coleoptera), flies (order Diptera), bees and wasps (order Hymenoptera), and butterflies and moths (order Lepidoptera) have been observed visiting the flowers of Chamaesyce hooveri and may potentially serve as pollinators (Stone et al. 1988, Alexander and Schlising 1997). (USFWS, 2005)

**Breeding Season**

Adult: Late May to October (USFWS, 2005)

**Reproduction Narrative**

Adult: Chamaesyce hooveri is a summer annual, but few details of its life history are known. Populations in Merced and Tulare Counties typically flower from late May through July, whereas those farther north in Stanislaus County and the Sacramento Valley flower from mid-June into October (Alexander and Schlising 1997, J. Silveira in litt. 2000, California Natural Diversity Data Base 2003). Beetles (order Coleoptera), flies (order Diptera), bees and wasps (order Hymenoptera), and butterflies and moths (order Lepidoptera) have been observed visiting the flowers of Chamaesyce hooveri and may potentially serve as pollinators (Stone et al. 1988, Alexander and Schlising 1997). (USFWS, 2005)

**Habitat Type**

Adult: Temporary pool (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Vernal pools (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (USFWS, 2005)

**Site Fidelity**

Adult: High (inferred from USFWS, 2005)

**Habitat Narrative**

Adult: Chamaesyce hooveri is restricted to vernal pools (Stone et al. 1988, Koutnik 1993, Skinner and Pavlik 1994). Deeper pools apparently provide better habitat for this species because the duration of inundation is longer and the deeper portions are nearly devoid of other vegetation, thus limiting competition from other plants (J. Stebbins in litt. 2000a, Stone et al. 1988). However, the plant appears to adapted to a wide variety of soils, which range in texture from clay to sandy loam. (USFWS, 2005)

***Dispersal/Migration***

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

25 (USFWS, 2023)

**Population Size:**

100-2,500 (USFWS, 2009)

**Population Narrative:**

Population numbers have ranged from less than 100 plants seen in 2001 to over 2,500 plants seen in 1993 (J. Silveira, in litt. 2009). Of the 31 known occurrences and sites, 27 are presumed to be extant (LSA 2003; CNDDB 2007). (USFWS, 2009) Hoover's spurge is endemic to the Central Valley of California. The known distribution is within a narrow zone of rolling topography formed by remnant alluvial fans and stream terraces on the eastern margin of the Sacramento and San Joaquin valleys (Stone et al. 1988, p. 102). Assessment of the historical range of Hoover's spurge is complicated as the earliest floristic surveys occurred after widespread conversion of potentially suitable habitat to agriculture (Stone et al. 1988, p. 106). The present distribution of Hoover's spurge is likely considerably fragmented compared to historical conditions (Stone et al. 1988, p. 106). Hoover's spurge is known from a few widely separated populations (see Table 1). Occurrences are recorded in four different vernal pool recovery regions. The main area of concentration is within the Northeastern Sacramento Valley Vernal Pool Region on the Vina Plains along the Tehama and Butte County line. Occurrences in the Solano-Colusa Vernal Pool Region are clustered on the Sacramento National Wildlife Refuge in Glenn County. In the Southern Sierra Foothills Vernal Pool Region, occurrences are adjacent to Turlock Lake State Recreation Area in Stanislaus County and on the Stone Corral State Ecological Reserve north of the City of Visalia in Tulare County. One occurrence is within the San Joaquin Valley Vernal Pool Region on the Grasslands Wildlife Management Area in western Merced County. The species' current distribution remains similar to the distribution as described in the 1997 listing rule and the 2009 status review. At the time of listing, Hoover's spurge was known from 29 populations found in Butte, Glenn, Merced, Stanislaus, Tehama, and Tulare counties, 25 of which were considered extant (Service, 1997, p. 1431). The 2009 status review notes a total of 31 occurrences of the species, including 30 occurrences recorded in the Diversity Database and an additional occurrence at the then-proposed Hamilton Ranch Conservation Bank that had not yet been included in the Diversity Database (Diversity Database 2007, entire; Service 2009, pp. 1–2). Twenty-seven occurrences were presumed to be extant in 2009 and the occurrences were distributed throughout the same counties and concentrated in the same areas as the populations described at the time of listing (Diversity Database 2007, entire; Service 2009, p. 2). There have been only minor changes to the occurrences of Hoover's spurge recorded in the Diversity Database since the 2009 status review. Currently the Diversity Database describes a total of 29 occurrences (see Table 1; Diversity Database 2023, entire). The new occurrence reported in the 2009 status review at the Hamilton Ranch Conservation Bank has been incorporated into the Diversity Database (occurrence #36). Two additional records (occurrences #34 and #35) have been added to the Diversity Database and four records (occurrences #17, #18, #20, and #31) have been combined with other existing occurrence records (see Table 1; Diversity Database 2007, entire; Diversity Database 2023, entire). The two additional records (occurrences #34 and #35) are located within the Sacramento National Wildlife Refuge in proximity to other occurrences of the species on the Refuge and were previously considered as parts of the other occurrences (Diversity Database 2023, pp. 33–34). Two previously unreported areas of occupied habitat documented by Witham (2013, pp. D-1–D-5) have also been added to the Diversity Database as part of existing records (occurrences #36 and #13) (Diversity Database 2023, pp. 13, 35). Twenty-five occurrences are currently presumed to be extant, two possibly extirpated, and two extirpated (Diversity Database 2023, entire). Since the 2009 status review, the status of occurrence #29, which is located in proximity to two other occurrences in the northern portion of the range, has changed from “presumed extant” to “possibly extirpated” due to the intensification of agriculture. Other “presumed extant” occurrences from the last status review remain in this category currently. Witham’s 2013 status review of Hoover’s spurge and its supporting habitat found potentially suitable habitat to be present at each “presumed extant” location (Witham 2013, entire). The current status of many “presumed extant” populations has not been reassessed through on-the-ground surveys in many years, and areas that may support the species remain to be surveyed. Thus, reliable estimates of the amount and distribution of suitable habitat is unknown (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat loss
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat loss occurs from direct destruction and modification of pools due to filling, grading, discing, leveling, paving, and other activities, as well as modification of surrounding uplands, which alters vernal pool watersheds and the supporting upland ecosystem. Fifty-five percent of presumed extant sites of C. hooveri are on private land and are not protected (CNDDB 2007). (USFWS, 2009)

**Stressor:** Agriculture conversion
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** During the 30 years prior to listing, agricultural land conversion was known to have caused the extirpation of one population and threatened two more populations of Chamaesyce hooveri in Tulare County (Stone et al. 1988). In Stanislaus County, the area east of Waterford and Hickman was being converted into grainfields, almond orchards, and irrigated pasture. Thus agricultural land conversion in this area threatened 2 more existing populations of C. hooveri (Stone et al. 1988). It is likely that several occurrences were eliminated by habitat losses before they became known, mainly from conversion of vernal pool habitat to agricultural uses (Stone et al. 1988). We estimated a total of nearly 5,600 acres had been converted, with the greatest acreage, approximately 5,000 acres, converted within the Merced core area. Additionally, one of the occurrences of Chamaesyce hooveri within the Vina Plains core area appears to have been converted to more intensive agriculture. (USFWS, 2009)

**Stressor:** Habitat degradation
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Vernal pool habitats in the Central Valley now represent approximately 9 percent of their former area (State of California 2003), and remaining habitats are considerably more fragmented and isolated than historically and during the recent past. California’s human population is expected to increase by 60 percent between 2000 and 2025 (California Department of Finance 2004) and almost double the 1990 State population. In areas where habitat remains, increased urban conversion of vernal pool habitat continues to threaten this species and habitat loss is expected to continue as urban boundaries expand further especially through high and low

terrace formations on the eastern side of the valley. Even in areas where habitat is protected, the urbanization of lands surrounding conserved areas results in the fragmentation of protected habitats, preventing dispersal between occurrences, as well as increased edge effects to pool complexes. Habitat conversion is expected to continue as the human population increases (Teitz et al. 2005). (USFWS, 2009)

**Stressor:** Nonnative plants
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Competition from invasive native or non-native plant species threatens nine of the extant occurrences, including eight in the Vina Plains and one on the Sacramento National Wildlife Refuge in Glenn County. Native competitors of Chamaesyce hooveri include Eryngium species (coyote-thistle), Malvella leprosa (alkali mallow), a noxious weed according to Hill (1993), Phyla nodiflora (lippia), Scirpus acutus var. occidentalis (hard-stemmed tule, alkali bulrush (Scirpus maritimus), and Xanthium strumarium (cocklebur). Non-native competitors include bindweed (a noxious weed according to Dempster 1993) and Crypsis schoenoides (swamp grass) (J. Silveira in litt. 2000; CNDDB 2007). On the Vina Plains Preserve, the pools with Chamaesyce hooveri also had the highest frequency of bindweed, at least in 1995 (Alexander and Schlising 1997). Increasing dominance by these competitors may be associated with changes in hydrology and livestock grazing practices (Stone et al. 1988, Alexander and Schlising 1997; CNDDB 2007). Due to late spring rains during the last few years, an invasive plant, Crypsis vaginiflora has become dominant in many Basin-Rim vernal pools within the Sacramento NWR Complex (Sacramento, Delevan and Colusa). (USFWS, 2009)

**Stressor:** Drought and climate change
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Chamaesyce hooveri is an obligate wetland species found only in vernal pools, typically on alluvial fans or terraces of ancient rivers or streams, with a few on the rim of the Central Valley basin. Therefore, maintenance of the natural hydrology of the pools is necessary for the survival and recovery of this species. Drought or flood conditions will place additional strains on the vernal pool ecosystem supporting C. hooveri occurrences, some of which are already fragmented or reduced by agricultural conversion and development. Where occurrences persist on only marginal habitat, the addition of extreme drought conditions is likely to result in higher rates of mortality in the short term with the effects of low reproductive output and survivorship persisting after the drought has ceased. (USFWS, 2009)

**Stressor:** Stochastic events
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Small population size poses a serious threat for at least four of the known occurrences, which total fewer than 100 individuals even in favorable years (CNDDB 2007). Such small populations are subject to extirpation from random events such as extended drought and genetic drift. Small population size makes it difficult for this species to persist while sustaining the impacts of habitat fragmentation. Such populations may be highly susceptible to extirpation

due to chance events, inbreeding depression, or additional environmental disturbance (Gilpin and Soule 1988; Goodman 1987). (USFWS, 2009)

**Stressor:** Neonicotinoid pesticides (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Environmental Protection Agency (Agency) recently released final biological evaluations assessing the effects of labeled uses of three neonicotinoid pesticides on listed species (Agency 2022a, entire; Agency 2022b, entire; Agency 2022c, entire). The three pesticides (clothianidin, imidacloprid, and thiamethoxam) are registered for use on a variety of agricultural crops; there are also some non-agricultural applications. All three pesticides were determined likely to adversely affect Hoover's spurge, primarily due to expected effects to its pollinators. The likely to adversely affect determination means that the Agency reasonably expects that at least one individual animal or plant, among a variety of listed species, may be exposed to the pesticide at a sufficient level to have an effect, which will be adverse. The three pesticides target insect neurotransmitters leading to their paralysis and death. The three pesticides are highly toxic to bees and available data suggest that all three pesticides are likely to affect honeybee and bumblebee colonies through brood reduction and declines in numbers of adults. The specific pollinators of Hoover's spurge are not known. Pollinators of similar species of Euphorbiaceae are usually generalists: small bees, flies, and wasps. During a field study of Hoover's spurge, Stone et al. (1998, p. 105) observed species of native bees and the western honeybee (Apis mellifera) visiting plants. Since the plant is believed to require insect pollination, a loss or severe decline in pollinators of Hoover's spurge would adversely impact the reproductive success of the species. The Agency anticipates releasing amended proposed interim decisions in 2023, which will include updates to some of the previously proposed mitigation measures to reduce neonicotinoid exposures for listed species. Mitigation measures will be finalized in the interim decisions, which the Agency expects to release in 2024 mitigation measures (USFWS, 2023).

**Stressor:** Livestock grazing
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Appropriate levels of grazing are a vital component of long-term management for vernal pools and vernal pool grasslands. Before their populations declined, elk (Cervus canadensis) and pronghorn (Antilocapra americana) grazed vernal pool landscapes; today, most grazing is done by domestic ungulates (Service 2005, p. I-16). The 2009 status review describes livestock grazing and trampling as an activity that may or may not adversely affect vernal pool plants, depending on how it is implemented (Service 2009, p. 16). The most recent occurrence report for Hoover's spurge from the Diversity Database lists 21 of the 25 "presumed extant" occurrences as threatened by grazing. Clarifying notes state the threat from grazing is due to trampling, winter grazing, and grazing aiding the establishment of weedy exotic plants. In one instance, threats are identified from undergrazing (Diversity Database occurrence #32). The threat grazing poses to Hoover's spurge, and other vernal pool plants, remains an active field of study. Most researchers and land managers currently agree that some level of grazing is beneficial if not necessary for maintaining the ecological health and functioning of vernal pools (Robins and Vollmar 2002, p. 402). New and collected research is presented here (USFWS, 2023).

**Stressor:** Climate change (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Significant research into the effects of climate change throughout California has been conducted since the previous status review in 2009. The most recent comprehensive climate change assessment for the state, California's Fourth Climate Change Assessment (Fourth Assessment), was published in 2018 (Bedsworth et al. 2018, entire). Climate change will increase temperatures, sea levels, intensity of heavy precipitation events, decrease snow accumulation, increase the frequency of drought, and increase the size of wildfires (Bedsworth et al. 2018, p. 22). Present-day temperatures have increased over most of the state by at least 1°F compared to earlier in the 20th century. Annual average maximum daily temperatures are expected to further increase by 2.5°F to 8.8°F by 2100 (van Vuuren et al. 2011, p. 11). Some variability is anticipated by region, but the direction of warming trends, as well as precipitation, drought, and wildfire are expected to be similar in the Sacramento Valley (Houlton and Lund 2018, pp. 6–8) and San Joaquin Valley (Fernandez-Bou 2021, pp. 7–10) of California where Hoover's spurge occurs. Climate models predict precipitation will be more volatile; the number of drought years will increase, while the storms that occur in wet years will bring more precipitation and flood risk concentrated in a fewer number of days (Bedsworth et al. 2018, pp. 25–26). Since vernal pool vegetation varies from year to year based on climatic conditions such as precipitation amount and timing and air temperatures, climate change could drive changes in plant communities (Montrone et al. 2019, p. 1004; Javornik and Collinge 2016, p. 66). An increase in drought occurrence can also lead to invasion of vernal pool habitats by invasive upland plants during low water years and could result in the competitive exclusion of vernal pool plants such as Hoover's spurge. Hoover's spurge is most often found in large, deep pools that are characterized by prolonged inundation in the spring followed by gradual desiccation during the late spring and early summer (Stone et al. 1988, p. 102). Populations of Hoover's spurge will likely be threatened by changes to vernal pool water budgets—the total length of time a pool is inundated, and the rate of drying—under climate change. Assuming precipitation levels remain near historical levels and only temperature increases, modeled data suggest a decrease in the length of time pools are filled (Montrone et al. 2019, p. 1004). A reduction in pool inundation period will likely impact species adapted to long inundation times to a greater degree (Gosejohn et al. 2016, p. 9; Montrone et al. 2019, p. 1004). Since Hoover's spurge is associated with pools with long inundation times, it could be at greater risk of decline or extirpation if average hydrological conditions become unfavorable. Increased temperatures can also impact the rate at which vernal pools dry in the late spring and summer. Increased temperature late in the growing season may cause the pools to dry too rapidly and hinder native plant development (Javornik and Collinge 2016, p. 66). Stone et al. (1988, p. 105) observed Hoover's spurge seedlings have less time to develop if a pool dries too rapidly. Under such conditions, plants can be poorly developed and have reduced reproductive success or may even die prematurely (Stone et al. 1988, p. 105). It should be noted that both the inundation length and rate of drying are controlled by multiple factors. The timing of rain events within a year, total amount of precipitation, and period between storms can influence the aquatic phase of vernal pools in addition to air temperature (Alexander and Schlising 1997, p. 120; Javornik and Collinge 2016, pp. 64–66). Due to its requirement for vernal pools with long inundation times and preference for long pool drying periods, Hoover's spurge will likely be negatively affected under most climate change scenarios (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 8C

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**
- Protect vernal pool habitat in the largest blocks possible from loss, fragmentation, degradation, and incompatible uses. (USFWS, 2005)
- Manage, restore, and monitor vernal pool habitat to promote the recovery of listed species and the long-term conservation of the species of concern. (USFWS, 2005)
- Conduct range-wide status surveys and status reviews for all species addressed in this recovery plan to determine species status and progress toward achieving recovery of listed species and long-term conservation of species of concern. (USFWS, 2005)
- Conduct research and use results to refine recovery actions and criteria, and guide overall recovery and long-term conservation efforts.
- Develop and implement participation programs. (USFWS, 2005)
- Protect vernal pool habitat from being destroyed or modified by development, agriculture, or other activities. Acquiring conservation easements or fee title to habitat lands are some ways that conservators can help guarantee protection of the species in perpetuity. (USFWS, 2009)
- Develop standardized population trend survey protocols and implement to complete updated status surveys, especially for populations on private lands where trends have not been recently updated. (USFWS, 2009)
- Manage invasive plants on preserves. Management should include research to determine effective eradication methods of nonnative competitors, and pool conditions that favor one plant over another. (USFWS, 2009)
- Create and convene regional vernal pool working groups in regions where Chamaesyce hooveri occurs. Regional vernal pool working groups will be important for the tracking the progress of recovery efforts, including the amount of suitable habitat protected for each of the species in the core areas. (USFWS, 2009)
- Collect seeds from each core area following the Center for Plant Conservation Guidelines (1991). Seed collections should be stored in at least two sites, including the National Center for Genetic Resources in Fort Collins, Colorado, and a facility certified by the Center for Plant Conservation. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***
- RECOMMENDATIONS FOR FUTURE ACTIONS: In this section, we propose recommendations that will aid in the recovery and conservation of Hoover’s spurge. The recommendations put forth in the Recovery Plan (Service 2005, pp. ix–xii) and the 2009 status review (Service 2009, p. 21) are still relevant. Three additional recommendations are added based on communication with species experts, a literature search, and a status review of existing records. 1. Protect vernal pool habitat from being destroyed or modified by development, agriculture, or other activities. Acquiring habitat

through conservation easements or fee title are some ways that conservators can help guarantee protection of the species in perpetuity. 2. Develop and implement standardized population trend survey protocols to complete updated status surveys, especially for populations on private lands where trends have not been recently updated. 3. Manage invasive plants on preserves. Management should include research to determine effective eradication methods of nonnative competitors, and pool conditions that favor native vernal pool plants over invasive plants. 4. Create and convene regional vernal pool working groups in regions where Hoover's spurge occurs. Regional vernal pool working groups will be important for tracking the progress of recovery efforts, including the amount of suitable habitat protected for the species in core areas. 5. Collect seeds from each core area following the standard accepted practices. After genetic studies are completed, additional collections should be made from each population that contains unique genotypes. Seed collections should be stored in at least two sites, including the National Center for Genetic Resources in Fort Collins, Colorado, and a facility certified by the Center for Plant Conservation. Repeated small collections of seed may be necessary over several years to avoid contributing to the decline of very small populations. 6. Conduct research to confirm pollinator species of Hoover's spurge. Initiate monitoring of pollinator species to determine if there are any trends in pollinator numbers that could be inhibiting the ability of Hoover's spurge to successfully reproduce. 7. Conduct research on potential grazing regimes that target invasive native and nonnative plant species without harming Hoover's spurge or its lifecycle. Gain a better understating of how periodic disturbance from livestock grazing might aid in reducing interspecific competition with Hoover's spurge. Any resulting recommendations should be based on observable habitat conditions, such as water levels in vernal pools, since inundation periods are variable between years and are anticipated to be impacted by climate change. 8. Continue research on the demography of Hoover's spurge and its seed ecology. A better understanding of the species seed bank viability is needed to determine when local populations may be assumed to be extirpated versus simply dormant. 9. In order to reflect the most current understanding of the species' taxonomy, formally change the species name in the Code of Federal Regulations from Chamaesyce hooveri to Euphorbia hooveri (USFWS, 2023).

# SPECIES ACCOUNT: *Chionanthus pygmaeus* (Pygmy fringe-tree)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 2/20/1987; Southeast Region (R4)

**Physical Description**

Pygmy fringe tree is a shrub or small tree that is often less than 1 m (3 feet tall), but can reach 4 m (feet). The twigs are opposite or sub-opposite and stiff, while the leaf scars and leaves are mostly opposite but sometimes alternate. The leaves are simple, mostly 3 to 10 cm (about 1 to 4 inches) long, and lacking stipules. They have short petioles, and the somewhat leathery blades are ovate to elliptic or obovate in shape, and acute to rounded at the tip. The base of the blade is attenuated to the petiole. The upper surface of the blade is dark yellow-green and smooth, but the lower surface is paler and reticulate. The inflorescence is a leafy-bracted panicle that appears with the new shoots from the axils of most leaf scars from the previous season. The axis (main stem) of the inflorescence is rather short with numerous opposite branches that are spreading, slender and dropping, terminating in clusters of three to six flowers. Bracts toward the base of the inflorescence are similar to, but smaller than, the leaves. The flowers are regular, perfect, and pleasingly fragrant. The four sepals are green, united at the base, and 1.5 to 2.0 millimeters (mm) long. The four petals are white, united at the base to a short, campanulate throat, with narrowly linear lobes, 1.0 to 1.5 cm long and somewhat spreading. The two stamens are fused (adnate) to the corolla base. The ovary is superior with a single style. The fruit is a drupe 2.0 to 2.5 cm long, oval, and green, becoming purplish-brown when ripe. (USFWS, 1999)

**Taxonomy**

Small (1933) named this species Chionanthus pygmaea. Since then there have been no other taxonomic treatments. There are no scientific synonyms, but the common name used in literature is pygmy fringetree and the spelling variation pygmy fringe-tree (Wood 1985, Ward and Godfrey 1979). The gender of the name has been unclear. When he named the species, Small (1933) used the Greek suffix -aea which indicates the species? status as a tree. The use of this ending has been questioned and every author since, including Hardin (1974), has used the suffix -aeus indicating its status as a shrub. (USFWS, 1999)

**Historical Range**

Lake, Osceola, Polk, and Highland Counties, Florida. No longer found on the Mount Dora Range (USFWS, 1999).

**Current Range**

Chionanthus pygmaeus is known from west of Lake Apopka in Lake County, northwestern Osceola County, and the Lake Wales Ridge in Polk and Highlands counties, Florida. (USFWS, 1999)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproduction Narrative**

Adult: Although the reproductive biology of this species has not been thoroughly investigated, it is known to spread by root sprouts and occasionally by seed (Stout in press). The plants appear to be functionally dioecious (Gill and Pogge 1974), and the female flowers have stunted anthers that usually do not open (Goodrum and Halls 1961). The four plants in the endangered species display garden at the Historic Bok Sanctuary (2 males, 2 females) flowered and set seed in 1997 (Center for Plant Conservation 2003). After spring flowering, fruiting probably occurs in June, with seed dispersal in September (Gill and Pogge 1974, Ward and Godfrey 1979). Seeds (drupes) may remain on the plants well into winter (Stout 2001, in press). Little is known about seed dissemination of pygmy fringe tree, and seed production is variable from year to year, with mixed reports for success of germination. In nursery conditions the best results are obtained with cleaned, air-dried seed, but whole fruits have also germinated. Bok Tower Gardens has achieved 60 to 70 percent germination rates under greenhouse conditions (T. Race, Bok Tower Gardens, personal communication 1996). Germination dates for pygmy fringe tree are unknown. Leafing occurs mid-March, budding occurs in March, and anthesis is from late March to early April. Recruitment is exceedingly slow in this species. At The Nature Conservancy's Tiger Creek Preserve (Possum Creek Trail Scrub), over 100 individuals of pygmy fringe trees have been tagged and monitored (I.J. Stout, University of Central Florida, personal communication 1997). In more than 10 years of monitoring, hundreds of root sprouts were found, but only one seedling was located. Despite this extremely low seedling recruitment, the number of individuals at the site appears to be stable. Due to population stability and this species' reliable resprouting after fires, The Nature Conservancy no longer conducts detailed monitoring on this species (B. Pace-Aldana, The Nature Conservancy, in litt. 2005). This species is long-lived and persists in scrub that is burned on a frequency between 20 and 70 years. However, it is a fire-dependent species that resprouts after fire events. This species has above-ground stems growing from rootstocks or buried stems that have survived the infrequent fires that are characteristic of the habitat (Kral 1983, Ward and Godfrey 1979). It has been observed to resprout from rootstocks following a spring burn (Stout in press). Fires may have an important indirect effect on pygmy fringe tree by regulating the numbers and sizes of plants that might shade or otherwise compete with it (Kral 1983). In the spring and summer of 1997, The Nature Conservancy burned sandhill vegetation at Tiger Creek Preserve that contains pygmy fringe tree. The effects of fire on these individuals were monitored (I.J. Stout, personal communication 1997). Burning to restore the sandhill vegetation's original grassy appearance continues, and Bea Pace has monitored the results (Center for Plant Conservation 2003). Pygmy fringe tree is also present at the Carter Creek tract of Lake Wales Ridge National Wildlife Refuge, where restoration of sandhill is being studied by Archbold Biological Station (Menges et al. 2005). Their results to date "suggest that burning is beneficial for sandhill community structure and the populations of several key species. Chainsawing as a pre-treatment has mixed results depending on the species. . . . The saw & burn treatment promotes more complete and intense fires (Menges et al. unpubl. data) and more open post-treatment subcanopies, which may have a number of benefits for restoration of the sandhill ecosystem and its species. Subsequent fires may be more effective in areas impacted once with this mechanical pre-treatment to fire."

**Habitat Type**

Adult: Dry/Xeric Hammocks

**Environmental Specificity**

Adult: Narrow (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Pygmy fringe tree inhabits excessively drained sandy soils on central Florida's LWR (and historically on the Mount Dora Ridge, Orange County). This species is found on low- nutrient St. Lucie fine sand soil which is subject to rapid drying (Wunderlin et al. 1981), as well as other dry sand soils. Pygmy fringe tree occurs primarily in scrub as well as high pine, dry hammocks, xeric hammocks, and transitional habitats. It is abundant at a few sites, where it may form thickets along with evergreen oaks and other shrubs such as tallow wood, silk bay, and scrub hickory. In some locations, it may be the dominant plant while in others it may be codominant or subdominant (Wunderlin et al. 1981). At Carter Creek, where it is relatively abundant, it is scattered among turkey oaks.

***Dispersal/Migration***

***Population Information and Trends***

**Population Narrative:**

This species is protected on a substantial number of conservation lands, most of them purchased after it was listed. It has been monitored at LWR State Forest (Weekley 1996, 1999), and it is clearly a long-lived resprouting species. The Service does not have current information on threats because this shrub is considered relatively abundant and secure by managers of the conservation lands of the Lake Wales Ridge, so limited funds for monitoring have been devoted to other species. After this plant was listed, an extensive network of state conservation lands and the Lake Wales Ridge National Wildlife Refuge came into existence, providing habitat and habitat management supported by extensive ecological research and monitoring programs.

***Threats and Stressors***

**Stressor:**
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The rapid loss of suitable scrub habitat in Central Florida to residential, recreational and related commercial development is of the utmost concern. Some of these well drained upland soils are also being converted to citrus production. The long term exclusion of fire from the scrub can lead to a dense canopy layer unfavorable to the growth of the short pygmy fringetree. (NatureServe, 2015)

***Recovery***

**Reclassification Criteria:**

1. Wen existing populations, within the historic range of C. pygmaeus, are adequately protected from further habitat loss, degradation, and fire suppression. Large areas of land are needed to support populations of this tree/shrub species. These sites must also be managed to maintain xeric oak scrub to support C. pygmaeus. Habitat destruction is occurring at an alarming rate. To ensure the survival of this species, actions must be taken to protect its remaining habitat.

Difficulty in conserving this species may be compounded by the low seed germination rates that could affect this plant's ability to rebound from a reduction of adult individuals. (USFWS, 1999)

Recovery Priority Number: 2

**Delisting Criteria:**
1. When enough demographic data are available to determine the appropriate numbers of self-sustaining populations required to ensure 95 percent probability of persistence for 100 years (USFWS, 1999)

2. When these populations, within the historic range of C. pygmaeus, are adequately protected from further habitat loss, degradation, and fire suppression (USFWS, 1999)

3. When these sites are managed to maintain the serial stage of xeric oak scrub to support C. pygmaeus (USFWS, 1999)

4. When monitoring programs demonstrate that these sites support sufficient population sizes, are distributed throughout the historic range, and are sexually or vegetatively reproducing at sufficient rates to maintain the population. (USFWS, 1999)

**Recovery Actions:**
- Determine current distribution of C. pygmaeus. This species' distribution is somewhat questionable for taxonomic reasons and ease of overlooking individuals. A thorough survey is needed to determine the distribution for this species. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties has been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- Conduct research on life history characteristics. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species, more specific biological information is needed. (USFWS, 1999)
- Monitor existing populations of C. pygmaeus. Develop monitoring protocol to assess population trends for C. pygmaeus. Develop a quantitative description of the population structure of C. pygmaeus. (USFWS, 1999)
- Provide public information about C. pygmaeus. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. However, caution should be taken to avoid revealing specific locality information of C. pygmaeus. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of C. pygmaeus and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level

research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS • Work with State, Federal, and non-profit partners to ensure adequate fire and invasive species management is achieved at sites that support pygmy fringe-tree. • Determine limiting factors and preferred microsites for seedling recruitment. • Develop a standard methodology for monitoring pygmy fringe-tree on conservation lands. • Acquire or secure permanent easements on private sites with existing populations from willing sellers, and restore scrub habitat on these sites, including implementing prescribed fire and vegetation thinning by hand. • Work with private landowners to conserve extant populations. • Initiate detailed demographic monitoring (Level 3 monitoring sensu Menges and Gordon 1996) at multiple sites throughout the species' range. • Conduct a prescribed fire in one or more of the study populations at Tiger Creek Preserve to better understand the response of pygmy fringe-tree and to integrate fire management into population viability models. • Determine the overall level of threat posed by seed and fruit predators, especially the unidentified weevil. • Determine the overall level of threat to pygmy fringe-tree posed by the moth larva Palpita illibalis and white-tailed deer. • Conduct basic research on the breeding system and pollination biology of pygmy fringe-tree. • Initiate studies to determine the genetic structure of pygmy fringe-tree populations throughout the species' range. • Ensure representation of pygmy fringe-tree at the National Center for Genetic Resources Preservation in Fort Collins, Colorado. • Strengthen ex situ conservation measures by including a wider sample (from numerous sites across the species range) of this species at Bok Tower Gardens, in both stored seed and living collections. • Conduct germination trials on stored seed to determine their long-term viability and factors that affect seed dormancy. (USFWS, 2021)

# SPECIES ACCOUNT: *Chorizanthe orcuttiana* (Orcutt's spineflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 10/07/1996; Pacific Southwest (R8) (USFWS, 2015)

**Physical Description**

An annual herb with prostrate, yellowish stems, 1-15 cm long. Yellow, densely hairy flowers (2.5-4 mm) bloom March-April and produce a single seed. (NatureServe, 2015)

**Taxonomy**

Not available

**Historical Range**

See current range/distribution.

**Current Range**

Known only from San Diego County, California. All of the known occurrences of this species are within 5 km of the Pacific Ocean at elevations below 100 m above mean sea level (Bauder 2000). (NatureServe, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (USFWS, 2007)

**Breeding Season**

Adult: March to April (NatureServe, 2015)

**Reproduction Narrative**

Adult: Chorizanthe orcuttiana (Orcutt’s spineflower) is a small (1-15 cm), annual plant species known only from San Diego County, California. C. orcuttiana flowers bloom from March to April (NatureServe, 2015). (USFWS, 2007; NatureServe, 2015)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Maritime shrubland/chaparral (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Small patches (USFWS, 2007)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from USFWS, 2007)

**Habitat Narrative**

Adult: Chorizanthe orcuttiana prefers open areas with sandy soils within low, fairly open southern maritime chaparral communities. (NatureServe, 2015). Soil samples examined were dominated by the sand fraction with moderate acidity, low organic content and nitrate nitrogen (Bauder 2000). The four extant occurrences are small patches often with constricted connectivity to adjacent patches. The habitat of C. orcuttiana is described as loose sandy soils in openings in coastal or maritime chaparral by Bauder (2000, p. 31). (USFWS, 2007; NatureServe, 2015)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Not available

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

9 Extant, 1 possibly extant (USFWS, 2021)

**Population Size:**

470 to 3,000 (USFWS, 2007)

**Population Narrative:**

Currently we consider there to be four extant occurrences of Chorizanthe orcuttiana, one at Oak Crest Park in Encinitas and three on Point Loma. For the four occurrences considered to be currently extant, the highest recorded number of plants for any single occurrence was 2,520 plants in 1998 at Point Loma (EO 12) (Bauder 1998). Recent plant counts for all of the extant occurrences combined range from a high of about 3,000 to a low of about 470 plants. (USFWS, 2007) In summary, annual monitoring of Chorizanthe orcuttiana occurrences since 2014 has provided new information about plant abundance. We have updated our 2014 occurrence status determinations and added the additional occurrences (Appendix A). Based on those updates, there are 21 occurrences of C. orcuttiana with 9 extant, 9 extirpated, 1 possibly extirpated, and 2 research sites. While the extant distribution within the range has increased since the last review, the historical range of C. orcuttiana remains highly limited and has not changed since the previous review. Occurrences of C. orcuttiana, including the newly discovered sites, remain small and isolated throughout the range, and likely susceptible to local stochastic events. Additionally, all occurrences continue to face multiple threats including habitat degradation (trampling, recreational use, erosion), habitat loss (development, road/trail maintenance, fire), invasive species pressure, small population size, and climate change. The information received since the previous review does not appreciably alter our understanding of the species’ distribution, ecology, or threats (Appendix A). (USFWS, 2021)

***Threats and Stressors***

**Stressor:** Habitat loss (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Maritime chaparral as the habitat type with which Chorizanthe orcuttiana is associated and it is estimated that there were 1,500 to 3,700 acres of southern maritime chaparral habitat remaining in San Diego County and 150 acres in Orange County. The Service stated that this represented an estimated loss of between 82 and 93 percent of southern maritime chaparral in San Diego County. (USFWS, 2007)

**Stressor:** Random events (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the final listing rule (USFWS 1996 p. 52381) Chorizanthe orcuttiana was considered threatened by naturally occurring random events exacerbated by drought or fire because of the species' restricted distribution and the small size of the known population. (USFWS, 2007)

**Stressor:** Invasive plant species (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive exotic grass and weed species as well as interruption of the natural fire cycle were also considered threats to this species. Muhlenbergia rigens (deergrass), a native grass species, was removed from some of the habitat at Oak Crest Park because of its potential to crowd out and shade the Chorizanthe orcuttiana (Bauder 2000 p. 21). The lack of a natural fire regime or managed alternative for the associated southern maritime chaparral may pose a threat to Chorizanthe orcuttiana by allowing the shrub canopy to cover over the sandy openings favored by the Orcutt's spineflower. (USFWS, 2007)

**Stressor:** Fire (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The natural fire cycles in the area have likely been altered. A single natural random event, such as a fire, could jeopardize the continued existence of the species at one or more of the occurrences by killing standing plants, reducing input to the seed bank, or by being intense enough to kill some of the seeds in the seed bank. Such an event could also reduce vegetation cover and result in erosion and loss of habitat. (USFWS, 2007)

**Stressor:** Invasive non-native plant species (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Invasive non-native plants are the greatest known threat to the occurrences of Orcutt's spineflower on Point Loma. The invasive non-native Carpobrotus edulis (Hottentot fig;

iceplant) covers many of the open sandy areas on Point Loma (Bauder 2000). Iceplant produces thick layers of prostrate, succulent stems and leaves over the soil surface, deposits organic material, and grows back readily after removal (Bauder 2000). Rhynchelytrum repens (Natal grass) is another nonnative plant that threatens Orcutt's spineflower (Rusev and Zink 2005). A potentially invasive Acacia spp. has also been identified at Point Loma (Bauder 2000). These species can prevent expression of the above ground population of Orcutt's spineflower. If this is a long-term condition, presumably the seed bank would eventually be depleted thereby diminishing the range of the species. (USFWS, 2007)

**Stressor:** Small populations (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Chorizanthe orcuttiana (Orcutt's spineflower) has never been known to be abundant or widespread. Local populations are still relatively to extremely small. (USFWS, 2007)

**Stressor:** Recreation (USFWS, 2007)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The occurrence at Oak Crest Park was fenced in 2000 with money from a section 6 grant through the State to the City of Encinitas. The open rail fence affords the occurrence protection from casual walkers and other recreational activities, noted as threats in the listing rule. (USFWS, 2007)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 5

**Delisting Criteria:**
Delisting criteria are not available.

**Recovery Actions:**
- Recovery actions are not available.
- Continue to work with the City of Encinitas and the U.S. Navy to protect and enhance habitat for Chorizanthe orcuttiana. (USFWS, 2007)
- Eliminate negative impacts from non-native and native vegetation on the known occurrence of the species in Oak Crest Park, Encinitas. (USFWS, 2007)
- Determine the presence and location of similar sites in Oak Crest Park, Encinitas and create clearings among the vegetation on suitable soils. (USFWS, 2007)
- Field-check the historical occurrence sites and suitable habitat identified by Bauder (2000) to verify the presence of suitable habitat and the presence or absence of the species. (USFWS, 2007)

- Determine the reproductive cycle of the species to include pollen and seed dispersal agents, fecundity of the species in relation to rainfall patterns, and any identifiable bottlenecks to the species survival other than those already known. (USFWS, 2007)
- Determine the most effective manner to consistently limit the impact of invasive non- native plants on this species. These may have to be site and/or species specific. (USFWS, 2007)
- Determine and implement an appropriate seed banking strategy for the species. (USFWS, 2007)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS The recommended actions listed below are to be initiated or completed over the next 5 years. Successful implementation of these actions will reduce threats to Chorizanthe orcuttiana and provide information to better understand the biological and physical factors limiting the population growth and distribution. We recognize that conservation of this taxon will require cooperation and coordination with partners to minimize impacts from current threats and aid with future restoration efforts. 1. Conduct additional discovery surveys of potential Chorizanthe orcuttiana habitat. 2. Enhance habitat where Chorizanthe orcuttiana occur, through nonnative plant control, erosion control, removal of excessive plant litter, selective trimming or removal of encroaching vegetation, and other appropriate measures. 3. Augment small occurrences (<1,000 individuals; CBI and AECOM 2021a, table 3.6-1) where necessary into areas of suitable habitat with a genetically appropriate seed source to increase population size and support gene flow. Follow best management practices for seed reintroduction as outlined in the Rare Plant Management Plan and the Seed Collection, Banking, and Bulking Plan (CBI and AECOM 2021a, pp. 253–294; CBI and AECOM 2021b, pp. 132–145) and IUCN Guidelines for Reintroductions and Translocations (IUCN/SSC 2013, entire). 4. Identify areas for habitat enhancement and conduct reintroduction of Chorizanthe orcuttiana to establish additional populations. 5. Prioritize additional research needs outlined in the SDMMP Rare Plant Management Plan (CBI and AECOM 2021a, pp. 293–294), with higher priority towards research that can directly inform species' management. For example: a. Research effects of fire and nonnative grasses and forbs on Chorizanthe orcuttiana fitness. b. Investigate effects of grass-specific herbicide on Chorizanthe orcuttiana to assess efficacy for controlling nonnative grasses in C. orcuttiana habitat. c. Determine viability rates of wild-collected and first-generation bulked seed to assess variability. (USFWS, 2021)

# SPECIES ACCOUNT: *Chorizanthe pungens var. hartwegiana* (Ben Lomond spineflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/07/1994; Pacific Southwest (R8)

**Physical Description**

a small annual herb in the buckwheat family (Polygonaceae). The plants grow up to 2.5 decimeters (10 inches) high. Whorls of bracts (involucres) below the flowers are 1.5—2.5 millimeters (0.6—1.0 inch) long and have pink scarious (thin and dry) margins. The tepals (undifferentiated petals and sepals) are irregularly toothed at the tips. Compared to other species in thepungens-robusta complex, Ben Lomond spineflower is more erect and the flower clusters and associated structures (infloresences) are pink with small distinct heads (Ertter 1996). (USFWS, 1998)

**Taxonomy**

Chorizanthe pungens was first described by George Bentham in 1836 based on a specimen collected in Monterey. This taxon was recognized by George Goodman in 1934 as the type species in describing the Pungentes section ofthe genus. Chorizanthe pungens var. hartwegiana was distinguished from C. pungens var. pungens by James Reveal and Clare Hardham (1989) based on a distinction between the coastal form and an inland form “in the Ben Lomond sandhills area.” (USFWS, 1998)

**Historical Range**

See current range/distribution.

**Current Range**

Monterey and San Luis Obispo counties, CA. (USFWS, 2912)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Insect pollinated (USFWS, 2007)

**Breeding Season**

Adult: Chorizanthe pungens var. hartwegiana seeds germinate in the late fall after the first substantial winter rains. The plants remain small through the winter, then grow quickly and begin producing flowers in April. The length of the flowering season may persist for several months if the climatic conditions during the spring and early summer are favorable (USFWS, 2007).

**Reproduction Narrative**

Adult: Chorizanthe pungens var. hartwegiana seeds germinate in the late fall after the first substantial winter rains. The plants remain small through the winter, then grow quickly and begin producing flowers in April. The length of the flowering season may persist for several months if the climatic conditions during the spring and early summer are favorable. Flowers are pollinated by a variety of insects, including wasps, bees, flies, and butterflies (Morgan 1997 in Service 1998). Seed set varies with site conditions; in controlled experiments with plants transplanted into grass, manzanita, and pine sites, seed set varied from none to about 60 seeds per plant. Higher seed set was closely tied to the lack of shading (Kluse 1994) (USFWS, 2007). This taxon is a short-lived annual species which undergoes large variations in population numbers from year to year depending on climatic conditions and other factors (USFWS, 2007). First-year and, frequently, second-year plants consist ofa basal rosette. In subsequent years, the basal roseffe withers as the main flowering stem develops. In Erysimum species, flowering may be postponed due to unproductive habitat; therefore, some adults may be older than two years old. Successful reproduction most likely depends on habitat characteristics and climatic conditions (Berg 1986) (USFWS, 1998).

**Habitat Type**

Adult: Ponderosa pine woodland (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Clumped (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (NatureServe, 2015)

**Tolerance Ranges/Thresholds**

Adult: Low (inferred from NatureServe, 2015)

**Site Fidelity**

Adult: High (inferred from NatureServe, 2015)

**Habitat Narrative**

Adult: Restricted to pockets of sandstone-derived coarse sandy soils - uplifted ancient marine terraces persisting in a mountain range of volcanic origin. These coarse sands create drier soil conditions than those in the surrounding substrates and support an unusual, open, park-like ponderosa pine woodland community. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the species specific habitat requirements and low number of known populations.

***Dispersal/Migration***

**Dispersal**

Adult: Seeds dispersed by large mammals (mule deer, coyotes, rabbits) and small mammals (on their fur). Insects also disperse seed (USFWS, 2012).

**Dispersal/Migration Narrative**

Adult: Seeds are dispersed by mule deer (Oidocoileus hemionus), coyotes (Canis latrans), rabbits (Sylvilagus spp.), and small mammals that come into contact with the plants in late June and July (McGraw 2004b). At that time, the seeds, which are contained in spiny involucres, are easily separated from the flower stems and adhere to the coats of mammals (McGraw 2004b). Insects, including ants, carry out secondary dispersal of those seeds that fall to the soil in late summer (McGraw 2004b). Dense patches of seedlings below the parent plant, however, suggest that many seeds are not widely dispersed (McGraw 2004b). With seeds viable only up to 1 year after production, and with germination less than 0.01 percent, there is little evidence to suggest that Chorizanthe pungens var. hartwegiana has an extensive seed bank (McGraw 2004b). New information concerning the soil seed bank of the closely related Chorizanthe pungens var. pungens was published in 2006 (Fox et al. 2006). This 5-year study found that the density of Chorizanthe pungens var. pungens in a population was directly related to the previous year's seed set, and that the species germinates well under most winter conditions and does not develop an extensive persistent soil seed bank (USFWS, 2012).

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2012)

**Number of Populations:**

21 (USFWS, 2022)

**Population Narrative:**

1-5 current EOs. (NatureServe, 2015). Population trends are unknown and will be difficult to monitor do to natural yearly fluctuations in populations (USFWS, 2012). Low resiliency, representation and redundancy are inferred based on the low number of known populations, specific habitat requirements and relatively small geographic area in which the species is known to occur. There are currently 21 known populations (USFWS, 2022)

***Threats and Stressors***

**Stressor:** Private development (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Private development was occurring on a limited scale within the habitat of the species at the time of listing, and is still occurring at low levels. Between 1993 and 1998, urban development has resulted in the loss of over 480 hectares (194 ha) of sandhills habitat (Service 1998). Construction of private homes, roads, and businesses has removed vegetation and modified soils through excavation, compaction, and disruption of soil horizons (Service 1998). Recent private development has had only a limited effect on the overall habitat and range of the species. One of the secondary effects of destruction and fragmentation of habitat by urban development is the introduction, either intentionally or inadvertently, of non-native plants to adjacent remaining habitat (USFWS, 2012).

**Stressor:** Recreational threats (USFWS, 2012)
**Exposure:**

**Response:**
**Consequence:** Loss of habitat/loss of individuals
**Narrative:** Recreational threats identified in the Recovery Plan, including hiking, equestrian use, off-road vehicles, mountain biking, and camping, have resulted in habitat degradation and fragmentation (Service 1998; McGraw 2004b). Mountain bikes and off-highway vehicles continue to pose the greatest recreational threats to sensitive habitat, and have caused extensive damage to suitable habitat - specifically at Henry Cowell Redwoods State Park (McGraw, in litt. 2011). These activities crush and remove vegetation, compact soils, promote soil erosion, and can occasionally result in oil and gasoline spills. Equestrian use, mountain biking, motorcycles and social gatherings that can include bonfires remain ongoing impediments to recovery of the species at Olympia Wellfield and Quail Hollow Quarry (C. Mitcham, in litt. 2011; McGraw 2009b). There is also evidence of people accessing Quail Hollow Quarry for games of paintball (McGraw 2009b). These factors continue to threaten the existence of this species and remain relatively unaddressed at this time (McGraw 2004b; McGraw, in litt. 2011) (USFWS, 2012).

**Stressor:** Increased vegetation cover (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Increased vegetation cover resulting from fire exclusion was not identified as a major threat at the time of listing, but is one of the most serious ongoing threats to the persistence of Chorizanthe pungens var. hartwegiana (McGraw 2004b; McGraw, in litt. 2011; T. Hyland, pers. comm. 2011). Encroachment by woody species and litter buildup, in large part stemming from the disruption of natural fire cycles, encourages habitat type conversion (McGraw 2004b). The exclusion of wildfires from sandhill communities results in longer intervals between fire events, and in the sand parkland and northern maritime chaparral communities, this has resulted in increased vegetation cover and heightened competition for space with other species over time. Increased shading due to abundant vegetation cover also may reduce the quality of the habitat for this species. Chorizanthe pungens var. hartwegiana has the potential to benefit from fire, but little is known about the fire regime to which it is adapted. Ongoing modifications to the sandhills habitat, including widespread invasive species and non-native annual grasses, may impact how Chorizanthe pungens var. hartwegiana interacts and responds to fire (McGraw 2009b). Furthermore, fire suppression methods, including application of fire retardant, foam, and large amounts of water, can influence how Chorizanthe pungens var. hartwegiana will recover after a fire, and they may affect the surrounding community assemblage by fertilizing the sandy soil and perhaps providing a competitive advantage to non-native annual grasses and other invasive species (McGraw 2009b) (USFWS, 2012).

**Stressor:** Disease or Predation (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of individuals (USFWS, 2012)
**Narrative:** Disease and predation were not identified as factors at the time of listing, and are not known to currently be factors. Limited herbivory by lepidopteran larvae (caterpillars) on Chorizanthe pungens var. hartwegiana rosettes and mammalian herbivory on seedlings were personally observed by Jodi McGraw, but do not seem to have a detrimental effect on overall seedling survivorship (McGraw 2004b) (USFWS, 2012).

**Stressor:** Inadequacy of Existing Regulatory Mechanisms (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Given the existing regulations, we have seen some benefit from the Federal and County regulations to Chorizanthe pungens var. hartwegiana. Several HCPs have been implemented by private landowners, who are required to mitigate the effects that their actions have on Chorizanthe pungens var. hartwegiana. The existing regulations can only prevent habitat loss if the HCP requires that landowners avoid habitat or restore degraded habitat (USFWS, 2012).

**Stressor:** Fire Exclusion (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Although not indicated at the time of listing, fire exclusion in Santa Cruz County was leading to encroachment by native woody species and non-native annual grasses threatening habitat type conversion and loss of suitable habitat for Chorizanthe pungens var. hartwegiana. Fire exclusion allows for the accumulation of understory litter and the establishment of plants with which Chorizanthe pungens var. hartwegiana cannot compete for light. The result from fire exclusion is a reduction in sand parkland habitat for the Chorizanthe pungens var. hartwegiana (McGraw 2004b). Chorizanthe pungens var. hartwegiana experiences reductions in population size as a result of competition with exotic species for open habitat (McGraw 2004b). Research was completed by McGraw (2004b) on various habitat management strategies, including the use of prescribed fire and manual clearing. Management efforts aimed at restoring Chorizanthe pungens var. hartwegiana habitat should apply these research findings (USFWS, 2012).

**Stressor:** Stochastic Extinction (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Extinction
**Narrative:** Due to its small population and restricted habitat within a narrow geographic range, Chorizanthe pungens var. hartwegiana is vulnerable to stochastic extinction (Service 1994; McGraw and Levine 1998). Typically, annuals and other monocarpic plants (individuals that die after flowering and fruiting), such as Chorizanthe pungens var. hartwegiana, are vulnerable to random fluctuations or variation (stochasticity) in annual weather patterns and other environmental factors (Huenneke et al. 1986). A small population size may make it difficult for a species to persist while sustaining other impacts such as habitat alteration that favors non-native species (USFWS, 2012).

**Stressor:** Climate Change (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** Current climate change predictions for terrestrial areas in the northern hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, Intergovernmental Panel on Climate Change (IPCC) 2007). Chorizanthe pungens var. hartwegiana’s small and isolated range increases

its vulnerability to random fluctuations in annual weather patterns and environmental disturbances such as can be brought about by climate change. Recently, the potential impacts of climate change on the flora of California were discussed by Loarie et al. (2008). Based on climate modeling, they predicted that species' distributions will shift in response to climate change and that the species will "move" to higher elevations and northward, depending on the ability of each species to do so. In the case of the sandhills ecosystem, which is limited to specific soil types in Santa Cruz County, the opportunities to move to higher elevations or further north are limited. Chorizanthe pungens var. hartwegiana's presence at relatively high elevations (90-610 meters (295-2000 feet)) does not make it immediately vulnerable to sea level rise; however, it is susceptible to an altered hydrological regime if changes in the annual precipitation schedule or fog patterns occur. The species requires full access to the sun to survive and reproduce, and an increase in fog cover or too much precipitation can reduce the reproductive capacity of the plant to unsustainably low levels. In general, the scientific community lacks adequate information to make specific and accurate predictions regarding how climate change, in combination with other factors such as limited geographical distribution, will affect species like Chorizanthe pungens var. hartwegiana. Small-ranged species, such as Chorizanthe pungens var. hartwegiana, however, are more vulnerable to extinction due to these changing conditions (Loarie et al. 2008) (USFWS, 2012).

**Stressor:** Nitrogen Deposition (USFWS, 2012)
**Exposure:**
**Response:**
**Consequence:** Loss of habitat
**Narrative:** The coarse nature of Zayante soils contributes to this sandy substrate generally having low moisture and nutrient availability. Traditionally, nitrogen can be one of the limiting nutrients in the sandhills, and increased nitrogen deposition from air pollution and urbanization can threaten the biodiversity of the ecosystem (Weiss 1999). Chorizanthe pungens var. hartwegiana could be impacted by increased nitrogen deposition, resulting primarily from the combustion of fossil fuels. Nitrogen can fertilize non-native annual grasses, such as rattlesnake grass (Briza maxima), rip-gut brome (Bromus diandrus), and rattail fescue (Vulpia myuros), which exert strong competitive effects on Chorizanthe pungens var. hartwegiana (McGraw 2004a). Competition with nonnative plants poses the greatest threat to Chorizanthe pungens var. hartwegiana (Service 1998). At the Bonny Doon Ecological Reserve, the presence of the non-native annual grass Vulpia myuros was shown to significantly inhibit the growth and reproductive success of Chorizanthe pungens var. hartwegiana where they occur together (Pollock 1995) (USFWS, 2012).

***Recovery***

**Reclassification Criteria:**
1. The 21 currently known populations have been secured through fee-title acquisition, conservation easements, or Habitat Conservation Plans. (USFWS, 1998)

2. Conservation measures for this species are included in Habitat Conservation Plans (Graniterock Quarry, Kaiser Sand and Gravel Felton Plant, and the County of Santa Cruz) that have been developed and implemented for the listed insect species. (USFWS, 1998)

3. Management plans for populations on Quail Hollow Ranch County Park and the adjacent State-owned parcel, Bonny Doon Ecological Reserve, Henry Cowell Redwoods State Park, Big Basin State Park, and Gray Whale Ranch State Park are developed and being implemented. (USFWS, 1998)

4. Population numbers are stable or increasing. (USFWS, 1998)

Recovery Priority Number: 9

**Delisting Criteria:**
When the downlisting criteria have been met for a species the species can be considered for delisting if: 1. Threats are reduced or eliminated so that populations are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species. (USFWS, 1998)

**Recovery Actions:**
- 1. Protect habitat for Santa Cruz Mountains species on private land through Habitat Conservation Plans and landowner agreements. Because of the extremely limited amount of habitat that exists, recovery cannot be achieved by the management of State and County lands alone (see task 2). Habitat Conservation Planning with local governments, quarry owners, and developers will provide additional protection. The long-term survival of these species will depend to a large extent on the protection that can be achieved on private lands (USFWS, 1998)
- 2. Manage habitat for Santa Cruz Mountains species. Management of the seven species included in this recovery plan and the habitats that support them will depend on data gathered from monitoring, threat analyses, and available conservation measures. Development and implementation of management programs should be specific to the species complex, ecological process, landowner, and particular threats to be managed. (USFWS, 1998)
- 3. Conduct research on the life history. ecology, and population dynamics of these species that will contribute to appropriate management strategies Research is needed to ensure that management actions that are undertaken are appropriate and will contribute to the long-term survival of these species and the habitats on which they depend. (USFWS, 1998)
- 4. Locate additional habitat/populations within the historic range of the species. The status of any new populations of these species that are discovered in the future should be evaluated and an assessment made of appropriate management actions. The value to the recovery strategy for these species of any additional habitat that is located should be assessed. (USFWS, 1998)
- 5. Develop and implement a public outreach program. An educational program should be established for the public, including private landowners whose property supports these taxa or suitable habitat, to encourage conservation and proper management of the taxa. Nongovernmental organizations such as the California Native Plant Society and the Santa Cruz Mountains Biodiversity Task Force should be approached about participating in this effort. (USFWS, 1998)
- 6. Evaluate progress of recovery effectiveness of management and recoverv actions and revise management plans. (USFWS, 1998)

- Recommended Action from 2012 5-Year Review: Coordination of recovery partners and consolidation of occurrence data is critical to get a better overview of the current status of Chorizanthe pungens var. hartwegiana (USFWS, 2012).
- Recommended Action from 2012 5-Year Review: Increased Service oversight as time allows, may accelerate completion of the HCP with the County of Santa Cruz and other management plans under development at Big Basin State Park, Henry Cowell Redwoods State Park, Gray Whale Ranch State Park, Quail Hollow Ranch County Park, and Bonny Doon Ecological Reserve. These plans need to be completed before implementation and effective recovery efforts may begin (USFWS, 2012).
- Recommended Action from 2012 5-Year Review: Surveys and ongoing monitoring should be undertaken to ensure that potential populations are identified and reliable demographic information is collected. These efforts should focus on sandhills habitats identified as population occurrences to clarify whether and where management actions are necessary. In addition, the CNDDB records should be updated with the most current information available. Specifically, the areas listed in McGraw (2004) as West Lompico, Weston Road, Hilton Drive, Sunset Ridge, Marion, and Landfill Heights; Gray Whale Ranch State Park; and Henry Cowell State Park (USFWS, 2012).
- Recommended Action from 2012 5-Year Review: More detailed knowledge of population occurrences and completion of management plans should allow active management to prevent encroachment of both native and nonnative species in fire-suppressed areas which may lead to type conversion of the habitat and potential extirpation of individual populations. Prescribed burns are the most natural way to restore the vegetation thinning needed to restore open habitat, but in many areas proximity of human habitation precludes this as an option. Mechanical means of vegetation and leaf litter removal (i.e., raking) have proven effective in reducing the chances of habitat type conversion and increased germination rates in Chorizanthe pungens var. hartwegiana seeds (McGraw, 2004). This method may be used in places where fire would create unacceptable risk to local communities (USFWS, 2012).
- Recommended Action from 2012 5-Year Review: Outreach to owners of private holdings with potentially conservable habitat and populations should be attempted. These parties should be provided with information necessary to facilitate management of habitats on these holdings. These private efforts could prevent habitat type conversion due to encroachment by other species in fire suppressed areas, minimize unnecessary impacts, and could aid in maximizing the conservation potential of all suitable habitat and populations (USFWS, 2012).
- Recommended Action from 2012 5-Year Review: The second criterion for downlisting in the recovery plan should be reworded. The criterion as currently worded lists specific HCPs by name. Many HCP projects are abandoned for various reasons. Additionally, entities listed on HCPs may change name and ownership over time and even requirements may change. These changes may in turn lead to alterations of the HCP title or content. For these reasons, including specific HCPs in draft form as downlisting or delisting criterion should be avoided. A blanket statement reflecting the need of the species to be included in any HCP that covers its geographic area would be more appropriate (USFWS, 2012).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Conduct surveys throughout the range of Ben Lomond spineflower to create a detailed and reliable map of occupied areas and suitable but unoccupied habitat. 2. Evaluate the presence and longevity of a seed bank at areas currently occupied, recently occupied, and historically occupied to better understand the need for supplemental seeding following habitat restoration. 3. Secure funding to support monitoring at all protected Ben Lomond spineflower locations (USFWS, 2022).

# SPECIES ACCOUNT: *Chorizanthe pungens var. pungens* (Monterey spineflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 02/04/1994; California/Nevada (R8) (USFWS, 2015)

**Physical Description**

Monterey spineflower (Chorizanthe pungens var. pungens) is a small annual plant, typically prostrate, that may form dense mats. Individual plants have spreading stems 2 to 6 inches long with clusters of generally dense flowers appearing white to pink (USFWS, 2024).

**Taxonomy**

Accepted by Kartesz (1994 checklist and 1999 floristic synthesis) and Flora of North America (2005); however, not listed specifically as distinct at the varietal level by Hickman (1993). Results from a molecular study indicate that Chorizanthe pungens var. pungens and C. robusta var. robusta are more closely related to each another than to the other subspecific taxa in the C. pungens and C. robusta complex; however, more analysis is needed to determine how this would their taxonomic treatment (Brinegar 2006, Baron and Brinegar 2007, Brinegar and Baron 2008 cited by USFWS 2009). (NatureServe, 2015)

**Historical Range**

Based on a single collection from 1842, it may have also occurred historically in extreme northern San Luis Obispo County near San Simeon (Flora of North America Editorial Committee 2005; CNPS 2009). (NatureServe, 2015)

**Current Range**

Plants are typically found in open areas between perennial vegetation where sandy soil limits competition from other plants. Monterey spineflower occurs in Santa Cruz and Monterey Counties (USFWS, 2024).

**Critical Habitat Designated**

Yes; 1/9/2008.

**Legal Description**

On January 9, 2008, the U.S. Fish and Wildlife Service (Service) designated revised critical habitat for Chorizanthe pungens var. pungens (Monterey spineflower) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes nine critical habitat units (CHUs), in California (73 FR 1525-1554). The 2008 Rule replaced critical habitat designated on May 28, 2002 (67 FR 37498-37546).

**Critical Habitat Designation**

The critical habitat designation for Chorizanthe pungens var. pungens includes nine CHUs in Santa Cruz and Monterey Counties, California. In total, approximately 11,055 acres (ac) (4,475 hectares (ha)) fall within the boundaries of this revised critical habitat designation (73 FR 1525-1554).

Unit 1: Sunset (85 ac (35 ha)): This unit consists of coastal beaches, dunes, and bluffs located west of Watsonville in southern Santa Cruz County. Unit 1 contains space for individual and population growth, including sites for seed dispersal and germination; provides the basic requirements for growth; and includes soils primarily in the coastal beach, dune land, and Baywood sand series (Soil Conservation Service 1978, pp. 13– 25; 1980 (maps)) (PCE 1). This unit was occupied at the time of listing (59 FR 5499) and is currently occupied (CNDDB 2006, California Department of Parks and Recreation (CDPR) 2006a). This unit consists exclusively of State land (85 ac (35 ha)) and is entirely within the boundaries of Sunset State Beach. The unit includes land from Sunset Beach Road south to the gate on Shell Road, just north of the mouth of the Pajaro River, and west of Shell Road, which extends the length of Sunset State Beach. Unit 1 is essential because it supports a large population of Chorizanthe pungens var. pungens that in some years numbers in the tens of thousands (CNDDB 2006; CDPR 2006a). The features essential to the conservation of the species may require special management considerations or protection in this unit due threats from invasive, nonnative plants, particularly European beachgrass, which forms dense stands on coastal beaches and crowds out C. p. var. pungens, and from recreational activities, including camping and foot traffic, which could trample plants.

Unit 2: Moss Landing (250 ac (101 ha)): This unit consists of coastal beaches, dunes, and bluffs to the north and south of the community of Moss Landing in northern Monterey County. Unit 2 contains space for individual and population growth, including sites for seed dispersal and germination; provides the basic requirements for growth; and includes soils in the coastal beach and dune land series (Soil Conservation Service 1978, pp. 13–25) (PCE 1). The northern portion of this unit includes lands owned and managed by the State (which includes portions of Zmudowski State Beach and Moss Landing State Beach between the mouths of the Pajaro River and Elkhorn Slough), 20 ac (8 ha) of private lands, and 6 ac (2 ha) of county lands. The southern portion of this unit includes State lands within Salinas River State Beach. This unit was occupied at the time of listing (59 FR 5499) and was included in the previous critical habitat designation. Herbarium records indicate that this site was occupied as early as 1933, and has remained occupied through time (Consortium of California Herbaria 2006 cites collections by H.S. Tates 1936; T. Craig 1933; and J. Thomas 1950). Chorizanthe pungens var. pungens was also recently observed in this unit (CDPR 2006b, unpaginated). This unit contains one of only five populations found along the coast, and it may provide connectivity between the Sunset Unit to the north and the Marina Unit to the south. The features essential to the conservation of the species may require special management considerations or protection in this unit due threats from invasive, nonnative plants, particularly ice-plant, which forms dense ground cover on coastal beaches and crowds out C. p. var. pungens, and from recreational activities including foot traffic, which could trample plants.

Unit 3: Marina (881 ac (357 ha)): This unit consists of coastal beaches, dunes, and bluffs ranging from just south of the mouth of the Salinas River, south to the city of Monterey in northern Monterey County; these lands are entirely west of Highway 1. Unit 3 contains space for individual and population growth, including sites for seed dispersal and germination; provides the basic requirements for growth; and includes soils in the coastal beach, dune land, and Oceano loamy sand soil series (Soil Conservation Service 1978, pp. 13–25, 54–55) (PCE 1). This unit was occupied at the time of listing (59 FR 5499) and it is currently occupied (CNDDB 2006; CDPR 2006; Service 2002, p. 54). Unit 3 is comprised of State lands, including Marina State Beach and Monterey State Beach. This unit is essential because it supports a population of Chorizanthe pungens var. pungens that numbers in the thousands in some years (CNDDB 2006; Service 1998,

p. 67); it is the southernmost of the Monterey Bay area coastal populations; and it may provide connectivity between the populations along the coast and the more interior populations found at former Fort Ord. The features essential to the conservation of the species may require special management considerations or protection in this unit due to threats from invasive, nonnative plants, particularly ice-plant, which forms dense ground cover on coastal beaches and crowds out C. p. var. pungens; recreational activities such as foot traffic, which could result in the trampling of plants; and edge effects of urban development.

Unit 4: Asilomar (48 ac (19 ha)): This unit consists of coastal dunes and bluffs near the communities of Pacific Grove and Pebble Beach on the Monterey Peninsula in northern Monterey County. This unit includes a portion of Asilomar State Beach, and extends just beyond Lighthouse Avenue to the north and terminates at the boundary of the Asilomar Conference Grounds. This unit's eastern boundary extends from Highway 68 north along Asilomar Avenue, and then turns west on Arena Avenue where the boundary connects to Sunset Drive. Unit 4 contains space for individual and population growth, including sites for seed dispersal and germination; provides the basic requirements for growth; and includes soils in the coastal beach, dune land, and Baywood sand soil series (Soil Conservation Service 1978, pp. 13–25) (PCE 1). This unit is comprised of 4 ac (1 ha) of Federal lands, 40 ac (16 ha) of State lands at Asilomar State Beach, and 4 ac (2 ha) of local government ownership. This unit was occupied at the time of listing (59 FR 5499) and is currently occupied. Herbarium records that contain specimens from this area include the following (collector and year): Lemmon 1881, L.C. Wheeler 1936, R. Hoover 1941 and 1963, and L.S. Rose 1963 (Consortium of California Herbaria 2006)). This unit currently supports a population of Chorizanthe pungens var. pungens that numbers in the hundreds (Moss 2000, unpaginated). This unit is essential because it is the southernmost of only five populations of C. p. var. pungens along the coast. Preserving the genetic characteristics that have allowed individuals at this site to survive at the southern end of the species' range along the coast is essential to the long-term survival and conservation of C. p. var. pungens. Protecting peripheral or isolated populations is necessary because they may contain genetic variation not found in core populations. The genetic variation results from the effects of population isolation and adaptation to locally distinct environments (Lesica and Allendorf 1995, pp. 754–757; Fraser 2000, pp. 49– 51; Hamrick and Godt 1996, pp. 291– 295). The features essential to the conservation of the species may require special management considerations or protection in this unit due to threats from invasive, nonnative plants, particularly ice-plant, which forms dense ground cover on coastal beaches and crowds out C. p. var. pungens; recreational activities such as foot traffic which could trample plants; and edge effects of urban development. An additional threat in this unit is the expansion of unregulated vehicle parking in the dunes associated with the high numbers of visitors this area receives each year.

Unit 5: Freedom Boulevard (24 ac (10 ha)): This unit consists of grassland, maritime chaparral, and oak woodland habitat near the western terminus of Freedom Boulevard and northeast of Highway 1 in Santa Cruz County. This unit consists entirely of private lands (24 ac (10 ha)). Unit 5 contains space for individual and population growth, including sites for seed dispersal and germination; provides for the basic requirements for growth; and includes soils in the Baywood sand and Ben Lomond sandy loam series (Soil Conservation Service 1980, pp. 64–65; maps) (PCE 1). This unit was occupied at the time of listing (59 FR 5499) and is currently occupied (CNDDB 2006, element occurrences (EOs) 32 and 34; Morgan 2006, unpaginated). This unit currently supports a population of Chorizanthe pungens var. pungens that numbers in the thousands in favorable years, but many fewer in unfavorable years (CNDDB 2006, EOs 32, 34). This unit is essential because it is the northernmost known occurrence. In the absence of genetic data, protecting populations at the boundaries of a taxon's range is necessary because they may contain genetic variation not found in core populations. The genetic variation results from the effects of population isolation and adaptation to locally distinct environments (Lesica and Allendorf 1995, pp. 754–757; Fraser 2000, pp. 49–51; Hamrick and Godt 1996, pp. 291–295). The features essential to the conservation of the species may require special management considerations or protection in this unit due to threats from invasive, nonnative plants, particularly annual grasses that crowd out C. p. var. pungens, and from edge effects of urban development.

Unit 6: Manresa (94 ac (38 ha)): This unit consists of coastal bluffs along the immediate coast, south of Seacliff State Beach and north of Sunset State Beach in Santa Cruz County. Unit 6 contains space for individual and population growth, including sites for seed dispersal and germination; provides the basic requirements for growth; and includes soils in the coastal beach, Baywood sand, and Elder sandy loam series (Soil Conservation Service 1980, pp. 11–70, maps) (PCE 1). This unit is comprised entirely of lands owned and managed by the State at Manresa State Beach. This unit was occupied at the time of listing (59 FR 5499) and is currently occupied. This unit is essential because it is the most northerly population that is known from the immediate coast and provides connectivity to populations in the Sunset Unit to the south. The features essential to the conservation of the species may require special management considerations or protection in this unit due to threats from invasive, nonnative plants and from recreational activities such as foot traffic, which could trample plants.

Unit 7: Prunedale (190 ac (77 ha)): This unit consists of grassland, maritime chaparral, and oak woodland in the area around Prunedale in northern Monterey County. On the west side of Highway 101, the unit includes the Manzanita County Park subunit located between Castroville Boulevard and San Miguel Canyon Road. On the east side of Highway 101, the unit consists of four additional subunits. The five subunits support similar plant communities and need similar types of special management; therefore, we discuss them as a unit. Unit 7 contains space for individual and population growth, including sites for seed dispersal and germination; provides the basic requirements for growth; and includes soils in the Arnold loamy sand, Santa Ynez fine sandy loam, and Arnold-Santa Ynez complex series (Soil Conservation Service 1978, pp. 9–11, 72–73) (PCE 1). This unit consists of 155 ac (63 ha) of State lands, 18 ac (7 ac) of local agency lands (Manzanita County Park), and 17 ac (7 ha) of Pacific Gas and Electric easement lands. This unit was occupied at the time of listing, was included in our listing rule in reference to the Prunedale area (59 FR 5499), and is currently occupied (Caltrans 2001; Consortium of California Herbaria 2006). This unit is essential because it is one of only four units that are known to support populations in maritime chaparral and oak woodland habitats more representative of hotter, interior sites and is the easternmost of the units in the interior hills. The features essential to the conservation of the species may require special management considerations or protections in this unit due to threats from invasive, nonnative plants, which crowd out Chorizanthe pungens var. pungens; edge effects from urban development; and recreational activities such as off road vehicles, which can crush plants and destroy seeds.

Unit 8: Fort Ord (9,432 ac (3,817 ha)): This unit consists of grassland, maritime chaparral, coastal scrub, and oak woodland on the former Department of Defense base at Fort Ord, east of the city of Seaside in northern Monterey County. This unit is entirely within the area formerly known as Fort Ord, bounded by Highway 1 on the northwest, the Salinas River to the east, and Monterey-

Salinas Road (Highway 68) on the south. Approximately 87 percent of this critical habitat unit is Federal land (8,172 ac (3,307 ha)) managed by BLM and the Army, 6 percent is State land (606 ac (245 ha)), and 7 percent is under local jurisdictions (654 ac (265 ha)). Portions of Fort Ord have been transferred to BLM; University of California, California State University at Monterey Bay; and local (city and county) jurisdictions. All of the lands included in this unit are designated as current or future habitat reserves under the Army's habitat management plan (Corps 1997, Attachment A map; Zander Associates 2002, Figures 4–6). About one-half of Unit 8 still must be cleaned of environmental contaminants by the Army before it can be transferred to BLM. Unit 8 contains space for individual and population growth, including sites for seed dispersal and germination; provides the basic requirements for growth; and includes soils in the Arnold-Santa Ynez complex, Baywood sand, and Oceano loamy sand series (Soil Conservation Service 1978, pp. 9– 73). Lands in this unit are intended to be managed at a landscape scale, using prescribed fire, as needed, to maintain a range of different-aged maritime chaparral stands (Corps 1997, pp. 4.24– 4.25), and by doing so preserve substantial populations of rare maritime chaparral species in the Monterey Bay area. This unit was occupied at the time of listing (59 FR 5499) and is currently occupied. This unit is essential because it currently supports multiple large populations of Chorizanthe pungens var. pungens that number in the tens of thousands in some years (CNDDB 2006, EO 2; Jones and Stokes 1992, Figure F– 3; BLM 2006), and it is one of only five units that include maritime chaparral and oak woodland habitats more representative of hotter, interior sites. The features essential to the conservation of the species may require special management considerations or protection in this unit due to threats from invasive species that crowd out C. p. var. pungens, munitions clean-up methods on former ranges that remove and chip all standing vegetation, and recreational activities and road and trail maintenance that could trample plants.

Unit 9: Soledad (51 ac (21 ha)): This unit consists of an interior dune in the floodplain of the Salinas River channel just south of the city of Soledad in central Monterey County on privately owned lands. Unit 9 contains space for individual and population growth, including sites for seed dispersal and germination; provides the basic requirements for growth; and includes soils in the dune land and Metz complex soil series (Soil Conservation Service 1978, pp. 24, 48–49) (PCE 1). This unit was occupied at the time of listing (59 FR 5499) and is currently occupied. Approximately 5,000 plants were observed in this unit in 1994 (CNDDB 2006, EO 28; Wesco 1994, pp. 5–8). This unit is essential because it is the southernmost interior location that supports a population and the only unit where Chorizanthe pungens var. pungens grows in interior floodplain dune habitat. This population is geographically remote from all others in this revised critical habitat designation. Protecting peripheral or isolated populations of rare species is highly desirable because they may contain genetic variation not found in core populations (Lesica and Allendorf 1995, pp. 755–757). The features essential to the conservation of the species may require special management considerations or protection in this unit due to threats from invasive, nonnative plants, which crowd out C. p. var. pungens; overspray of herbicides and pesticides from agricultural operations; and vegetation clearing activities associated with road maintenance.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The primary constituent element of critical habitat for Chorizanthe pungens var. pungens (73 FR 1525-1554) is a vegetation structure arranged in a mosaic with openings between the dominant elements (e.g., scrub, shrub, oak trees, or clumps of herbaceous vegetation) that changes in spatial position as a result of physical processes such as windblown sands and fire and that allows sunlight to reach the surface of the following sandy soils: coastal beaches, dune land, Baywood sand, Ben Lomond sandy loam, Elder sandy loam, Oceano loamy sand, Arnold loamy sand, Santa Ynez fine sandy loam, Arnold—Santa Ynez complex, Metz complex, and Metz loamy sand.

**Special Management Considerations or Protections**

Critical habitat does not include manmade structures (such as buildings, aqueducts, airports, and roads) and the land on which such structures are located, existing within the legal boundaries on the effective date of this rule.

***Life History***

**Food/Nutrient Resources**

**Breeding Season**

Adult: March to June (USFWS, 2009)

**Reproduction Narrative**

Adult: Chorizanthe pungens var. pungens is a prostrate annual species in the buckwheat family (Polygonaceae). Flowering occurs from late March to June, depending on weather patterns, and seed is dispersed in mid-summer. Chorizanthe pungens var. pungens plants produce a maximum of one seed per flower and, depending on the vigor of the plant, produce dozens of seeds per plant (Fox et al. 2006). (USFWS, 2009)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Forest Edge, Forest/Woodland, Grassland/herbaceous, Old field, Sand/dune, Savanna, Shrubland/chaparral, Woodland - Hardwood (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Mild maritime climate, characterized by fog and winter rains (USFWS, 1998)

**Geographic or Habitat Restraints or Barriers**

Adult: Found in open areas: openings between shrubs, roadsides, firebreaks, and a heavily disturbed firing range. (NatureServe, 2015)

**Spatial Arrangements of the Population**

Adult: Scattered (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist (inferred from USFWS, 2009)

**Habitat Narrative**

Adult: Chorizanthe pungens var. pungens is found scattered on sandy soils within coastal and near-coastal dune, coastal scrub, grassland, maritime chaparral, and oak woodland communities. Found in open areas: openings between shrubs, roadsides, firebreaks, and a heavily disturbed firing range. This plant occurs in areas of relatively mild maritime climate, characterized by fog and winter rains. The fog helps keep summer temperatures cool and winter temperatures relatively warm, and provides moisture in addition to the normal winter rains. Other plants associated with this species include beach-bur (Ambrosia chamissonis), coastal sagewort (Artemisiapycnocephala), and mock heather (Ericameria ericoides). (USFWS, 1998; NatureServe, 2015)

***Dispersal/Migration***

**Motility/Mobility**

Adult: High (inferred from USFWS, 2009)

**Dispersal**

Adult: High (inferred from USFWS, 2009)

**Dependency on Other Individuals or Species for Dispersal**

Adult: Animals (USFWS, 2009)

**Dispersal/Migration Narrative**

Adult: Seed dispersal in C. p. var. pungens is likely facilitated by hooked spines on the structure surrounding the seed. In the Chorizanthe genus, these are believed to attach to passing animals and disperse seeds between plant colonies and populations (Reveal 2001). Wind also likely disperses seeds within colonies and populations. (USFWS, 2009)

***Population Information and Trends***

**Population Trends:**

Declining

**Number of Populations:**

51 CNDDB occurrences (USFWS, 2024)

**Population Size:**

~ 2,000,000 across all occurrences (USFWS, 2024)

**Adaptability:**

Moderate (USFWS, 2009)

**Population Narrative:**

Approximately 18 occurrences observed since 1989 (CNDDB 2008). Populations in the hills between Watsonville and Aptos are small, declining, and have been impacted by developments throughout the 1990s (Hayes and Taylor 2006). C. pugens var. pugens has the ability to recolonize sites when invasive plants are removed if there is a seed source (USFWS 2009). The original survey used large blocks of habitat and the calculations included closed canopy blocks of woody vegetation. The reduction in estimated occupied habitat yields a population between 200,000 and 2,000,000 individuals. (USFWS, 1998; USFWS, 2009; NatureServe, 2015). At the time of listing, we knew of Monterey spineflower occurrences in sand dunes along the coast between Manresa State Beach and the Monterey Peninsula, in Manzanita Park in the Prunedale Hills, throughout the former Fort Ord, and in historical collections from Soledad and San Simeon (Service 1994, 59 FR 5500). We estimated the population size to be approximately 2 million individuals across seven occurrences (Service 1998, p. iii). Between the time of listing in 1994 and the publication of the Recovery Plan in 1998, the number of occurrences had increased to 26 (Service 1998, pp. 66-67). By 2009, 29 occurrences had been described (Service 2009, pp. 5, 18). Currently, the California Natural Diversity Database (CNDDB) lists 51 occurrences with no changes since the 2020 5-year review (CNDDB 2024a, data). Unprocessed data from the CNDDB online field survey form shows 11 submissions not currently in the CNDDB (CNDDB 2024b, data). Ten of these submissions are likely to provide updated information for existing occurrences and each show that the occurrences are extant. One submission may become a new occurrence at the northeastern range of the species in the Santa Cruz Mountains. Unpublished data from Caltrans suggests that the species may be more common in the eastern portion of its known range east of Prunedale (Caltrans 2004, data). These locations are also not represented in the CNDDB. The available information suggests the species is more widespread than was known at listing . Of the 51 CNDDB occurrences, 21 (41 percent) occur on land that is owned and managed by an entity with conservation objectives (e.g. California State Parks, Elkhorn Slough Foundation, The Nature Conservancy, federal lands, and others). The remaining 30 occurrences (59 percent) occur on mostly private land.(USFWS, 2024).

***Threats and Stressors***

**Stressor:** Development for residential, commercial and industrial uses (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Conversion of lands for urban development continues in the Monterey Bay area. Development projects have been proposed or approved in the last 5 years that would remove or fragment habitat of Chorizanthe pungens var. pungens in the Prunedale Hills (e.g., the Prunedale Improvement Project, Pesante Canyon developments), coastal region (e.g., at Armstrong Ranch, Monterey Airport), and on the Monterey Peninsula (e.g., at Pebble Beach) (Lowe 2001, Monterey County 2005, California Department of Transportation (Caltrans) 2005, City of Marina 2007, Rana Creek Habitat Restoration 2007). Development is also planned within the boundaries of the 28,000-acre former Fort Ord military base in Monterey County. On former Fort Ord, Chorizanthe pungens var. pungens is found in maritime chaparral, coastal sage scrub, and in openings in oak woodland. It occurs on parcels designated for development and habitat reserve, as well as in the margins of areas to be redeveloped. (USFWS, 2009)

**Stressor:** Recreation (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Chorizanthe pungens var. pungens requires open sandy habitat in which to grow, so it consequently colonizes openings along roads and trails and may colonize trail beds, if use is infrequent. In at least one State Park site, at Sunset State Beach where recreational use was previously heavy, new barriers have been introduced to funnel recreational traffic and allow C. p. var. pungens to expand into the area from nearby occurrences (State Parks 2006a). Grading of trails (e.g., at former Fort Ord) may also diminish populations. However, on Fort Ord Public

Lands, BLM hopes to maintain adequate open space along the margins of trails and thereby retain trail use by people and continued occupancy by C. p. var. pungens along trail margins (BLM 2003). It appears that light recreational use, such as foot traffic, maintains more open habitat suitable for C. p. var. pungens, but excludes the taxon where traffic is frequent during the growing season. (USFWS, 2009)

**Stressor:** Dune stabilization (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Non-native species were introduced for dune stabilization and subsequently, compete for habitat with C. pungens var. pugens. (USFWS, 2009)

**Stressor:** Land ownership (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The dune scrub habitat of Chorizanthe pungens var. pungens is protected from development at numerous coastal locations. In Santa Cruz County, populations occur at Sunset State Beach and Manresa State Beach. In Monterey County, coastal populations occur along the Monterey Bay on preserved lands at Zmudowski, Moss Landing, Salinas River, Marina, Monterey, and Asilomar State Beaches, the latter of which is on the Monterey Peninsula near the southern end of this taxon’s extant range (Moss 2000, State Parks 2006b, CNDDB 2007). The interior occurrences in Santa Cruz County (e.g., Freedom Boulevard and Bel Mar areas (Service 2002: 67 FR 37498)), which are not discussed in the specific recovery criteria above, are not secure from development. In northern Monterey County in the Prunedale Hills, populations occur on easements owned by Pacific Gas and Electric, on private lands, on lands owned or managed by conservation-oriented organizations such as the Elkhorn Slough Foundation, at a County Park, and on State lands managed by the California Department of Transportation (Caltrans). The eventual use of the Caltrans land has not been determined (Siepel pers. comm. 2004; Robison 2006). Chorizanthe pungens var. pungens also occurs at numerous places on former Fort Ord, a closed military base and Superfund site that is being cleaned and planned for reuse. The population in a river dune near Soledad is privately owned and represents the southernmost interior population known to be extant. (USFWS, 2009)

**Stressor:** Invasive non-native species (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The final rule identifies competition from invasive nonnative species, such as the iceplants (sea-fig) (Carpobrotus edulis, Mesembryanthemum crystallinum), and European beach grass (Ammophila arenaria), as a threat to this taxon (59 FR 5499). These species are particularly adept at colonizing dune sands and several of them have been used in California to promote dune stabilizations (Albert 2000). Invasive nonnative species remain a threat to Chorizanthe pungens. var. pungens. In addition to the species noted in the final rule, others that have invaded maritime chaparral and coastal sage scrub where C. p. var. pungens occurs include jubata grass (Corterderia jubata), French broom (Genista monspessulana), and invasive annual grasses of European origin, such as wild oats (Avena sp.), soft chess (Bromus hordeaceus), and ripgut brome

(Bromus diandrus) (BLM 2003, Parsons 2004, Fusari and McStay 2007). These latter species are typically able to colonize disturbed sites with more well-developed soils than occur on dunes. In addition to the direct effects that invasive, non-native plant species may have on Chorizanthe pungens var. pungens, Chorizanthe species may be indirectly affected by these species via diminished pollinator visitation. Many of the hymenopteran pollinators important to Chorizanthe pollination (e.g., sphecid wasps, bumblebees, and bees from the families Halictidae and Anthophoridae), require bare ground for nesting (Murphy 2003). (USFWS, 2009)

**Stressor:** Climate change (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the northern hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). Beaches along the coast will be subject to greater and more frequent wave attack, resulting in erosion and shoreline retreat (CCC 2001). The extent to which such events are caused by climate change and the extent to which it could affect Chorizanthe pungens var. pungens are unknown at this time. (USFWS, 2009)

**Stressor:** Agricultural Land Conversion
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Aerial imagery suggests that nine of 51 occurrences (18 percent) have been developed or converted to agriculture, but the amount of acres or number of individuals affected cannot be determined without survey data. Currently, there is very little land where Monterey spineflower occurs that could be converted to agriculture. We expect that the threat of agricultural land conversion will continue to decrease with time because coastal populations are not subject to agricultural conversion and the majority of inland suitable habitat occurs on the former Fort Ord where conversion to agriculture is not planned. (USFWS, 2020)

**Stressor:** Sand Mining
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A sand extraction operation was run on a portion of sand dunes and beach between Marina State Beach and the Salinas National Wildlife Refuge from 1986 through 2013 (CCC 2017, Exhibit 5, p. 3). The effect of this operation was the loss of approximately 243,000 cubic yards/year of sand from the Southern Monterey Bay littoral cell resulting in causing or worsening shoreline retreat and dune erosion (CCC 2017, Exhibit 5, p. 3). A settlement agreement in 2017 closed the operation and initiated reclamation of the extraction operation (CCC 2017, Appendix A, entire). Under the settlement agreement, removal of extraction equipment and facilities, and regrading and restoration will occur between 2020 and 2025 (CCC 2017, Appendix A, pp. 33-37). The closure of the sand extraction operation is likely to result in greater amounts of sand deposition on beaches within the range of the Monterey spineflower and reduce effects of shoreline retreat and coastal erosion. If the settlement agreement timeline is adhered to, sand mining will no longer be a threat to individuals or habitat of Monterey spineflower. (USFWS, 2020)

**Stressor:** Recreation
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Recreation from hiking, biking, equestrian, or other activities may create open space that can provide habitat for Monterey spineflower. However, sustained use of open areas is not likely to support the species because of direct damage to plants through trampling, erosion along trail systems, and introduction of invasive species that compete with Monterey spineflower. Recreation had historically been a threat at Sunset State Beach, but has been reduced through fencing that directs the impacts of recreational use to areas not occupied by Monterey spineflower (Service 2009, p. 8). It is possible that as the former Fort Ord becomes more open to the public that recreational use will increase and potentially impact Monterey spineflower. (USFWS, 2020)

***Recovery***

**Reclassification Criteria:**
Reclassification criteria are not available.

Recovery Priority Number: 15

**Delisting Criteria:**
1. The Fort Ord disposal and reuse process has led the management agencies to develop, fund, and implement permanent protection plans for the species' habitat including permanent iceplant suppression programs. (USFWS, 2009)

2. Beach-dune occurrences on State Park and private lands throughout its current range from Santa Cruz to the Monterey Peninsula are covered under a permanent protection plan. Plans at the time of writing to conserve roughly 60 percent of Fort Ord appear sufficient for recovery of the interior occurrence. A reassessment would be made should plans call for conservation of less habitat. Existing management along the coast at the State Parks units needs to be supplemented with protection and management on private lands to be determined after a thorough analysis of the beach populations. (USFWS, 2009)

3. Populations in the protected areas are stable or increasing over a 15 year period, which will include wet and drought years. (USFWS, 2019)

**Recovery Actions:**
- Protect habitat of the listed species and their occurrences on private lands by informing landowners and consulting with local lead agencies (USFWS, 1998)
- Minimize threats to the plants by minimizing the threats from invasive non-native plants and threats on private and public lands. (USFWS, 1998)
- Develop management strategies through a research program to document the listed species' life histories and their responses to vegetation management. (USFWS, 1998)
- Develop and implement management practices for the occurrences and habitat of Chorizanthe pungens var. pungens by establishing a working group to collaborate with private and public landowners and appropriate agencies to develop specific management

guidelines. (USFWS, 1998)

- Monitor occurrences and threats to determine effectiveness of management and to establish delisting criteria including trends, effectiveness of reduce threats, and survey likely habitat for additional occurrences.
- Coordinate recovery actions to protect other listed species and species of special concern.
- Develop and implement an outreach program
- The criteria should be revised to identify the importance of having protected populations in the interior north (Santa Cruz) and central (Prunedale Hills) portions of this taxon's range.
- Encourage the State to establish a permanent protection and management mechanism for the Caltrans managed lands in the Prunedale Hills.
- Continue to support and partner with organizations, agencies, and individuals to preserve, restore, and enhance lands on which this taxon occurs.
- Develop a Memorandum of Understanding or coordinate with land managers on other mechanisms (e.g., a set of management actions within a management plan) that would meet the recovery criterion of ensuring adequate management (primarily control of nonnative species and maintaining openings in native vegetation) on lands that support Chorizanthe pungens var. pungens.
- The current recovery criteria call for 15 years of monitoring. Coordinate with land managers to determine the most efficient means to implement and document adequate monitoring to ensure that the general trend or persistence of the populations is being tracked. Focus surveys and monitoring in years of high rainfall when the extent of its distribution is most likely to be apparent.
- Evaluation of Recovery Criteria 1. The Fort Ord Reuse Authority rescinded their application for a state incidental take permit and federal HCP in 2020. The 1997 Habitat Management Plan guides development and use of the former Fort Ord in the absence of a permanent protection plan and projects are evaluated as they arise. As a result, there is no unified plan for the permanent protection, monitoring, or management of Monterey spineflower throughout the former Fort Ord. 2. A majority of beach dune occurrences occur on protected land (California State Parks), but there is no permanent or range-wide protection or monitoring plan. 3. There is no range wide monitoring program that has 15 years of data by which to evaluate population trends. Population data is sparse throughout the range, and areas that do have some amount of continuous data are usually smaller portions of large parcels, such as the former Fort Ord (Service 2020, p. 8). Data that have been collected within an occurrence, but not part of a monitoring plan designed to represent the entire occurrence, should not be used to evaluate the stability of Monterey spineflower throughout the whole occurrence (USFWS, 2024).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: The following actions are recommended based on the current 5-year review: • A range wide monitoring program should be created in order to evaluate occurrences of Monterey spineflower that are deemed essential to the recovery of the species. • Monitoring of Monterey spineflower populations on California State Beaches and the former Fort Ord should begin with the goal of having continuous long-term monitoring that will meet the intent of the stated recovery criteria. • Restoration and reintroduction should be attempted in coastal dune systems where past disturbance or invasive species have inhibited establishment of Monterey spineflower. • The taxonomy of the varieties of Chorizanthe pungens and Chorizanthe robusta should be reevaluated to determine if revisions are necessary or warranted. • The recovery criteria should be revisited to evaluate the importance of having protected populations in the interior north (Santa Cruz) and central (Prunedale Hills) portions of this taxon's range. (USFWS, 2020)

- RECOMMENDATIONS FOR FUTURE ACTIONS: In the 2020 5-year review, we recommended the following actions, which remain valid for this 5-year review: • A range wide monitoring program should be created in order to evaluate occurrences of Monterey spineflower that are deemed essential to the recovery of the species. • Monitoring of Monterey spineflower populations on California State Beaches and the former Fort Ord should begin with the goal of having continuous long-term monitoring that will meet the intent of the stated recovery criteria. • Restoration and reintroduction should be attempted in coastal dune systems where past disturbance or invasive species have inhibited establishment of Monterey spineflower. • The taxonomy of the varieties of Chorizanthe pungens and Chorizanthe robusta should be reevaluated to determine if revisions are necessary or warranted. • The recovery criteria should be revisited to evaluate the importance of having protected populations in the interior north (Santa Cruz) and central (Prunedale Hills) portions of this taxon's range (USFWS, 2024).

# SPECIES ACCOUNT: *Chorizanthe robusta var. robusta* (Robust spineflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 02/04/1994; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

Chorizanthe robusta var. robusta is an annual spineflower in the Pungentes section of the genus Chorizanthe in the buckwheat family (Polygonaceae) (Figure 1). Like other spineflowers, it is branched from the base and subtended by a rosette of basal leaves. The plant has an erect to spreading or prostrate habit, usually standing not more than 20 cm (8 in high). The whorl of bracts subtending the flowers (involucres) has thin white to pinkish scarious (thin and translucent) margins along the basal portions of the teeth. Relative to other spineflower taxa in the Pungentes section, the flower heads are large (1.5 to 2.0 cm in diameter and distinctly aggregate. (USFWS, 2004)

**Taxonomy**

Accepted by Kartesz (1994 checklist and 1999 floristic synthesis) and Flora of North America (2005). However, Hickman (1993) does not list this taxon as distinct. Results from a molecular study indicate that Chorizanthe pungens var. pungens and C. robusta var. robusta are more closely related to each another than to the other subspecific taxa in the C. pungens and C. robusta complex; however, more analysis is needed to determine how this would their taxonomic treatment (Brinegar 2006, Baron and Brinegar 2007, Brinegar and Baron 2008 cited by USFWS 2009). (NatureServe, 2015)

**Historical Range**

Occurrences of Chorizanthe robusta var. robusta populations have been recorded since the late 1800s, occurring as far north as San Francisco and Alameda Counties, and south into Monterey County.  Inland occurrences were documented in and around San Jose and Los Gatos in Santa Clara County.  Coastal and near coastal occurrences have been documented in San Mateo County and Santa Cruz County where it is found today (CNDDB). (USFWS, 2010)

**Current Range**

Currently, there are 11 populations in Santa Cruz County over a range of approximately 21 miles (33.8 km). (USFWS, 2010)

**Critical Habitat Designated**

Yes; 5/28/2002.

**Legal Description**

On May 28, 2002, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Chorizanthe robusta var. robusta (Robust spineflower) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in California (67 FR 36822-36845).

**Critical Habitat Designation**

The critical habitat designation for Chorizanthe robusta var. robusta includes six CHUs in Santa Cruz County, California. This species critical habitat encompasses approximately 469 acres (ac) (190 hectares (ha)) (67 FR 36822-36845).

Unit A: Pogonip Unit: Unit A consists of sandy openings within mixed forest habitat within Pogonip Park in the City of Santa Cruz. Of the 64 ha (159 acre) unit, 62 ha (152 ac) are owned and managed by the City; and the remainder are privately owned. As of the year 2000, two colonies comprising approximately 800 individuals occupied this site. This unit is important to the conservation of the taxon because it supports extant colonies of Chorizanthe robusta var. robusta. This unit also includes habitat that is important for the expansion of existing colonies and connectivity between the two colonies. In addition, it is also important because, aside from the Wilder Creek location which we were not aware of at the time of the proposed rule, Pogonip Park is the most northerly and westerly location known for the species. It is also one of only three known locations where C. r. var. robusta is found more than 5 km (3 mi) away from the beach. Preserving the genetic characteristics that have allowed individuals at this site to survive under these slightly different environmental conditions may be important for the long-term survival and conservation of C. r. var. robusta.

Unit B: Branciforte Unit: Unit B consists of an old field/ grassland unit within the city limits of Santa Cruz. The 4-ha (9-ac) unit is privately owned. As of the year 2001, this unit supported a Chorizanthe robusta var. robusta population of approximately 500 individuals. This unit also includes habitat that is important for the expansion of the existing population. This unit is important to the conservation of the species because it contains one of the only eight known locations of C. r. var. robusta. It is the only other unit in close proximity to Unit A

Unit C: Aptos Unit: Unit C consists of sandy openings within maritime chaparral. The 28 ha (70 ac) unit is comprised entirely of private lands. As of the year 2000, this unit supported a Chorizanthe robusta var. robusta population of approximately 3,000 individuals. This unit also includes habitat that is important for the expansion of the existing population. It is also one of only three locations that supports C. r. var. robusta more than 5 km (3 mi) away from the beach. Preserving the genetic characteristics that have allowed individuals at this site to survive under these slightly different environmental conditions (i.e., more inland conditions) may be important for the long-term survival and conservation of C. r. var. robusta.

Unit D: Freedom Unit: Unit D consists of grasslands and sandy areas in openings within maritime chaparral and oak woodland. This 4 ha (9 ac) unit is comprised of private and Pajaro Unified School District lands. As of the year 2001, this unit supports a Chorizanthe robusta var. robusta colony of several hundred individuals. Additionally, other colonies of C. r. var. robusta occur within a few hundred yards of the first colony; these additional colonies are outside the critical habitat boundary. This unit is important to the conservation of the taxon because it supports one of only eight known extant locations of C. r. var. robusta. This unit also includes habitat that is important for the expansion of the existing colony and connectivity between the two colonies.

Unit E: Buena Vista Unit: Unit E consists of grasslands within maritime chaparral and oak woodland on the Buena Vista parcel. The 55 ha (135 ac) unit is comprised entirely of private lands. As of 1999, this unit supports multiple colonies of Chorizanthe robusta var. robusta comprising approximately 1,500 individuals. This unit is important to the conservation of the species because it is one of only two units that supports multiple extant colonies of C. r. var.

robusta. This unit also includes habitat that is important for the expansion of the existing colonies, and connectivity between the multiple colonies.

Unit F: Sunset Unit: Unit F consists of coastal dune habitat, and is identical to critical habitat that is being designated for the Chorizanthe pungens var. pungens. All of this 35 ha (86 ac) unit is within Sunset State Beach. As of 2001, this unit supports the largest concentration of C. r. var. robusta, including dozens of colonies of comprising tens of thousands of individuals. This unit is important to the conservation of the species because it is only one of two units that supports multiple extant colonies of C. r. var. robusta. This unit also includes habitat that is important for the expansion of these existing colonies into areas that were historically occupied, and for maintaining connectivity between the multiple colonies. The unit is also important because it is the most southerly location known for the species and the only location, aside from Manresa State Beach which was not proposed for critical habitat, where C. r. var. robusta is found so close to the beach. Preserving the genetic characteristics that have allowed individuals at this site to survive under these slightly different environmental conditions (i.e., more coastal conditions) may be important for the long-term survival and conservation of C. r. var. robusta. Lands designated as critical habitat are under private, city, and State jurisdiction. The approximate areas of designated critical habitat by land ownership are shown in Table 1.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Chorizanthe robusta var. robusta critical habitat consists of four components (67 FR 36822-36845):

(i) Sandy soils associated with active coastal dunes, coastal bluffs with a deposition of windblown sand, inland sites with sandy soils, and interior floodplain dunes;

(ii) Plant communities that support associated species, including coastal dune, coastal scrub, grassland, maritime chaparral, oak woodland, and interior floodplain dune communities, and have a structure such that there are openings between the dominant elements (e.g, scrub, shrub, oak trees, clumps of herbaceous vegetation);

(iii) Plant communities that contain no or little cover by nonnative species which would complete for resources available for growth and reproduction of Chorizanthe robusta var. robusta; and

(iv) Physical processes, such as occasional soil disturbance, that support natural dune dynamics along coastal areas.

**Special Management Considerations or Protections**

Special management considerations or protections may be needed to maintain the primary constituent elements for Chorizanthe robusta var. robusta within the units being designated as critical habitat. In some cases, protection of existing habitat and current ecological processes may be sufficient to ensure that populations of C. r. var. robusta are maintained, and have the ability to reproduce and disperse into surrounding habitat at those sites. In other cases, however, active management may be needed to maintain the primary constituent elements for C. r. var. robusta. We have outlined below the most likely kinds of special management and protection that C. r. var. robusta may require. (1) In near-coastal areas, the supply and movement of sand along the coast must be maintained to create the dynamic dune habitats that are needed for

Chorizanthe robusta var. robusta. (2) In more interior locations, the sandy soils on which Chorizanthe robusta var. robusta is found should be maintained to optimize conditions for the species. Physical properties of the soil, such as its chemical composition, salinity, and drainage capabilities would best be maintained by limiting or restricting the use of herbicides, fertilizers, or other soil amendments. (3) The associated plant communities must be maintained to ensure that the habitat needs of pollinators and dispersal agents are maintained. The use of pesticides should be limited or restricted so that viable populations of pollinators are present to facilitate reproduction of Chorizanthe robusta var. robusta. Fragmentation of habitat through construction of roads and certain types of fencing should be limited so that seed dispersal agents may move seed of C. r. var. robusta throughout the unit. (4) In some plant communities, it may be important to maintain a mosaic of different-aged stands of coastal scrub or maritime chaparral patches so that openings that support Chorizanthe robusta var. robusta will be maintained. Depending on location, the use of prescribed fire, thinning, or other forms of vegetation management may be useful in creating and maintaining this type of mosaic. (5) In all plant communities where Chorizanthe robusta var. robusta occurs, invasive, non-native species such as harding grass (Phalaris aquaticus), veldt grass (Ehrharta spp.), European beachgrass, iceplant, and other species need to be actively managed to maintain the open habitat that C. r. var. robusta needs. (6) Certain areas where Chorizanthe robusta var. robusta occurs may need to be fenced to protect them from accidental or intentional trampling by humans and livestock. While C. r. var. robusta appears to withstand light to moderate disturbance, heavy disturbance may be detrimental to its persistence. Seasonal exclusions may work in certain areas to protect C. r. var. robusta during its critical season of growth and reproduction.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual (self-fertilization) (USFWS, 2010)

**Lifespan**

Adult: 1 year (annual) (USFWS, 2010)

**Breeding Season**

Adult: April to June (USFWS, 2010)

**Key Resources Needed for Breeding**

Adult: Murphy (2003) revealed that insect pollination significantly increased seed set for C. robusta var. robusta, suggesting that pollinators may enhance its overall fitness. (USFWS, 2010)

**Reproduction Narrative**

Adult: Chorizanthe robusta var. robusta is a short-lived annual spineflower in the Pungentes section of the genus Chorizanthe, in the buckwheat family (Polygonaceae). Chorizanthe robusta var. robusta is self-compatible and capable of self-fertilization, seed set was demonstrated to be higher in individuals that were insect pollinated. Germination of Chorizanthe robusta var. robusta occurs during winter months; flowering occurs from April through June, and in some cases throughout the summer. (USFWS, 2010)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Sand/dunes (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Requires open canopy; shade intolerant (USFWS, 2010)

**Environmental Specificity**

Adult: Narrow/specialist

**Site Fidelity**

Adult: Moderate (inferred from USFWS, 2010)

**Habitat Narrative**

Adult: Specific biological and physical habitat components that are essential to the conservation of Chorizanthe robusta var. robusta include sandy soils associated with active coastal dunes and inland sites with sandy soils; plant communities that support associated species, including coastal dune, coastal scrub, grassland maritime chaparral, and oak woodland communities, and have a structure such that there are openings between the dominant elements; plant communities that contain little or no cover by nonnative species that would compete for resources available for growth and reproduction of C. robusta var. robusta; and physical processes, such as occasional soil disturbance, that support natural dune dynamics along coastal areas (Service 2004). (USFWS, 2010)

***Dispersal/Migration***

**Motility/Mobility**

Adult: High (inferred from USFWS, 2010)

**Dispersal**

Adult: High (inferred from USFWS, 2010)

**Dispersal/Migration Narrative**

Adult: Seeds disperse when the involucral spines attach to passing animals. Small mammals and birds are the most likely seed dispersers of Chorizanthe robusta var. robusta; though wind also plays a part in the dispersal of seeds (Service 2004). (USFWS, 2010)

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

11 Populations. 9 populations with plants (extant) (USFWS, 2023).

**Population Size:**

Total counts ~199,000 total plants (9 populations) (USFWS, 2023).

**Population Narrative:**

Currently, there are 11 populations in Santa Cruz County over a range of approximately 21 miles (33.8 km). Three sites are on park lands that support large populations on the order of 10,000 individuals or more; the other seven sites support significantly smaller populations (USFWS 2004). Population size value left blank for this seed-banking annual because the large number of individuals suggests a sense of security that is not warranted. Approximately 12 occurrences observed since 1989 (CNDDB 2008). Known from 10 sites that support a total of 12 populations (USFWS 2004). Recent management actions performed by Baron and Eidam at the Pogonip sites may prove that slight disturbance can be beneficial for populations of C. robusta var. robusta. The disturbance can create necessary open areas that increase light, heat, and water, and may improve conditions for ground nesting pollinators (Murphy 2003). While we believe stochastic extinction is less of a threat now for C. robusta var. robusta than at the time of listing, it is still a concern for several of the smaller-sized populations. (USFWS, 2010) . 11 Populations. 9 populations with plants (extant). Total counts ~199,000 total plants (9 populations (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Recreation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the various park units at Pogonip and Sunset and Manresa State Beaches, recreational activities can have an impact on Chorizanthe robusta var. robusta, although low to moderate levels of impacts may be beneficial. Recent management actions performed by Baron and Eidam at the Pogonip sites may prove that slight disturbance (in this case, scraping with a McLeod) can be beneficial for populations of C. robusta var. robusta. The disturbance can create necessary open areas that increase light, heat, and water, and may improve conditions for ground nesting pollinators (at Pogonip, Steniolia elegans (digger wasp) and an undescribed wasp species of the genus Tachysphex (Murphy 2003)). These populations at Pogonip showed a large increase in numbers after management actions were implemented (Baron and Eidam 2008). Conversely, without proper management, high levels of recreational impact at these park sites (i.e., horseback riding and mountain biking) may eliminate the taxon altogether (Service 2004). (USFWS, 2010)

**Stressor:** Invasive plants (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** An observation in 2009 reported that the Branciforte population appears healthy; however, the presence of a chain link fence for excluding off-highway vehicles is barring fire safety mowing that had previously helped control invasive trees from encroaching into the population. As a result, the population is now also being threatened by invasives, particularly Ailanthus altissima (tree of heaven) (Cheap, in litt. 2009a). Upon further observation at the Branciforte site, it is clear that Chorizanthe robusta var. robusta is well established there and has the potential to flourish. However, Ailanthus altissima is prolific and abundant within the C.

robusta var. robusta population and is an even more imminent threat than originally considered (Chang and Glenn, Service biologists, pers. obs. 2009b). The shade created by this non-native tree will inevitably eliminate C. robusta var. robusta from the site. In addition to Ailanthus altissima, other species that have been identified as threats to the Branciforte population are Rubis ursinus (Pacific blackberry), Rubis discolor (Himalayan blackberry), Carpobrotus edulis (iceplant), Lathyrus latifolius (sweet pea), Genista monspessulana (French broom), Lobularia maritima (sweet alyssum), and Lotus scoparius var. scoparius (deerweed) (Boursier and Hardwicke 2007). (USFWS, 2010)

**Stressor:** Residential development (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Populations of Chorizanthe robusta var. robusta on private lands are subject to additional and sometimes more serious threats. The Branciforte site has been approved by the City of Santa Cruz for a housing development project, though it is unknown when construction activities will begin. The Service and the California Native Plant Society (CNPS) submitted comments recommending larger buffer areas for C. robusta var. robusta populations. In the early 1990s, the Freedom population at Aptos High School suffered losses of Chorizanthe robusta var. robusta individuals when land was modified in preparation for lot divisions. Additionally, in the late 1990s, the school widened a foot path running through the population in order to accommodate vehicles (Service 2004). An observation made in 2004 recorded in the CNDDB reported that a large colony east of the school baseball field remained intact, but that plants below the parking lot were eliminated by construction. Upon subsequent observation at this site, C. robusta var. robusta was visible along a foot trail southeast of the baseball field, growing on the edges of the trail, where the sandy soil is loose and there is less growth of other plants (Chang and Glenn, pers. obs. 2009a). (USFWS, 2010)

**Stressor:** Herbivory (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Baron and Bros (2005) investigation of insect herbivory on Chorizanthe robusta var. robusta concluded that insect herbivores reduced plant size, significantly decreasing both size and lifetime seed production of C. robusta var. robusta, subsequently compromising the plant's ability to obtain resources. In addition, rabbits browsing on C. robusta var. robusta removed mature seed heads from 11 percent of the study plants. The results of this study suggest that effects of herbivory can potentially be a threat to C. robusta var. robusta, or exacerbate other threats to C. robusta var. robusta populations (Baron and Bros 2005). (USFWS, 2010)

**Stressor:** Variation in annual weather patterns (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Annuals and other monocarpic plants (individuals that die after flowering and fruiting), such as Chorizanthe robusta var. robusta, are typically vulnerable to random fluctuations or variation in annual weather patterns and other environmental factors (Service 1994). (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999; Cayan et al. 2005; IPCC 2007). However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species at this time. (USFWS, 2010)

**Stressor:** Stochastic extinction (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A small population size may make it difficult for a species to persist while sustaining other impacts such as habitat alteration that favors non-native species. Although Chorizanthe robusta var. robusta is self-compatible and capable of self-fertilization, seed set was demonstrated to be higher in individuals that were insect pollinated. Small populations may also have a more difficult time attracting pollinators and therefore may experience lower seed viability rates. Many of the populations appear to be stable or support a larger number of individuals than we knew of at the time of listing. While we believe stochastic extinction is less of a threat now for C. robusta var. robusta than at the time of listing, it is still a concern for several of the smaller-sized populations. (USFWS, 2010)

**Stressor:** Competition (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Competition from nonnative species, or native shrub and tree species, can lead to declines in population abundance from shading and competition for resources (Service 2004, pp. 22-23; Service 2010, pp. 10, 12). The Freedom population, as well as the Ellicott Slough population, are believed to have declined to zero at least in part from shrub and tree shading as well as invasion by nonnative annual grasses (Service 2010, pp. 10, 12). Management actions to reduce competing vegetation and reduce canopy shading at the Branciforte and both Pogonip populations have resulted in increasing abundance of robust spineflower at those locations, suggesting that competition remains a threat to the species, but is a threat that can be successfully mitigated with management. The coastal populations at Manresa and Sunset State Beaches are likely persisting in the absence of management due to natural habitat conditions that inhibit establishment of shrub, trees, and nonnative annual species through moderate levels of disturbance. In the absence of natural disturbance processes, or management to reduce competing biomass, competition will remain a threat to robust spineflower (USFWS, 2023).

**Stressor:** Herbivory (USFWS, 2023)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Moth larvae and brush rabbits have been observed to decrease plant size and reduce seed output of robust spineflower, but herbivory has not been attributed to the declines observed at the Ellicott Slough and Freedom populations (Baron and Bros 2005). Herbivory is most likely not a severe threat to robust spineflower but is a contributing factor that may be inhibiting recovery or exacerbating the effects of other threats (USFWS, 2023).

**Stressor:** Vandalism (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** There have been four documented instances of vandalism at three different occurrences of robust spineflower since 2019. A trailer was moved onto the Merk Road occurrence and abandoned in 2019 (Olberding 2019, pp. 20-21). This resulted in a broken fence and rutting, although the population appeared to rebound without management upon the removal of the trailer (Olberding 2021b, p. 13). In both 2019 and 2021, a homeless encampment was established at the Pogonip 1 occurrence which resulted in trampling and trash accumulation. Remediation in both years involved removing debris and the population appeared to rebound without additional management (K. Lyons pers. com. 2022). At the Branciforte population, a firebreak was established outside of the timeframe established in the Mitigation and Monitoring Plan (Olberding 2021a, pp. 20-21, 24; Olberding 2021b pp. 21, 24-25). The effect to the population is likely low since the disturbance was confined to the margin of the preserve area used as a buffer zone. Enforcement of the timing of establishing fire breaks has proven difficult because the action is being undertaken by an unknown entity. The prohibited actions are not believed to have resulted in a significant decline of individuals due to the estimated abundance observed during annual monitoring relative to the comparatively small loss of individuals. However, the repeated nature of the events shows that enforcement has been unsuccessful and future, more destructive vandalism is possible at this location. Each of these vandalism events were not purposeful actions to remove robust spineflower. The Pogonip occurrence appears to have a location that is attractive to the establishment of homeless encampments, and this may continue to occur as this societal problem persists. The Merk Road location is along a road lending itself towards vehicle or other refuse abandonment. The vandalism at the Branciforte occurrence was conducted for perceived safety reasons and not to intentionally remove robust spineflower. Fortunately, none of these actions have been observed to have resulted in sustained declines of individuals and monitoring at all locations is planned for future years (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**

1. Within each recovery unit, the number of populations and acreage of occupied habitat for each population has been protected. (USFWS, 2004)

2. Habitat in each protected population has been appropriately managed and restored. (USFWS, 2004)

3. Population monitoring shows a stable or increasing trend in population size or density during favorable precipitation years over at least 10 years. (USFWS, 2004)

Recovery Priority Number: 9

**Delisting Criteria:**
1. Within each recovery unit, the number of populations and acreage of occupied habitat for each population has been protected. (USFWS, 2004)

2. Habitat in each protected population has been appropriately managed and restored. (USFWS, 2004)

3. Population monitoring shows a stable or increasing trend in population size or density during favorable precipitation years over at least 10 years. (USFWS, 2004)

4. The total number of populations has increased to at least 18, at least 15 of which have an average population of 1,000 individuals in favorable (nondrought) rainfall years over at least 10 years (beyond the downlisting monitoring period). (USFWS, 2004)

**Recovery Actions:**
- Protect habitat for Chorizanthe robusta var. robusta at all existing sites. (USFWS, 2004)
- Manage habitat for Chorizanthe robusta var. robusta at existing sites. (USFWS, 2004)
- Conduct management-oriented research. (USFWS, 2004)
- Establish populations in appropriate habitat within the historical range of the species. (USFWS, 2004)
- Review and revise recovery criteria as new information becomes available. (USFWS, 2004)
- Develop and implement an outreach program. (USFWS, 2004)
- 1. Establish and/or continue long-term management and monitoring programs for Chorizanthe robusta var. robusta populations, particularly those on park and refuge lands. (USFWS, 2010)
- 2. Continue genetic research to clarify uncertainties within the Chorizanthe robusta/Chorizanthe pungens complex. (USFWS, 2010)
- 3. Investigate opportunities for conservation of the Branciforte population, and remove Ailanthus altissima (tree of heaven) and other invasive species at the site, in accordance with the “Branciforte Creek Residential Development Robust Spineflower (Chorizanthe robusta var. robusta) Management and Monitoring Plan,” whether or not planned development goes forth. (USFWS, 2010)
- 4. Conduct surveys on suitable habitat and within the historical range to locate new populations, in conjunction with examination of genetic information to ensure the plant’s identity. Discovery of additional new populations such as the population at Merk Road will broaden our understanding of Chorizanthe robusta var. robusta’s status, its habitat, and range. (USFWS, 2010)
- 5. Initiate an outplanting program to establish new Chorizanthe robusta var. robusta populations in appropriate habitat within its historical range by: a. locating appropriate habitat for outplanting; b. conducting experimental habitat enhancement; c. applying appropriate habitat enhancement techniques; d. conducting propagation experiments to determine the best techniques for developing material to use in introductions; e. conducting experimental introductions; f. developing a protocol to guide introductions; g. conducting large-scale introductions on appropriate sites; and h. monitoring newly established populations (Service 2004). (USFWS, 2010)

- 6. Establish an outreach program to increase public awareness for populations on both public and private lands, particularly on park lands, refuges, and at Aptos High School. (USFWS, 2010)
- 7. Revise the recovery plan and recovery criteria as appropriate based on new information and/or research. (USFWS, 2010)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS 1. All occurrences should be revisited to evaluate presence and suitable habitat. 2. Occurrences currently protected from development should be managed to reduce competing vegetation using the Pogonip occurrences or Branciforte as an example of successful methodologies. 3. Reintroductions within the current and historical range should be considered to evaluate techniques for population establishment and specific ecological site conditions (USFWS, 2023).

# SPECIES ACCOUNT: *Chorizanthe valida* (Sonoma spineflower)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 06/22/1992; California/Nevada (Region 8)

**Physical Description**

A herbaceous annual, very similar in appearance to Chorizanthe howellii (Howell's spineflower), the primary distinguishing characteristic of C. valda being its ascending to erect growth habit and the brightly colored red and white involucres. The bright red base of the involucre's straight spines contrasts with their bright ivory tips, and the red spine bases contrast sharply with the dull-colored involucral tube. The basal leaves of C. valida are 1 to 2.5 centimeters (0.4 to 0.9 inch) long, 4 to 8 millimeters (0.2 to o.3 inch) wide, and often less hairy on the top surface than underneath. The flowers are 5 to 6 millimeters (0.2 to 0.3 inch) long. (USFWS, 1998)

**Taxonomy**

Closely related to C. pungens (Bittman 1998). (NatureServe, 2015) The Sonoma spineflower, Chorizanthe valida, was described by Sereno Watson in 1877 from specimens collected in 1840-41 by Ilya G. Vosnesensky, an entomologist and curator ofthe Zoological Museum in St. Petersburg, Russia, who traveled and collected in northern California. (USFWS, 1998)

**Historical Range**

The Point Reyes area in Marin County, California. Possible historical occurrences from the interial portion of Sonoma County. (USFWS, 2010)

**Current Range**

Near the eastern end of Abbott's Lagoon on the Lunny "G" Ranch, at Point Reyes National Seashore (PRNS) in Marin County, California. (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 1 year (USFWS, 1998)

**Breeding Season**

Adult: June to August (USFWS, 1998)

**Reproduction Narrative**

Adult: Chorizanthe valida is an herbaceous annual in the buckwheat family (Polygonaceae). Flowers, which appear June through August, are white to lavender to rose in color, are 5 to 6 mm (0.20 to 0.24 in long (Reveal and Hardham 1989) and occur in dense, ball-shaped, pinkish clusters with green bracts below. (USFWS, 1998; USFWS, 2010)

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Grassland/herbaceous (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Mild maritime climate, characterized by fog and winter rains (USFWS, 1998)

**Environmental Specificity**

Adult: Very Narrow (USFWS, 2010)

**Habitat Narrative**

Adult: The Abbott's Lagoon colony is located in coastal prairie grassland and occurs on the Sidrak sand soil type, consisting of well-drained, Pleistocene dune sands with a 2-4 percent slope, bearing to the north-northwest (towards Abbott's Lagoon). This soil type has low to moderate available water capacity, and can support only a limited plant community that is drought tolerant (Davis and Sherman 1992). The species occurs in areas of relatively mild maritime climate, characterized by fog and winter rains. The fog helps keep summer temperatures cool and winter temperatures relatively warm, and provides moisture in addition to the normal winter rains. (USFWS, 1998; USFWS, 2010)

***Dispersal/Migration***

**Motility/Mobility**

Adult: Low (USFWS, 1998)

**Dispersal**

Adult: Low (USFWS, 1998)

**Dispersal/Migration Narrative**

Adult: After about a month, the dull brown flowerhead begins to disintegrate and the spiny seeds are dispersed on the ground nearby. (USFWS, 1998)

***Population Information and Trends***

**Population Trends:**

Variable (USFWS, 2010)

**Number of Populations:**

1 (USFWS, 2024)

**Population Size:**

low of 62,580 individuals in 2006 and a high of 958,380 individuals in 2010 (USFWS, 2024).

**Additional Population-level Information:**

Following rediscovery and prior to listing, abundance information was collected by the Marin Chapter of the California Native Plant Society. Between 1983–1986, the area occupied by the species fluctuated between 100 square meters and 17,000 square meters (Service 1998, p. 26). Since listing, the estimated area covered by the species and estimated number of individuals has continued to fluctuate. Refer to Table 1 below for all abundance information for the natural occurrence following the species rediscovery. Data gathered from 2002 to 2004 have been rejected due to statistical invalidity; following 2004, updated survey methods were enacted to assess the population size more accurately and rapidly (Service 2010, p. 5). With that, from 2005–2023, the average abundance of the natural Sonoma spineflower population was 208,648 individuals, with a low of 62,580 individuals in 2006 and a high of 958,380 individuals in 2010 (USFWS, 2024).

**Population Narrative:**

A single extant endemic population of Chorizanthe valida exists near the eastern end of Abbott's Lagoon on the Lunny "G" Ranch, at Point Reyes National Seashore (PRNS) in Marin County, California at an elevation of approximately 15 meters (49 feet) above sea level. The population of Chorizanthe valida at Abbott's Lagoon exists as two disjunct subpopulations that are spatially separated from each other by approximately 80 meters (262 feet). The larger of the two subpopulations is referred to as the "main population" and is approximately 4 times as large as the smaller of the two subpopulations. The smaller of the two subpopulations is referred to as the "sub-population". Based on the results of mapping the spacial distribution of the population in 1999, 2000, 2005, 2006 and 2008, the area occupied by Chorizanthe valida at Abbott's Lagoon fluctuates seasonally, but does not appear to be contracting (Williams 2008). According to the recovery plan (Service 1998), the entire Abbott's Lagoon population of C. valida was estimated to cover 358 square meters (1,076 square feet) in 1983. In 1984, more than 2,000 plants covered an area of 5,130 square meters (16,829 square feet) (Fowler and Fellers 1984). According to Davis and Sherman (1992), the entire population exists within 17,000 square meters (55,773 square feet). Between 1983 and 1998, the California Native Plant Society (CNPS) conducted a census of the population and the number of individuals varied widely from 100 to 30,000 plants (Rogers 2005). In 1999, PRNS staff began developing a long-term, quantitative monitoring program for the Abbott's Lagoon population. Over the next 6 years, several monitoring methods were tested. In 1999, the number of Chorizanthe valida plants in the main population was estimated to be 18,000. In 2001, the number was calculated to be 184,311 individuals. The main population was not counted in 2000 or after 2002. From 2002 to 2004 permanent monitoring plots were used as indicators of the overall population trend in the main population. However, data collected using these permanent plots have now been rejected due to statistical invalidity. The number of plants in the sub-population has increased dramatically each year it has been censused, from 4,707 individuals in 1999 to 16,836 in 2001. Beginning in 2005, PRNS staff began sampling the main population of Chorizanthe valida using a macroplot. The macroplot is 100 x 40 meters (328 x 131 feet), encompassing 35 temporary quadrats each measuring 40 x 0.05 meters (131 x 0.16 feet). Sample results estimated there were 560,171 plants in the macroplot in 2005, with 95% confidence that the true number of plants in the macroplot is between 470,000 and 650,275. Data extrapolation to the entire population is beyond reasonable statistical inference. Since 2005, the population within the macroplot has fluctuated from an estimated 62,580 individuals in 2006 to 710,460 individuals in 2009. (USFWS, 2010)

***Threats and Stressors***

**Stressor:** Recreation (USFWS, 2010)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Trampling by hikers and accidental incursion still pose a minor threat to C. valida. (USFWS, 2010)

**Stressor:** Off-road vehicles (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Due to the presence of a road that bisects the Abbott's Lagoon population, which is used for ranching activities, off-road vehicle use still poses a threat. However, off-road vehicle use within PRNS is not permitted for recreational purposes and the road bisecting the Abbott's Lagoon population is scheduled for realignment in 2010; thus, this threat will be drastically reduced as a result. (USFWS, 2010)

**Stressor:** Cattle grazing (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The unknown effects of cattle grazing also remain a threat. However, since Chorizanthe valida is unpalatable to cattle and cattle consume many of the nonnative invasive plants that threaten the species, the removal of cattle from the system could in itself threaten the species. Due to the results of Davis and Sherman (1992), it is now believed the damaged caused by livestock trampling is outweighed by the benefits of grazing livestock in reducing competition with other plant species. (USFWS, 2010)

**Stressor:** Stochasticity (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Because Chorizanthe valida exists as a single endemic population and a single reintroduced population, with plant densities that fluctuate annually, it is highly susceptible to stochastic events such as prolonged drought, fire, disease, or other unforeseen causes of extinction. Stochasticity remains a major threat to the species. (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Impacts to this species as a result of climate change are unclear. A trend of warming in the mountains of western North America is expected to decrease snowpack, hasten spring runoff, and reduce summer stream flows, and increased summer heat may increase the frequency and intensity of wildfires (IPCC 2007). While it appears reasonable to assume that the species may be affected, we lack sufficient certainty on knowing how and when climate change will affect the species, the extent of average temperature increases in California/Nevada, or potential changes to the level of threat posed by drought, fire, etc. (USFWS, 2010)

**Stressor:** Nonnative invasive species (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The population of Chorizanthe valida at Abbott's Lagoon is surrounded by the invasive perennial grass species Holcus lanatus (common velvetgrass) on all sides. This nonnative invasive grass is of concern to the long term management of this population. As part of the Preventing Extinction Grant awarded to PRNS, H. lanatus and Lupinus arboreus will be removed from the area. Regardless, nonnative invasive species remain an ongoing threat to C. valida. (USFWS, 2010)

**Stressor:** Fire suppression (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The effects of fire suppression on Chorizanthe valida are not known. The natural fire return interval at PRNS is likely relatively long due to persistently moist and cool conditions coupled with relatively low incidence of lightning strikes (Keeley 2002). However, the use of fire by Native Americans in the area is not known. (USFWS, 2010)

***Recovery***

**Reclassification Criteria:**
A/1: At least six successful populations have been established. These populations will be considered self-sustaining populations after 15 years, which includes a normal precipitation cycle. (USFWS, 2019)

A/2: The area of each Sonoma spineflower population is maintained at or above approximately 2 acres in size. (USFWS, 2019)

A/3: The cover of invasive native and non-native plants, such as bush lupine, at all sites is controlled at <1% within areas containing Sonoma spineflower. (USFWS, 2019)

A/4: There are management measures implemented to address the threats of invasive species and other problems, including pedestrians and off-road vehicles at some sites. (USFWS, 2019)

A/5: Monitoring reveals that management actions are successful in reducing threats of invasive non-native species. (USFWS, 2019)

E/1: The number of individuals within each Sonoma spineflower population remains at or above 90,0004 for 15 years, which includes cycles of normal precipitation. (USFWS, 2019)

E/2: Seeds are stored in at least two Center for Plant Conservation certified facilities; seed germination, propagation, and out-planting propagation techniques are understood. (USFWS, 2019)

Recovery Priority Number: 5

**Delisting Criteria:**
A/1: At least eight successful populations have been established on appropriate habitat [that] has been secured within the historic range. Populations will be self-sustaining after 15 years, which includes a normal precipitation cycle. (USFWS, 2019)

A/2: Further invasion or increase in non-native or native invasive plant species has been prevented, including perennial species such as bush lupine and coyotebrush, within all Sonoma spineflower populations. (USFWS, 2019)

A/3: Habitat occupied by the species that is needed to allow delisting has been voluntarily secured, with long-term commitments and, if possible, endowments to fund [the] conservation of the native vegetation. (USFWS, 2019)

E/1: Ensure that seed banking practices, including seed germination, propagation, and outplanting propagation techniques, are understood and implemented as needed. (USFWS, 2019)

E/2: Seeds at banking facilities are renewed at a rate to ensure that seed stores remain viable in perpetuity. (USFWS, 2019)

**Recovery Actions:**
- Protect habitat of the listed species and their occurrences on private lands. The listed species should be secured where they occur on private lands through conservation easements, conservation agreements, or purchase where there are willing sellers. This is necessary to prevent further declines in distribution and abundance of the listed species from loss and degradation of habitat. The development of cooperative weed control programs will greatly facilitate recovery of these species, so it is a high priority to develop landowner incentives and providing funds for control of invasive exotic vegetation is a high priority. This task regularly refers to “occurrences” as defined by the NDDB. Readers are reminded that “occurrences” are convenient units for storing data, and do not necessarily coincide with biological populations nor with geographic units of vegetation or geological features such as the dune fields upon which these plants depend. (USFWS, 1998)
- Minimize threats to the plants from invasive non-native species, and minimize threats on private and public lands. Invasive non-native plant species are immediate biological threats the listed plant species. Infestations of invasive plant species need to be controlled. (USFWS, 1998)
- Develop management strategies through a research program to document the listed species’ life histories and their responses to vegetation management. Habitat management for the species in this recovery plan is needed to control the threats to their existence. Data must be obtained to determine how to conduct the management. (USFWS, 1998)
- Manage occurrences and habitats. Management of the listed plant species and its habitat will depend upon information gained from monitoring, threat analysis and the evaluation of protection alternatives. It will be important to involve the expertise of local landowners, land managers, and species experts to develop conservation programs. There may be different management programs for each species. The management program selected will require periodic review to ensure that it is effective in protecting the species. (USFWS, 1998)
- Monitor occurrences and threats to determine effectiveness of management and to establish delisting criteria. (USFWS, 1998)

- Coordinate recovery actions to protect other listed species and species of special concern. Other rare and endangered wildlife species occur within the ranges of the listed plant species. Management actions, such as the removal of invasive non-native plant species through herbicide application, may affect these species. Management actions should avoid adverse impacts to these species and their habitats, and actively include them in recovery actions to facilitate their reoccupation of historic ranges and prevent range collapse or declines in their abundance. (USFWS, 1998)
- Develop ecosystem restoration and multi-species reintroduction projects at degraded dune systems. Numerous dune systems within the historic range of listed species and species of concern have either reduced value or none for them because of past or ongoing degradation of habitat quality. Benefits for multiple species can be efficiently regained by establishing habitat and population restoration programs for these undermanaged or degraded dune systems. By returning independent dune systems within historic range of rare species to current ecological function, the risk of species extinction can be substantially decreased. (USFWS, 1998)
- Develop and implement an outreach program. Increasing public awareness of the listed plant species will facilitate efforts to preserve the species,, associated rare species, and the coastal dune ecosystem. Prepare and distribute regionally specific informational brochures and audio-visual and sign programs on preservation and recovery. Through the cooperative interagency working groups, prepare brochures and audio-visual materials that describe the plight of the listed species and the regional efforts being undertaken for their recovery. Disseminate the brochures to affected landowners and other community facilities. Provide the audio-visual materials to public facilities, such as park interpretive programs and school programs. Prepare interpretive educational signs for PRNS and other locations. (USFWS, 1998)
- Additional Site-specific Recovery Actions from 2019 Amended Recovery Plan: 1. Establish or protect additional populations of Sonoma spineflower. 1.1 Introduce at least three new self-sustaining populations (Priority 1) 1.2 Research possible insect pollinator species to determine appropriate management strategies for reintroduction sites. 1.3 Continue work on seedbank dynamics with the goal of using the information to run a population viability analysis on the species (Priority 2). 1.4 Research to determine what might cause population declines within the wild population, focusing on grazing intensity and pollinators (Priority 1) (USFWS, 2019)
- Additional Site-specific Recovery Actions from 2019 Amended Recovery Plan: 2. Conduct research to better understand life history and annual establishment. 2.1 Determining the extent of Sirdrak Sand outside of the park to help inform the location of potential introduction sites (Priority 3). 2.2 Conduct an analysis of soil type and nutrients/water balance, vegetation cover, disturbance dynamics (grazing, rodents, rabbits) to identify new introduction sites outside of the PRNS to determine if appropriate habitat exists for possible reintroductions (Priority 3). 2.3 Research the potential to augment nesting habitat for main pollinators near some of the current and future introduction sites (Priority 3). (USFWS, 2019)
- Additional Site-specific Recovery Actions from 2019 Amended Recovery Plan: 3. Monitor and manage existing populations on protected lands. 3.1 Maintain shrub cover within existing sites at acceptable levels through removal, as necessary (Priority 3). 3.2 Determine where some of the main pollinators identified in the two years of study on Sonoma spineflower nest near these populations (Priority 3). 3.3 Research the potential to augment

nesting habitat for main pollinators near some of the current and future introduction sites (Priority 3). (USFWS, 2019)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several conservation and monitoring recommendations, which we believe will aid in the recovery of the Sonoma spineflower. Some of these recommendations have already been discussed in the 2010 5-Year Review and 2019 Recovery Plan Amendment (Service 2010, p. 15; Service 2019, pp. 8–9) and remain valid. 1. Continue annual surveys at all occupied sites. 2. Finalize the species' management plan for the Point Reyes National Seashore. 3. Manage competing vegetation: a. Remove/reduce yellow bush lupine and coyote brush in all occupied areas to prevent continued habitat degradation. b. Remove thatch and competing vegetation annually. c. Consider the removal of other invasive species outside of occupied areas, which may be influencing cattle to graze more frequently in Sonoma spineflower habitat. 4. Research to determine what might cause population declines within the wild population, focusing on grazing intensity and pollinators. 5. Investigate the feasibility of augmenting nesting habitat for main pollinators near some of the current and future introduction sites. 6. Consider re-seeding previously seeded areas that were unsuccessful or are self-sustaining in low numbers. 7. Identify and consider permanently protecting locations within the Sonoma spineflower's historical range that contain suitable habitats for future outplantings. 8. Attempt outplanting at new locations on protected private and public land within the Sonoma spineflower's historical range (USFWS, 2024)

# SPECIES ACCOUNT: *Chromolaena frustrata* (Cape Sable Thoroughwort)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 11/25/2013; Southeast Region (R4) (USFWS, 2015)

**Physical Description**

Chromolaena frustrata is a perennial herbaceous plant. Mature plants are 5.9 to 9.8 inches (in) (15 to 25 centimeters (cm)) tall with erect stems. The blue to lavender flowers are borne in heads, usually in clusters of two to six. Flowers are produced mostly in the fall, though sometimes year round. (USFWS, 2014)

**Taxonomy**

Chromolaena frustrata (Family: Asteraceae)was first reported by Chapman, from the Florida Keys in 1886, naming it Eupatorium heteroclinium (Chapman 1889). Synonyms include Eupatorium frustratum B.L. Robinson and Osmia frustrata (B.L. Robinson) Small. (USFWS, 2014)

**Historical Range**

Chromolaena frustrata was historically known from Monroe County, both on the Florida mainland and the Florida Keys, and in Miami-Dade County along Florida Bay. The species was observed historically on Big Pine Key, Boca Grande Key, Fiesta Key, Key Largo, Key West, Knight's Key, Lignumvitae Key, Long Key, Upper Matecumbe Key, and Lower Matecumbe Key. (USFWS, 2013)

**Current Range**

In Everglades National Park, 11 Chromolaena frustrata populations supporting approximately 1,600 to 2,600 plants occur in buttonwood forests and coastal hardwood hammocks from the Coastal Prairie Trail near the southern tip of Cape Sable to Madeira Bay. In the Florida Keys, Chromolaena frustrata is now only known from Upper Matecumbe Key, Lower Matecumbe Key, Lignumvitae Key, Long Key, Big Munson Island, and Boca Grande Key (USFWS, 2013)

**Critical Habitat Designated**

Yes; 2/7/2014.

**Legal Description**

On January 8, 2014, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective February 7, 2014) for Chromolaena frustrata (Cape Sable Thoroughwort) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes nine critical habitat units (CHUs), in Florida (79 FR 1552-1590).

**Critical Habitat Designation**

The critical habitat designation for Chromolaena frustrata includes nine CHUs in Sabine and San Augustine Counties, Texas. This species critical habitat encompasses approximately 10,968 acres (ac) (4.439 hectares (ha)). General descriptions are presented below. Maps depicting the CH units are available in the Final Rule. (79 FR 1552-1590).

Unit 1: Everglades National Park, Monroe County and Miami-Dade County: Unit 1 consists of a total of 6,166 acres (2,495 hectares) in Monroe and Miami-Dade Counties. This unit is composed entirely of lands in Federal ownership, 100 percent of which are located within the Everglades National Park.

Unit 2: Key Largo, Monroe County: Unit 2 consists of a total of 3,431 acres (1,388 hectares) in Monroe County. This unit is composed of Federal lands within Crocodile Lake National Wildlife Refuge (NWR) (804 acres (325 hectares)); State lands within Dagny Johnson Botanical State Park, John Pennekamp Coral Reef State Park, and the Florida Keys Wildlife and Environmental Area (2,170 acres (878 hectares)); and parcels in private ownership (457 acres (185 hectares)).

Unit 3: Upper Matecumbe Key, Monroe County, Florida: Unit 3 consists of 69 acres (28 hectares) in Monroe County. This unit is comprised of State lands within Lignumvitae Key State Botanical Park, Indian Key Historical State Park (24 acres (10 hectares)); City of Islamorada lands within the Key Tree Cactus Preserve and Green Turtle Hammock Park and parcels in private ownership (45 acres (18 hectares)).

Unit 4: Lignumvitae Key, Monroe County: Unit 4 consists of a total of 180 acres (73 hectares) in Monroe County. This unit is composed entirely of lands in State ownership, 100 percent of which are located within the Lignumvitae Key Botanical State Park on Lignumvitae Key in the Florida Keys. This unit includes the entire upland area of Lignumvitae Key.

Unit 5: Lower Matecumbe Key, Monroe County: Unit 5 consists of a total of 44 acres (18 hectares) in Monroe County. The unit is composed of State lands within Lignumvitae Key Botanical State Park and parcels owned by the Florida Department of Transportation (22 acres (9 hectares)), and parcels in private ownership (22 acres (9 hectares)).

Unit 6: Long Key, Monroe County: Unit 6 consists of a total of 208 acres (84 hectares) in Monroe County. This unit is composed of State lands within Long Key State Park (151 acres (61 hectares)) and parcels in private ownership (57 acres (23 hectares)).

Unit 7: Big Pine Key, Monroe County: Unit 7 consists of a total of 780 acres (316 hectares) in Monroe County. This unit is composed of Federal land within the National Key Deer Refuge (686 acres (278 hectares)) and parcels in private ownership (94 acres (38 hectares)).

Unit 8: Big Munson Island, Monroe County Unit 8 consists of a total of 28 acres (11 hectares) in Monroe County. This unit is composed entirely of lands in private ownership.

Unit 9: Boca Grande Key, Monroe County: Unit 9 consists of a total of 62 acres (25 hectares) in Monroe County. This unit is composed entirely of lands in Federal ownership, 100 percent of which is located within the Key West National Wildlife Refuge.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Chromolaena frustrata critical habitat consists of four components (79 FR 1552-1590):

(i) Areas of upland habitats consisting of coastal berm, coastal rock barren, coastal hardwood hammock, rockland hammocks, and buttonwood forest. (A) Coastal berm habitat that contains: (1) Open to semi-open canopy, subcanopy, and understory; and (2) Substrate of coarse, calcareous, storm-deposited sediment. (B) Coastal rock barren (Keys cactus barren, Keys tidal rock barren) habitat that contains: (1) Open to semi-open canopy and understory; and (2) Limestone rock substrate. (C) Coastal hardwood hammock habitat occurring in Everglades National Park that contains: (1) Canopy gaps and edges with an open to semi-open canopy, subcanopy, and understory; and (2) Substrate of marl covered with a thin layer of highly organic soil. (D) Rockland hammock habitat that contains: (1) Canopy gaps and edges with an open to semi-open canopy, subcanopy, and understory; and (2) Substrate with a thin layer of highly organic soil, marl, humus, or leaf litter on top of the underlying limestone. (E) Buttonwood forest habitat that contains: (1) Open to semi-open canopy and understory; and (2) Substrate with calcareous marl muds, calcareous sands, or limestone rock.

(ii) Plant communities of predominately native vegetation with either no invasive, nonnative species or with low enough quantities of nonnative, invasive plant species to have minimal effect on the survival of Chromolaena frustrata.

(iii) A disturbance regime, due to the effects of strong winds or saltwater inundation from storm surge or infrequent tidal inundation, that creates canopy openings in coastal berm, coastal rock barren, coastal hardwood hammock, rockland hammocks, and buttonwood forest.

(iv) Habitats that are connected and of sufficient area to sustain viable populations in coastal berm, coastal rock barren, coastal hardwood hammock, rockland hammocks, and buttonwood forest.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. Special management considerations or protection are necessary throughout the critical habitat areas to avoid further degradation or destruction of the habitat that contains those features essential for the conservation of the species. The primary threats to the physical or biological features that Chromolaena frustrata depends on include: (1) Habitat destruction and modification by development; (2) competition with nonnative, invasive plant species that changes the habitat composition and structure; (3) wildfire that destroys habitat; (4) hurricanes and storm surge, if too frequent or severe destroy or modify habitat making it unsuitable; and (5) sea-level rise that changes the habitat to a more saline environment. Some of these threats can be addressed by special management considerations or protection while others (e.g., sea-level rise, hurricanes) are beyond the control of landowners and managers. However, while landowners or land managers may not be able to control all the threats, they may be able to address the results of the threats to the habitats. Management activities that could ameliorate these threats include the monitoring and minimizing recreational activities impacts, nonnative species control, and protection from development. Precautions are needed to avoid the inadvertent trampling of Chromolaena frustrata in the course of management activities and public use. Development of recreation facilities or programs should avoid impacting these habitats directly or indirectly. Ditching and filling should be avoided because they alter the hydrology and species composition of these habitats. Sites that have shown increasing encroachment of woody species over time may require efforts to maintain the open nature of the habitat, which favors these species. Nonnative species control programs are needed to reduce competition and prevent habitat degradation. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this rule. All critical habitat requires active management to address the ongoing threats listed. In summary, we find that each of the areas we are designating as critical habitat contain features essential to the conservation of Chromolaena frustrata that may require special management considerations or protection to ensure conservation of the species. These special management considerations and protections are required to preserve and maintain the essential features provided to C. frustrata by the ecosystems upon which it depends. A more detailed discussion of these threats is presented in the proposed rule under ‘‘Summary of Factors Affecting the Species’’ (77 FR 61836; October 11, 2012).

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual (USFWS, 2014)

**Key Resources Needed for Breeding**

Adult: Insect pollinators (USFWS, 2014)

**Reproduction Narrative**

Adult: The reproductive biology and genetics of Chromolaena frustrata have received little study. Fresh C. frustrata seeds show a germination rate of 65 percent, but germination rates decrease to 27 percent after the seeds are subjected to freezing, suggesting that long-term seed storage may present difficulties (Kennedy et al. 2012, pp. 40, 50–51). While there have been no studies on the reproductive biology of C. frustrata, the Service can draw some generalizations from other species of Chromolaena, which reproduce sexually. New plants originate from seeds. Pollinators are likely to be generalists, such as butterflies, bees, flies, and beetles (USFWS, 2014).

**Habitat Type**

Adult: Terrestrial (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Barrens, forest, dune (NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Moderate to full sun exposure (USFWS, 2013)

**Environmental Specificity**

Adult: Narrow (NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits coastal rock barrens and berms, and sunny deges of rockland hammocks. The environmental specificity is narrow, as the plants occur only along the shore zone of limestone outcrops in southern Florida (NatureServe, 2015). Grows in open canopy habitats in coastal berms and coastal rock barrens and in semi-open to closed canopy habitats, including buttonwood forests, coastal hardwood hammocks and rockland hammocks (USFWS, 2014). It prefers moderate to full sun exposure (USFWS, 2013).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seed dispersal is largely by wind (Lakshmi et al. 2011, p. 1) (USFWS, 2014).

***Population Information and Trends***

**Population Trends:**

Decline of 70-90% (NatureServe, 2015)

**Species Trends:**

30 - 50% decline (NatureServe, 2015)

**Number of Populations:**

8 (USFWS, 2013)

**Population Size:**

~5,000 (NatureServe, 2015)

**Adaptability:**

Moderate (inferred from USFWS, 2014)

**Population Narrative:**

Eupatorium frustratum's restricted ecological range, and its drastic loss of habitat suggest that the number of individuals is declining (Halupa 2002). It once ranged widely in the Florida Keys, and is now known there only from a few small sites; on the mainland, it had several historical localities, and is now known from just one site. This species has experienced a long-term decline of 70-90% and short-term decline of 30 - 50%. Thousands of plants occur densely in one area on Big Munson Island, making counting difficult; a few hundred plants altogether occur at the other sites. In total, fewer than 5,000 plants were estimated in 2003 (Bradley and Gann 2004) and the only population discovered since is not large (USFWS 2005). Only one population has good viability/integrity (NatureServe, 2015). The species appears to be able to rebound at affected sites within a few years (Bradley 2009, pers. comm.) (USFWS, 2014). The current range of Chromolaena frustrata includes eight populations spread across 209 km (130 mi) (USFWS, 2013).

***Threats and Stressors***

**Stressor:** Habitat modification and destruction (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Habitat destruction and modification resulting from development are considered a major threat to Chromolaena frustrata throughout the species' range. The populations on Fiesta Key, Knights Key, Key Largo, and Key West were lost due to development. Fiesta Key is completely developed as a Kampgrounds of America (KOA) campground and is devoid of native plant communities. Knights Key is almost completely developed and has no remaining suitable habitat. Key Largo has undergone extensive disturbance and development. Two Chromolaena

frustrata populations, including the largest population (Big Munson Island), are located on private lands (the population at Long Key Layton Hammock only partially so), which are vulnerable to further development. (USFWS, 2013)

**Stressor:** Herbivory (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** On Big Munson Island, much of the Chromolaena frustrata population was observed to suffer from severe herbivory in 2004. No insects were observed on any plants, and the endangered Key deer (Odocoileus virginianus clavium) was the suspected culprit The significance of herbivory on C. frustrata population dynamics is unknown. (USFWS, 2013)

**Stressor:** Nonnative plant species (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Schinus terebinthifolius (Brazilian pepper), a nonnative, invasive tree, occurs in the habitat of this species. Schinus terebinthifolius forms dense thickets of tangled, woody stems that completely shade out and displace native vegetation. Schinus terebinthifolius can dramatically change the structure of rockland hammocks, coastal berms, and shell mounds, making habitat conditions unsuitable for Chromolaena frustrata, which prefers moderate to full sun exposure. Colubrina asiatica (lather leaf), a nonnative shrub, has invaded large areas of coastal berm and coastal berm edges. Colubrina asiatica also forms dense thickets and mats, and is of particular concern in coastal hammocks. Casuarina equisetifolia (Australian pine) invades coastal berm and is a threat to suitable habitat at most sites that could support this species. Casuarina equisetifolia forms dense stands that exclude all other species through dense shade and a thick layer of needles that contain substances that leach out and suppress the growth of other plants. (USFWS, 2013)

**Stressor:** Small, isolated populations (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The current range of Chromolaena frustrata includes eight populations spread across 209 km (130 mi) between ENP and Boca Grande Key; four of eight C. frustrata populations consist of fewer than 100 individuals. These populations may not be viable in the long term due to their small number of individuals. Threats exacerbated by small population size include hurricanes, storm surges, climate change, freezing temperatures, and recreation impacts. (USFWS, 2013)

**Stressor:** Climate change (USFWS, 2013)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Projections suggest that sea level rise is the largest climate-driven challenge to low-lying coastal areas and refuges in the subtropical ecoregion of southern Florida (U.S. Climate Change Science Program (CCSP) 2008). This species occurs in habitats near sea level in areas of south Florida where considerable habitat is projected to be lost to sea level rise by the year 2100.

Most populations are located less than 2 m (6.6 ft.) above mean sea level, and the effects of sea level rise are expected to be a continual problem for these species and their habitats. Using Rahmstorf et al. (2007), sea level rise projections of 100 to 140 cm, 80.5 to 92.2 percent of the Florida Keys land area would be inundated by 2100. A 1.8-m (5.9-ft) rise would inundate all existing mainland Chromolaena frustrata occurrences in ENP (USFWS, 2013).

***Recovery***

**Reclassification Criteria:**
Not available - this species does not have a recovery plan.

**Delisting Criteria:**
Not available - this species does not have a recovery plan.

**Recovery Actions:**

- Not available - this species does not have a recovery plan.
- Fairchild Tropical Botanic Garden (FTBG) has 44 seed collections of Chromolaena frustrata from ENP, which were provided to the National Center for Genetic Resources Preservation (NCGRP) for testing and storage, and one collection from Lignumvitae Key. Key West Botanical Garden (KWBG) has one collection of Chromolaena frustrata from Big Munson Island. Numerous C. frustrata are planted on the KWBG grounds (USFWS, 2013).
- The Service; NPS; State of Florida; Sarasota, Charlotte, Lee, Miami-Dade, and Monroe Counties; and several local governments conduct nonnative species control efforts on sites that support Chromolaena frustrata (USFWS, 2013).

# SPECIES ACCOUNT: *Cirsium fontinale var. obispoense* (Chorro Creek bog thistle)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 1/17/1995; California/Nevada (Region 8)

**Physical Description**

A biennial or short-lived perennial plant up to 2 meters (m) (6.6 feet (ft)) tall in the aster and sunflower family (Asteraceae). The leaves are spiny with glandular hairs on the upper and lower surfaces. The flowers are white, pink, or lavender with a drooping posture (Figure 1). Each flower head produces an average of 73 seeds up that are up to 4 millimeters (mm) (0.2 inches (in)) long (Turner and Herr 1996). Seeds are topped with a pappus (set of bristles) that aids in dispersal. (USFWS, 2014)

**Taxonomy**

Chorro Creek bog thistle (Cirsiumfontinale var. obispoense) is in the composite family (Asteraceae) and is one of three varieties of C. fontinale and is distinguished from the other two by a combination of morphological characteristics involving the stem, leaf, inflorescence, flower, and fruit. Cirsium fontinale var. obispoense is geographically separated from the other two varieties. The species first was described by Edward L. Greene in 1886 as Cnicus fontinalis. Six years later, he transferredthe plant to the genus Carduus, and in 1901 Jepson transferred the plant to the genus Cirsium. In 1938, J.  (USFWS, 2014)

**Historical Range**

Local endemic on serpentine in San Luis Obispo County, California. (NatureServe, 2015)

**Current Range**

In San Luis Obispo County, California.  The known geographic range comprises 462 square km (178 square mi), extending from San Simeon Creek (35.630897°N, 121.060711°W) to the vicinity of the city of San Luis Obispo (a distance of 56 km (35 mi)). All known occurrences of Cirsium fontinale var. obispoense are west of the outer coast ranges of the Central Coast Region in San Luis Obispo County, California. (USFWS, 2014)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 2-3 years (USFWS, 2014)

**Breeding Season**

Adult: May to July and occasionally extends into September or October (Magney 2006). (USFWS, 2014)

**Reproduction Narrative**

Adult: Cirsium fontinale var. obispoense typically live 2 or 3 years. The plants usually flower during the second spring and then die after flowering. However, some plants may persist into a third year if sufficient energy reserves remain (Chipping 1994). Flowering occurs generally during May to July and occasionally extends into September or October (Magney 2006). Each flower head produces an average of 73 seeds up that are up to 4 mm (0.2 in) long (Turner and Herr 1996). (USFWS, 2014)

**Habitat Type**

Adult: Palustrine wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Bog/fen, herbaceous wetland (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Found at elevations of 37 to 381 m (120 to 1,250 ft) (USFWS, 2014)

**Spatial Arrangements of the Population**

Adult: Colonies (USFWS, 2014)

**Environmental Specificity**

Adult: Very Narrow (USFWS, 2014)

**Habitat Narrative**

Adult: Cirsium fontinale var. obispoense occupies perennial seeps and springs in serpentine soil and rock in western San Luis Obispo County, California (Figure 3). The plants usually occur on slopes, with existing records at 37 to 381 m (120 to 1,250 ft) elevation (CDFW 2013a). The plants often grow in colonies (spatial groups of presumably separate individuals). (USFWS, 2014)

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seeds are topped with a pappus (set of bristles) that aids in dispersal. (USFWS, 2014)

***Population Information and Trends***

**Population Trends:**

Not available

**Number of Populations:**

22 (USFWS, 2022)

**Population Size:**

~10,000 (inferred from USFWS, 2014)

**Adaptability:**

Low (inferred from USFWS, 2014)

**Population Narrative:**

The taxon is currently known from 19 occurrences, and multiple colonies comprise most occurrences. The Service considers stochastic events, in particular drought, an ongoing threat. Because Cirsium fontinale var. obispoense is associated with seeps and springs, a severe or prolonged drought could reduce or eliminate its specialized habitat and result in the extirpation of some occurrences. Six occurrences have been reported to comprise more than 1,000 plants at particular points in time: occurrence 1 at San Simeon Creek (1,076 plants in 1993; CDFW 2013a), occurrence 2 at Laguna Lake Park (approximately 2,075 plants in 2006; M. Elvin, Service, pers. obs. 2006), occurrence 3 at Camp San Luis Obispo (1,872 plants in 2008; Holland 2009), occurrence 6 in the El Chorro Biological Reserve (2,200 plants in 1993; Chipping 1994), occurrence 10 at Miossi Creek (more than 1,000 plants in 1997; CDFW 2013a), and near Serpentine Lane (more than 4,000 plants in 2001; CDFW 2013a). The other 13 occurrences are each likely comprised of fewer than 1,000 plants in 2014, with the most recent estimates ranging from 0 to 800 plants per occurrence. (USFWS, 2014). In 2022, Chorro Creek bog thistle is known from 22 occurrences (CDFW 2021a, p. 1–2), with one of these possibly extirpated (occurrence 7). Nine occurrences are protected, but effectiveness for one of these (occurrence 12) is questionable, and 13 occurrences are not protected. To the best of our knowledge, all threats identified in USFWS (2014) and Kofron and Havlik (2016) still remain (USFWS, 2022).

***Threats and Stressors***

**Stressor:** Road maintenance (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Road maintenance (including grading, road expansion, mowing, herbicide application) and water diversions were identified as potential threats at that time (Wikler and Morey 1992). (USFWS, 2014)

**Stressor:** Invasive plants (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Although the serpentine substrate is not conducive for most invasive plant species (Harrison et al. 2006.), Cortaderia (pampas grass) became established in the habitat and which the City of San Luis Obispo removed in 2010. Magney (2006) reported that the invasive Sonchus asper (prickly sow thistle) was invading the habitat and that it was being eradicated. Some occurrences are threatened by dense vegetation in and near the habitat, including native (E. macrostachya, Distichlis spicata (salt grass)) and invasive species (Helminthotheca echioides (bristly oxtongue), Centaurea calcitrapa (purple star-thistle), S. asper) (J. Olson, Colorado State University, pers. comm. 2012). (USFWS, 2014)

**Stressor:** Cattle grazing (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Several properties where Cirsium fontilae var. obispoense is found is zone for grazing. Light, controlled cattle grazing is conducted in some habitats, which appears to benefit Cirsium fontinale var. obispoense by reducing invasive plants (Siepel, pers. comm. 2012). (USFWS, 2014)

**Stressor:** Agriculture (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** A small area (approximately 2 ha (5 ac)) of the property on the northern side of Chorro Creek is planted with row-crops, and likewise the adjacent property. This agriculture is in close proximity to Cirsium fontinale var. obispoense in Chorro Creek and is not compatible with its survival. (USFWS, 2014)

**Stressor:** Predation by insects (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Eurasian flower-head weevil has been reported predating Cirsium fontinale var. obispoense at several sites (Service 1994), including San Simeon Creek (Chipping 1994; Herr 2004), Laguna Lake Park (Herr 2004), and Camp San Luis Obispo (California Army National Guard 2012). In a study on one property at San Simeon Creek, 28 percent of the flower heads of Cirsium fontinale var. obispoense were infested throughout the plant's growing season, with 27 percent of the seeds destroyed on average in the predated flower heads. (USFWS, 2014)

**Stressor:** Herbivory by cattle (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** There are two issues to consider regarding cattle grazing in and near the habitat of Cirsium fontinale var. obispoense: herbivory and trampling. Trampling by cattle while grazing in the habitat could severely damage established plants, especially when water becomes limited to the cattle and they congregate at the seep or spring. (USFWS, 2014)

**Stressor:** Stochastic events (USFWS, 2014)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Species with small populations are vulnerable to extinction by stochastic events (Ricklefs 2008). This means that chance or random events can cause the population size of the species to decrease, possibly below the level of sustainability and down to extinction. We consider stochastic events, in particular drought, an ongoing threat. Because Cirsium fontinale var. obispoense is associated with seeps and springs, a severe or prolonged drought could reduce or eliminate its specialized habitat and result in the extirpation of some occurrences. (USFWS, 2014)

**Stressor:** Climate change (USFWS, 2014)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** We identify climate change as a new threat. Current climate change projections for terrestrial areas in the northern hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999; Cayan et al. 2005; IPCC 2007). We lack adequate information to make specific and accurate predictions regarding how climate change in combination with other factors such as isolation at perennial seeps and springs will affect Cirsium fontinale var. obispoense. However, limited-ranged taxa are likely to be more vulnerable to extinction due to these changing conditions. Our major concern is the effects of extreme weather events (e.g., severe drought, severe storm, harsh winter) due to climate change on the 19 occurrences of Cirsium fontinale var. obispoense. (USFWS, 2014)

***Recovery***

**Reclassification Criteria:**
1. Populations from throughout the range, each made up of multiple colonies, and their habitat at six sites are secure from human-induced threats, including water diversions or drawdowns. (USFWS, 1998)

2. At least three of these sites are in protected areas larger than 100 acres and populations are deemed viable and stable or increasing as determined by monitoring over a precipitation cycle that includes multiple years of below average rainfall. (USFWS, 1998)

3. Protected sites are being managed in a way that will support the continued existence of Cirsium fontinale var. obispoense and its wetland habitat. (USFWS, 1998)

4. Management is effective, as shown by at least 10 years of monitoring. (USFWS, 1998)

Recovery Priority Number: 9

**Delisting Criteria:**
When the downlisting criteria have been met for a species, the species can be considered for delisting if:

1. Threats are reduced or eliminated so that occurrences are capable of persisting without significant human intervention or perpetual endowments are secured for management necessary to maintain the continued existence of the species (USFWS, 2019)

2. An ex situ seedbank is established in a Center for Plant Conservation-affiliated botanic garden. While sufficient seedbank in the soil would typically provide a strategy for the taxon to persist through several years of short- or medium-term drought, it may not be sufficient to persist through long-term drought. Therefore, an ex situ seedbank would provide assurance that a occurrences could be reseeded, should long-term drought – or other stochastic events – make it necessary; (USFWS, 2019)

3. All existing occurrences are stable or increasing in the wild for at least 10 years. We expect above-ground occurrences size to fluctuate annually, based on response to amount and timing of rainfall (e.g. see Fox et al. 2006). Therefore, a period of 10 years should be long enough to include most of the variability in rainfall that occurs in this region (Zedler & Black 1989; NOAA

2018). Ten occurrences were surveyed during the 5-year period from 2012 to 2016, which will provide a baseline for the status of these occurrences; these data should provide a basis for monitoring occurrence attributes to determine trajectory over time. (USFWS, 2019)

**Recovery Actions:**

- Secure populations and habitat on unprotected lands. Methods for securing lands include in-fee purchase, gifts of easement or fee interest by the property owner, deed restrictions (provided restrictions cannot be changed privately without the knowledge of Federal, State and County agencies), acquisition of property rights (e.g., development rights) or permanent conservation easements. (USFWS, 1998)
- Manage secured lands to control or eliminate other known threats. Although habitat alteration through development is currently the most substantial and irreversible threat facing all of the species in this plan, the management of lands secured from development will remain a formidable task, made more so in those cases where the secured habitats are adjacent to high density residential and urban development. (USFWS, 1998)
- Evaluate potential threats and conduct management-oriented research. Conduct habitat-oriented research for Morro Bay species. Conduct species-specific research. Evaluate research results and use in future management. (USFWS, 1998)
- Determine population dynamics and effects of recovery efforts. Studies should be conducted to learn the number and size of successful self sustaining populations for the species to establish criteria for its reclassification. (USFWS, 1998)
- Develop and implement an education/information program. The benefits of protecting native species and their habitats and maintaining native biological communities should be explained clearly to all concerned parties. (USFWS, 1998)
- Reevaluate recovery criteria and revise recovery plan based on expanded knowledge from research, monitoring, and management. The scientific validity of the recovery criteria and recovery plan should be reviewed and revised as more information becomes available. The criterion of maintaining sufficient numbers of populations or conservation areas should be assessed, and the success or failure of management actions should be evaluated. (USFWS, 1998)
- Recommendation from 2014 5-Year Review: Additional occurrences of Cirsium fontinale var. obispoense likely exist in San Luis Obispo County, and also possibly in Monterey and Santa Barbara Counties. We recommend that searches be conducted in potentially suitable habitat with serpentine soil and rock in San Luis Obispo, Monterey and Santa Barbara Counties. (USFWS, 2014)
- Recommendation from 2014 5-Year Review: We recommend that the Service seek partnerships with the private landowners for assisting them to manage Cirsium fontinale var. obispoense on their properties. (USFWS, 2014)
- Recommendation from 2014 5-Year Review: We recommend that a range-wide census of the 19 occurrences be conducted in 2015 as a team effort including the California Army National Guard, the California Native Plant Society (San Luis Obispo Chapter), California Polytechnic State University, the City of San Luis Obispo, the private landowners, and the Service. The methods should be standardized in advance. (USFWS, 2014)
- Recommendation from 2014 5-Year Review: We recommend that the relevant biologists, landowners, and land managers monitor for invasive plant species in and near the habitat of Cirsium fontinale var. obispoense and take the necessary actions to eliminate this threat. (USFWS, 2014)

- Recommendation from 2014 5-Year Review: We recommend that any cattle grazing in the habitat of Cirsium fontinale var. obispoense be controlled and monitored. A controlled grazing regime may benefit Cirsium fontinale var. obispoense by reducing other vegetation (invasive and native) in and near the habitat and by providing favorable sites for the germination of seeds. Herbivory of Cirsium fontinale var. obispoense would be minor because their spiny characteristics make them generally unpalatable. However, trampling could severely damage the established plants, especially when water becomes limited to the cattle and they congregate in the seep or spring. (USFWS, 2014)
- Recommendation from 2014 5-Year Review: The relevant biologists, landowners, and land managers should be aware of the introduced Eurasian flower-head weevil and the threat it poses to Cirsium fontinale var. obispoense. We recommend that they monitor for and report the presence of this introduced insect to the U.S. Fish and Wildlife Service, Ventura, California, and to the Department of Agriculture for San Luis Obispo County, California. (USFWS, 2014)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Coordinated conservation and research are needed to better understand the biology and ecology of Chorro Creek bog thistle, in particular to restore and maintain the existing occurrences. These efforts should include the following: • Conduct a more-detailed analysis of the status, threats, distribution, biology and ecology of Chorro Creek bog thistle, with a coordinated team effort including site visits by USFWS and partners. Priority should be given to visiting occurrences that have not been visited in the past 5 years. • Conduct modelling to anticipate the effects of climate change on distribution and abundance of Chorro Creek bog thistle, including changes in temperature and precipitation. • Implement management actions to benefit the individual occurrences of Chorro Creek bog thistle, including removing invasive and native plants that are threats. • Conserve and protect habitat in vicinity of and near the occurrences of Chorro Creek bog thistle. • Conduct searches for additional occurrences and locations of Chorro Creek bog thistle, with possible use of drones for searching large expanses of potential habitat and potential habitat in difficult terrain. In particular, U.S. Forest Service should search the upper reaches of Chorro Creek, Pennington Creek, San Luisito Creek and San Bernardo Creek on Los Padres National Forest (Keil 2022, p. 1). • Conduct a search to determine the precise location of occurrence 11, which is based on two herbarium specimens with imprecise location data (Kofron and Havlik 2016, p. 173). We suspect the location is near 35.275649/-120.603870. • Collect seeds for conservation seed banking. • Develop protocols for long-term restoration success. 1. Consider methods of Eckberg et al. (2017, p. 33–66). 2. In light of the threat of climate change with severe drought and increased temperatures, also consider methods for cultivating seeds for propagation and outplanting in arid lands used by Abella et al. (2012, entire), Abella et al. (2015, entire), Abella (2017, entire) and Abella et al. (2020, entire). • Introduce Chorro Creek bog thistle into living collections at several botanic gardens. (USFWS, 2022)

# SPECIES ACCOUNT: *Cirsium hydrophilum var. hydrophilum* (Suisun thistle)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 11/20/1997; California/Nevada (Region 8) (USFWS, 2015)

**Physical Description**

A perennial herb with erect stems, usually 1-1.5 m tall, and with spiny, deeply lobed leaves. Pale lavender or pink flower heads, 2-2.5 cm long, are borne singly or in loose groups. In the pre-flowering phase, it grows as a short, broad, vegetative rosette with large leaves, approximately 0.3 to 0.9 m long. Stems are typically branched above the middle of the main stem, but up to 15 stems may occasionally branch from the base of single large plants (P. Baye unpubl. data 2000). Leaves on stems are much smaller, more deeply lobed, and spinier than juvenile leaves of the rosette. The egg-shaped flowerheads (2.5 cm) are composed of small individual florets united into a single unit. Flowerheads occur either as solitary units or in clusters. The bracts of the flowerheads have a distinct green, glutinous ridge on the back that distinguishes C. hydrophilum var. hydrophilum from other Cirsium species in the area. (USFWS, 2013)

**Taxonomy**

Cirsium hydrophilum var. hydrophilum was originally described as Cnicus breweri Gray var. vaseyi Gray (Gray 1888). Cnicus breweri is a taxon now placed in Cirsium douglasii DC var. breweri (A. Gray) (Keil and Turner 1993). Subsequent synonyms, now invalid, include Carduus hydrophilus Greene (Greene 1892) and Cirsium vaseyi (Gray) Jepson var. hydrophilum (Greene) Jepson (Jepson 1925). Jepson (1901) was the first to apply the combination Cirsium hydrophilum. The species Cirsium hydrophilum, as now interpreted, (Howell 1969, Keil and Turner 1993) comprises two morphologically similar varieties: C. hydrophilum var. vaseyi, (synonym: Cirsium vaseyi [A. Gray] Jepson), a related rare thistle endemic to seeps in serpentine soils on Mount Tamalpais, Marin County, and C. hydrophilum var. hydrophilum, endemic to brackish tidal marshes in Suisun Marsh, Solano County. (USFWS, 2013)

**Historical Range**

Not available

**Current Range**

Cirsium hydrophilum var. hydrophilum is only known from locations in Suisun Marsh.

**Critical Habitat Designated**

Yes; 4/12/2007.

**Legal Description**

On April 12, 2007, the U.S. Fish and Wildlife Service (Service) designated critical habitat for Cirsium hydrophilum var. hydrophilum (Suisun thistle) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes five critical habitat units (CHUs), in California (72 FR 18518-18553).

**Critical Habitat Designation**

The critical habitat designation forCirsium hydrophilum var. hydrophilum includes three CHUs in Solano County, California. This species critical habitat encompasses approximately 2,052 acres (ac) (830 hectares (ha)) (72 FR 18518-18553).

Unit 1: Hill Slough Marsh: Unit 1 consists of approximately 525 ac (213 ha) located north of Potrero Hills between Grizzly Island Road and Highway 12. As discussed in ‘‘Criteria Used to Identify Critical Habitat for Cirsium hydrophilum var. hydrophilum’’ above, this unit is currently unoccupied and was unoccupied at the time of listing, but it is essential to the conservation of the subspecies because it is the single best area for establishment of an additional population (see response to Comment 2). It contains all the necessary PCEs and is the subject of ongoing planning and restoration efforts within the Suisun Marsh. The unit consists of approximately 440 ac (178 ha) of Stateowned land (Hill Slough Wildlife Area), which is managed by the CDFG, and 85 ac (35 ha) of privately owned land. The unit receives tidal inundations irregularly (not daily) (NWI 2005) from Hill Slough and a flood control channel along the western unit boundary.

Unit 2: Peytonia Slough Marsh: Unit 2 consists of approximately 346 ac (140 ha) of tidal marsh (PCE 1) located adjacent to Cordelia Road to the west, Suisun Slough to the east, Peytonia Slough to the south, and Suisun City to the north. The unit consists of approximately 192 ac (78 ha) of State-owned land (Peytonia Slough Ecological Reserve), which is managed by the CDFG, and 154 ac (62 ha) of privately owned high tidal marsh. Although the unit is bisected, north to south, by an elevated railroad line, much of the track is on trestle rather than berm, allowing tidal waters to reach both sides of the unit through Peytonia Slough and several smaller unnamed sloughs (NWI 2005; Vollmar 2005a, pp. 2, 3, 5; Huffman 2006, p. 1). Because of this hydrological connection, we are treating designated habitat on both sides of the track as a single unit, rather than splitting it into two subunits as we did in the proposed designation. Cirsium hydrophilum var. hydrophilum occupied the unit at the time of listing as identified in the final listing rule (62 FR 61916; November 20, 1997) and contains the features essential to the conservation of C. hydrophilum var. hydrophilum.

Unit 3: Rush Ranch/Grizzly Island Wildlife Area: Unit 3 consists of approximately 1,181 ac (477 ha) of tidal marsh located adjacent to Suisun Slough to the west, Cutoff and Montezuma Sloughs to the south, and Potrero Hills to the North. This unit consists of 231 ac (93 ha) of State-owned land (the Joice Island portion of Grizzly Island Wildlife Area), which is managed by the CDFG, and 950 ac (384 ha) of land owned by the Solano Land Trust (local nonprofit public land trust). Cirsium hydrophilum var. hydrophilum occupied the unit at the time of listing as identified in the final listing rule (62 FR 61916; November 20, 1997) and contains the features essential to the conservation of C. hydrophilum var. hydrophilum. The unit receives regular tidal inundations at least once daily (NWI 2005) from the abovementioned tidal sloughs. Additional special management considerations or protection beyond the special management required for common threats, as discussed above, may be required to control the presence of Rhinocyllus conicus (a nonnative biological control weevil) or other planteating insects that could reduce the reproductive potential of C. hydrophilum var. hydrophilum.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Cirsium hydrophilum var. hydrophilum critical habitat consists of three components (72 FR 18518-18553):

(i) Persistent emergent, intertidal, estuarine wetland at or above the mean high-water line (as extended directly across any intersecting channels);

(ii) Open channels that periodically contain moving water with oceanderived salts in excess of 0.5 percent; and

(iii) Gaps in surrounding vegetation to allow for seed germination and growth.

**Special Management Considerations or Protections**

When designating critical habitat, we assess whether the areas determined to be occupied at the time of listing and that contain the PCEs may require special management considerations or protection. Most of the PCEs and the known occurrences of Cirsium hydrophilum var. hydrophilum and Cordylanthus mollis ssp. mollis are threatened by: (1) tidal wetland conversions to diked, managed, or muted tidal marshes; (2) changes to channel water salinity and tidal regimes; (3) mosquito abatement activities; (4) marsh invasions by nonnative plants; (5) plant-eating insects; (6) urban, industrial, and agricultural encroachment; (7) impacts from livestock overgrazing; (8) feral pigs (Sus scrofa); and (9) impacts from unauthorized foot and off-road vehicle traffic. These combined threats result in the loss and fragmentation of suitable habitat for C. hydrophilum var. hydrophilum and C. mollis ssp. mollis, which could significantly affect their long-term survival. Individually, these threats may require special management considerations or protection as addressed under the critical habitat unit descriptions below.

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual (vegetative) (USFWS, 2013)

**Lifespan**

Adult: 1 year (USFWS, 2013)

**Dependency on Other Individuals or Species**

Adult: Bees and insects (USFWS, 2009)

**Breeding Season**

Adult: July to September (USFWS, 2009)

**Reproduction Narrative**

Adult: Cirsium hydrophilum var. hydrophilum is an annual plant, dying after one year of seed reproduction. Its vegetative period is usually one year (biennial), but if small vegetative plant size or unfavorable environmental conditions delay flowering, it may regenerate from the central root crown for more than one year. Pale lavender-rose flower heads appear between July and September. Flowering plants may produce hundreds of seed heads. Seed heads observed in July 2000 had three to five ripe seeds per head, but many of them contained aborted seeds or were found with insect larvae in active seed predation (Baye 2000). Specific flower pollinators of Cirsium hydrophilum var. hydrophilum have not been directly studied; however, field observations indicate that several bee species may be important in pollinating the species (LCLA 2003). The most common insect species observed gathering pollen at Rush Ranch was the yellow-faced bumble bee (Bombus vosnesenskii) (LCLA 2003). (USFWS, 2009; USFWS, 2013)

**Habitat Type**

Adult: Tidal marsh (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Restricted to regularly flooded and permanently saturated habitats within 50 to 100 feet of the high water mark of tidal channels (USFWS, 2009)

**Spatial Arrangements of the Population**

Adult: Discrete colonies or clusters of small patches (USFWS, 2013)

**Environmental Specificity**

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

**Habitat Narrative**

Adult: The dispersion pattern of C. hydrophilum var. hydrophilum (California Department of Water Resources in litt. 1996) in discrete colonies or clusters of small patches suggests there may be limited seed dispersal. Most known Cirsium hydrophilum var. hydrophilum occurrences are found in regularly flooded and permanently saturated habitats, along the banks of canals or ditches, within 50 to 100 feet of the high water mark of natural tidal channels; and on tidal floodplains within tidal marshes (U.S. Fish and Wildlife Service 2007). (USFWS, 2009; USFWS, 2013)

***Dispersal/Migration***

**Motility/Mobility**

Adult: Low (USFWS, 2013)

**Dispersal**

Adult: Low (USFWS, 2013)

**Dispersal/Migration Narrative**

Adult: The dispersion pattern of C. hydrophilum var. hydrophilum (California Department of Water Resources in litt. 1996) in discrete colonies or clusters of small patches suggests there may be limited seed dispersal. (USFWS, 2013)

***Population Information and Trends***

**Population Trends:**

Long-term decline of 50 - 70% (NatureServe, 2015)

**Number of Populations:**

4 (USFWS, 2009)

**Population Size:**

22,300 to 873,200 individuals, with a best estimate of 137,500 individuals (LCLA 2003). (USFWS, 2013)

**Adaptability:**

Low (USFWS, 2009)

**Population Narrative:**

It was once widespread in Suisun Marsh, but, due to habitat loss, in the last two decades has been found in only four localities: Grizzly Island, Peytonia Slough, Rush Ranch, and Hill Slough. These populations have been in decline in the 1990s and 2000s. The species was considered to belong to a large, single population of approximately 22,300 to 873,200 individuals, with a best estimate of 137,500 individuals (LCLA 2003) in a recent comprehensive survey in 2003. The resulting small populations are still highly susceptible to extinction due to random natural and human-made events, such as pest outbreaks, extended drought, oil spills, genetic or demographic problems or a combination of these events. Long-term trends suggest a decline of 50-70% due to massive changes in the Suisun Marsh due to water projects and utilization. (USFWS, 2009; USFWS, 2013; NatureServe, 2015)

***Threats and Stressors***

**Stressor:** Alteration of tidal regime (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Diking and filling involved in agricultural land conversion and urbanization, ditching for mosquito abatement, changes to freshwater inflow, and habitat fragmentation are threats to Cirsium hydrophilum var. hydrophilum. Private lands continue to experience development (Grewell, pers. comm. 2007). Derelict and actively maintained levees from historic diking practices continue to result in muted (damped) tidal flows, which in turn, reduce available habitat for C. hydrophilum var. hydrophilum. Alteration of natural tidal cycles still exists in much of the potential habitat and represents both the most significant historic and current threat to Cirsium hydrophilum var. hydrophilum and its habitat. With respect to effects to C. hydrophilum var. hydrophilum, alteration of tidal cycles includes muting of tidal flows, increases in freshwater runoff and diversion of freshwater for agricultural and municipal uses. A large portion of historic tidal marshes in Suisun Bay were diked and managed for waterfowl. These historic reductions of habitat have affected the extent and composition of tidal marsh communities. The brackish tidal wetlands in Rush Ranch have been ditched extensively to drain standing water, in an effort to reduce mosquito breeding habitat. Ditching has greatly altered the hydrology of the marsh, primarily because the ditches cut across natural drainage patterns. As a result, mosquito ditches have led to the reduction of tidal inundation and the consequent infilling of first order channels, creating new mosquito breeding habitat (Collins et al. 1986, WRA et al. 1989). Originally, ditching may have reduced Cirsium hydrophilum var. hydrophilum habitat by reducing tidal influence in first order channels. However, the mosquito ditching currently provides new, artificial habitat for C. hydrophilum var. hydrophilum similar enough to first order channels to promote colonization of these ditches. (USFWS, 2009)

**Stressor:** Feral pigs (USFWS, 2009)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** The threat from feral hogs (Sus scrofa) to Cirsium hydrophilum var. hydrophilum was not described in the listing rule, however, it is a present threat at both known locations of the species. Thirty-four percent of the C. hydrophilum var. hydrophilum subpopulations at Rush Ranch showed signs of damage due to rooting and trampling of feral pigs when surveyed in 2003 (LCLA 2003). Further, disturbances on the landscape created by feral pigs may enhance colonization opportunities for a non-native plant Lepidium latifolium (perennial pepperweed), to threaten the tidal marsh ecosystem, discussed further under Factor E (LCLA 2003). (USFWS, 2009)

**Stressor:** Sea-level rise (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Sea level rise, such as that potentially associated with global climate change, and anticipated associated flood control responses, though not discussed in the listing rule, may impose significant long-term threats to conservation of Cirsium hydrophilum var. hydrophilum. Conservation of high marsh zones in the face of sea level rise requires landward transgression (displacement) of the marsh profile on broad, sloping plains (Field et al. 1999, Baye 2006). If the sea level rises, conflicting needs for flood protection, agriculture, and marsh transgression could effectively compress tidal marsh zones to a point at which they could not support C. hydrophilum var. hydrophilum habitat (Grewell 2006). (USFWS, 2009)

**Stressor:** Thistle weevil (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The presence of a thistle weevil (Rhinocyllus conicus) in a portion of the Cirsium hydrophilum var. hydrophilum population was stated to be a possible threat to the species. This threat was discovered by California Department of Water Resources in June 1996 when the weevil was collected inside C. hydrophilum var. hydrophilum flower heads, many of which had no seeds (U.S. Fish and Wildlife Service 1997). The larval stage of this weevil is known to feed on seeds. Plant-eating insects can significantly limit seed production and plant demography as seen in several other Cirsium species (Louda and Potvin 1995; Palmisano and Fox 1997; Rose et al. 2005). (USFWS, 2009)

**Stressor:** Caterpillars (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Phyciods mylitta caterpillars were collected on a population of C. hydrophilum var. hydrophilum in September 1996. These caterpillars have caused significant damage to the rosettes of plants that will flower the following year (U.S. Fish and Wildlife Service 1997). Though documented in the listing rule to have occurred previously at Rush Ranch, Phyciods mylitta caterpillars were not located there during LCLA’s 2003 study. (USFWS, 2009)

**Stressor:** Non-native plants (USFWS, 2009)

**Exposure:**
**Response:**
**Consequence:**
**Narrative:** All known populations of Cirsium hydrophilum var. hydrophilum are negatively affected by nonnative plants. The most problematic and widespread invasive plant in Suisun Marsh is the perennial herb, Lepidium latifolium (Grewell 2005). It occurs along the high marsh edge of San Francisco Bay, especially in disturbed areas, deposits of sand or tidal litter, or levee slopes. In brackish marshes with lower salinity, it invades the middle marsh plain and channel edges. Lepidium latifolium forms large monotypic patches that displace native marsh vegetation (Renz 2000). As much as 40 percent of L. latifolium biomass is below-ground, with most of it concentrated in the upper 24 inches (Renz 2000). This concentration of biomass in surface roots enhances the weed's competitiveness for water and nutrients. Further, as well as being a prolific seed producer, its roots fragment easily and can sprout even after exposure on the soil over the winter. Root fragments also can be carried by water and establish new populations where they are deposited (Renz 2000). (USFWS, 2009)

**Stressor:** Hybridization (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Hybridization with Cirsium vulgare, a non-native, also is a potential threat to Cirsium hydrophilum var. hydrophilum. Hybridization with C. vulgare was suggested as a possible explanation for the previously presumed extinction of C. hydrophilum var. hydrophilum (Smith and Berg 1988). Though recent studies have indicated that the two species coexist at Rush Ranch, no genetic studies have been conducted since the time of listing to determine if hybridization has indeed occurred. L.C. Lee and Associates (2003) found that 45 percent of C. hydrophilum var. hydrophilum subpopulations at Rush Ranch contained C. vulgare. It is known that C. vulgare hybridizes readily with other Cirsium species. (USFWS, 2009)

**Stressor:** Chronic pollution (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Oil spills and chronic pollution from point and non-point sources (heavy metal contamination from point and non-point sources) continue to occur in or near habitat for Cirsium hydrophilum var. hydrophilum (U.S. Fish and Wildlife Service 2007). On April 27, 2004, Kinder Morgan Energy Partners, L.P. spilled 123,774 gallons of diesel fuel through a ruptured pipeline in western Suisun Marsh near Roos Cut. The spill occurred within known habitat for C. hydrophilum var. hydrophilum and contaminated 225 acres of the marsh to varying degrees (Solano County 2005). It is not known whether populations of C. hydrophilum var. hydrophilum were directly affected. (USFWS, 2009)

**Stressor:** Fire (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** It is not known how fire affects the viability of Cirsium hydrophilum var. hydrophilum or its seed, but it is considered a minor threat nonetheless. Human-caused fires present a

continual threat of at least temporary habitat loss in Suisun Marsh. Three fires have occurred recently within existing and potential C. hydrophilum var. hydrophilum habitat in Suisun Marsh (Grewell pers comm. 2007). Arsonists set fire in 2001 to a large portion of Peytonia Slough Ecological Reserve, burning all vegetation from Suisun Slough to the Southern Pacific Railroad tracks, including the only remaining previously known population at Peytonia Slough Ecological Reserve. (USFWS, 2009)

**Stressor:** Random events (USFWS, 2009)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Since the time of listing, the distribution of the species within its range has not increased and the habitat of the species remains restricted due to fragmentation and historic conversion to other uses. The resulting small populations are still highly susceptible to extinction due to random natural and human-made events, such as pest outbreaks, extended drought, oil spills, genetic or demographic problems or a combination of these events. (USFWS, 2009)

***Recovery***

**Reclassification Criteria:**
1. The minimum area inhabited annually by the species must be 2,000 acres over a period of five years. (USFWS, 2013)

2. A minimum of 4,000 acres must be permanently preserved and under protective management. This must include existing or successfully restored tidal marsh areas with suitable habitat for the species and encompass a minimum of 80 percent of the extant occurrences of the species. (USFWS, 2013)

3. Reduction in extant Lepidium latifolium populations in tidal areas of Suisun Marsh (in and down-gradient of the high marsh-upland ecotone) to less than ten percent cover for five years. (USFWS, 2013)

4. Natural tidal range must be restored at Hill Slough and the ponded area at Rush Ranch to return periodic tidal flooding. (USFWS, 2013)

5. At least three separate populations or one large population must occur within Suisun Marsh. Required target number of individuals is dependent on whether separate populations are easily identifiable, as described below. A population shall be any concentration of plants with closest individuals to other populations greater than 1 kilometer (0.6 mile) apart over a period of five years. (USFWS, 2013)

6. Over five years of monitoring, a mean of at least 3,000 individuals must occur annually over the entire range of the species. The third-largest separate population over the same period must have a mean of at least 300 individuals. If there are fewer than three separate populations, a mean of at least 5,000 individuals must occur annually throughout the entire range of the species over a period of five years. The entire species must not fall below 800 individuals for two consecutive years over a period of five years. (USFWS, 2013)

Recovery Priority Number: 3C

**Delisting Criteria:**
1. The minimum area inhabited annually by the species must be 3,000 acres over a period of eight years. (USFWS, 2013)

2. A minimum of 6,000 acres of suitable habitat must be permanently preserved and under protective management. This must include existing or successfully restored tidal marsh areas with suitable habitat for the species and encompass a minimum of 80 percent of the species, as well as habitat supporting adequate self-sustaining populations of pollinators. (USFWS, 2013)

3. All conditions under downlisting criterion number 3 have been met. In addition, a plan must be developed and implemented for early detection and control of Lepidium latifolium following any future increase beyond ten percent cover in tidal areas of Suisun Marsh (in and down-gradient of the high marsh-upland ecotone). Also, a funding source must be secured to fund such actions in perpetuity. (USFWS, 2013)

4. All conditions under downlisting criterion number 4 have been met. (USFWS, 2013)

5. Reliable propagation and reintroduction methods must be developed and available. (USFWS, 2013)

6. Trampling and rooting damage to Cirsium hydrophilum var. hydrophilum by feral pigs must have been eliminated at all populations for five years. (USFWS, 2013)

7. Unnaturally high seed predator pressures on C. hydrophilum var. hydrophilum from thistle weevil (Rhinocyllus conicus) must fall below a level at which it negatively affects long-term population persistence. (USFWS, 2013)

8. At least four separate populations must occur within Suisun Marsh. Over eight years of monitoring, a mean of at least 4,000 individuals must occur annually, spread across at least four populations and the fourth-largest population over the same period must have a mean of at least 500 individuals. If not divisible into separate populations, a mean of at least 7,000 individuals must occur annually throughout the entire range of the species over a period of eight years. The entire species must not fall below 1,000 individuals for two consecutive years over a period of eight years. (USFWS, 2013)

9. Seed banking of all extant populations and representative genetic diversity (per commonly accepted seed banking protocols) must be complete. (USFWS, 2013)

10. Research must be conducted to determine if hybridization is occurring between Cirsium hydrophilum var. hydrophilum and Cirsium vulgare. If research shows that hybridization is occurring, extant C. vulgare populations must be eliminated in Suisun Marsh and a monitoring plan must be in place to detect and eliminate future infestations of C. vulgare. (USFWS, 2013)

11. To minimize impacts sustained after oil spills occurring at or near populations, the San Francisco Bay and Delta Area section of the Sector San Francisco-Area Contingency Plan must be revised to place high priority on the emergency protection of Cirsium hydrophilum var.

hydrophilum. (USFWS, 2013)

12. High marsh/upland transition lands must be preserved or created as part of new marsh restoration efforts and managed to provide opportunity for landward migration of species in response to sea level rise. (USFWS, 2013)

**Recovery Actions:**

- Short-term recovery actions should be implemented concurrently with long-term habitat restoration and should focus on protecting and managing existing populations and habitats. Recovery strategies include: suppression of invasive non-native plant species, protection and management of nearby native bee and wasp habitats, control of Cirsium vulgare, if research indicates necessity, restoration of normal tidal range and salinity, seed banking of Cirsium hydrophilum var. hydrophilum, monitoring of populations and habitat, and research aspects of life history, population ecology, and seed predation of C. hydrophilum var. hydrophilum. (USFWS, 2013)
- A recovery plan for Cirsium hydrophilum var. hydrophilum should be developed which describes recovery strategies and specific tasks necessary for recovery of the species. A draft recovery plan for this species and five other listed tidal marsh species is currently in development by the Service. (USFWS, 2009)
- Natural tidal cycles should be maintained (and restored at Hill Slough and the ponded area of Rush Ranch) because the middle to high marsh area, with periodic tidal flooding, is vital to Cirsium hydrophilum var. hydrophilum. (USFWS, 2009)
- Control of Lepidium latifolium should be conducted at Peytonia Slough Ecological Reserve, Rush Ranch, Hill Slough, Grizzly Island Wildlife Area, as appropriate, to reduce competition with Cirsium hydrophilum var. hydrophilum. (USFWS, 2009)
- Research should be conducted to determine whether hybridization is occurring between Cirsium hydrophilum var. hydrophilum and Cirsium vulgare at Rush Ranch. (USFWS, 2009)
- Research should be conducted to determine the extent to which seed predation by Rhinocyllus conicus is negatively affecting populations of Cirsium hydrophilum var. hydrophilum. If a substantial threat exists, research into effective means of Rhinocyllus conicus control should be researched and implemented at appropriate sites. (USFWS, 2009)
- Surveys should be conducted within potential Cirsium hydrophilum var. hydrophilum habitat as well as at known population centers to identify potential new occurrences as well as to provide an updated species status with which to make management decisions. Specifically, Peytonia Slough Ecological Reserve should be surveyed to determine if that population is extant and the Hill Slough area should be more extensively surveyed to determine the abundance of C. hydrophilum var. hydrophilum there. (USFWS, 2009)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Several areas of future action over the next five years are suggested, which build on the actions articulated in Service (2013) and the tidal marsh ecosystem sections of Service (2019a, 2019b). Consider developing, reviewing and implementing the following survey and monitoring plans: • A range-wide Cirsium hydrophilum var. hydrophilum survey and monitoring plan. This plan would include locations to be surveyed; the group(s) responsible for coordinating surveys; survey timing including the month(s) surveys are to be conducted; and the frequency of surveys (e.g., annually vs. every three years). These surveys should be conducted by well-trained individuals capable of reliably identifying Cirsium hydrophilum var.

hydrophilum, should be reproducible, and should provide at a minimum the following information: an estimated population size with confidence interval(s); the number and locations of known populations; an estimate of the area inhabited by Cirsium hydrophilum var. hydrophilum (acres); and an estimate of the area inhabited by Cirsium hydrophilum var. hydrophilum that occurs on preserved properties (acres). • A Lepidium latifolium survey and monitoring plan for areas occupied by Cirsium hydrophilum var. hydrophilum. This would include locations to be surveyed; the group(s) responsible for coordinating surveys; survey timing including the month(s) surveys are to be conducted; and the frequency of surveys. These surveys should be reliable and reproducible and at a minimum provide an estimate of the percent of the total distribution of Cirsium hydrophilum var. hydrophilum in which Lepidium latifolium also occurs. • A range-wide thistle weevil predation pressure monitoring plan for Cirsium hydrophilum var. hydrophilum. This plan would include information about how predation pressure will be estimated, the group(s) responsible for coordinating monitoring, and locations to be monitored including the timing and frequency of predation pressure surveys. • A feral pig and cattle damage monitoring plan to evaluate the extent of feral pig and cattle damage to Cirsium hydrophilum var. hydrophilum populations. This plan would include information about how feral pig and cattle activity and damage will be monitored, the group(s) responsible for coordinating surveys, locations to be surveyed for damage including survey timing, and the frequency of damage surveys. Consider developing and implementing the following Cirsium hydrophilum var. hydrophilum restoration actions: • A tidal marsh restoration plan for Cirsium hydrophilum var. hydrophilum, and complete the actions that are achievable within 5 years. • An upland marsh restoration plan for Cirsium hydrophilum var. hydrophilum, and complete the actions that are achievable within 5 years. • A propagation and reintroduction plan for Cirsium hydrophilum var. hydrophilum, and complete the actions that are achievable within 5 years. • A seed banking plan for Cirsium hydrophilum var. hydrophilum, and complete the actions that are achievable within 5 years. Other future actions to consider include continued research on the habitat requirements and seed bank dynamics of Cirsium hydrophilum var. hydrophilum, which may lead to helpful information and insights in guiding long-term recovery efforts, including identifying areas for possible development of new populations of Cirsium hydrophilum var. hydrophilum within Suisun Marsh. This future work could include an analysis of how environmental variables, such as precipitation and temperature patterns, and seeding and out-planting influence population dynamics in currently occupied areas and colonization of newly restored areas. A study of the current pollinators of Cirsium hydrophilum var. hydrophilum would help add to the Service's understanding of the natural history of this plant and identify which potential pollinators, or groups of pollinators, to monitor to ensure that healthy and diverse pollinator populations continue to occur. Statistical and numerical modeling, such as with habitat suitability analysis and population dynamics modeling, can provide insights into possible locations to search for unknown populations of Cirsium hydrophilum var. hydrophilum and for identifying future locations for development of new populations, and future dynamics of these populations. Vasey et al. (2020) began developing a species distribution model for Cirsium hydrophilum var. hydrophilum. It is possible that a continuation of this line of investigation will lead to improved insights into where and how to develop additional areas that will support the recovery of Cirsium hydrophilum var. hydrophilum. It may also be useful to consider developing population viability analyses (PVA) that are specifically developed for Cirsium hydrophilum var. hydrophilum. For example, it is possible that a stage-structured matrix population model similar to the model developed by Thomson (2005; also see Gotelli 2001, Kéry and Schaub 2012) could be used to form a foundation for PVA analysis. It is also possible that building and parameterizing such a model, and then projecting this model into various possible futures, including under the influence of changing climate and hydrology conditions, could help provide useful insights. As part of efforts to improve statistical analysis and modeling, creating a well-vetted and archived dataset of all Cirsium hydrophilum var. hydrophilum surveys, and resolving any discrepancies in counts identified during this review will be critical to progressing on this objective. The San Francisco Bay-Delta Fish and Wildlife Office has convened a recovery implementation team (RIT) to focus on the listed tidal marsh species described in Service (2013), including Cirsium hydrophilum var. hydrophilum. The primary goal of this group is to encourage Service biologists, managers and external experts to collectively consider recovery priorities for these species and tidal marsh ecosystems in northern and central California, and continue to stay abreast of emerging research related to Cirsium hydrophilum var. hydrophilum and related tidal marsh taxa, tidal marsh ecology, and other relevant topics. This group could help develop a recovery implementation strategy for Cirsium hydrophilum var. hydrophilum, which would strive to articulate relatively short-term recovery goals (e.g., on a 2-3 year time horizon) related to the long-term recovery criteria discussed in detail above and in Service (2013). (USFWS, 2021)

# SPECIES ACCOUNT: *Cirsium loncholepis* (La Graciosa thistle)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 04/19/2000; California/Nevada (Region 8)

**Physical Description**

a biennial or short-lived perennial plant that flowers once and then dies (Lea 2002, p. 67; Teed 2003, p. iv; Baldwin et al. 2012, p. 289), with a probable life span of 2 to 6 years (Lea 2002, p. 68). It is an erect or spreading mound-like plant with spines on the leaves and flower heads. The plants have one or more stems that range usually from 10 to 100 cm/4 to 39 in tall but occasionally up to 150 cm/59 in. The lower leaves are 10 to 30 cm/4 to 12 in long with spiny petioles (leaf stalks) and usually deeply lobed with secondary lobes or teeth. The leaves have a wavy edge, with the bases of the middle and upper leaves forming short, spiny wings along the petiole. Flower heads are 2 to 4 cm/0.8 to 1.6 in wide in tight clusters and at the tips of stems. The flowers are 25 to 30 mm/1.0 to 1.2 in long, and nearly white with a purplish tube containing purple anthers (Figure 2). The fruits are achenes (dry fruit containing one seed only; Lea 2002, p. 7), 3 to 4 mm/0.1 to 0.2 in long, and topped with a pappus (umbrella of small hairs) 15 to 25 mm/0.6 to 1.0 in long (Keil and Turner 1993, p. 236) that facilitates wind dispersal. La Graciosa thistle can be confused with the clustered thistle (Cirsium brevistylum; Table 3) and cobwebby thistle (Cirsium occidentale). (USFWS, 2018)

**Taxonomy**

Cirsium loncholepis was described and named by Petrak (1917, p. 375) from a specimen collected “near La Graciosa” by Alice Eastwood in 1906. It is in the aster and sunflower family (Asteraceae; Baldwin et al. 2012, p. 289). The common name La Graciosa thistle is in reference to the collection site of the holotype, which apparently was near Graciosa railway station or La Graciosa village (now south Orcutt; Figure 1) in Santa Barbara County (Wilken 2009, p. 3). (USFWS, 2018)

**Historical Range**

See Current Range.

**Current Range**

La Graciosa thistle is associated with wetland features such as dune swales, dune slack ponds, and dune lakes within the Guadalupe-Nipomo Dunes Complex, in western San Luis Obispo County, on the Central Coast of California. Historically, it also occurred in other wetland feature types including marshes, seeps, intermittent streams, mesic floodplains, and river margins within the riparian habitats of the Santa Maria River and a few other, more isolated areas within northern Santa Barbara County (USFWS, 2024)

**Critical Habitat Designated**

Yes; 12/3/2009.

**Legal Description**

On November 3, 2009, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective December 3, 2009) for Cirsium loncholepis (La Graciosa thistle) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in California (74 FR 56978-57046).

**Critical Habitat Designation**

The critical habitat designation for Cirsium loncholepis includes six CHUs in San Luis Obispo and Santa Barbara Counties, California. This species critical habitat encompasses approximately 24,103 acres (ac) (9,754 hectares (ha)). Brief descriptions are provided below; detailed coordinates and maps are included in the Final Rule (74 FR 56978-57046; USFWS, 2009).

Unit 1: Callender-Guadalupe Dunes (9,690 ac (3,921 ha)) Unit 1 is located in the southwestern corner of San Luis Obispo County, California. It stretches along 8.5 mi (13.5 km) of coast from Arroyo Grande Creek to the Santa Maria River. This unit is south of Pismo Beach, west of Nipomo and north of Guadalupe.

Unit 2: Santa Maria River-Orcutt Creek (13,227 ac (5,353 ha)) Unit 2 is located along the lower 5 mi (8 km) of the Santa Maria River and along the length of Orcutt Creek (approximately 13 mi (21 km)) in San Luis Obispo and Santa Barbara Counties, California.

Unit 3: Canada de las Flores (740 ac (299 ha)) Unit 3 is located approximately 5 mi (8 km) northwest of the town of Los Alamos and southwest of the Solomon Hills in Santa Barbara County, California.

Unit 4: San Antonio Creek (185 ac (75 ha)) Unit 4 is located in the northwestern portion of Santa Barbara County, California. The majority of Unit 4 lands occur on VAFB.

Unit 5: San Antonio Terrace (52 ac (21 ha)) Unit 5 is located in western Santa Barbara County, California. We determined that all lands in Unit 5 (7,334 ac (2,968 ha)) on San Antonio Terrace are essential to the conservation of Cirsium loncholepis. Unit 5 stretches along 4 mi (6.5 km) of the coast north from San Antonio Creek.

Unit 6: Santa Ynez River (210 ac (85 ha)) Unit 6 is located in the western portion of Santa Barbara County, California. Unit 6 is west of Lompoc and east of Surf.

**Primary Constituent Elements/Physical or Biological Features**

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of Cirsium loncholepis critical habitat consists of four components (74 FR 56978-57046):

(i) Mesic areas associated with: (A) Margins of dune swales, dune lakes, marshes, and estuaries that are associated with dynamic (changing) dune systems including the Santa Maria Valley Dune Complex and Santa Ynez Valley Dune Complex; (B) Margins of dynamic riparian systems including the Santa Maria and Santa Ynez Rivers and Orcutt and San Antonio Creeks; and (C) Freshwater seeps and intermittent streams found in other habitats, including grassland, meadow, coastal scrub, and oak woodland. These areas provide space needed for individual and population growth including sites for germination, reproduction, seed dispersal, seed bank, and pollination;

(ii) Associated plant communities including: Central dune scrub, coastal dune, coastal scrub, freshwater seep, coastal and valley freshwater marsh and fen, riparian scrub (e.g., mule fat scrub, willow scrub), oak woodland, intermittent streams, and other wetland communities, generally in association with the following species: Juncus spp. (rush), Scirpus spp. (tule), Salix spp. (willow), Toxicodendron diversilobum (poison oak), Distichlis spicata (salt grass), Baccharis pilularis (coyote brush), and B. douglasii (Douglas' baccharis);

(iii) Soils with a sandy component including but not limited to dune sands, Oceano sands, Camarillo sandy loams, riverwash, and sandy alluvial soils; and

(iv) Features that allow dispersal and connectivity between populations, particularly: (A) Natural riparian drainages in Santa Maria River, Orcutt Creek, San Antonio Creek, and Santa Ynez River that are not channelized or confined by barriers or dams, such that they have soft bottoms and sides and a natural flood plain (allowing uninterrupted water flows); and (B) Natural aeolian geomorphology in the Santa Maria Dune Complex and Santa Ynez Dune Complex, and along the Santa Maria River, Orcutt Creek, San Antonio Creek, and Santa Ynez River drainages that is not confined by barriers or wind-blocks such as large manmade structures, tree rows, or windbreaks (allowing uninterrupted winds across these areas).

**Special Management Considerations or Protections**

Many of the known occurrences of Cirsium loncholepis are threatened by direct and indirect effects from energy-related operations (i.e., maintenance activities, hazardous waste cleanup); development that results in additional habitat modification or land use changes (i.e., conversion of agricultural and urban development); county zoning changes; issuance of development permits; non point source pollution such as from urban and agricultural runoff (e.g., herbicides, fertilizers); facility accidents by oil companies or VAFB; groundwater extraction throughout the range of the species; hydrological alterations; direct and indirect effects from off highway vehicle (OHV) activity (i.e., habitat disturbance, hazardous materials spills); small population size; and habitat fragmentation and loss through the invasion of aggressive nonnative weeds such as Ammophila arenaria (European beach grass), Carpobrotus spp. (iceplant), Ehrharta calycina (veldt grass), and Mesembryanthemum crystallinum (crystalline iceplant). These threats may require special management to ensure the long-term conservation of C. loncholepis.

The essential features found in Unit 1 may require special management considerations or protection resulting from: (1) direct and indirect effects from energy-related operations (i.e., maintenance activities, hazardous waste cleanup, facility accidents); (2) ground water extraction which lowers the water table, dries the wetlands, and can destroy surface and subsurface hydrologies; (3) stochastic (i.e., random) extirpation/extinction events that occur because the population size is small or isolated; (4) trampling and grazing from trespass of cattle; (5) competition from invasive, aggressive, nonnative weeds (e.g., Ammophila arenaria , Carpobrotus spp., Ehrharta calycina, Mesembryanthemum crystallinum); (6) direct and indirect effects from OHV activity (i.e., habitat disturbance, hazardous materials spills); (7) habitat fragmentation; and (8) nutrient inputs in the water systems that are above concentrations known to adversely affect freshwater ecosystems and cause adverse ecological effects including altering the composition of the plant community and inducing biostimulation.

The essential features found in Unit 1 may require special management considerations or protection resulting from: (1) direct and indirect effects from energy-related operations (i.e., maintenance activities, hazardous waste cleanup, facility accidents); (2) ground water extraction which lowers the water table, dries the wetlands, and can destroy surface and subsurface hydrologies; (3) stochastic (i.e., random) extirpation/extinction events that occur because the population size is small or isolated; (4) trampling and grazing from trespass of cattle; (5)

competition from invasive, aggressive, nonnative weeds (e.g., Ammophila arenaria , Carpobrotus spp., Ehrharta calycina, Mesembryanthemum crystallinum); (6) direct and indirect effects from OHV activity (i.e., habitat disturbance, hazardous materials spills); (7) habitat fragmentation; and (8) nutrient inputs in the water systems that are above concentrations known to adversely affect freshwater ecosystems and cause adverse ecological effects including altering the composition of the plant community and inducing biostimulation.

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: 2-3 years (inferred from USFWS, 2011)

**Dependency on Other Individuals or Species**

Adult: Pollinators (potential pollinators include ants, beetles, bees, flies, and butterflies( (USFWS, 2024)

**Breeding Season**

Adult: Blooms from April to September (USFWS, 2018)

**Other Reproductive Information**

Adult: La Graciosa thistle blooms from April to September (Baldwin et al. 2012, p. 289). Potential pollinators include ants, beetles, bees, butterflies and flies (Keil 2001, p. 1; Lea 2002, p. 80). Seed dispersal is by wind (Keil and Turner 1993, p. 236; Lea 2002, p. 7; USFWS 2016a, p. 68) and also likely by water because it is a wetland plant. The seed bank of La Graciosa thistle may be similar to that of the wetland jewelweed (Impatiens capensis) for which no persistent seed bank exists (Simpson et al. 1985, p. 307). This is supported by the data in our Table 2. Of the 13 occurrences for which zero plants were recorded and then a subsequent census conducted, 11 also had zero plants recorded in the subsequent census. In other words, only two of 13 occurrence were found to be extant after a previous census record of zero plants. This combined with the observations of Hendrickson (1990b, p. 23), Lea (2002, p. 45) and Teed (2003, p. 29) indicate that La Graciosa thistle has only a minimally persistent seed bank. (USFWS, 2018). We presume that La Graciosa thistle reproduces sexually; potential pollinators include ants, beetles, bees, flies, and butterflies (Service 2020, p. 7). Many wetland-adapted (hydrophytic or aquatic) plant species persist in the soil as a seedbank (DeBerry and Perry 2000, p. 4), and La Graciosa thistle appears to have at least a minimally persistent seedbank (Service 2020, pp. 8–9 and 59). Seed dispersal is by wind and likely also by water. (USFWS, 2024)

**Reproduction Narrative**

Adult: Cirsium scariosum var. loncholepis (La Graciosa thistle) is a short-lived monocarpic perennial (a plant that blooms once, then dies) (Hendrickson 1990, Keil and Turner 1993, Teed 2003). C. loncholepis flowers bloom between June to August (NatureServe, 2015). Large individuals produce more flowering heads and more seeds per head (average = 473 seeds per plant) than smaller individuals (average = 168 seeds per plant), and therefore contribute disproportionately to the future seedbank of the population (M. Lea, California Polytechnic State University, San Luis Obispo, pers. comm. 2001).

**Habitat Type**

Adult: Wetlands (USFWS, 2011)

**Habitat Vegetation or Surface Water Classification**

Adult: Mesic wetlands, coastal dunes, brackish marshes and swamps (USFWS, 2011; NatureServe, 2015)

**Dependencies on Specific Environmental Elements**

Adult: Intermediate moisture (USFWS, 2011)

**Geographic or Habitat Restraints or Barriers**

Adult: Requires medium moisture conditions that are neither very wet nor very dry (USFWS, 2011)

**Environmental Specificity**

Adult: Narrow/specialist

**Habitat Narrative**

Adult: La Graciosa thistle exists as groups of individuals in wetland habitats in an arid and semi-arid landscape. The plants inhabit the margins of wetlands (swales, lakes, ponds, freshwater marshes, streams, rivers, seeps) in southwestern San Luis Obispo County and western Santa Barbara County in central coastal California. The majority of occurrences are associated with wetlands in the backdunes of two coastal sand dune complexes, the Callender Dunes and the Guadalupe Dunes (Figure 1). Many of the wetlands in the sand dune complexes occur where the groundwater table is at or near the surface (Lea 2002, p. 66; California Department of Fish and Game 2005, p. 328), and the water levels rise and fall naturally with rainfall. Low water levels can be exacerbated by drought (Holland et al. 1995, p. 23). (USFWS, 2018)

***Dispersal/Migration***

**Motility/Mobility**

Adult: High (USFWS, 2011)

**Dispersal**

Adult: High (USFWS, 2011)

**Dispersal/Migration Narrative**

Adult: The achenes (fruit) are 0.01 to 0.02 inches (3 to 4 mm) long and topped by an umbrella of long awns (0.6 to 1.0 in) that are ideal for wind dispersal (Keil and Turner 1993). Research has shown that Cirsium scariosum var. loncholepis are long-distance dispersers. (USFWS, 2011)

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2018)

**Species Trends:**

Declining (USFWS, 2018)

**Resiliency:**

In summary, of the 21 known occurrences of La Graciosa thistle, 16 are likely extirpated, four are extant, and one has unknown status. Three of the four extant occurrences have moderate resiliency, suggesting a moderate ability of these three remaining occurrences to withstand stochastic events and natural environmental variation. One of the four extant occurrences has low resiliency, indicating a reduced ability to withstand stochastic events and natural environmental variation. Of the four extant occurrences, one is protected on a National Wildlife Refuge, one is protected on private property by a conservation easement, one is currently protected on private property by a biological opinion, and one is on two private properties with current protection on one by a biological opinion (USFWS, 2018).

**Representation:**

In summary, the results indicate that the genetic diversity and the spatial extent of La Graciosa thistle have declined substantially from historical conditions. Gene flow among the four extant occurrences appears limited, and it was likely much greater historically. The four extant occurrences are in the Sand Dune Complexes population. Representation in the other three populations appears to have been lost, suggesting the species has lost potential capability for adapting to changes (natural or human caused) in its environment (USFWS, 2018).

**Redundancy:**

In summary, with only four extant occurrences and 16 likely extirpated occurrences (and one occurrence with unknown status), the redundancy of La Graciosa thistle is severely reduced. This reduction decreases the ability of the species to withstand catastrophic events and to survive in the face of unpredictable and highly consequential events for which adaptation is unlikely (USFWS, 2018).

**Number of Populations:**

8 extant occurrences; 15 likely extirpated occurrences (USFWS, 2024)

**Additional Population-level Information:**

There are currently 23 La Graciosa thistle EOs (CNDDB 2024b, website); two of these EOs (36 and 37) are new and one EO (16) has changed from extirpated to extant. We now consider eight EOs extant, including portions of EO 6, and EO 11, EO 12, EO 16, EO 18, EO 31, EO 32, and EO 36. We consider 14 EOs likely extirpated, including EO 1, EO 2, EO 3, EO 4, EO 8, EO 10, EO 13, EO 14, EO 19, EO 20, EO 28, EO 30, EO 34, and EO 37. The status of EO 33 remains unknown because it is privately owned, and we have not been able to access it for surveys. At the time of listing, we noted that the dune La Graciosa populations were small, isolated, and showed reduced reproductive vigor (Service 2000, p. 14889). We stated that 7 of the known populations were reported to have fewer than 60 individuals each. We also said that the Santa Maria River population had a substantial number of plants, but fluctuated between 6,000 and 54,000 individuals, and that this population experienced a significant disruption due to a flooding event that occurred in 1998 (USFWS, 2024).

**Population Narrative:**

Currently, 21 extirpated and extant occurrences range coastally from Pismo State Beach (occurrence 14; 35.107367, -120.625009), San Luis Obispo County, southward to the floodplain of the Santa Ynez River near the south entrance of Vandenberg Air Force Base (occurrence 1;

34.662962, -120.556957), Santa Barbara County (32.7 km/20.3 mi distance), and from the Pacific Ocean eastward to a freshwater marsh 1.6 km/1.0 mi northeast of Los Alamos (occurrence 33; 34.748658, -120.259412), Santa Barbara County (31.7 km/19.7 mi distance). The occurrence previously reported in Monterey County has since been determined to be the Alameda County thistle (Cirsium quercetorum) (Lea 2002, p. 3). The majority (n = 17) of occurrences are within 6.3 km/3.9 mi of the coast, while four occurrences are at substantially greater distances. Most of the occurrences (n = 16) are in or proximal to two coastal sand dune complexes in San Luis Obispo County: the Callender Dunes just south of Arroyo Grande, and the contiguous Guadalupe Dunes just north of the Santa Maria River Of the 21 known occurrences, 16 are likely extirpated, four are currently extant (occurrences 6, 11, 18, 31), and one has unknown status. The four extant occurrences are on lands of various ownership: one occurrence on private property of Chevron Corporation (18), one occurrence on private properties of Chevron Corporation and another landowner (6), one occurrence on private property with a conservation easement to the Land Conservancy of San Luis Obispo County (11), and one occurrence on Guadalupe-Nipomo Dunes National Wildlife Refuge (31). (USFWS, 2018)

***Threats and Stressors***

**Stressor:** Habitat loss (USFWS, 2018)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The primary threat to La Graciosa thistle in 2018 is lack of water, with groundwater decline as the likely major source. The groundwater decline appears to be a result of extraction for urban, agricultural and industrial uses, and it is exacerbated by drought and climate change. Groundwater decline causes habitat loss and degradation for La Graciosa thistle. Past development and agriculture have also caused substantial habitat loss and fragmentation by conversion of land for other uses (Hendrickson 1990b, p. 22). From the 1850's to 1987, 90% of California's coastal wetlands disappeared (Caughman and Ginsberg 1987, p. 24). In the 21st century, the remaining wetlands in central coastal California continue to decrease in quantity and quality (USFWS 2011, p. 11). Due to its minimally persistent seed bank, any occurrence of the species that has not had flowering plants over several consecutive years is at risk of extirpation. (USFWS, 2018)

**Stressor:** Urbanization (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Most of the historical occurrences and their surrounding areas are urbanized and/or indirectly impacted by urbanization (Service 2009a, CNDDB 2010). As mentioned above in the Abundance and Population Trends section, Cirsium scariosum var. loncholepis has experienced considerable declines throughout its range in the number of populations, occurrences, and individuals. It is only known to be extant at 8 of the 21 known occurrences (see Table 1). This decline in range, populations, occurrences, and individuals has further limited this species' ability to colonize or recolonize adjacent and intermediate locations of suitable habitat. (USFWS, 2011)

**Stressor:** Development of habitat for petroleum extraction (USFWS, 2011)
**Exposure:**

**Response:**
**Consequence:**
**Narrative:** Habitat loss has been implicated from petroleum related activities. (USFWS, 2011)

**Stressor:** Cattle grazing and herbivory (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Cattle have been documented crushing and breaking C. scariosum var. loncholepis plants on the Guadalupe-Nipomo National Wildlife Refuge (Elvin 2007d). Trampling and crushing impacts from cattle have been documented in and among plants at the Chevron project site in the Guadalupe Dunes (Elvin 2006). Cirsium scariosum var. loncholepis was last reported at the Cañada de Las Flores population in 1989 (Service 2009a). This population has been overgrazed according one local rancher (Elvin 2007c). This overgrazing has reduced plant cover, compacted the soil, and may have crushed plants at this population. Trampling and crushing of plants and compaction of soil may have been an exacerbating circumstance that led to the possible extirpation of this species at this population. While this plant may be able to withstand some herbivory, it may cause a reduction in its reproductive success due to the loss of flowers and the corresponding reduction in the production of seeds. (USFWS, 2011)

**Stressor:** Loss of connectivity between populations (Long-Distance Dispersal) (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Recent research on species that are long-distance dispersers (such as Cirsium scariosum var. loncholepis) determined that when the distances between suitable habitat sites for a species become greater than its dispersal distance (such as due to habitat fragmentation), its long-term survival will be threatened unless the long-distance dispersal between the sites can be re-established (Trakhtenbrot et al. 2005). Alterations of hydrological regimes (e.g., flood control) have increased the lack of connectivity between populations (Service 2009a). Wilken (2009a) stated that the current hydrological regulatory process in the Santa Ynez River may not be conducive to conditions favoring establishment of C. scariosum var. loncholepis. Connectivity between populations, particularly natural riparian drainages in Santa Maria River, Orcutt Creek, San Antonio Creek, and Santa Ynez River that are not channelized or confined by barriers or dams, such that they have soft bottoms and sides and a natural flood plain (allowing uninterrupted water flows) is one of the primary constituent elements for C. scariosum var. loncholepis in the final critical habitat rule (Service 2009a) and is important to maintain connectivity between populations for see dispersal and the establishment of intermediate linkage populations that may be transitory in nature. Habitat that would provide connectivity between occurrences and populations is essential to recover C. scariosum var. loncholepis (Service 2009a). (USFWS, 2011)

**Stressor:** Water quality (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Threats identified since the time of listing discussed above under Factor A include excessive amounts of nitrogen and other nutrients in watersheds that either currently support or

historically supported Cirsium scariosum var. loncholepis. These nutrient levels have a direct effect on the vegetation in these watersheds, which causes excessive growth that is consistent with biostimulation and eutrophication. Excessive nutrient inputs can lead to vegetation community composition changes due to biostimulatory effects (California State Water Resources Control Board 2006b, Central Coast Ambient Monitoring Program 2002, Dodds et al. 1998). (USFWS, 2011)

**Stressor:** Genetics as affected by small population size (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The limited gene pool of this species may depress its reproductive vigor. Human-caused or natural environmental disturbances (e.g., flood, drought, disease) could increase the risk of extinction of Cirsium scariosum var. loncholepis. Small populations are threatened by inbreeding depression (Ellstrand and Elam 1993). Small plant populations can have significantly lower germination rates than larger populations of the same species due to high levels of homozygosity (Menges 1991); this has already been observed in C. scariosum var. loncholepis (Hendrickson 1990). Genetic stochasticity results from changes in gene frequencies due to founder effect, random fixation, or inbreeding (Shaffer 1981). Low levels of genetic variation among and within populations could impair a species' ability to adapt to changes in the environment or contribute to inbreeding depression (i.e., loss of reproductive fitness or vigor) (Arias et al. no date). The existence of less than 10 populations and the small number of individuals in these populations places Cirsium scariosum var. loncholepis at extreme risk of extinction due to low levels of genetic diversity. (USFWS, 2011)

**Stressor:** Climate change (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, a rise in sea level, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). The extent to which climate change could affect C. scariosum var. loncholepis is unknown at this time due to the general nature of these predictions. Despite the uncertainty regarding the specific effects of climate change on this species, an increase in the rate of sea level rise has been predicted for the coast of California (CCC 2001, California Climate Change Center 2006, Heberger et al. 2009). In particular, dunes along the coast will be subject to greater and more frequent wave attack, resulting in erosion and shoreline retreat estimated to be between 459 and 1,083 feet (140 and 330 m), corresponding to an estimated loss of approximately 1.4 square miles (896 acres) of dunes in San Luis Obispo County by the year 2100 (CCC 2001, Heberger et al. 2009). Because Cirsium scariosum var. loncholepis occurs in coastal dune habitats, erosion of these areas and corresponding loss or decreased quality of habitat could potentially adversely affect the species. (USFWS, 2011)

**Stressor:** Flood Control Management and Maintenance Activities (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Flood Control Management and Maintenance Activities. Historical winter storm events in 2023 caused substantial sedimentation, debris deposits, and flooding, with multiple channel breaches and extensive inundation in the City of Guadalupe, Santa Barbara County. From 2023 to 2024, the Santa Barbara County Flood Control District (SBCFCD) completed an emergency sedimentation removal, flood control, and maintenance project within the Santa Maria River channel, surrounding riparian corridor and floodplain, and immediately adjacent areas. The project area extended from approximately the intersection of the river with the overpass bridge along State Highway Route 1, to the Pacific Ocean, totaling approximately eight km (five mi) in length. SBCFCD removed excavated sediment and debris across approximately 150 acres of the project area and constructed an earthen berm along the southern side of the riverbank to serve as a barrier directing flows back into the river channel (U.S. Army Corps of Engineers, Los Angeles District 2023, entire) (USFWS, 2024).

***Recovery***

**Reclassification Criteria:**
La Graciosa thistle may be considered for downlisting when the following criteria are met: 1) At least nine occurrences exist, with a minimum of two occurrences from each of two different population units, and they display stable or increasing trends over 10 consecutive years.1 2) Each of the nine occurrences is being consistently managed in a way that will support the continued existence of La Graciosa thistle and its habitat, including seed banking, propagation and outplanting efforts, invasive weed abatement, and assurances for adequate hydrology within associated aquatic features. 3) Annual monitoring and reporting demonstrate that management is effective over 10 consecutive years. 4) An ex situ conservation seed bank is established and maintained at one or more facilities certified by the Center for Plant Conservation. (USFWS, 2021)

Recovery Priority Number: 2

**Delisting Criteria:**
Once the downlisting criteria have been met, La Graciosa thistle may be considered for delisting when the following criteria are met: 1) At least 13 occurrences exist, with a minimum of two occurrences from each of three different population units and they display stable or increasing trends over 10 consecutive years. 2 2) Each of the 13 occurrences is secure from known, plausible threats including from groundwater decline. 3) Each of the 13 occurrences is being consistently managed in a way that will support the continued existence of La Graciosa thistle and its habitat, including seed banking, propagation and outplanting efforts, invasive weed abatement, and assurances for adequate hydrology within associated aquatic features. 4) Annual monitoring and reporting demonstrate that management is effective over 10 consecutive years. (USFWS, 2021)

**Recovery Actions:**

- Recommendation for Future Actions from the 2019 5-Year Review: The results of our 2018 SSA indicate that La Graciosa thistle viability has declined sharply from historic conditions and has continued to decline since the 2011 5-year review. Both near-tenn and long-term efforts are required to achieve recovery. Several recommendations designed to halt this downward trajectory and ultimately reverse it, so that La Graciosa thistle can recover and persist into the future, are provided below. (USFWS, 2018)

- Near-term Recovery Actions: • Annual monitoring at the five extant occurrences; • Collect seed for banking and bulking, test seed viability; 10 • Conduct outplanting of La Graciosa thistle at historical occurrences and in other potentially suitable habitats; • Conduct habitat restoration and management at five extant occurrences and any newly established sites (including but not limited to- invasive species management, manual disturbance such as removal of thatch and vegetation clearing, supplemental watering, removal of overgrown hydrophytic species, re-introduction of controlled grazing regimes as a potential invasive species management tool, and installation of cages around individual plants during particular phenological stages); • Conduct education and outreach; and • Utilize the La Graciosa thistle Recovery Team and other potential recovery partners and stakeholders to facilitate ongoing collaborations. (USFWS, 2018)
- Longer-term Recovery Actions: • Establish living La Graciosa thistle collections at botanic gardens; • Pursue site access to occurrences (both historic and unknown) and potentially suitable habitats on private properties for surveys; and • Establish easements to support La Graciosa thistle recovery endeavors. (USFWS, 2018)
- Research Needs: • Habitat suitability modeling to identify potential outplanting sites throughout the species range; • Evaluation of the role of disturbance and management techniques for species recovery; • Seed viability and germination testing; • Hydrology and groundwater analyses; • Genetics work; • Pollination studies; and • Regional climate change simulations and projections. (USFWS, 2019)
- Near-Term Recovery Actions The aim of the near-term recovery actions is to prevent extirpation of the species at the eight extant occurrences, all of which are in the Sand Dunes Complex Population Unit. The actions include: 1) Habitat Restoration – invasive weed treatments with herbicides, abatement and removal to prevent re-infestations; woody debris removal to clear out downed trees and tree limbs; possibly thinning and trimming excessive arroyo willow (Salix lasiolepis), poison oak (Toxicodendron diversilobum) and blackberry (Rubus spp.); and management of dense thatch. Habitat restoration may also require dredging of aquatic features and other remedial measures to augment and renovate local hydrologic regimes. 2) Supplemental Watering – when necessary during drought or lack of water, specifically to ensure survival of particular individual plants and/or colonies. 3) Installation of Exclusionary Fencing and/or Cages – around individuals and colonies of La Graciosa thistle to prevent herbivory from mammals such as deer (Odocoileus hemionus) and rabbit (Sylvilagus audubonii), and trampling from wild pig (Sus scrofa). Fencing may also be used for disturbance studies associated with seasonal cattle grazing. 4) Propagation and Outplanting – coordinated and directed efforts to collect seed when and if it is readily available to produce seedlings from tracked maternal lines, which will be outplanted at locations that are extirpated, that have extremely low numbers of individuals and could become extirpated, or at appropriate sites located within close proximity to the extant occurrences. 5) Annual Monitoring and Reporting – these efforts are required to assess the effectiveness of the near-term actions, track and census the numbers of individuals at each occurrence and to both guide and determine future recovery actions. The property owners/managers of each extant occurrence have agreed to complete five consecutive years of annual monitoring with reporting and to participating in the near-term La Graciosa thistle recovery program. Longer-Term Recovery Actions The longer-term recovery actions are intended to inform the strategic future development of the species recovery program, fill important knowledge gaps and to systematically move the species towards downlisting and eventual delisting. These actions can occur within any and all of the population units, include future research needs, and consist of the following: 1) Establish and Maintain a

Conservation Seed Bank – seed will be collected from all extant occurrences and deposited into a permanent conservation collection at a facility that is certified by the Center for Plant Conservation. Certified affiliates are part of a national network that follow stringent guidelines for seed conservation banking set by the International Board for Plant Genetic Resources and in consultation with the National Laboratory for Genetic Resource Preservation. Once deposited, seed will be stored and curated in perpetuity to serve as emergency back-up if the species becomes extinct in the wild and for other recovery purposes. 2) Seed Viability Studies and Bulking – once the conservation seed bank is established, research will be conducted to evaluate the viability of La Graciosa thistle seed and efforts to bulk the seed will be pursued. These activities are to ensure that abundant seed is readily available for subsequent outplanting projects and recovery efforts. 3) Re-establish Several Extirpated Occurrences – facilitate outplanting efforts at numerous sites that are likely to have cooperative recovery partners based on the current land ownership status and land use practices and/or that conducive conservation easements are already established. These priority sites include and are presented in numeric order: • Occurrence 1 at Vandenberg Air Force Base; Vandenberg South Population Unit, would re-establish the species in the southwestern part of the geographic range. • Occurrence 13 at Oso Flaco Lake in Oceano Dunes State Vehicular Recreation Area; Sand Dune Complex Population Unit; owned by California Department of Parks and Recreation. • Occurrence 14 at Pismo State Beach; Sand Dune Complex Population Unit; owned by California Department of Parks and Recreation. This site also has the Oceano Dunes District Visitor Center, which could provide an opportunity to promote public education/outreach for La Graciosa thistle. • Occurrence 16 at Black Lake Ecological Area; Sand Dune Complex Population Unit; owned by Land Conservancy of San Luis Obispo County. 4) Establish cooperative relationships with other landowners – engage potential partners with the goal of surveying parcels not previously surveyed for additional occurrences or suitable habitat that could be used for additional outplanting efforts. 5) Fulfill Research Needs – work with partners to fund research and other collaborative studies to fill knowledge gaps about the species including (but not limited to) the following: best management practices and methods for the various life stages of the species; species response to disturbance from grazing, thatch removal and other vegetation management techniques; demographic studies, pollination ecology research, genetics research, habitat suitability analyses and modeling, groundwater testing and mapping and other hydrologic modeling for evaluating variable climate change scenarios. (USFWS, 2021)

***Conservation Measures and Best Management Practices:***

- Conservation Measures for La Graciosa Thistle: In 2018, conservation measures are being implemented on two properties: the private property of Chevron Corporation, and Oceano Dunes State Vehicular Recreation Area (1,457 ha/3,600 ac). Since 2005, Chevron Corporation has managed occurrences 6, 18 and 32 (Table 6) in the Guadalupe Oil Field under a biological opinion (USFWS 2005, entire) issued under the U.S. Endangered Species Act. Specifically, their actions have included the following: • annual monitoring of three occurrences of La Graciosa thistle on their property (a fourth occurrence was identified in 2018); • salvaging and transplanting 1,629 individuals that would have been impacted by remediation and restoration activities, of which 1,136 individuals survived; • outplanting 2,842 individuals (2,826 grown from seed), of which 1,893 individuals flowered; • managing invasive plants in the Guadalupe Oil Field; and • removing feral pigs.
- RECOMMENDATIONS FOR FUTURE ACTIONS 1. Conduct comprehensive annual surveys of abundance, assess the overall status of the species, and evaluate current threats at each of the eight

extant EOs. Include estimates of the total number of La Graciosa thistle individuals present at each location, using uniform methodologies suitable for trend analyses, and map the total occupied area. Collect other pertinent ecological and demographic data including co-occurring and co-dominant species, hydrologic regimes, presence and abundance of nonnative, invasive species, timing of phenology, effective population size, and continue observations of any potential insect pollinators, and seed and foliage herbivory. 2. Conduct experimental research to determine the most effective management techniques for occupied La Graciosa thistle sites to ensure persistence and expansion of the species. We recommend evaluating the use of grazing and other disturbance techniques designed to manage nonnative, invasive weeds and overgrown hydrophytic and other woody riparian vegetation. 3. Obtain conservation easements or acquire other sites within the species current range to introduce the species to new locations or repatriate it at extirpated sites. Include long-term management strategies to ensure success and persistence of the species. 4. Continue making conservation seedbank accessions of La Graciosa thistle seed for banking every three to five years and prioritize those EOs that do not yet have accessions. Conduct seed bulking activities to ensure an ample supply of seed for recovery efforts and for insurance in the event of stochastic loss or extirpation (USFWS, 2024).

# SPECIES ACCOUNT: *Cirsium pitcheri* (Pitcher's thistle)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 8/17/1988; Great Lakes-Big Rivers Region (R3)

**Physical Description**

Pitcher's thistle is a monocarpic (flowers and sets seed only once), perennial, herbaceous plant, generally flowering after a 5-8 year juvenile stage (Loveless 1984). The stems and leaves of juveniles and adults are woolly-white, and the leaves are deeply pinnatifid with the lobes less than 1 centimeter (cm) wide and up to 4 cm long. Minute spines are concentrated along the edge of the leaf at its base, with a few spines between the lobes of the distal leaf margins. The flowering stems are up to 1 meter (m) tall and have several to a dozen widely scattered leaves. Individuals typically have a single branching flowering stem with terminal and axillary flowering heads of a cream or pinkish color. Juveniles and adults have a taproot that may reach 2 m in length (McEachern and Pavlovic pers. obs.). (USFWS, 2002)

**Taxonomy**

This distinctive dune plant, often referred to as the dune thistle, was first noted by Dr. Zina Pitcher about 1827 at the Grand Sable Dunes of the Upper Peninsula of Michigan. The species was first described by Eaton (1829) as Cnicus pitcheri from the type specimen which was apparently collected in 1827 on or near Mackinac Island by Dr. Edwin James (Voss 1996). (USFWS, 2002)

**Historical Range**

Pitcher's thistle (Cirsium pitcheri) is endemic to the beaches and grassland dunes of Lakes Michigan, Superior, and Huron. Distribution of the species extends along the Lake Michigan shoreline in Wisconsin. In the east it ranges through northern Lake Huron to the Manitoulin Island archipelago and southern Georgian Bay in Ontario. Pitcher's thistle extends as far south as Lambton County, Ontario, Canada on Lake Huron, (USFWS, 2002)

**Current Range**

Current distribution is Illinois (Lake County), Indiana (Porter County), and Michigan (Alcona, Alger, Allegan, Alpena, Antrim, Arenac, Benzie, Berrien, Charlevoix, Cheboygan, Chippewa, Delta, Emmet, Grand Traverse, Huron, Iosco, Leelanau, Mackinac, Manistee, Mason, Muskegon, Oceana, Ottawa, Presque Isle, Schoolcraft, Van Buren Counties), and Wisconsin (Door, Manitowoc, and Sheboygan Counties). (USFWS, 2019)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Sexual

**Other Reproductive Information**

Adult: Pitcher's thistle reproduces only sexually. Pollination occurs through a variety of insects but primarily through bees (Hymenoptera). Pitcher's thistle blooms from June to September and is protandrous (pollen maturing before stigmas are receptive on individual flowers), and partially self-compatible (Higman and Penskar 1999). Seed dispersal occurs from June to August (McEachern 1992), depending on latitude, and does so through individual seeds blowing from the inflorescence head or by the whole plant and heads falling to the ground at the end of the growing season. A secondary means of dispersal is by wind blowing seed and seed heads across the sand, snow or water surface (Loveless 1984). The seeds are subject to herbivory by artichoke plume moth larvae (Platyptilia carduidactyla), ground squirrels, birds, especially goldfinches (Spinus tristis), and deer. Seed dormancy is broken by cold, moist stratification (Hamzé and Jolls 2000), with seed germination occurring in May and June (Loveless 1984). After germination, seedlings emerge producing one to six leaves in the first season (Loveless 1984). Seedling densities are greater where bare ground is abundant (McEachern et al. 1989) than in stabilized sites with greater vegetation cover. Juvenile plants typically consist of one rosette and may remain dormant for one or two years as a result of drought (McEachern 1992). The chances of juvenile mortality decrease as the plants increase in size. Causes of mortality include trampling (Keddy and Keddy 1984; Gibson 1988), sand deposition and erosion, drought, and herbivory. Juveniles grow or maintain a constant size throughout the growing season, but may diminish in size over the winter (Loveless 1984; McEachern 1992). Observations indicate juvenile plants in foredunes grow by increasing leaf number, whereas in inland stabilized habitats they grow by increasing leaf size (Loveless 1984). These growth differences may be significant in determining the age when juveniles reach a critical flowering size. The probability of insect herbivory increased with juvenile size, large juvenile density, and population successional stage (Stanforth et al. 1997). However, Rowland and Maun (2001) found that plants negatively affected by herbivory were able to recover and compensate for lost tissue by the following growing season. Conversely, plants subjected to herbivory, required a longer juvenile period to reach reproductive stage, thus increasing the period of vulnerability to herbivory and environmental stresses. Pitcher's thistle typically reaches reproductive age after 5 to 8 years. Reproduction appears to be correlated with habitat as Loveless (1984) found that adults bloom sooner in more stabilized habitats than in foredunes. Specific reproductive triggers are unknown, but the length of the longest leaf (Loveless 1984) and the root crown diameter (McEachern 1992) were found to be significant predictors of timing of reproduction. However, flowering probably involves an interaction between plant size (growth rate) and age, as small plants have also been observed to flower (USFWS 2002). Pitcher's thistle plants exhibit overcompensation as a response to damage (i.e., herbivory) by producing multi-stemmed plants. Multi-stemmed plants produce more seeds per plant and exhibit higher pollination activity than single-stemmed plants (Dao 2013). (USFWS, 2018)

**Reproduction Narrative**

Adult: Cirsium pitcheri is closely related to C. canescens, a thistle of the sand hills of the Great Plains (Ownbey and Hsi 1963). Recent electrophoretic evidence has shown that the thistles share the same genetic loci, but differ greatly in the level of genetic diversity (Loveless and Hamrick 1988). Cirsium pitcheri possesses a much reduced level of genetic variability than does C. canescens, suggesting derivative-progenitor relationship, respectively. It is believed that Pitcher's thistle migrated to the Great Lakes region soon after the close of the Wisconsinan glaciation and that its reduced genetic diversity is a result of repeated and prolonged population bottlenecks (Loveless and Hamrick 1988).Seed germination in C. pitcheri has been observed during June in Ontario (Keddy and Keddy 1984, Keddy 1981), Michigan and Indiana (McEachern et al. 1989). Keddy and Keddy (1984) found that the highest seedling mortality typically occurred in sand substrates, with the lowest in substrate of debris. In a season of drought, Ziemer (pers. comm.) still found seedling survivorship in the species to be fairly high (roughly 40%). Seedling survivorship in her study was found to be highest of the lakeward side of the foredune where active sand deposition and associated grasses (Ammophila and Calamovilfa) were common. Although Keddy and Keddy (1984) found that mortality did not significantly differ between seedlings growing in clusters or individually, Ziemer (pers. comm.) arrived at different conclusions. In her study, seedling survivorship was found to be highest in areas where other seedlings occurred.Once established in the rosette form, mortality is low (Keddy and Keddy 1984). This is, in part, due to the fact that immature plants can withstand burial by up to 15 cm of sand (Weller in litt.) and possess taproots that often reach down 5 to 7 feet, to where available moisture lies (Pepoon 1927). Of 193 rosettes studied in Ontario by Keddy and Keddy (1984), only seven died (due in part to caribou trampling and human intervention). Plume moth (Platyptilia carduidactyla) larvae occur within the centers of rosettes but do not appear to cause mortality (Keddy and Keddy 1984). They can, however, cause injury to the apical meristem of the plant, resulting in a multi-branched parental plant.Cirsium pitcheri is a monocarpic species which exists in a rosette for 5-8 years, flowers the following year, then dies (Crispin and Penskar 1990, McEachern et al. 1989, Dobberpuhl and Gibson 1987). Plants can remain in the rosette form until enough resources have been obtained in the root system to fuel the bolting plant and subsequent seed production (Keddy and Keddy 1984). The proportion of juvenile to adult plants is not unexpectedly skewed in favor of juvenile plants, 71.8% : 28.2% in Door County and 69.8% : 31.2% in Manitowoc County, Wisconsin (Dobberpuhl and Gibson 1987).According to Keddy and Keddy (1984) in Ontario, plants in grassland habitat dominated by beach grass and horsetail produced over twice as many branches and flower heads than plants in the debris habitat or on a crescent beach. Those on the crescent beach were nearly all vertical. This branched growth form may be attributed to the abundance of plume moth (Platyptilia carduidactyla) larvae in the grass habitat (Keddy and Keddy 1984). Attacks, by these larvae typically result in multi-branched individuals, as discussed above.Growth of C. pitcheri plants is also hindered at times by spittlebugs which lay eggs in the meristems of the plants, damaging newly-forming leaves (Crispin and Penskar 1990). This apparently causes mortality in some plants.Flowering begins in late June, peaks in late July, then declines rapidly (McEachern et al. 1989, Loveless 1983). According to Loveless (1983), many plants are dead and dying by early August, but some continue flowering until mid-September. After four to seven days of blooming, flowers begin to wither and die (Keddy 1981). As flowers brown, the involucral bracts gradually close in around them, protecting developing seeds. Flower heads per stalk vary from two to as many as 125 (Keddy 1981).Flower tubes of C. pitcheri contain several micro-liters of sweet-scented nectar secreted by a ridge at the base of the style (Keddy 1981, Knuth 1908). Apparently, a wide array of potential pollinators are attracted to this nectar. Of the 10 species of insects listed as flower visitors in Ontario (Keddy and Keddy 1984) and 23 insect visitors observed by Loveless (1983) in Michigan, only one species was the same, a bumblebee (Bombus perplexus). Insect pollen vectors include species within the genus Bombus (bumble-bees), Megachile (megachilid bees), Melissodes (anthophorid bees), Lasioglossum (small halictid bees), Agapostemon (large halictid bees), and butterflies and skippers of several genera (Loveless 1983). Other visitors to the flowers include flies, wasps, honeybees and sedentary beetles and bugs (Loveless 1983). Keddy and Keddy (1984) listed lepidopterans, dipterans and hymenopterans as flower visitors in Ontario, the most abundant of which was Bombus vagans. Prominent butterfly pollinators included Vanessa cardui and Daneus peleyippus (Crispin and Penskar 1990). Nocturnal visitors have not been studied, but moths are believed to visit the flowers (Loveless 1983). For a species list of known pollen vectors and flower visitors, see Loveless (1983) and Keddy and Keddy (1984).Seed set is known to decline between late July and August in C. pitcheri. This decline in seed set has been attributed, in part, to pollinator availability which parallels this decline (Loveless 1983). Loveless (1983) observed that many plants died prior to maturing a single flower head, suggesting that the species allocates its resources early in the season when the likelihood of maturing fruits is highest.The artichoke plume moth (Platyptilia carduidactyla) larvae feed on the immature seeds of C. pitcheri, sometimes causing flower mortality (McEachern et al. 1989, Keddy and Keddy 1984). This insect has been observed by Loveless (1983) in Michigan, Keddy and Keddy (1984) in Ontario, and Dobberpuhl and Gibson (1987) in Wisconsin. In Ontario, Keddy and Keddy (1984) found that most plants were affected by the moth only in July, with predation highest in a grass habitat. Fewer plants were infected in a habitat of debris, while predation was non-existent in a crescent beach population. Loveless (1983), however, found that levels of seed damage in various habitats were nearly equal, suggesting that seed predation was density-dependant. In addition, Loveless observed that seed predation in Michigan did not markedly change throughout the season. For a brief description of the plume moth life cycle, see Keddy (1981). McEachern (pers. comm.) stated that she had observed a larva within the flower head in Michigan but is unsure as to its identity at this time.Mosquin et al. (1986) suggested that the presence of the plume moth in C. pitcheri populations may be mutually beneficial. Presence of larvae in the rosettes of C. pitcheri causes the plant to become multi-branched (Keddy and Keddy 1984). As a consequence, more flowers and seeds are produced. At present, there is little information to substantiate this hypothesis. In addition, the moth is also known to feed on the seeds of the thistle, so there may be a simple trade off or net loss of seed production despite the multiple-branched stemming of the plant. Keddy and Keddy (1984), in fact, suggested that up to 40% of the normal seed crop was lost in a given year in Ontario as a result of the moth predation.American goldfinches were observed to devour approximately 50% of the seeds within a given flowerhead (Loveless 1984). Other birds, primarily sparrows, forage on unburied seeds. The thirteen-lined ground squirrel (Spermophilus tridecemlineatus) is ;   (NatureServe, 2015)

**Habitat Type**

Adult: Great Lakes sand dunes

**Environmental Specificity**

Adult: Broad (USFWS, 2016)

**Habitat Narrative**

Adult: Cirsium pitcheri occurs most prominently in Michigan, occurring in 18 counties along the shorelines of Lakes Michigan, Huron and Superior (Nepstad 1981). In Wisconsin, the species currently exists in eight sites in four counties on the Lake Superior shoreline (Alverson 1981). The species occurs at seven extant sites along Lake Michigan in Indiana (IN NHP 1989), but has been extirpated from Illinois (Sidle 1987, White 1981). It is also known from roughly 12 extant sites in Ontario, including a population on the shoreline of Lake Superior (Keddy and Keddy 1984, Keddy 1988).Pitcher's thistle is a regional endemic restricted to the dune habitats in the western Great Lakes region (USFWS 1987, Dobberpuhl and Gibson 1987, Keddy and Keddy 1984, Loveless 1983, Guire and Voss 1963). The species is a colonizer on open dune ridges, dune blowouts, and along disturbed sites in sand dunes, but is found on stabilized grassy sand terraces, sandy gravel flats and dune valleys as well (Loveless 1983). In all habitat types, however, the species appears to establish itself only in very open, sandy soil (Loveless 1983).McEachern et al. (1989) described the habitats associated with the lakeshores as: 1) extremely exposed open communities on lake level foredunes and dune bluff edges dominated by Ammophila breviligulata, 2) transitional communities dominated by three dune grasses, A. breviligulata, Calamovilfa longifolia and Schizachyrium scoparium, and 3) stabilized inland blowouts characterized by S. scoparium/C. longifolia codominance and moderate vegetation and litter accumulation. These three habitat types mark a successional gradient, in which A. breviligulata, adapted to high rates of sand deposition occurring in the shoreline habitats, is replaced by the more competitive C. longifolia and finally, S. scoparium in progressively stable inland areas (McEachern et al. 1989). Associated with this change in dominant vegetation along a shoreline to inland transect, there is an equally significant reduction in the percentage of bare ground. This amount of bare ground is apparently significant, for it is in the most stable, S. scoparium dominated areas that C. pitcheri is the least abundant (McEachern et al. 1989).In Michigan, C. pitcheri is most common along the northern and northeastern shore of Lake Michigan, although small populations are known from the southeastern shores of Lake Michigan and northern Lake Huron (Crispin and Penskar 1990). A few populations also occur along Lake Superior. Cirsium pitcheri typically grows in association with Ammophila breviligulata, Schizachyrium scoparium, Arabis lyrata, Arctostaphylos uva-ursi, Calamovilfa longifolia and Agropyron dasystachyum (Crispin and Penskar 1990, MI NFI 1990). At disturbed sites, Asclepias syriaca may be present (Crispin and Penskar 1990).At Sleeping Bear Dunes National Lakeshore in Michigan, the species is apparently doing well, even in the intensely utilized areas around the marina (Hazlett and van de Kopple 1983). A recent survey by McEachern et al. (1989) found that C. pitcheri was occupying much of its potential habitat: foredunes, blowouts, dune ridges, valleys and slopes. Although C. pitcheri was least common from the backslopes of inland dunes, localized populations were found there as well.On the Manitou Islands portion of Sleeping Bear Lakeshore, plants have been found on perched (260 feet above Lake Michigan, on glacial moraines) and coastal dunes. McEachern et al. (1989) found that plants growing on the dunes of South Manitou Island appeared more stunted and were more dispersed than those on the mainland, possibly reflecting the harsher environment of the island. Associates on a gravel lag behind a coastal dune complex at Dimmick's Point on North Manitou Island include Agropyron dasystachyum, Schizachyrium scoparium, Anemone multifida, Artemisia caudata, Betula papyrifera, Campanula rotundifolia, Carex garberi, Thuja occidentalis and Zygadenus glaucus with an overstory of Betula papyrifera. Associates in a dune blowout on South Manitou include Schizachyrium scoparium, Anemone multifida, Arctostaphylos uva-ursi, Arenaria stricta, Aster sp., Calamovilfa longifolia, Coreopsis palmata, Equisetum hyemale, Ostrya virginiana, Polygonatum pubescens, Prunus virginiana, Trientalis borealis, Trillium grandiflorum, Viburnum acerifolium, Viola canadensis and Viola sp. (Hazlett and van de Kopple 1983). For additional habitat information pertinent to Sleeping Bear National Lakeshore, see McEachern et al. (1989), Hazlett (1986) and Loveless (1983).At Grand Sable Dunes within the Pictured Rocks National Lakeshore of Michigan, McEachern et al. (1989) found the populations occupying dune and blowout habitats ranging from the dune bluff inland to wooded areas. In contrast to Sleeping Bear, populations were scattered and were far less abundant. For habitat information concerning populations at Pictured Rocks National Lakeshore, see McEachern et al. (1989).Within the state of Indiana, plants have been observed on dunes, foredunes, blowouts and beaches along Lake Michigan (IN NHP 1989). At the Indiana Dunes National Lakeshore, Bowles et al. (1985) found Cirsium pitcheri restricted to early and mid-successional blowouts on the high dunes adjacent to Lake Michigan. It appeared to be absent from the first foredune. Sites were extremely well-drained and support sparse dry sand prairie-like communities (Bowles et al. 1985). A recent survey of the site by McEachern et al. (1989) produced similar conclusions. In all, six small populations were found, all on the steep, lakeward-facing slopes or grassland blowouts of the secondary dunes. No plants were observed on the beach and foredune complexes still rebuilding since the high-water levels of 1986 and 1987.Dobberpuhl and Gibson (1987) stated that in Wisconsin, the plant is found in three habitats: (1) dry sand of partially-stabilized dunes along Lake Michigan, (2) dry, open areas of loose sand (sand blowouts) behind the main foredune and infrequently on (3) low, moist to wet beaches. Colonies thrive best in situations where the dunes are somewhat stabilized, in various slope aspects and degrees of steepness. Two populations in Wisconsin are at the mouths of creeks, where continual sand deposition from the creeks provides new habitat and increasing site longevity (WI NHP 1990, Dobberpuhl and Gibson 1987). Associated plants species in Wisconsin include Agropyron dasystachyum, Calamovilfa longifolia var. magna, Elymus canadensis, Ammophila breviligulata, Agropyron trachycaulon, Artemisia caudata, Lathyrus maritimus, Oenothera parviflora, Potentilla anserina and Solidago gillmani (WI NHP 1990, Alverson 1979, Johnson and Iltis 1963).In Canada, C. pitcheri is found only in Ontario on sandy beaches and dunes of the shores of Lake Huron and Georgian Bay (Moore and Frankton 1974) and Lake Superior (Keddy and Keddy 1984, Keddy 1981). At Lake Superior sites in Pukaskwa National Park, plants grow approximately 1-2 meters above the lake level on gently sloping sand beaches in three distinct habitats: 1) grass (dominated by Ammophila breviligulata and Equisetum variegatum), 2) debris (dominated by Prunus pumila and Festuca saximontana) and 3) shrub (dominated by Juniperus horizontalis and Arctostaphylos uva-ursi) (Keddy and Keddy 1984, Keddy 1981). Most plants (79%) were found in the grass habitat, with 21% growing in the debris habitat. Less than 1% were found in the shrub habitat (NatureServe, 2015). The Pitcher's thistle (Cirsium pitcheri), also known as dune thistle, is a Great Lakes endemic that is typically found on open beaches and grassland dunes and occasionally on lag gravel associated with the shoreline dunes. The Service listed Pitcher's thistle as a threatened species under the Act on July 18, 1988 (USFWS 2002). Pitcher's thistle is one of a few plant species endemic to the post-Wisconsinan Great Lakes sand dunes. It is found most frequently in the near-shore plant communities where it colonizes patches of open, windblown areas of the landscape. The species gradually declines locally as the density of vegetation and ground litter increases through plant succession and in areas heavily used by people. Pitcher's thistle density peaks in mid-successional habitats and requires 70% open sand for successful seedling establishment and survival (McEachern 1992). Healthy populations of Pitcher's thistle are an indication of the general well-being of dune ecosystems. No species is known to depend completely on Pitcher's thistle. However, the rust, Puccinia laschii, that is sometimes found on adult Pitcher's thistle leaves may be host-specific, and therefore, dependent on it (Saville 1970). In addition, Pitcher's thistle is a food (pollen, nectar, and seed) source for many organisms (Keddy and Keddy 1984; Loveless 1984). Pitcher's thistle depends on the geomorphic processes that maintain dune systems to create sparsely vegetated habitats where successful population growth can occur. Populations are prone to extirpation due to successional change, erosional loss, and catastrophic events depending on their location. A shifting mosaic of dune processes on a large dune system landscape can ensure this species' persistence as long as seed is available to disperse to existing or newly created adjacent suitable habitats. For a particular occurrence of Pitcher's thistle to survive, disturbance must be frequent enough to prevent extirpation from succession and infrequent enough to allow juveniles to reach maturity; thus, the Pitcher's thistle life history is finely tuned to a specific disturbance regime (McEachern 1992). Disturbances may eliminate local occurrences, but as long as those disturbances are not synchronous throughout the landscape and occurrence creation exceeds decline, the species will persist (Pavlovic 1994).

***Dispersal/Migration***

**Dispersal/Migration Narrative**

Adult: Seed dispersal occurs from June to August (McEachern 1992), depending on latitude, and does so through individual seeds blowing from the inflorescence head or by the whole plant and heads falling to the ground at the end of the growing season. A secondary means of dispersal is by wind blowing seed and seed heads across the sand, snow or water surface (Loveless 1984). The seeds are subject to herbivory by artichoke plume moth larvae (Platyptilia carduidactyla), ground squirrels, birds, especially goldfinches (Spinus tristis), and deer.

***Population Information and Trends***

**Number of Populations:**

222 (USFWS, 2023)

**Population Size:**

> 1,000,000 in the U.S. (USFWS, 2023)

**Population Narrative:**

NatureServe (2023) notes there “are an estimated 50,000 plants in Canada, 10,000 to 20,000 in Wisconsin, 500-1000 in Indiana, and possibly over 1,000,000 individuals in Michigan (Slaughter and Cuthrell 2017)” and that over “the last 10 years this species has remained stable in Michigan, stable to slightly increased in Canada, declined >50% in Indiana, and stable to declined <25% in Wisconsin.” There is a total of 222 known occurrences of PITH in the United States (Figure 1). In Michigan, there are 182 extant occurrences, in Indiana there are 24 extant occurrences, in Illinois there are 5 known occurrences, and in Wisconsin there are 11 extant occurrences (personal comm. Pavlovic 2023). At the time of the previous 5-year review in 2018, several of the EOs that were found to be decreasing were located in southern Lower Michigan (Slaughter and Cuthrell 2017), and it was stated that inbreeding depression and other factors could leave EOs in southern Michigan prone to extirpation, resulting in fragmentation and isolation of remaining colony sites in other parts of the southern Great Lakes (Gauthier et al. 2010, Slaughter and Cuthrell 2017). There are 45 populations of PITH now known in Canada. Three populations at Pukaskwa National Park were surveyed annually between 1982 and 2015, and an additional 33 populations on Lake Huron were monitored annually between 2000 and 2017, with methods standardized in 2004 (Nantel et al. 2018). Monitoring at each location consisted in recording the total number of plants by life stage (i.e., seedling, rosette, or mature/flowering). Overall, habitat size increased from 2000 to 2010, stayed relatively constant until 2015, and has decreased since then (Nantel et al. 2018) (USFWS, 2023).

***Threats and Stressors***

**Stressor:** Habitat destruction (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Pitcher’s thistle is threatened by habitat destruction, overuse, and repeated disturbance from trampling by beach and dune visitors and off-road vehicles. Approximately ten

percent of its population has been lost, modified or curtailed through these actions. Some populations have also been lost or negatively impacted through alteration of local dune geomorphic processes, which prevent the creation and maintenance of Pitcher's thistle habitat. In addition, shoreline stabilization projects, such as sea walls, rip rap, and planting of beach grass, northern white cedar, and some non-native species, also alter dune building processes and may decrease habitat available to Pitcher's thistle. (USFWS, 2016)

**Stressor:** Non-native and invasive species
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Encroachment by non-native and invasive species, such as spotted knapweed, baby's breath, and Lombardy poplar, also pose a threat to Pitcher's thistle. For example, spotted knapweed is known to negatively influence the soil in its vicinity to prevent the growth of native species (Louda et al. unpub. data 2007), as well as out-compete native species for resources. The introduction and spread of non-native insect species for biological control is an additional threat. Two species of non-native weevils used for biological control have been documented in Michigan, as well as some of the surrounding states, and these newly emerging threats place the range-wide existence of Pitcher's thistle at risk. These non-native weevils oviposit eggs near the base of developing seed heads (Louda et al. 1997, Louda et al. 2005, McEachern and Pavlovic 2013). Larvae develop inside the receptacle tissue at the base of the head, feeding on receptacle and eventually seeds within the ovary (Louda et al. 1997, Louda et al. 2005, McEachern and Pavlovic 2013). As the seed head matures, the weevils emerge as adults, often leaving visible exit holes at the base of the head (McEachern and Pavlovic 2013). The weevils' actions prevent seeds from forming or flowering. Flowerhead weevil (Rhinocyllus conicus) was introduced from Europe in 1969 to control Carduus species, especially musk thistles (Carduus nutans) and others plants (Rees 1982, Bradley 2007, Sauer and Bradley 2008). The weevil also develops on multiple native Cirsium species in the United States (Goeden and Ricker 1986a, 1986b, 1987a, 1987b; Turner et al. 1987; Louda et al. 1997). Laboratory and garden host specificity tests revealed that flowerhead weevils fed, oviposited, and developed completely on Pitcher's thistle, as well as its target species, and taller Pitcher's thistle plants with more flowerheads were significantly more vulnerable to the weevil (Louda et al. 2005). Rhinocyllus conicus has been documented in Wisconsin, where it was released in 1975, with a second release in 1978 (Sauer and Bradley 2008). It has since spread to several other counties (Sauer and Bradley 2008); however, it has not yet been documented in wild populations of Pitcher's thistle in the state. The weevil was also found on Pitcher's thistle in a common garden at Chicago Botanic Garden (CBG) in 2007 (J. Fant, CBG, pers. comm. 2007; N. Pavlovic, USGS, pers. comm., 2007) and in a Pitcher's thistle nursery at Illinois Beach State Park near a restoration site in 2011 (Bell and Hankins, unpublished, cited in McEachern and Pavlovic 2013). In 2012, R. conicus was collected from Pitcher's thistle at the Miller Dunes unit of the Indiana Dunes National Lakeshore (McEachern and Pavlovic 2013). Based on the 2012 surveys conducted in Michigan, the weevil was observed on musk thistles in Jackson and Lenawee counties (D. Landis, Michigan State University, pers. comm. 2012), which are not within range of Pitcher's thistle. A greenhouse test documented the weevil in approximately 40% of Pitcher's thistle seed heads and reduced seed set by 95% in those heads during the first year of infestation (Louda et al. 2005, Havens et al. 2012a). A demographic model suggests that R. conicus will reduce Pitcher's thistle population growth rate by 15% per year and the time to halve the population size from 66.9 years to 4.0–4.0 years (K. McEachern, USGS, pers. comm. 2011). In addition to reducing seed numbers in Pitcher's thistle, R. conicus predation is also

expected to reduce seed mass (M. Bowles, The Morton Arboretum, pers. comm. 2013). Larinus planus, a seed-eating weevil, was inadvertently introduced into the U.S. from Eurasia in the 1960s and has since been redistributed for control of Canada thistle (Cirsium arvense L.) (White 1972, Havens et al. 2012a, McEachern and Pavlovic 2013). In 2010, L. planus was first documented in Pitcher's thistle populations at Whitefish Dunes State Park, Door County, Wisconsin, in approximately one-third of examined seed heads (Havens et al. 2012). No viable seeds were found in those heads (Havens et al. 2012a). A more extensive survey of the Whitefish Dunes population in 2011 found the weevil in half the seed heads and almost no viable seeds (Havens et al. 2012a). Subsequent surveys of public and private lands throughout the Door Peninsula found L. planus in every Pitcher's thistle population (Havens et al. 2012a). In 2012, three Pitcher's thistle heads collected from research plots at Wilderness State Park, Emmet County, Michigan, had adult L. planus emerge from the flower heads in late-July 2012 (Havens et al. 2012b). Consequently, a more extensive search for the weevil was conducted at six element occurrences of Pitcher's thistle at Wilderness in mid-August 2012. Suspected weevil-damaged seed heads were collected and sent to CBG to examine for L. planus infestation. Although CBG found no adult weevils, most element occurrences had at least one damaged seed-head that was consistent with the weevil damage observed in Wisconsin, which consisted of one or more of the following characteristics: destruction of all or nearly all developing seeds, mass of digested ovules, seeds, frass remnants, and a pupal chamber visible in the receptacle tissue (Havens et al. 2012b). Currently, there is limited knowledge about the life-history of weevils, their relationships with Pitcher's thistle, and lack of knowledge of how to control the weevils along Great Lakes shoreline. (USFWS, 2016)

**Stressor:** Seed predation (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Pitcher's thistle seeds are subject to pre- and post- dispersal herbivory (USFWS 2002). American goldfinches (Spinus tristis) are one of the species listed in the recovery plan as being a pre-dispersal herbivore of Pitcher's thistle (USFWS 2002). The goldfinches have recently become more abundant at Indiana Dunes National Lakeshore (IDNL) and have been observed feeding on Pitcher's thistle seeds, prying open the phyllaries as seeds are developing, often consuming 90% of the seed crop of an individual thistle plant (McEachern and Pavlovic 2013). Miller High Dunes of IDNL has had up to 100% seed predation by goldfinches (Pavlovic, pers. comm. 2013). With the already small and declining populations of Pitcher's thistle at IDNL, the increase in goldfinch seed feeding has compounded the potential weevil threat (McEachern and Pavlovic 2013). (USFWS, 2016)

**Stressor:** Inadequate regulation (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Government units below State level generally do not provide adequate protection for rare plants. A few townships passed zoning ordinances designed to protect some natural resources, but other townships with outdated zoning ordinances remain ill-equipped to deal with current development. At the State level, MDEQ continues to permit home development in Critical Dune Areas. Although permits may include conditions to avoid immediate loss of existing plants, these permits do not address fragmentation or potential alteration of dune-sustaining

processes. The State of Michigan has no authority to require protection of plants from indirect effects and does not require State-level endangered species permits if direct impacts to the species are not expected. In Wisconsin, State agencies do not have authority to protect listed species from impacts on private lands unless the activity otherwise requires a Federal permit or funding. (USFWS, 2016)

**Stressor:** Climate Change (USFWS, 2016)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Our analyses under the Act include consideration of ongoing and projected changes in climate. The terms “climate” and “climate change” are defined by the Intergovernmental Panel on Climate Change (IPCC). “Climate” refers to the mean and variability of different types of weather conditions over time, with 30 years being a typical period for such measurements, although shorter or longer periods also may be used (IPCC 2007). The term “climate change” thus refers to a change in the mean or variability of one or more measures of climate (e.g., temperature or precipitation) that persists for an extended period, typically decades or longer, whether the change is due to natural variability, human activity, or both (IPCC 2007). Various types of changes in climate can have direct or indirect effects on species. These effects may be positive, neutral, or negative and they may change over time, depending on the species and other relevant considerations, such as the effects of interactions of climate with other variables (e.g., habitat fragmentation) (IPCC 2007). In our analyses, we use our expert judgment to weigh relevant information, including uncertainty, in our consideration of various aspects of climate change. In the Great Lakes region, the climate will likely grow warmer and probably drier overall during the 21st century (Kling et al. 2003). Although average annual precipitation may increase slightly by the end of the century, seasonal precipitation cycles are predicted to become more extreme. Winter and spring rains are likely to increase, while summer rains are expected to decrease by up to 50 percent. These potential impacts of climate change are increasingly evident in the Great Lakes region. Summer lake water temperatures are increasing, with Lake Superior’s average summer surface water temperature increasing by 4.5° F since 1980 (Austin and Colman 2007). Ice forms later and melts earlier throughout the region. Earlier models had indicated that altered precipitation patterns, higher air temperatures, and reduced ice cover would increase evaporation in the Great Lakes, resulting in lake level drops of 1.5 feet to as much as 8 feet (Sousounis and Glick 2000; AMEC 2006; Kling et al. 2003). However, more recent models show a more variable response in lake levels. A majority of the model simulations run by Angel and Kunkel (2010) resulted in reductions in lake levels, yet also showed a high degree of uncertainty in possible future lake levels, depending on future emissions. Furthermore, Hayhoe et al. (2010) suggest that the competing effects of shifting precipitation and warmer temperatures will result in little change in Great Lake levels until the end of the century, when net decreases in lake levels are expected under higher emission scenarios. If Great Lakes levels recede, more dune formation may occur, potentially increasing habitat for shoreline occurrences of Pitcher’s thistle (M. Penskar, Michigan Natural Features Inventory, pers. comm. 2009). Increased water temperatures will also result in decreased ice cover that when combined with an expected intensity of winter storms, will leave coastal areas more vulnerable to the effects of winter storms and flooding (Fang and Stefan 2000; AMEC 2006), altering Pitcher’s thistle habitat. A warmer climate could also bring about a northward shift and an even greater increase in invasive species that may be more problematic in the dunes and lakeshore systems, thus increasing competition with native plant species (Malcolm et al. 2002; AMEC 2006; Penskar, pers. comm.

2009). (USFWS, 2016)

**Stressor:** Development (USFWS, 2023)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of the 2002 Recovery Plan, about 39% of the extant occurrences in the U.S. were in public ownership and an additional 20% occurred on a mix of public and private ownership. The public ownership includes populations at three National Park Service units, two National Forests, two National Wildlife Refuge units, several State Parks, and other types of protected State or local public lands. In addition, several PITH occurrences are on privately held land conservation lands (e.g., Door County Land Trust, Land Conservancy of West Michigan, Little Traverse Conservancy, Michigan Nature Association, The Nature Conservancy, etc.). In Canada, of the 30 total extant populations assessed in 2010, 4 small populations were noted in National or Provincial parks (COSEWIC 2010). As part of the Species Status Assessment, we will update and access the land ownership of the PITH occurrences as part of evaluating potential threats. Private lands supporting PITH are subject to both pressures for new development and shore protection for existing structures. Between 1992 – 2001, over 21% of all newly developed land within the Great Lakes watershed occurred within 10 km of the Great Lakes shoreline (an area which makes up 0.27% of the watershed) (Wolter et al. 2006). Much of this loss of shoreline habitat is due to urban or suburban sprawl, including second home development (Wolter et al. 2006). The strongest predictors of the distribution of second homes in the Upper Great Lakes were the presence of natural areas and the presence of water (Shellito 2006). When Great lakes water levels are high the demand for adding shoreline protection measures can increase significantly. The State of Michigan reported a nearly ten-fold increase in approved permits Great Lakes shoreline protection from Fiscal Year (FY) 2019 to FY2020's total (i.e., 2,238 shoreline protection permits approved in FY2020). Several PITH populations are also affected by sand mining (Slaughter and Cuthrell 2017). The loss and development of shoreline habitat makes it more difficult for shoreline ecosystems to shift in space with water level fluctuations as they once could (USFWS, 2023).

***Recovery***

**Reclassification Criteria:**
Not applicable.

Recovery Priority Number: 8C

**Delisting Criteria:**
1. The essential habitat associated with a total of 115 priority occurrences representing each biogeographic region and dune type is protected and managed under a management plan, including: a) all Federal and State owned essential habitat and occurrences, b) all publicly and privately-owned essential habitat and occurrences having a rank of A, AB, B, or BC, c) all occurrences in southern Lower Michigan, Indiana, and Wisconsin, and d) all complex perched dune systems. (USFWS, 2002)

2. Regular field surveys to verify occurrences and record new occurrences have been established. (USFWS, 2002)

3. Landowner contacts have been initiated and protection has been investigated for the remaining (rank < BC) public and private occurrences. (USFWS, 2002)

4. Monitoring of known sites shows a stable or increasing trend toward recovery and that protective plans are being implemented. (USFWS, 2002)

5. Restoration of two occurrences from among historical sites where sufficient habitat remains in Illinois, Indiana, Wisconsin, and southern Lower Michigan has been completed. (USFWS, 2002)

6. Research necessary to protect, manage and restore Pitcher's thistle has been conducted. (USFWS, 2002)

**Recovery Actions:**

- 1. Protect and manage known occurrences and essential habitat, giving priority to essential habitat. To ensure the long-term perpetuation of Cirsium pitcheri, planned protection for all 115 priority occurrences must occur and the remaining lower priority sites should receive some protection. Protection strategies will depend on cooperation between Federal and State agencies, private conservation organizations, regional planning councils, local jurisdictions, private developers and landowners. Principal cooperators include State and provincial resource agencies, The Nature Conservancy (TNC), The Nature Conservancy of Canada, the Center for the Great Lakes' Great Legacy program, the U. S. Forest Service (USFS), the National Park Service (NPS), and the U. S. Fish and Wildlife Service (Service). Working together should assure the highest level of protection for each site (USFWS, 2002)
- 2. Establish and conduct ongoing field surveys to verify known and record new occurrences. Pitcher's thistle is highly dependent upon the fluctuating environment of its lakeshore habitat. Therefore it is important to monitor the status of populations and habitats on a regular basis over periods of several decades to detect responses to fluctuating lake levels and habitat changes. Monitoring of sites is necessary for effective management. The monitoring should be designed to detect fluctuations in Pitcher's thistle population size and age class distribution and collect information on age at flowering. This will permit assessment of implemented management actions and determine if remedial action is required. (USFWS, 2002)
- 3. Inform the public, recreationists, public land managers, and private landowners. Knowledgeable individuals are an important part of the recovery process. Informing managers, recreational groups and landowners about Pitcher's thistle, its status as a protected species, and protection methods is an important step toward cooperative protection and management. Accurate and current information can foster interest and appreciation for the Pitcher's thistle. Groups such as the Michigan Nature Association, Michigan Natural Areas Council, The Nature Conservancy, The Nature Conservancy of Canada, Center for the Great Lakes, the International Joint Commission, Federal, State, provincial and local resource agencies, and local Audubon groups and garden clubs should be kept informed of recovery efforts. Federal land managers must be aware of the need to protect, and methods of protecting, Pitcher's thistle on Federal lands to facilitate decisions that will protect the species. Cooperators will develop, distribute, and update information and make recommendations for managers to protect Pitcher's thistle and its essential habitat. Information sent to individual managers will include the location of occurrences and

essential habitat, as well as the specific known and suspected threats to the species under the manager’s care. Public utilities, with their promotion of environmental programs, may underwrite or sponsor public awareness campaigns. Resource agencies may encourage greater conservation through liaisons with public utilities. (USFWS, 2002)

- 4. Monitor occurrences for stable and increasing trends and implementation of protective plans. Protective management of Pitcher’s thistle requires knowledge of its current status and threats. Inventory must incorporate population size, quality, and threats to be useful for scientific assessment and planning. (USFWS, 2002)
- 5. Restore Pitcher’s thistle to an element rank of at least BC on at least one appropriate site within its historical range. C. pitcheri has been extirpated from parts of its natural range, so restoration is necessary to recover Pitcher’s thistle throughout the area addressed in the recovery objective. Restoration is intended to recolonize sites where the species formerly occurred and cannot be used as justification or mitigation for destruction of an existing high quality occurrence elsewhere. Restoration planning should be integrated with ongoing interagency coordination and should be complementary and reinforcing. Restoration guidelines are needed in order to meet the objective of preserving populations throughout the species range. (USFWS, 2002)
- 6. Conduct research necessary for protection, management, and restoration. Answers to questions related to seed production, viability, dispersal distances, and predation would allow managers to assess risk to the species from different management scenarios. Improved understanding about the needs of Pitcher’s thistle would focus management goals for the species and lead to better protection of Pitcher’s thistle habitat(USFWS, 2002)
- Continue to plan and implement regular surveys, monitor occurrences, and document habitat conditions and population trends at all Pitcher's thistle locations. (USFWS, 2018)
- Monitor an approach of using biocontrol insects to manage non-native plant species. (USFWS, 2018)
- Seek funding opportunities to support research that addresses the following knowledge gaps: Demographic features of Pitcher's thistle populations located on Sleeping Bear Dunes National Lakeshore and other NPS properties within the Great Lakes region. Assess the threat of invasive weevils, including Larinus planus. . (USFWS, 2018)
- Work with partners to conduct a population viability analysis or similar for Pitcher's thistle . (USFWS, 2018)
- Complete Pitcher's Thistle Species Status Assessment (SSA) by 2024. Investigate whether possible extirpation of populations in southern Michigan is significant in terms of representation. (USFWS, 2018)

***Conservation Measures and Best Management Practices:***

- Recommendations for future actions • Continue to plan and implement regular surveys, monitor occurrences, and document habitat conditions and population trends at PITH locations. (Recovery Plan Action 2, 4 & 6)) • Monitor an approach of using biocontrol insects to manage non-native plant species. • Seek funding opportunities to support research that addresses the following knowledge gaps that assess the threat of invasive weevils, including Larinus carlinae. (Recovery Plan Action 4.41)) • Complete PITH Species Status Assessment by 2024. o Investigate whether possible extirpation of populations in southern Michigan is significant in terms of representation (USFWS, 2023).

# SPECIES ACCOUNT: *Cirsium vinaceum* (Sacramento Mountains thistle)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened; 06/16/1987; Southwest Region (R2) (USFWS, 2016)

**Physical Description**

A robust perennial herb with a purple stem that grows up to 2 m tall. The deeply lobed, spine-tipped leaves can be as long as 5 dm. Many nodding, white to purple flower heads appear in late summer. The plant's nectar is highly attractive to hummingbirds, bees, and butterflies (NatureServe, 2015).

**Taxonomy**

It was originally named Carduus vinaceus in accordance with generic concepts at that time. Wooton and Standley (1915) later combined it with the genus Cirsium where it was maintained by Petrak (1917) in his revision of the North American species of Cirsium. Although Cirsium is a common genus in the New Mexico flora, Cirsium vinaceum is a distinctive species with no close relatives within its range of occurrence. Its closest relative is the Mexican species, Cirsium conspicuum (USFWS, 1993).

**Historical Range**

Endemic to the Sacramento Mountains of south-central New Mexico (Otero County) (USFWS, 2010).

**Current Range**

The range occurs approximately 6 mi northeast to 17 mi south of Cloudcroft. Greater than 95% of the known thistle habitats occur on the Lincoln National Forest (USFWS, 2010).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual: vegetative (USFWS, 2010); sexual (inferred from USFWS, 1993)

**Key Resources Needed for Breeding**

Adult: Insect and hummingbird pollinators (USFWS, 1993)

**Reproduction Narrative**

Adult: This species is a monocarpic, short-lived perennial initially forming robust rosettes of spiny leaves that live for one or more years as juvenile plants (Burks 1994). It is capable of root sprouting to produce multiple rosettes (clones) per genetic individual (USFWS, 2010). Pollen vectors include hummingbirds and numerous species of bees, beetles, flies, and moths (USFWS, 1993).

**Habitat Type**

Adult: Riparian (NatureServe, 2015); wetland (USFWS, 2010)

**Habitat Vegetation or Surface Water Classification**

Adult: Stream banks, wet meadows (NatureServe, 2015); conifer forest, valley (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**

Adult: 2,460 - 3,020 m elevation (USFWS, 2010)

**Spatial Arrangements of the Population**

Adult: Dense patches (USFWS, 2010)

**Environmental Specificity**

Adult: Moderate (NatureServe, 2015)

**Habitat Narrative**

Adult: Inhabits moist banks of streams, wet meadows, and other moist areas. Remaining populations are mostly in the vicinity of springs flowing out of limestone, where steep calcium carbonate deposits have formed. These receive less grazing and trampling than the surrounding flat areas and have provided a refuge for the species. The environmental specificity is moderate; it is an obligate wetland species that is dependent on streams or springs (NatureServe, 2015). It is endemic to elevations between 2,460 and 3,020 m. It is a wetland-obligate species inhabiting saturated alkaline soils in valley bottoms. Many of the travertine deposits are covered with dense patches of C. vinaceum to the point of being nearly a monoculture of this species (Thomson 1991). Thistle habitats occur in mixed conifer forests and open valleys (USFWS, 2010).

***Dispersal/Migration***

**Dispersal**

Adult: Low to moderate (inferred from USFWS, 2010; 1993)

**Dispersal/Migration Narrative**

Adult: Craddock and Huenneke (1997) determined that stream flow dispersal and occasional thistle establishment in streamside habitats were sufficient to genetically link some discrete patches of thistles (USFWS, 2010). The seed is heavy, but fairly dispersible by wind. Therefore, gene flow from pollen vectors and seed dispersal is probably effective up to about 0.5 mile (USFWS, 1993).

***Population Information and Trends***

**Population Trends:**

Declining (USFWS, 2022)

**Species Trends:**

Declining (USFWS, 2022)

**Number of Populations:**

~20 (NatureServe, 2015)

**Population Size:**

100,000 - 1,000,000 individuals (NatureServe, 2015)

**Population Narrative:**

Thirty-seven+ occurrences (10/96), but some may be part of a continuous population resulting in about 20 populations (11/12). Five populations were extirpated between 1995 and 2007 (10 - 30% decline). The estimated population size is 100,000 - 1,000,000 individuals (NatureServe, 2015). Overall, the Sacramento Mountains thistle appears to continue to be declining across all known locations; however, because survey methods used to count populations prior to 2010 were not available for replication, it is likely that surveys conducted in 2012 and 2018 undercounted the number of thistle rosettes. The population estimates recorded during 2012 were significantly lower that previous census counts (Roth, 2013) but remain relatively unchanged from 2013 to 2018, based on limited survey data from the Lincoln National Forest. Similarly, native and non-native insects are likely contributing to the species decline by depredating seeds and lowering the seed set, as well as lowering fecundity (Sivinski, 2007; Roth, 2013); however, the number of populations with predatory insects does not appear to have expanded beyond those identified by Roth in 2013. Fecundity may also be low due to low pollination success possibly caused by inbreeding depression; a phenomenon associated with small, isolated populations (Roth, 2013), or due to asynchronous timing between when thistles flowering and pollinator availability. Drought has likely played an increasing role in the number and distribution of Sacramento Mountains thistle by reducing overall habitat availability since the previous review was completed, with New Mexico experiencing years mixed with below average and above average precipitation. The role that drought has played in reducing the availability of habitat and resources has yet to be studied fully for the thistle. Declines in the thistle population size and distribution have mainly been contributed to a combination of drought, insect predation, and herbivory by livestock during the growing season (Roth, 2013), with no ranking of the threats provided. Some of these threats could be ameliorated using existing regulatory mechanisms (e.g., livestock herbivory) and some may be uncontrollable (e.g., insect predation, drought) by land management agencies. The Sacramento Mountains thistle is currently listed as a threatened species, i.e., one that is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range. As a wetland obligate species, the thistle occurs exclusively at springs, seeps, or drainage areas that are affected by drought and other resource management practices. Though there appears to be a continued decline of reproducing thistles, actual counts of reproductive individuals appear similar between surveys conducted in 2013 and 2018. The presence of predatory insects in thistle populations has been documented since the early 2000s. The apparent expansion of these insects into different populations of Sacramento Mountains thistle is likely an artifact of additional, targeted survey specifically looking for insect infestation. All other threats identified for the species in its recovery plan and in the last 5-year review remain unchanged; thus, because of the continued threats to this species, we recommend that the Sacramento Mountains thistle should retain its current listing status as a threatened species.(USFWS, 2022)

***Threats and Stressors***

**Stressor:** Water diversions/altered hydrology (USFWS, 2010)
**Exposure:**
**Response:**

**Consequence:**
**Narrative:** Appropriation of water rights from springs for uses such as livestock water, farming, domestic use, or recreational facilities, usually uses points of diversion that curtail natural surface flows. One diversion for a residential subdivision currently is taking water from an aquifer on private property above a small thistle habitat in Fresnal Canyon and has been for several years (Sivinski, unpublished observation, 2005). Several thistle habitats have been subjected to direct and indirect impacts from land uses that damage travertine substrates and hydrological characteristics. Increasing population and associated agricultural and economic activities will require additional water from this relatively dry region (USFWS, 2010).

**Stressor:** Exotic weeds (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Huenneke and Thomson (1995) surmised that if a dense cover of teasel, or other exotic weeds, became established in thistle habitats, thistle germination would be inhibited by access to light, and the population might decline. Huenneke (1996) also noted that during drought, the drying soils in thistle habitats provided excellent conditions for teasel and other non-native plants, possibly lending non-natives a competitive edge in drier conditions (USFWS, 2010).

**Stressor:** Forestry (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Historically, negative effects of timber harvest and management on Sacramento Mountains thistle habitat have been associated with roads and other surface disturbance that directly impacted thistle habitats or made changes in hydrology and erosion. Mortality to thistles growing in moist areas along roadsides occasionally occurs from mowing, road maintenance, or herbicides (Tonne 2007; Guaderrama, pers. Comm. 2007) (USFWS, 2010).

**Stressor:** Recreation (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Recreational impacts to Sacramento Mountains thistles from human destruction have been noted to occur at the Bluff Springs habitat location (USFWS 1993, USFWS 2008, Barlow-Irick 2008, USFS 2008b, USFWS 2010). Recreationalists have also been observed driving ATVs through exclosures typically fenced to exclude livestock; cut fences and opened gates have been noted in the same exclosed areas (USFS 2008b) (USFWS, 2010).

**Stressor:** Livestock and wildlife (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Grazing and trampling of Sacramento Mountains thistle by livestock and wildlife can reduce photosynthetic tissue, damage seedlings, rosettes, and flowering stems, as well as inflict hoof damage to travertine and soft substrates in occupied and potential habitat (Thompson

1991; USFS 1994). Thistle habitats on travertine springs and the soft-bottom valley habitats provide the majority of watering locations for livestock and elk. These fragile habitats are subjected to trampling and hoof damage. At present, Sacramento Mountains thistle habitats continue to be exposed to livestock with consistently detrimental effects to the thistle, particularly on the Sacramento Grazing allotment (USFS 2007) (USFWS, 2010).

**Stressor:** Insect damage (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Burks (1994) determined that overall seed predation by insects consumed or damaged roughly 17% of the seeds produced by this thistle before dispersal. Sivinski (2007, 2008) documented insect seed predation from four native and one introduced species, which damaged flower heads or cause premature stem death of the thistle. In September 2007, these insect predators significantly damaged flowering stems. Seed production from insect attack was significantly reduced from 2007 to 2009 in the Silver Springs population, particularly as a result of the stem boring weevil (Sivinski 2007, 2008, 2009b) (USFWS, 2010).

**Stressor:** Pesticides (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** USFWS Standards and Guidelines allow for the use of pesticides to control forest pests and such use is likely to adversely affect the thistle by reducing pollinator populations (USFWS, 2010).

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** For mountain tops in New Mexico, weather patterns remain unpredictable, yet most likely will reflect regional trends of warming and drying, leading to the shrinking of cooler and moister habitats associated with higher elevations (Agency Technical Work Group State of New Mexico 2005, Archer and Predick 2008). Drought conditions have been detected in the Sacramento Mountains based on decreased water flows at occupied springs and the contraction of the numbers and area occupied by Sacramento Mountains thistle (USFS 2007) (USFWS, 2010).

***Recovery***

**Reclassification Criteria:**
Not available

**Delisting Criteria:**
1. Acquire water rights specifically for the maintenance of travertine spring habitats at a minimum of 30 percent of the occupied spring localities, including at least 1 occupied spring locality in each of the 20 known canyons of occurrence (USFWS, 2010).

2. Develop habitat management plans to alleviate threats to the species and ensure permanent protection of at least 75 percent of the known occupied habitats according to steps outlined in the plans. Sites should include both core populations at springs as well as other occupied riparian habitats. Unoccupied steam habitat downstream of occupied springs should be protected for future colonization by the thistle (USFWS, 2010).

3. Establish a 10-year monitoring and research program to demonstrate the effectiveness of management implemented under the plans (USFWS, 2010).

**Recovery Actions:**

- Develop and implement a policy for spring development on LNF and acquire water rights to springs if in-stream flow legislation is ever passed in New Mexico (USFWS, 2010).
- Implement livestock management practices to protect plants and their associated spring and riparian habitats (USFWS, 2010).
- Implement logging practices that minimize indirect hydrologic and erosion effects on Sacramento Mountains thistle habitat (USFWS, 2010).
- Study impacts of exotic plant competitors and biological controls (USFWS, 2010).
- Conduct long-term monitoring to evaluate effectiveness of management (USFWS, 2010).
- Other (conduct genetic and hydrologic studies, locate new populations, manage recreation activities, engage in education and law enforcement) (USFWS, 2010).
- The recovery plan should be revised or amended. The criterion for acquiring water rights to maintain Sacramento Mountains thistle habitats does not reflect the legal challenges in obtaining such rights through legislation in the State of New Mexico. A revised criterion that also relies upon suitable points of diversion could have an additive effect on recovery, in conjunction with the existing criterion for water rights acquisition, should be considered. The recovery plan should also be amended to include criteria for uplisting Sacramento Mountains thistle to endangered species status (USFWS, 2010).
- The arrivals of an invasive seed-head weevil, Rhinocyllus conicus, and a stem boring weevil, Lixus pervestitus, in the immediate environment of Sacramento Mountains thistle are potential new threats to the survival of this threatened species. Additional research should be conducted to track the distribution of both weevil species in the Sacramento Mountains and the presence or absence of these weevils in Sacramento Mountains thistle seed heads and stems. Effects of R. conicus and native seed predators on seed production of the Sacramento Mountains thistle need to be ascertained (USFWS, 2010).
- Exclosures preventing livestock access to wetland thistle habitats should be constantly maintained. Resources to construct fencing around thistle populations exposed to livestock, especially those on the Sacramento Grazing Allotment, should be obtained and additional exclosures should be constructed to prevent thistles and promote thistle recovery (USFWS, 2010).
- Erecting signage, indicating the value and conservation status of the Sacramento Mountains thistle, should be considered at the Bluff Springs site (USFWS, 2010).
- continue to monitor invasive plants in thistle habitat. Should invasive thistle and teasel in the region continue to encroach upon Sacramento Mountains thistle habitats, hand-applied use of an EPA-approved, novel herbicide, aminopyralide, commercially known as Milestone, may be warranted (Fletcher, pers, comm. 2007) (USFWS, 2010).
- Monitoring of the Sacramento Mountains thistle populations, reproductive individuals, and rosettes should be conducted biennially by experienced biologists. Demonstrated impacts of

invasive wetland plants and insect predators in particular should be studied to prevent further population declines of the thistle. Interactions among thistle population trends in response to grazing, exclosures, invasive plants, and insect herbivory, along with predictions of warmer average temperatures and potentially less average precipitation potentially associated with climate change, should be monitored to direct future management for the thistle (USFWS, 2010).

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS Establishing a specific survey protocol and methodology to document population trends and gain an accurate assessment of population size and extent would be beneficial for the thistle. Additionally, threats that could be managed through landowner action such as livestock herbivory and water development/diversion should be reduced to the maximum extent practical and monitored to determine existing and on-going impacts to the Sacramento Mountains thistle. A species status assessment to inform a recovery plan revision should, when workload permits, be conducted to incorporate new information on the species. Research is needed to understand how predatory insects, inbreeding depression, or other factors that may exist are affecting thistles and provide management recommendations that would limit or prevent thistles from declining in population size and resilience. Investigation is also needed to determine if the acquisition of water rights under the existing water rights law established by the state of New Mexico is possible to protect habitat for the Sacramento Mountains thistle.

# SPECIES ACCOUNT: *Cirsium wrightii* (Wright's marsh thistle)

***Species Taxonomic and Listing Information***

**Listing Status:** Threatened

**Physical Description**

Wright's marsh thistle is a biennial (a plant completing development in 2 years, and producing flowers in its 2nd year) or a weak monocarpic perennial (a plant that flowers, sets seed, then dies), in the sunflower family (Asteraceae). The plant is prickly with short black spines and a 3- to 8-foot (ft) (0.9- to 2.4-meter (m)) single stalk covered with succulent leaves (Sivinski 1996, p. 1; Arizona Game and Fish Department (AGFD) 2001, p. 1). Numerous slender flowering branches emerge from the stalk, starting about one-third up the length of the plant stalk. The ends of the branches support one or a few small flowering heads, which have numerous slender phyllaries (a modified leaf associated with the flower) (Sivinski 1996, p. 1). Flowers are white to pale pink in areas of the Sacramento Mountains, but are vivid pink in all the Pecos Valley locations (Sivinski 1996, p. 1). Blooms March-August.

**Taxonomy**

Kingdom: Plantae; Phylum: Anthophyta; Class: Dicotyledoneae; Order: Asterales; Family: Asteraceae (Asters, sunflowers). Wright's marsh thistle is a wetland obligate that was originally collected in 1851 at San Bernardino Cienaga, Cochise County, Arizona (Gray 1853, p. 101; Smithsonian 1849, p. 1).

**Historical Range**

Mexico - Uncertain; U.S. - Arizona, New Mexico. Wright's marsh thistle has been extirpated from all previously known locations in Arizona (e.g., San Bernardino Cienega) (Sivinski 1996, pp. 1, 4, 9, 2006a, 2009a, p. 1, 2012, p. 2; Worthington 2002a, p. 4; Baker 2011, entire), many in New Mexico (Roswell, Lake Valley), and was misidentified and likely not ever present in Texas (Poole 1992, entire; 2010, entire; Sivinski 1996, p. 2). The status of the species in Mexico is uncertain, with few verified collections of the plant (Sivinski 2012, p. 5).

**Current Range**

In New Mexico, eight general confirmed locations of Wright's marsh thistle cover an area of approximately 43 ha (106 ac): Santa Rosa, in Guadalupe County; Bitter Lake National Wildlife Refuge (NWR), in Chaves County; Blue Spring, in Eddy County; La Luz Canyon, Karr/Haynes Canyon, Silver Springs, and Tularosa Creek, in Otero County; and Alamosa Creek, in Socorro County (Bridge 2001, p. 1; Sivinski and Bleakly 2004, p. 2; NMRPTC 2009, p. 1; Sivinski 1994, p. 1; Sivinski 1996, p. 2; Sivinski 2005, p. 1, 3–5; Sivinski 2009; USFWS 1998, p. 1; Worthington 2002, p. 1–3). In Otero County, the Sacramento Mountains have four unique populations of the species clustered within about 16 kilometers (km) (10 miles (mi)) of each other on the west slope of the mountains. The remaining four localities are widely disjunct, separated from the Sacramento localities by about 120 to 225 km (75 to 140 mi) and from each other by about 120 to 345 km (75 to 215 mi). In the Sacramento Mountains, two of these four localities occur on the Lincoln National Forest, one locality is on private land, and the remaining locality is on the Mescalero Apache Reservation. In the Pecos River Valley, one locality is on public lands on Bitter Lake NWR; one is on private land near Blue Springs and the Black River; and one is in the vicinity of Santa Rosa on private, municipal, and State lands. The remaining locality is on private land on

Alamosa Creek, Socorro County. Localities vary in relative population size from fewer than 20 individuals covering only about 0.02 ha (0.03 ac) at the Silver Springs locality (Sivinski 2012, p. 21), to several thousand individuals on Bitter Lake NWR, covering almost 9.3 ha (23 ac). (USFWS, 2020)

**Critical Habitat Designated**

Yes; 5/25/2023.

**Legal Description**

We, the U.S. Fish and Wildlife Service (Service), determine threatened species status under the Endangered Species Act of 1973 (Act), as amended, for the Wright's marsh thistle (Cirsium wrightii), a thistle species from New Mexico. We also designate critical habitat. In total, approximately 156.8 acres (63.4 hectares) in Chaves, Eddy, Guadalupe, Otero, and Socorro Counties, New Mexico, fall within the boundaries of the critical habitat designation.

**Critical Habitat Designation**

Critical habitat units are depicted for Chavez, Eddy, Guadalupe, Otero, and Socorro Counties, New Mexico.

Unit 1: Santa Rosa, Guadalupe County, New Mexico. (i) Unit 1 consists of 26.6 hectares (ha) (65.7 acres (ac)) in Guadalupe County, New Mexico, and is composed of lands in State (12.65 ha (31.2 ac)), City of Santa Rosa (9.88 ha (24.4 ac)), and private (4.09 ha (10.16 ac)) ownership.

Unit 2: Alamosa Springs, Socorro County, New Mexico. (i) Unit 2 consists of 1.58 ha (3.9 ac) in Socorro County, New Mexico, and is composed of lands in private ownership.

Unit 3: Bitter Lake, Chaves County, New Mexico. (i) Unit 3 consists of 19.0 ha (47.0 ac) in Chaves County, New Mexico, and is composed of lands under Federal management, specifically the U.S. Fish and Wildlife Service's Bitter Lake National Wildlife Refuge.

Unit 4 has been excluded from this critical habitat designation. (10) Unit 5: La Luz Canyon, Otero County, New Mexico.

Unit 5 consists of 0.01 ha (0.03 ac) in Otero County, New Mexico, and is composed of lands under Federal management, specifically the U.S. Forest Service's Lincoln National Forest.

Unit 6: Silver Springs, Otero County, New Mexico. (i) Unit 6 consists of 0.38 ha (0.95 ac) in Otero County, New Mexico, and is composed of lands under Federal management, specifically the U.S. Forest Service's Lincoln National Forest.

Unit 7: Karr/Haynes Canyon, Otero County, New Mexico. (i) Unit 7 consists of 1.79 ha (4.42 ac) in Otero County, New Mexico, and is composed of lands in private ownership.

Unit 8: Blue Springs, Eddy County, New Mexico. (i) Unit 8 consists of 14.04 ha (34.7 ac) in Eddy County, New Mexico, and is composed of lands in private ownership.

**Primary Constituent Elements/Physical or Biological Features**

The physical or biological features essential to the conservation of Wright's marsh thistle consist of the following components:

(i) Water-saturated soils with surface or subsurface water flow that allows permanent root saturation and seed germination

(ii) Alkaline soils

(iii) Full sunlight

(iv) Diverse floral communities to attract pollinators

**Special Management Considerations or Protections**

Management activities that could ameliorate these threats include, but are not limited to:

(1) Conservation efforts to ensure sufficient water availability

2) managing livestock grazing via the use of exclosures

(3) control of native and nonnative plants via controlled burning or mechanical treatments

(4) spill prevention and groundwater protection during oil and gas development and mining

(5) watershed/wetland restoration efforts

(6) efforts to restore a diverse floral community sufficient to attract pollinators. These management activities would protect the physical or biological features for Wright's marsh thistle by providing for surface or subsurface water flow for permanent root saturation, soil alkalinity necessary for all life stages, the availability of direct sunlight for plant development, and habitat for pollinators to complete cross pollination of the thistle. Additionally, management of critical habitat lands would help limit the impacts of current risks to population viability.

***Life History***

**Food/Nutrient Resources**

**Lifespan**

Adult: Cirsium wrightii can display life history traits of a biennial (a plant completing development in 2 years, flowering in its second year) or a weak monocarpic perennial (USFWS, 2017).

**Breeding Season**

Adult: Flowering occurs August to October

**Reproduction Narrative**

Adult: Flowering occurs August to October (USFWS, 2017). Pollination—Species of Cirsium may be pollinated by a wide variety of insects, including social bees, solitary bees, flies, and beetles (Powell et al. 2010, pp. 910–911; Sivinski 2017b, pers. comm.). Bees are the primary pollinators of C. wrightii, especially bumble bees (Bombus spp.), with butterflies also being common pollinators (Sivinski 2017b, pers. comm.). Bumble bees are large, strong fliers and some species frequently travel 1 mile (mi) (1.5 kilometer (m)) or more to patches of desirable forage plants (Osborne et al. 2008, p. 406). Sivinski (2017b, pers. comm.) observed bumble bees, black swallowtails (Papilio polyxenes), green June beetles (Cotinis nitida), and oblique syrphid flies (Allograpta obliqua), among other insect pollinators, visiting C. wrightii. Hummingbirds have been observed visiting C. wrightii flower heads as well, but it is unknown if hummingbirds affect much pollination of the plant (Keil 2006, p. 131). The presence of other species of native flowering plants may help to attract abundant pollinators, and thus also benefit Cirsium wrightii. This may be more important for western populations of C. wrightii, where there are fewer thistles. In the larger eastern populations, there are likely enough individual C. wrightii to attract pollinators (USFWS, 2017).

**Habitat Type**

Adult: In New Mexico, the species occurs in wet, alkaline soils in spring seeps and marshy edges of streams and ponds between 3,450 and 7,850 ft (1,152 and 2,393 m) in elevation (Sivinski 1996, p. 1; 2005a, pp. 3-4; Worthington 2002a, entire). C. wrightii appears to be an obligate of seeps, springs, and wetlands that have saturated soils with surface or subsurface water flow (Sivinski 1996, 2012, entire; Service 1998, pp. 1-2; Worthington 2002a, p. 2; NMRPTC 2009). Plants commonly found in areas inhabited by this species include Scirpus spp. (bulrush), Salix spp. (willow), Baccharis glutinosa (seepwillow), Helianthus paradoxus (Pecos sunflower), Juncus spp. (rush), and Typha spp. (cattail) (Sivinski 1996, pp. 2-5; Sivinski and Bleakly 2004, p. 2; Worthington 2002a, pp. 1-2).

**Habitat Vegetation or Surface Water Classification**

Adult: Palustrine habitat: Herbacious wetland; Terrestrial habitat: Desert; marshy wetlands (cienegas) near springs in otherwise semi-arid to arid areas. (NatureServe)

**Dependencies on Specific Environmental Elements**

Adult: Wright's marsh thistle appears to be an obligate of seeps, springs, and wetlands that have saturated soils with surface or subsurface water flow (Sivinski 1996, 2012, entire; Service 1998, pp. 1-2; Worthington 2002a, p. 2; NMRPTC 2009).

**Environmental Specificity**

Adult: Very Narrow (inferred from USFWS, 2014)

**Habitat Narrative**

Adult: Wright's marsh thistle is a wetland obligate (occurs only in water-saturated soils) that was originally collected in 1851 at San Bernardino Cienaga, Cochise County, Arizona (Gray 1853, p. 101; Smithsonian 1849, p. 1). In the New Mexico portion of the species range, C. wrightii appears to be an obligate of seeps, springs, and wetlands that have saturated soils with surface or subsurface water flow (Sivinski 1996, 2012, entire; Service 1998, pp. 1-2; Worthington 2002a, p. 2; NMRPTC 2009). Plants commonly found in areas inhabited by this species include Scirpus spp. (bulrush), Salix spp. (willow), Baccharis glutinosa (seepwillow), Helianthus paradoxus (Pecos sunflower), Juncus spp. (rush), and Typha spp. (cattail) (Sivinski 1996, pp. 2-5; Sivinski and Bleakly 2004, p. 2; Worthington 2002a, pp. 1-2).

***Dispersal/Migration***

**Dispersal**

Adult: Water/Wind

**Dispersal/Migration Narrative**

Adult: In addition, seed banks of C. wrightii may be reduced annually due to predation from insects and birds, by seed moving to non-habitat via wind or water dispersal, or by the germination of many seeds which grow into the sometimes thousands of rosettes that have been reported from sites (USFWS, 2017).

***Population Information and Trends***

**Population Trends:**

Unknown

**Species Trends:**

Unknown

**Number of Populations:**

8 populations in 5 counties (Otero, Chavez, Guadalupe, Eddy, and Socorro)

**Population Size:**

populations of 2 to ~18,000

**Population Narrative:**

There are eight general localities of Wright's marsh thistle extant within New Mexico. Additional historical populations have been extirpated, including at least two larger and two smaller populations in New Mexico, and the population at the type locality in Arizona. The population at BLNWR is likely the most robust, with between 14,000 to 18,000 individuals (Sivinski 2012, p. 30). Santa Rosa contains scattered localities throughout four sections of land, and some of these have been extirpated recently. However, the population in 2012 was estimated between 12,000 to 14,000 individuals (Sivinski 2012, p. 52). The population along Tularosa Creek has undergone a significant reduction since 1995 and now contains only four individuals (Sivinski 2012, p. 21). The remaining populations in the Sacramento Mountains are mostly small, containing from two to perhaps several hundred individuals (Sivinski 2012, p. 9-24). The populations at Blue Spring and Alamosa Springs were recently discovered. There have been no subsequent surveys at Blue Spring to determine whether this population is stable or declining. Alternatively, in 2012, the population at Alamosa Springs was estimated at 900 flowering individuals (Sivinski 2012, p. 9), indicating a relatively stable status since its discovery in 2005). An experimental planting of 61 rosettes occurred at Burro Cienega in 2011, but was not monitored during 2012 to determine success or failure. The collections from Texas were misidentified, and we conclude C. wrightii never occurred in the state. Finally, there is only one verified historic collection from Mexico, and no recent information on the status of the species from this population. For these reasons, the status of this species remains tenuous.

***Threats and Stressors***

**Stressor:** Agricultural and urban development

**Exposure:** Water withdrawal
**Response:**
**Consequence:**
**Narrative:** Past and present alteration of rare desert springs, seeps, and wetland habitats that support Wright's marsh thistle is a significant threat. The four largest localities of C. wrightii at Blue Spring, BLNWR, Santa Rosa, and Alamosa Creek have the potential to be further modified by ongoing and future water withdrawal. Changes in water tables throughout the range of C. wrightii have also resulted in diminished discharge from springs or complete loss of surface water. Therefore, there has been a trend of diminishing habitat quantity and excessive degradation of habitat quality for the species throughout its range, as a result of agriculture and urban development, diversion of springs, and drought.

**Stressor:** Introduced plants
**Exposure:** Increased fire risk, competition and changes in hydrology
**Response:**
**Consequence:**
**Narrative:** The presence of and effects from Phragmites australis (common reed) threatens C. wrightii localities through increased fire risk, competition, and changes in hydrology.

**Stressor:** Inadequate regulatory protection
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Wright's marsh thistle receives inadequate protection from the Clean Water Act. Similarly, the species lacks adequate regulatory protection from its various designationsa Forest Service sensitive species, or endangered status by the State of New Mexico because these designations only serve to notify the public of the species' status and do not require conservation or management actions. We are not aware of any other existing regulatory mechanisms. Wright's marsh thistle is currently threatened by the inadequacy of existing regulatory mechanisms. This will continue into the foreseeable future.

**Stressor:** Livestock Grazing (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In the semi-arid southwestern United States, wet marshes and other habitat of Wright’s marsh thistle attract ungulates (e.g., livestock, elk, and deer) because of the availability of water and highquality forage (Hendrickson and Minckley 1984, p. 134). Livestock grazing is present at localities in the Sacramento Mountains, Santa Rosa, Blue Springs, and Alamosa Springs. At the Santa Rosa locality, photographs indicate that the growth of Wright’s marsh thistle and the integrity of its habitat have been negatively affected by livestock herbivory and trampling (Sivinski 2012 pp. 33–53). Dry periods likely increase the effects of livestock trampling and herbivory on Wright’s marsh thistle when other water and forage plants are not available (75 FR 67925). Grazing may be more concentrated within habitats similar to those occupied by Wright’s marsh thistle during drought years, when livestock are prone to congregate in wetland habitats or where forage production is greater than in adjacent dry uplands (USFS 2003, entire). Livestock may trample individual plants and eat the thistle when other green forage is scarce, and when the seedlings or rosettes are developing and abundant. Further, livestock may eat

mature plant inflorescences (the complete flower head), which could reduce seed production. For example, the threatened Sacramento Mountains thistle (C. vinaceum) (52 FR 22933), which is also found in New Mexico and associated with habitats similar to those occupied by Wright's marsh thistle, is eaten by livestock and appears to be the preferred forage at some times of the year. It may provide some of the only green forage during droughts (NMRPTC 2009, p. 2). Also, it is possible that livestock grazing within and adjacent to spring ecosystems could alter or remove habitat or limit the distribution of the thistle (USFWS 2017). (USFWS, 2020)

**Stressor:** Native and Nonnative Plants (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Some native and nonnative plants pose a threat to Wright's marsh thistle and its habitat through habitat encroachment and competition for resources at most localities. The native plants include cattails (Typha spp.); nonnative species include the common reed (Phragmites australis), purple loosestrife (Lythrum salicaria), Russian olive (Elaeagnus angustifolia), saltcedar (Tamarix spp.), and Russian thistle (Salsola spp.) (Sivinski 1996, p. 6). These particular native and nonnative species all have the same effect on Wright's marsh thistle by functioning as invasive species with respect to the thistle's habitat. Though cattails and Wright's marsh thistle may have evolved in the same area, decreased water availability has altered habitat conditions such that cattails have a competitive advantage in Wright's marsh thistle habitat. These plants present unique challenges and potential threats to the habitat, including shade effects on Wright's marsh thistle seedlings and rosettes. For example, the common reed, a nonnative invasive plant introduced from Europe and Asia, increases the potential for wildfire and is increasing in density at some locations in New Mexico. The dense plant growth blocks sunlight to other plants growing in the immediate area and occupies all available habitat (PCA 2005, p. 1). The increase of the common reed in Wright's marsh thistle habitat is a current threat to the species through increased wildfire risk, competition, and changes in hydrology (impacts on degree of soil saturation), especially when habitat is disturbed through burning or drying. The impacts vary based on location, with the greatest impacts occurring at Santa Rosa, Bitter Lake NWR, Blue Spring, and Tularosa Creek. We expect that the threats caused by native and nonnative plant competition and habitat loss will likely continue and possibly intensify, due to lack of vegetation management practices at several locations (Santa Rosa, Blue Spring, Tularosa Creek) and the pervasiveness of native and nonnative plants despite ongoing efforts for habitat restoration at other locations (Bitter Lake NWR). As this species is comprised of small, isolated populations, the impacts of native and nonnative plants could pose a significant stressor to the thistle. Attempts to manage native and nonnative plants through herbicide use and mowing may also exacerbate effects to Wright's marsh thistle as these techniques are difficult to preferentially apply to only the native and nonnative plant species when habitat is shared. In addition, we expect increases in drought periods to exacerbate the effects of this stressor. (USFWS, 2020)

**Stressor:** Oil and Gas Development and Mining (USFWS, 2020)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Oil and gas development occurs within and adjacent (i.e., within 10 miles) of some areas occupied by Wright's marsh thistle including Santa Rosa, Bitter Lake NWR, and Blue Spring

(New Mexico State Lands Office, 2017; NMDGF 2007, pp. 18–19; NMDGF 2005, p. 35). There are also mining activities adjacent (i.e., within 5 miles) to other areas such as a potential beryllium mine at Alamosa Springs, and subsurface drilling and exploration of the mineral bertrandite on Sullivan Ranch near Alamosa Springs (New Mexico Mining and Minerals Division 2010; New Mexico State Lands Office, 2017; Sivinski 2012, p. 9). As of February 2020, the Service has no information on any new actions towards developing the potential beryllium mine at Alamosa Springs. The main impacts from oil and gas development and mining include the potential for contamination. Contamination from oil and gas development has been observed within close proximity (i.e., within 16 km (10 mi) of some Wright's marsh thistle localities (New Mexico State Lands Office, 2017). While laws and regulations related to water quality have reduced the risk of contamination in and near occupied locations from oil and gas production, the likelihood that a spill could impact these habitats is still present based on the high volume of oil and gas leases near these areas. Potential contamination from both oil and gas development and mining could have several impacts on plants (such as Wright's marsh thistle), including the following: increased available nutrients, which may favor competitive or nonnative plant growth; altered soil pH (either higher or lower), which can kill plants; absorption of chemicals, which can poison plants or cause poor growth or dead spots on leaves; and plant mortality. In addition, oil and other contaminants from development and drilling activities throughout these areas could enter the aquifer supplying the springs and seeps inhabited by Wright's marsh thistle when the limestone layers are pierced by drilling activities. An accidental oil spill or groundwater contamination has the potential to pollute water sources that support Wright's marsh thistle, and mining activities could alter or destroy habitat. The largest occupied habitat area is less than 16 ha (40 ac), and more than half the known populations are less than 2 ha (5 ac) in size. Even a small, localized spill has the potential to contaminate and destroy a population. The loss of even one of the eight populations would result in loss of representation and redundancy to the species as a whole. Because this species is comprised of small, isolated populations, these stressors could potentially negatively affect the thistle, but it is unclear whether these impacts would be localized or widespread stressors as the interaction between contaminant spills and groundwater and surface water hydrology is poorly understood. Therefore, we have determined that oil and gas development and mining functions as a stressor to the future viability of the species via impacts to water sources that provide habitat for Wright's marsh thistle. (USFWS, 2020)

***Recovery***

**Recovery Actions:**

- Establish additional grazing exclosures in riparian areas on Forest Service lands, on the Lincoln National Forest to support expansion of extant populations of Wright's marsh thistle.
- Investigate the possibility of reintroductions to historically occupied habitat where natural recolonization is unlikely. Transplants of rosettes within existing localities may also assist in the expansion of occupied habitat.
- Conduct additional surveys for Wright's marsh thistle particularly springs and cienegas in southeastern New Mexico and Mexico.
- Coordinate closely with BLNWR on management of the species. For example, investigate how Wright's marsh thistle responds to changing water levels on the refuge, when soils are not continuously saturated throughout the growing season.
- Develop a conservation strategy for the species, to guide coordinated conservation efforts by multiple partners. This strategy would also include an educational component to inform private and State landowners of wetland permitting requirements when they fill or drain

their lands.

- Monitor and evaluate whether insect predators are a threat to Wright's marsh thistle, particularly in Sacramento Mountains.
- Control populations of Pyhragmites Australis where they threatened Wright's marsh thistle.

# SPECIES ACCOUNT: *Clarkia franciscana* (Presidio clarkia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 03/06/1995; California/Nevada Region (R8)

**Physical Description**

A slender, erect, herbaceous annual of the evening-primrose family (Onagraceae), 40 centimeters (16 inches) tall with few, very small, and narrow leaves. The lavender-pink petals have a lighter basal portion and a reddish-purple basal spot. The slender capsule is 2 to 4 centimeters (1 to 2 inches) long. Clarkia franciscana can be distinguished from Clarkia rubicunda (ruby chalice clarkia), a related species that may occur in the same area, by its petals that have irregular teeth on the apical margin (the edge near the tip). Clarkia rubicunda has petals that are rounded at the apex (Lewis and Raven 1958a) and usually twice the length of Clarkia franciscana (Lewis and Raven 1958a, Lewis 1977). (USFWS, 1998)

**Taxonomy**

The type specimen of Clarkia franciscana (Presidio clarkia) was collected by Peter Raven in 1956. Clarkia franciscana was described by Harlan Lewis and Peter Raven (1958a). (USFWS, 1998)

**Historical Range**

In California, in San Francisco County, and later found in Alameda County. (USFWS 1998).

**Current Range**

It is restricted to serpentine soils in grassland and coastal scrub communities and is known from only two locations within highly urbanized areas of the San Francisco Bay Area: 1) the Presidio of San Francisco (the Presidio) within the city and county of San Francisco, California; and 2) the Oakland Hills within the City of Oakland, Alameda County, California (Oakland Hills) 17 miles to the east of the Presidio population (USFWS, 2024).

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Predominantly self-pollinated with possibility cross-pollination (USFWS, 2010)

**Dependency on Other Individuals or Species**

Adult: Presidio clarkia is thought to be predominately self-pollinated (Gottlieb and Edwards 1992, p. 2). Small halictid bees (sweat bees), however, have been observed visiting the flowers and could potentially be pollinators for the species (USFWS, 2024)

**Breeding Season**

Adult: May to July (USFWS, 2010)

**Reproduction Narrative**

Adult: Presidio clarkia flowers from May to July. Flowers develop from erect buds and set seed in late summer or early fall. It is thought to be predominantly self-pollinated; however, there is some evidence to suggest that small halictid bees (sweat bees) could potentially be pollinators for the species. Due to its mechanism of self-pollination, there is restricted genetic variability in the populations. (USFWS, 2010). Presidio clarkia is thought to be predominately self-pollinated (Gottlieb and Edwards 1992, p. 2). Small halictid bees (sweat bees), however, have been observed visiting the flowers and could potentially be pollinators for the species (USFWS, 2024)

**Habitat Type**

Adult: Grassland and coastal scrub communities (USFWS, 2010)

**Geographic or Habitat Restraints or Barriers**

Adult: restricted to serpentine soil

**Spatial Arrangements of the Population**

Adult: Clumped

**Environmental Specificity**

Adult: special habitat requirements

**Site Fidelity**

Adult: high

**Habitat Narrative**

Adult: C. franciscana is known from only two locations within highly urbanized areas of the San Francisco Bay Area, California (the Presidio within the City of San Francisco [SF Presidio] and the Oakland Hills within the City of Oakland, Alameda County [Oakland Hills]), where the plant is restricted to serpentine soils in grassland and coastal scrub communities (Skinner and Pavlik 1994). Serpentine soils are formed from weathered volcanic (ultramafic rocks) such as serpentinite, dunite, and peridotite. The C. franciscana has adapted to the harsh environments of serpentine soils that limit plant growth: low calcium : magnesium ratios; lack of essential nutrients such as nitrogen, potassium, and phosphorus; and high concentrations of heavy metals (mineral toxicity).

***Dispersal/Migration***

**Motility/Mobility**

Adult: not mobile

**Dispersal**

Adult: limited

**Dispersal/Migration Narrative**

Adult: Not much information is available regarding the dispersal of this species (USFWS, 2010)

***Population Information and Trends***

**Population Trends:**

Unknown (USFWS, 2019)

**Species Trends:**

Unknown (USFWS, 2019)

**Population Growth Rate:**

unknown

**Number of Populations:**

5 (USFWS, 2024)

**Population Size:**

In our 1995 listing rule we noted that although population sizes fluctuated greatly, the highest total of Presidio clarkia plants reported in “recent years” was about 8,000 (Service 1995, p. 6674). This consisted of approximately 4,000–5,000 plants in Redwood Regional Park, 230 plants at the other two known Oakland Hills locations (Service 1995, p. 6681), and the rest (2,770 to 3,770 plants) at the two Presidio locations. In our 2010 status review we provided several years of survey data indicating the population numbers we had reported at the time of listing were likely from the 1980s for Presidio populations, and from 1991 for the Oakland Hills population (Service 2010, pp. 14–17). Abundances since those times again showed large fluctuations but large overall increases at the Inspiration Point population in the Presidio (54,351 plants in 2009) and the Redwood Regional Park subpopulation in the Oakland Hills (105,420 plants in 2009) (Service 2010, pp. 14–15). Other surveyed populations and subpopulations were much smaller, however, with only 29 plants in the World War II Memorial population at the Presidio in 2009, and 20 to 548 plants in the various suburban Oakland Hills subpopulations in 2008 (Service 2010, pp. 16–17) (Service 2010, pp. 16–17) (USFWS, 2024).

**Additional Population-level Information:**

As described above, Presidio clarkia can be found in two general locations: the Presidio and the Oakland Hills (Service 2010, pp. 5–8). At the time of listing, two populations of the plant were known in the Presidio and three occupied areas were known in the Oakland Hills (Occurrence 4) (Service 1995, pp. 6673–6674). Population locations in the Presidio consisted of the World War II Memorial (Occurrence 1) and Inspiration Point (Occurrence 2) (Diversity Database 2023a, pp. 1, 3). A third population near McDowell Avenue (Occurrence 3) had previously been identified but was considered “possibly extirpated" at the time of listing because it had not been seen since 1908 (Diversity Database 2023a, p. 5). The three occupied areas in the Oakland Hills consisted of a large subpopulation in Redwood Regional Park (extending into Joaquin Miller Park), and two subpopulations in the suburbs to the south (Service 1995, pp. 6673–6674, 6681; Diversity Database 2009, Aug shapefile; Service 2010, p. 16). Although we originally referred to the three occupied Oakland Hills areas as “populations” (Service 1995, p. 6673), we now refer to them as “subpopulations” because they are within 0.25 miles of each other and thus constitute a single occurrence as defined by the Diversity Database (Diversity Database 2020, p. 10). In our last status review, we noted that a new population (Coastal Bluffs) had been experimentally introduced at the Presidio in 2008 (Service 2010, pp. 5, 10). We also noted that, of the three extant populations at the Presidio, only the one at Inspiration Point occurred naturally (Service 2010, p. 4). The World War II Memorial population had been reintroduced by artificial seeding in 1972. Seeds for that reintroduction, as well as for the experimental Coastal Bluffs population, were obtained from the Inspiration Point population (Chassé. 2021, p. 14). At the time of our last review, the Oakland Hills population (Occurrence 4) had increased to seven total subpopulations due to the discovery of four additional subpopulations in the suburbs south of Redwood Regional Park (Diversity Database 2009, Aug shapefile; Service 2010, pp. 6–8). Since our last review two additional subpopulations have been added to the experimentally introduced population at Coastal Bluffs in the Presidio (which does not yet have a Diversity Database occurrence number, and which has also been referred to as “Presidio Coastal Bluffs” and “Presidio Bluffs”) (Chassé and Forrestel 2015, p. 16; Chassé undated (c), p. 17; Diversity Database 2023a, entire; Chassé in litt. 2024a, p. 1). One of the new subpopulations is actually within 250 feet of the World War II Memorial population and about half a mile from other Coastal Bluffs subpopulations (Chassé undated (b), pp. 14–15; Chassé 2021, p. 15). It is treated as part of the Coastal Bluffs population because it is on land managed by the National Park Service, which conducts annual surveys of it (Presidio Trust 2002, pp. 3, 5; Chassé 2021, p. 14). The World War II Memorial population is on lands managed by the Presidio Trust. A new population has also been introduced on Presidio Trust lands at West Crissy Bluffs, close to or possibly in the same location as the extirpated McDowell Avenue population (Occurrence 3) (Chassé and Forrestel 2014, p. 14). New subpopulations were added to the World War II Memorial Population in 2015, and to the West Crissy Bluffs population in 2016 (Chassé 2016, p. 18; Chassé undated (a), p. 21). See Table 1a for a summary of the Presidio populations (USFWS, 2024).

**Population Narrative:**

This species is known to occur in only two locales, the Presidio in San Francisco County and Oakland Hills in Alameda County, California. Since the approval of the 1998 recovery plan, new locations for Presidio clarkia within these two locales have been either introduced or discovered. The 2010 5-year review for Presidio clarkia (Service 2010b) summarizes the introduction along the Pacific coast at the Presidio (“Coastal Bluffs” site) and the discovery of four additional sites in Oakland Hills (for seven total Oakland Hills sites). Since the 2010 5-year review, Presidio clarkia was also reintroduced at the historical “West Crissy Bluffs” site (also referred to as “McDowell Avenue,” CNDDB occurrence #3) at the Presidio (Chassé and Forrestel 2014). The CNDDB (2018) reflects all known Presidio clarkia sites in Oakland Hills (CNDDB occurrence #4), but has not been updated for the Coastal and West Crissy bluffs introductions at the Presidio. - Ongoing habitat restoration and enhancement at the Presidio and Redwood Regional Park have increased local distributions and abundances of Presidio clarkia at these managed sites. Inspiration Point (Presidio; CNDDB occurrence #2) and Redwood Regional Park (Oakland Hills) continue to be the largest and most productive Presidio clarkia sites. The average population estimates for a 1.0-hectare (2.5-acre) plot at Inspiration Point is 58,904 individuals (2006-2018) and for a 3.0-hectare (7.4-acre) plot at Redwood Regional Park is 59,758 individuals (2008-2011, 2014-2015, and 2017). Since monitoring began, abundances at the other Presidio clarkia sites did not exceed 2,000 individuals3 until 2018. The 2018 censuses recorded 2,924 and 3,223 individuals at the Presidio’s West Crissy Bluffs and WWII Memorial sites, respectively. Despite the recent increase in numbers, the likelihood that the West Crissy Bluffs site (or the Coastal Bluffs site) will continue to support Presidio clarkia is in question. - All of the seven Oakland Hills sites are likely the remaining portions of a single population that was fragmented by residential development. Six of the Oakland Hills sites contain only small patches of serpentine that are surrounded by residences, roads, and a tennis club. These sites, held by the City of Oakland or private landowners, are rarely monitored. Thus, the status of Presidio clarkia in these patches is currently unknown. Prior to 2010, these six Oakland Hills sites had abundances that ranged from 20 to over 1000 plants (summarized in Service 2010b). (USFWS, 2019)

***Threats and Stressors***

**Stressor:** Habitat disturbance (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The six small Oakland Hills sites remain unprotected and are especially vulnerable to erosion, roadside maintenance for fire management, competing plant species, and residential development. Presidio clarkia has likely persisted in some of these habitat fragments because the steep terrain is unconducive for development and landscaping. Thus, the terrain is also erosive and Presidio clarkia plants and seeds are subject to being washed into roads and disposed of. The habitat fragments that are not too steep and erosive are frequently mowed prior to seed set (R. Kanz, conservationist and Oakland resident, pers. comm. 2018; Service 2010b). Unlike the protected sites, the Oakland Hills fragments are not managed to reduce nonnative plant competition and trees are typically favored in residential areas. Plans for a residential development on the Crestmont Drive site are in process, though it is uncertain when the development will be constructed. The City of Oakland has not yet approved the lot divisions for the development because the requirements for a rare plant conservation easement have not all been fulfilled (M. Grefsrud, CDFW, pers. comm. 2018). At the Presidio in San Francisco County, Presidio clarkia at the West Crissy Bluffs site are threatened by the site’s small size, high disturbance rate, and position just below a road. Declining numbers of Presidio clarkia at the Coastal Bluffs introduction site could be due to inadequate seed input (only one year of seeding), or because the coastal climate and habitat are not suitable for Presidio clarkia (M. Chassé, pers. comm. 2018). (USFWS, 2019)

**Stressor:** Erosion and altered hydrology (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** In 1978, the Ecology Trail was routed through a then unknown subpopulation of Clarkia franciscana at Inspiration Point. Since then, the trail has been fenced off but the Inspiration Point subpopulation of C. franciscana at the SF Presidio continues to be threatened by trail erosion, storm drain runoff, and other hydrologic issues. A storm drain flows directly into the Inspiration Point site. This is thought to potentially threaten the C. franciscana because, as observed at the War Memorial site, the species does not do well under wetter conditions.  - In the Oakland Hills, most of the subpopulations of Clarkia franciscana occur on very steep, highly erosive serpentine roadcuts, and, therefore, are vulnerable to altered hydrology and accelerated erosion resulting from human disturbance. The C. franciscana has become restricted to areas with steeper slopes and thinner soils in the Oakland Hills due to the invasion of nonnative annual grasses onto the deeper serpentine soils. The lower Tennis Club site within the Tennis Club/Sunrise subpopulation is highly vulnerable to altered hydrology and erosion due to its location in a steep gully between the Sunrise Assisted Living Facility and the Oakland Hills Tennis Club. Only the Chadbourne Way subpopulation and some patches of the Redwood Regional Park subpopulation are not currently threatened by erosion and altered hydrology do to their locations on more gentle slopes. - Until recently, concerns about landslides slowed residential

development on some of the steeper serpentine slopes in the Oakland Hills where Clarkia franciscana occurs. However, since the Federal listing of the species, many residential developments have been constructed on steep serpentine soils that may or may not have had C. franciscana. In some cases, these residential developments proceeded without environmental review. - The Crestmont Drive subpopulation of Clarkia franciscana may be threatened by altered hydrology and erosional gullying due to the construction of seven single family homes immediately upslope on Colgett Drive between 1998 – 2003. A local resident and member of Friends of Oakland's Endangered Species reports "observations of the site [Crestmont Drive] indicate the impacts of water from uphill properties [on Colgett Drive] may be causing rilling and erosion". (USFWS, 2010)

**Stressor:** Small populations (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Recovery Plan (Service 1998) recommends securing populations containing a minimum of 2,000 plants each (but preferably more). The probability of population persistence over the long-term is expected to be higher for larger populations because large size decreases the likelihood of reduced viability or population extirpations due to random demographic or genetic events (Barrett and Kohn 1991, Ellstrand and Elam 1993). Currently, only two of the nine subpopulations of Clarkia franciscana (Inspiration Point and Redwood Regional Park) exceed the criteria for containing a minimum of 2,000 plants. Thus, the C. franciscana continues to be threatened by habitat fragmentation, a small number of populations, and the small size of most of the subpopulations. (USFWS, 2010

**Stressor:** Loss of pollinators (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The Clarkia franciscana is thought to reproduce primarily through self-pollination. However, small halictid bees (sweat bees) have been observed visiting the flowers and could potentially be pollinators for the species (Lewis and Raven 1958). Thus, the use of pollinators by the C. franciscana could be important for increasing gene flow among populations and maintaining the genetic variability of the species. A study by Gottlieb and Edwards (1992) verified the low intrapopulation genetic variability within the SF Presidio population and the Oakland Hills population (Redwood Regional Park) as is expected for a species that is predominately self-pollinated (Stebbins 1978). Species with small populations and low genetic variability, such as the C. franciscana, are at greater risk of extirpation from natural catastrophic events (disease, fire, and drought) (Menges 1991). The reproduction and genetic variability of the Clarkia franciscana could be threatened by the recent worldwide decrease in pollinators. Pollinators are threatened by the use of both regulated (e.g., malathion) and unregulated pesticides (e.g., pyrethroids) (Department of Pesticide Regulation 2006, Keith 2006, Service 2000). More recently, the decline in pollinators observed across North America has been attributed to introduced parasites, in particular the varroa mite (Varroa jacobsoni), which affects the honey bee (Apis millifera) (Nielsen 2006, National Research Council 2006). The potential effects of introduced parasites on C. franciscana pollinators are not known. Hafernik (2009), however, reported a rich diversity of bees at the SF Presidio, including 56 species representing 23 genera. The diversity and abundance of bees and other pollinators in the Oakland Hills is not known at this time. (USFWS, 2010)

**Stressor:** Loss of genetic diversity (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** The SF Presidio and Oakland Hills populations of the Clarkia franciscana are separated by 17 miles and the San Francisco Bay resulting in two genetically distinct populations (Gottlieb and Edwards 1992). However, the genetic distinctiveness of the Oakland Hills population of C. franciscana could potentially be threatened by genetic swamping from C. franciscana plants of SF Presidio genetic stock (which had been cultivated for 40 years at Tilden Botanical Garden) planted by residents within the Oakland Hills. (USFWS, 2010)

**Stressor:** Climate change (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, Intergovernmental Panel on Climate Change 2007). However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species at this time. The Clarkia franciscana has evolved to adapt to the highly specific soil, environmental, and microclimatic conditions that are unique to the two locations where it occurs in the San Francisco Bay Area: the SF Presidio and the Oakland Hills. Observations at the War Memorial site demonstrate that the C. franciscana is not very tolerant of certain microclimatic conditions associated with this coastal location (cooler, wetter, and greater exposure to wind and fog) (Chassé et al. 2009). Thus, due to the highly restrictive soil, environmental, and microclimatic conditions under which the C. franciscana can grow, the species may be vulnerable to even small changes in climate. (USFWS, 2010)

**Stressor:** Competition from plant species (USFWS, 2019)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Presidio clarkia, throughout its limited range, is threatened with competition from nonnative invasive grasses, native shrubs, nonnative trees, and native trees planted outside of their natural range. Invasive grasses compete by depleting shallow soil moisture and creating dense thatch that smothers and suppresses seedling recruitment in native plants. Elevated atmospheric nitrogen deposition from increased air pollution exacerbates the invasive grass problem because additions of nitrogen to nutrient-deficient soils, like serpentine, facilitate the invasion of weedy species (Weiss 2006). Nitrogen deposition in nitrogen-limited ecosystems may also affect mycorrhizal communities and increase plant susceptibility to other environmental stressors (summarized in Service 2010b). Shrubs and trees compete by shading annual grassland plants. Trees also bury the nutrient-poor serpentine soil with a thick layer of organic material, which encourages further invasion of non-serpentine species. (USFWS, 2019)

**Stressor:** Atmospheric nitrogen deposition from air pollution (USFWS, 2010)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Elevated atmospheric nitrogen deposition from air pollution is particularly harmful to the nutrient-poor serpentine grasslands where the Clarkia franciscana occurs because nitrogen is the primary limiting nutrient for plant growth on serpentine soils (Weiss 1999). The use of catalytic converters on vehicles has increased the availability of nitrogen in a form that is directly absorbed by plants (EBRPD 2009a). The excess nitrogen deposited leads to increases in nonnative annual grasses which outcompete the native flora (Fenn et al. 2003, Weiss 1999). Other potential effects of elevated atmospheric nitrogen deposition on plants in nitrogen-limited ecosystems (Wolkowski et al. 2008), such as that in which the Clarkia franciscana grows, include decreased diversity of mycorrhizal communities. Increased nitrogen deposition can also predispose plants to other environmental stresses such as elevated concentrations of ozone, drought, frost, or insect attacks. It is not known at this time if elevated atmospheric nitrogen deposition from air pollution impact C. franciscana mycorrhiza. (USFWS, 2010)

**Stressor:** Development (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Development remains a general threat for the subpopulations on private lots south of Redwood Regional Park. However, there do not appear to be any such development projects currently ongoing on occupied sites (Merkamp in litt. 2024, pp. 1–2). The Crestmont Project mentioned in our last status review (Service 2010, p. 28) has not been carried out (Grefsrud in litt. 2024a, p. 1), leaving both the proposed 4-lot residential development and the accompanying 0.85 acre managed conservation easement (Service 2010, p. 28), unimplemented. Mitigation measures mentioned in our last review for construction of the Sunrise Assisted Living Facility (Service 2010, p. 30) have not been carried out either, despite construction of the facility (Grefsrud in litt. 2024b, p. 1). These measures included removal of invasive French broom (Genista monspessulana) and development of an approved revegetation and monitoring plan (Service 2010, p. 30). (USFWS, 2024)

**Stressor:** Mowing (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Mowing, including string trimming, currently remains a threat for the suburban subpopulations south of Redwood Regional Park. Mowing requirements in those subpopulations differ according to land ownership. The city of Oakland owns the land supporting the Chadbourne Way subpopulation, as well as those portions of the Old Redwood Road subpopulation that are west of Old Redwood Road (Alameda County Assessor's Office (Alameda Assessor) 2024, pp. 1, 57). Note that we described the Old Redwood Road subpopulation as occurring entirely on cityowned land in our last review (Service 2010, p. 8), but most of it is actually on private land. For over a decade, the City of Oakland has been mowing the areas as a method of fire prevention, using string trimmers in May or June and then raking and removing the cut material (Kanz in litt. 2023, pp. 1–2). Since Presidio clarkia seeds typically mature in late

summer or early fall (Service 2010, p. 3) such practices likely prevent new seeds from maturing and germinating and may have contributed to the absence of Presidio clarkia plants at the Chadbourne Way subpopulation in recent years (USFWS, 2024)

**Stressor:** Competition (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Competition with non-native and woody plants remains an issue at all monitored locations (Chassé undated (c), p. 17; Naumovich 2021, pp. 14, 15). Non-native competitors at the Presidio include invasive grasses and tocalote (Centauria melitensis), while woody competitors include California blackberry (Rubus ursinus) and poison oak (Toxicodendron diversilobum) (Chassé undated (c), p. 17). Since our last review, the National Park Service has continued vegetation removal treatments, which involve pulling and cutting by hand in the areas supporting Presidio clarkia, and use of landscape fabric and string trimmers in adjacent areas (USFWS, 2024)

**Stressor:** Inbreeding Depression (USFWS, 2024)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** Populations that become small too quickly can suffer genetic impacts such as inbreeding depression because they randomly lose beneficial gene variants as the population shrinks (Soule 1980, pp. 157–158). This is less of a threat to species with a seed bank, such as Presidio clarkia, because gene variants lost from the plant population in a given year may be preserved in the seed bank and return in a subsequent year. However, the Chadbourne Way subpopulation has been mowed and raked on a yearly basis, and may now be reduced to a relatively few viable seeds (see Mowing, above). The entire subpopulation, including the seed bank, may have thus been reduced to very low numbers over several years. This would leave it vulnerable to inbreeding depression, if still extant. (USFWS, 2024)

***Recovery***

**Reclassification Criteria:**
A/1: A minimum of five populations of Presidio clarkia, which shall include Inspiration Point at the Presidio and Redwood Regional Park in Oakland Hills, are fully protected and managed with the primary intention of preserving the populations in perpetuity. Each protected area includes occupied habitat and known former habitat along with adjacent unoccupied habitat and a 150-meter (500-foot) buffer. (USFWS, 2019)

A/2: Management plan(s), approved by the Service, are implemented for the populations described in A/1 and any occupied or unoccupied habitat identified as essential to survival. The plans include provisions for standardized annual monitoring of populations. (USFWS, 2019)

E/1: Each population described in A/1 contains a minimum of 2,000 (but preferably more) individuals each year for a minimum of 20 years. (USFWS, 2019)

E/2: Each population described in A/1 has numbers of individuals that exhibit a stable or increasing trend over a period of 20 years that includes two normal precipitation cycles (or longer if suggested by the results of demographic monitoring). (USFWS, 2019)

E/3: Impacts from competing plant species are managed so they do not pose a threat to the persistence of any of the Presidio clarkia populations described in A/1. (USFWS, 2019)

E/4: Seeds, representative of the breadth of the species' genetic diversity, are stored in at least two Center for Plant Conservation certified facilities and reliable seed germination and propagation techniques are understood. Unless storage techniques and/or research show otherwise, stored seeds are replenished every 10 years in order to ensure seed viability. (USFWS, 2019)

Recovery Priority Number: 5C

**Delisting Criteria:**
A/1: A minimum of ten self-sustaining populations of Presidio clarkia are established on suitable habitat within or near the plant's known historical range, and are fully protected and managed with the primary intention of preserving the populations in perpetuity. Each protected area includes occupied habitat with adjacent unoccupied habitat and a 150-meter (500-foot) buffer, where possible. Additional populations are protected if indicated by modeling or research. (USFWS, 2019)

A/2: All lands upslope from the populations described in A/1 are protected from incompatible uses. (USFWS, 2019)

A/3: Each of at least six of the populations described in A/1 are contained in a protected area comprised of at least 12 hectares (30 acres) of rehabilitated serpentine grassland. (USFWS, 2019)

E/1: For a minimum of 20 consecutive years79 that include two normal precipitation cycles, each population described in A/1 exhibits a stable or increasing population trend with a minimum of 2,000 individuals81 each year. (USFWS, 2019)

E/2: For a minimum of 20 consecutive years82 that include two normal precipitation cycles, each of the six populations described in A/3 contains a minimum of 28,000 individuals84 each year with a rolling 20-year average of at least 140,000 individuals. (USFWS, 2019)

E/3: The populations described in A/1 adequately represent the genetic diversity present in the range of the species. At least two of the six populations described in A/3 represent the genetic diversity of Presidio clarkia at the Presidio and another two of six populations represent the genetic diversity in Oakland Hills. (USFWS, 2019)

E/5: The populations described in A/1 occupy serpentine grasslands with negligible nonnative plant cover and with species-appropriate disturbance regimes such as grazing and/or burrowing mammal populations. Impacts from competing plant species are managed so they do not pose a threat to the persistence of Presidio clarkia in any of the populations described in A/1. (USFWS, 2019)

E/6: Long-term management of Presidio clarkia habitat is both practically and financially sustainable. Active management is not required more frequently than once every 5 years. Financial resources for long-term habitat management are secured. (USFWS, 2019)

**Recovery Actions:**

- 1. Protect Presidio clarkia sites and establish additional populations. 1.1. Identify and protect potential introduction sites. (Priority 1). 1.2. Develop and implement a seed increase or collection program that represents the breadth of genetic diversity in the species. (Priority 1). 1.3. Establish, by seeding, new populations within or near the species' known historical range. Seeding should take place in suitable habitats that also exhibit a range of natural environmental conditions. Numerous introductions may be necessary to achieve adequate success rates and determine the range of habitat conditions under which successful establishment can be achieved. (Priority 1). 1.4. Secure populations through land acquisitions, conservation easements, or other means. (Priority 1). 1.5. Work with the City of Oakland and private landowners to maintain Presidio clarkia sites for the long-term survival of the species on their lands. Collaboratively determine the best management practices to accomplish both landowner objectives and conservation goals. Educate local roadside maintenance crews and landscapers. (Priority 1). (USFWS, 2019)
- 2. Research Presidio clarkia life history and conservation strategies. 2.1. Conduct genetic research on existing populations to determine the species' genetic structure and diversity. (Priority 2). 2.2. Research optimal habitat characteristics, mechanisms of dispersal, pollination biology, seed viability of populations from both the Presidio and Oakland Hills, and potential impacts from climate change. (Priority 2). 2.3. Study the demography and reproductive biology of populations. (Priority 3). (USFWS, 2019)
- 3. Monitor and manage Presidio clarkia populations. 3.1. Implement site-specific management plans for Presidio clarkia and other native serpentine species. Manage habitat in occupied areas and in surrounding areas that affect, or could affect, conditions in occupied areas (e.g. weedy species invade from adjacent areas). . Best habitat management practices may include complete eradication of nonnative species and restoration of native serpentine plant communities. (Priority 1). 3.2. Implement a standardized annual monitoring program with the power to detect population trends. (Priority 2). 3.3. Store seeds in at least two Center for Plant Conservation certified facilities. Unless storage techniques and/or research show otherwise, replenish seed stock every 10 years to ensure seed viability. (Priority 2). 3.4. Establish a Service-approved monitoring plan to cover a minimum of 5 years post-delisting. The plan will be ready for implementation at the time of delisting to ensure the ongoing conservation of the species and the continued effectiveness of management actions. Adequate funding must be dedicated in order to implement the delisting management plan. (Priority 3). (USFWS, 2019)
- 1. Implement and evaluate the effectiveness of the habitat enhancement recommendations suggested by Weiss and Neiderer (2009) and EBRPD (Appendix B in EBRPD 2010) (e.g., tree removal, reseeding, scraping, fall tarping, fall flaming (post-germination), spring mowing, and installation of protective fencing), for increasing the survivorship of Clarkia franciscana, controlling nonnative annual grasses, and expanding C. franciscana populations into adjacent areas . (USFWS, 2010)
- 1a. The effectiveness of various habitat enhancement measures may vary dependent on sitespecific conditions as observed in the different results obtained in studies of the SF Presidio (Weiss and Neiderer 2009) and Oakland Hills (EBRPD 2010) populations. Monitor the results, determine the best treatment intervals, and adaptively manage. (USFWS, 2010)

- 1b. Expand Clarkia franciscana plants into adjacent areas of suitable habitat by collecting clarkia seeds from nearby plants and actively seeding in areas of bare ground and low cover of nonnative annual grasses. Collect seeds at different times in the season from C. franciscana plants throughout the adjacent areas, from large and small individuals, to capture a range of genetic diversity (Appendix B in EBRPD 2010). To avoid overcollecting, seed collection should be limited to less than 1 percent of the seedset in the first year while efficacy is being tested (EBRPD 2010). (USFWS, 2010)
- 1c. Persuade private landowners in the Oakland Hills (e.g., Oakland Hills Tennis Club, Sunrise Assisted Living Facility, and the proposed Crestmont development) to monitor the Clarkia franciscana subpopulations on their lands and control invasive species as required under their management plans that were developed during the CEQA process (e.g., Center for Biological Diversity 2007; Kanz in litt. 2009; EBRPD 2009b; City of Oakland 2006b). (USFWS, 2010)
- 1d. Persuade the City of Oakland and private landowners in the Oakland Hills (e.g., Colgett Drive, Kimberlin Heights Drive, and Crestmont Drive) to remove trees where they have been planted in suitable Clarkia franciscana habitat as is being done at Redwood Regional Park and the SF Presidio. (USFWS, 2010)
- 2. Reintroduce Clarkia franciscana to suitable habitat at the SF Presidio (restored site at the West Crissy serpentine grassland near McDowell Avenue; historic location for the species) (Chassé et al. 2009). (USFWS, 2010)
- 3. Address storm drain runoff and erosion issues at Inspiration Point in the SF Presidio and at Crestmont Drive in the Oakland Hills. (USFWS, 2010)
- 4. Increase education of City of Oakland road maintenance and vegetation and fire management teams in how to avoid and minimize impacts to the Clarkia franciscana including delaying their activities (e.g., mowing and weed-whacking) in areas with C. franciscana (Chadbourne Way, Old Redwood Road, and Redwood Regional Park subpopulations) until after the clarkia have set seed (late summer, early fall). (USFWS, 2010)
- 5. Analyze the genetic diversity among the seven subpopulations of Clarkia franciscana within the Oakland Hills. Store seeds representing the genetic diversity within the Oakland Hills population at the University of California Botanical Garden, Berkeley, California, and the Rancho Santa Ana Botanic Gardens, Claremont, California. Also collect seeds from the SF Presidio population of C. franciscana for storage at the Rancho Santa Ana Botanic Gardens, Claremont, California. (USFWS, 2010)

***Conservation Measures and Best Management Practices:***

- RECOMMENDATIONS FOR FUTURE ACTIONS: Here we propose several conservation and monitoring recommendations, which we believe will aid in the recovery of the Presidio clarkia. Some of these recommendations have already been discussed in our previous status review (Service 2010, pp. 56–57) and remain valid. 1. Continue non-native and woody plant removal at the Presidio and Redwood Regional Park, now that these practices have been shown to be effective. Continue efforts to expand Presidio clarkia occupied habitat where possible (primarily at Redwood Regional Park). 2. Seek funding to resume monitoring of all Presidio clarkia occurrences at the Presidio. Also seek funding and qualified personnel to monitor subpopulations in the suburbs south of Redwood Regional Park. If any of those subpopulations have been extirpated (such as at Chadbourne Way), seek funding, personnel, and agreements with landowners to reseed the area and re-establish the subpopulation. 3. Support adoption of the vegetation management plan currently proposed by the

City of Oakland. Work with the City to amend the Fire Code to allow the rare-plant protections in the vegetation management plan to be applied on private lots. Work with the City to support management and monitoring of Presidio clarkia in Joaquin Miller Park. 4. Obtain seeds from all five Presidio clarkia occurrences and store them at a second certified botanic garden such as the Rancho Santa Ana Botanic Gardens in Claremont, California. Also store seeds from the Presidio populations, and from Oakland Hills subpopulations other than Crestmont, at the UC Botanical Garden (which currently only has seeds from the Crestmont site) (USFWS, 2024).

# SPECIES ACCOUNT: *Clarkia imbricata* (Vine Hill clarkia)

***Species Taxonomic and Listing Information***

**Listing Status:** Endangered; 11/21/1997; California/Nevada (Region 8)

**Physical Description**

An erect annual herb in the Onagraceae (Evening primrose) family, growing up to 60 centimeters (2.5 feet) tall, with unbranched or numerous short branches in the upper parts. This plant is densely leafy, with entire (smooth leaf margins), lanceolate leaves (tapering to a point at the apex and sometimes at the base) 2.0 to 2.5 cm (0.8 to 1.0 in long and 4 to 7 mm (0.2 to 0.3 in broad that are ascending and overlapping. Showy inflorescences appear from late June through July. Flowers are grouped closely together and each flower has a conspicuous funnel shaped tube at its base and four fan-shaped, lavender petals 2.0 to 2.5 cm (0.8-1.0 in) long with a V-shaped purple spot extending from the middle to the upper margin of the petal. Clarkia imbricata is distinguished from other morphologically similar Clarkia species by the broad, overlapping, ascending leaves. (USFWS, 2015)

**Taxonomy**

In 1953, Frank H. Lewis and Margaret Lewis described Clarkia imbricata from specimens collected on July 10, 1951, along Vine Hill Road, near Pitkin Ranch in Sonoma County, California. Clarkia imbricata is distinguished from other morphologically similar Clarkia species by the broad, overlapping, ascending leaves. (USFWS, 2015)

**Historical Range**

Same as current range. (USFWS, 2015)

**Current Range**

Vine Hill Area, Sonoma County, California. in the area of Vine Hill Road between the cities of Forestville and Santa Rosa. (USFWS, 2015)

**Critical Habitat Designated**

No;

***Life History***

**Food/Nutrient Resources**

**Reproductive Strategy**

Adult: Asexual (self-fertilization) (USFWS, 2015)

**Lifespan**

Adult: 1 year (USFWS, 2015)

**Breeding Season**

Adult: June to August (USFWS, 2015)

**Reproduction Narrative**

Adult: Clarkia imbricata is self-compatible (capable of self-fertilization). Plants begin to flower in June, and often bloom through August. Seeds generally set in early September. It is not known when seeds germinate or how flowers are pollinated. As with many annual plants, numbers can vary substantially from year to year, depending on seasonal weather variations. (USFWS, 2015)

**Habitat Type**

Adult: Palustrine wetland (NatureServe, 2015)

**Habitat Vegetation or Surface Water Classification**

Adult: Herbaceous wetland, grassland/herbaceous, shrubland/chaparral (NatureServe, 2015)

**Geographic or Habitat Restraints or Barriers**

Adult: Restricted to open grassland near freshwater marsh at elevations between 60 to 75 m (California Native Plant Society, 2001) (NatureServe, 2015)

**Environmental Specificity**

Adult: Narrow/specialist

**Habitat Narrative**

Adult: All known populations of Clarkia imbricata have been found between 60 to 75 meters (197 to 246 feet) elevation, on what has been mapped as Goldridge acidic sandy loams, in an area sometimes referred to as the Sonoma Barrens. Clarkia imbricata is restricted to Vine Hill region on Goldridge acidic sandy loam soil series. Historically the vegetation growing in the Vine Hill region was “chaparral or Sonoma barren”, a mixture of chaparral and Douglas-fir/oak woodland, mixed evergreen forest in the canyons and freshwater marsh and riparian habitat along Pitkin, Green Valley and Atascadero Creeks in Sonoma County. C. imbricata inhabited open grassy portions of this area. (USFWS, 2011)

***Dispersal/Migration***

**Motility/Mobility**

Adult: Low (inferred from USFWS, 2015)

**Dispersal**

Adult: Low (inferred from USFWS, 2015)

**Dispersal/Migration Narrative**

Adult: Clarkia imbricata plants would likely be unable to shift their range naturally because of their dependence on specific soil characters, climate, the presumably low dispersal-potential of the species, and natural and anthropogenic barriers to dispersal (agriculture and housing developments).

***Population Information and Trends***

**Population Trends:**

Previous reports have described the population trend to be increasing and stable (USFWS 2011, 2016). However, recent data suggest the population has declined in the past decade. (USFWS, 2019)

**Number of Populations:**

1 (USFWS, 2024)

**Population Size:**

Variable; past surveys have noted from 60 to 10,900 plants (USFWS, 2024)

**Additional Population-level Information:**

The only known, extant population of Vine Hill clarkia exists at the Vine Hill Preserve (preserve) in Sonoma County, California. The preserve is owned and managed by CNPS volunteers (USFWS 2016; K. Symonds, in litt. 2018). Historically, there were as many as three locations where the plant existed in central Sonoma County. All known populations existed on Goldridge acidic sandy loam soils, in an area known as the Sonoma Barrens. Past surveys have documented as many as 8,700 plants and as few as 60 plants at the reserve, suggesting a high degree of population variation at the site, typical of annual plant species (USFWS 2016; S. Gordon, in litt. 2018). Previous reports have described the population trend to be increasing and stable (USFWS 2011, 2016). However, recent data suggest the population has declined in the past decade. Vine Hill clarkia continues to be located only within the 0.6 hectare (1.5 acre) Vine Hill Preserve (K. Symonds, pers. comm. 2018; S. Gordon, pers. comm. 2018). (USFWS, 2019). Distribution: Prior to listing, three occurrences of Vine Hill clarkia were known: (1) along the roadside of Vine Hill Road north of Guerneville Road (Lewis-type); (2) east of Vine Hill Road, off Sequoia Circle (Sequoia Circle); and (3) along a path to Pitkin Marsh and on a dry slope bordering Pitkin Marsh (Pitkin Ranch) (Service 2016, p. I-2). All three occurrences were within 0.4 miles of each other (Service 2016, p. I-2). By 1974, the Lewis-type occurrence was believed to have been extirpated (Service 2016, p. I-2). Sometime between 1981–1984, the Pitkin Ranch occurrence was believed to have been extirpated (Service 2016, p. I-2). At the time of listing in 1997, the Vine Hill clarkia was known to be distributed between the naturally occurring Sequoia Circle occurrence and an out-planted population within the California Native Plant Society, Milo Baker Chapter's Vine Hill Preserve – herein, Vine Hill Preserve. The naturalized population at the Vine Hill Preserve was created in 1974 or 1975 from seed collected at Sequoia Circle (Service 1997, pp. 55794). The Sequoia Circle population has not been surveyed since listing (Service 2011, p. 6); however, the population has likely been extirpated due to a change in ownership and cessation of land management practices conducive for the species' success (Service 2011, p. 2; Service 2016, pp. I-2, I-5). The Vine Hill Preserve remains the only known, presumed extant occurrence of this species. In recent years, Vine Hill clarkia have also been seen moving onto a neighboring property (Service 2011, p. 6; S. Gordon, Laguna de Santa Rosa Foundation, pers. comm. 2023). Abundance: Prior to listing, little abundance information for any of the three-known natural sites was maintained (Service 2016, p. I-2). As mentioned above, the Lewis-type locality was extirpated in 1974. The Pitkin Ranch locality declined after its habitat was converted to a Christmas tree farm around 1976 (Service 2016, p. I-2). Survey efforts for the Pitkin Ranch locality in 1977, 1978, and 1981 noted a few plants growing, but the species ultimately disappeared from the site following 1981 (Service 2016, p. I-2). At the time of listing, the Sequoia Circle occurrence contained between 2,000 to 5,000 plants and the Vine Hill Preserve supported between 200 to 300 plants (Service 1997, p. 55794). Shortly after listing, the ownership of Sequoia Circle changed, and the new owners did not continue land management practices that had previously benefited the species (Service 2016, p. I-2). Based on the current land management practices and poor condition of the plants at the time of last survey, it is unlikely the site continues to support Vine Hill clarkia (Service 2016, p. I-2) The out-planted population at Vine Hill Preserve has fluctuated significantly. Since the last 5- Year Review, the population has demonstrated an overall upward trend, including during drought years. Additional out-plantings occurred at the Vine Hill Preserve in 2019 and 2020 and resulted in successful reproduction. The out-plantings and follow-up surveys are further discussed in the Conservation Efforts section. Refer to Table 1 below for the assessed total number of Vine Hill clarkia individuals at the Vine Hill Preserve since 1978. As mentioned above, some Vine Hill clarkia plants have also been observed on a neighboring property. This property has been routinely mowed in June before the Vine Hill clarkia sets seed, so the number of individuals there remains low and often unquantified (USFWS, 2024).

**Population Narrative:**

Narrowly endemic to a small area in Sonoma County, California. Historically, four populations were known; currently, there is one natural population, with a total of about 5000 plants, and one planted population with < 400 plants (NatureServe, 2015). Based on monitoring by The Nature Conservancy and CNPS, in 1978, 60 plants were observed; from 1988 to 1993, the population fluctuated from about 200 to 300 plants; and, from 2007 to 2012, the population fluctuated from approximately 500 to 8,781 plants. In 2013, the population of C. imbricata at Vine Hill Preserve was estimated at 908 individuals (S. Gordon, personal communication 2013) and in 2015 was estimated at 270 plants (S. Gordon, personal communication 2015). The number of C. imbricata plants on the property to the east of the Vine Hill Preserve fluctuates from zero to 100 plants, depending on property maintenance activities. In 2010, the area occupied by C. imbricata on the Vine Hill Preserve was measured at 1,540 square meters (16,576 square feet), up from 1,467 square meters (15,791 square feet) in 2009. (USFWS, 2011; USFWS, 2015; NatureServe, 2015)

***Threats and Stressors***

**Stressor:** Land use conversion (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
**Narrative:** At the time of listing in 1997, the most significant threat to the two remaining populations of Clarkia imbricata was extirpation through land use conversion to housing, vineyards and orchards. Land use conversion is now lesser threat given that of the two populations that existed at the time of listing, only one is known to remain and it is on the Vine Hill Preserve which is protected by the California Native Plant Society (CNPS). The second population (Sequoia Circle) was on private land with restricted access and plants have not been surveyed since 1997. The extant Vine Hill Preserve population is protected, monitored and managed by CNPS, but the plants growing on the adjacent property are not protected. Thus habitat destruction, modification or curtailment due to land use conversion remains a threat, but a lesser one than at the time of listing. In 2011 land use changes on the adjacent parcel reduced the available habitat for C. imbricata. (USFWS, 2011)

**Stressor:** Shading and nonnative species (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**

**Narrative:** Another mechanism for habitat destruction, modification or curtailment that is probably a greater threat than at the time of listing is succession of the grassland habitat that Clarkia imbricata requires. This threat has increased because there is now only a single known population that is restricted to the open, grassy area of the Vine Hill Preserve. The open area will decrease if the grassland is allowed to progress through successional stages into chaparral and forest. This will shade C. imbricata and enrich the soil with leaf litter which may encourage competing non-native species such as Holcus lanatus, a perennial plant that reseeds readily and can tolerate fire. Invasive species such as Holcus lanatus threaten C. imbricata through competition for space and resources. In areas where H. lanatus grows, C. imbricata is shaded and grows at a lower density. H. lanatus has increased in numbers over the last few years in an area of the Vine Hill Preserve that lies under trees growing on a neighboring property (S. Gordon, personal communication 2010). (USFWS, 2011)

**Stressor:** Over-collection (USFWS, 2011)
**Exposure:**
**Response:**
**Consequence:**
